DOI 10.1055/s-0046-1821644

Aims Pancreatic cancer stands 3rd in cancer-related death. Endoscopic ultrasound (EUS) plays a key role in characterizing and diagnosing solid pancreatic lesions. The literature suggests, with limited evidence, that ancillary EUS techniques like EUS-guided elastography, which assess tissue stiffness, potentially improve the differentiation of malignant lesions. In this single-center retrospective study, we analyzed the performance of EUS-guided elastography in characterizing solid pancreatic lesions compared with histopathological results.

Methods Our team conducted a retrospective analysis of 508 consecutive patients who underwent Endoscopic Ultrasound (EUS) at the Institute of Pancreatic Diseases, Semmelweis University, between January and October 2025. We included 108 patients with suspected solid pancreatic tumors and divided them into two groups. The first group (54 patients) had elastography and histopathological results. The second group (54 patients) had histopathological results but no elastography. Demographic parameters, endoscopic data (elastography, ROSE, MOSE) were collected for both groups. Statistical analysis was performed using Microsoft Office Excel and GraphPad (Prism10) software.

Results In the elastography group (EG), the median age was 70 years (95 % CI: 66–74), compared to 68 years (95 % CI: 61–71) in the non-elastography group (NEG), with similar mean ages between groups (69.09 vs. 65.07 years; 95 % CI for the mean: 66.03–72.16 vs. 62.12–68.03). Regarding sex distribution, 38.89 % of patients in the EG were male and 61.11 % female, whereas in the NEG, males comprised 62.96 % and females 37.04 % (P = 0.01; OR = 0.37; 95 % CI 0.17–0.80).
Pancreatic adenocarcinoma was the most frequent diagnosis in both groups, 57.4 % in the EG and 66.7 % in NEG (P > 0.05). Median tumor size was 675 mm^2 (median dimensions: 27x25mm) in the EG and 900 mm^2 (median dimensions: 30x29mm) in NEG (P = 0.1417). Tumors most frequently involved the pancreatic head in both groups (EG: 54.74 %; NEG: 50.00 %) (P = 0.1448).
The use of MOSE and ROSE showed high prevalence in both groups. MOSE was applied in 96.36 % of patients in the EG group and in 94.44 % of patients in the NEG group. ROSE was utilized in 77.78 % of cases in the EG group and in 72.22 % of cases in the NEG group.
Among the 54 patients who underwent elastography (EG), 43 (79.62 %) exhibited blue colour, while 11 (20.37 %) demonstrated mixed colour. In blue-EG cohort, 34 (79.07 %) had malignant lesions and 9 (20.93 %) had benign lesions (P = 0.69, OR = 1.41, 95 % CI 0.34–5.63). In mixed-EG cohort, 8 (72.73 %) had malignant lesions and 3 (27.27 %) had benign lesions (P = 0.69, OR = 1.41, 95 % CI 0.34–5.63).
In EG, rebiopsy was required in 14 (25.93 %) patients, 11 (78.57 %) blue colour and 3 (21.42 %) mixed colour (P > 0.99, OR = 0.91, 95 % CI 0.19–3.65). Among the rebiopsy cases with blue colour, 5 (45.45 %) were malignant and 6 (54.55 %) were benign (P > 0.99, OR = 0.41, 95 % CI 0.02–4.70), while among rebiopsy cases with mixed colour, 6 (75.00 %) were malignant and 2 (25.00 %) benign (P = 0.25, OR = 3.22, 95 % CI 0.47–18.07).
In EG group, the sensitivity, specificity, positive predictive value, negative predictive value and likelihood ratio are 0.80 (0.66–0.90), 0.25 (0.08–0.53), 0.79 (0.64–0.88), 0.27 (0.09–0.56) and 1.07 respectively.
In the NEG, 46 (85.19 %) had malignant lesions and 8 (14.81 %) had benign lesions. Rebiopsy was necessary in 10 (18.52 %) patients (95 % CI 0.09–0.30). Among the rebiopsied patients, 7 (70.00 %) cases were malignant and 3 (30.00 %) cases were benign.

Rebiopsy data showed no statistically significant difference between EG (malignant lesions: 25.93 %) and NEG (malignant lesions: 18.52 %) groups.

Conclusions Our results suggest that elastography does not significantly improve overall sampling success or reduce the need for rebiopsy, which aligns with observations reported in the international literature regarding the use of elastography. However, because the study is a small, single-center retrospective analysis, a larger multicenter prospective randomized trials incorporating both quantitative and qualitative assessments are needed.

DOI 10.1055/s-0046-1821645

Abstract Text

A 43-year-old male patient who underwent laparoscopic cholecystectomy 3 weeks back, presented with massive right sided pleural effusion and gross ascites. Pleural fluid and ascitic fluid analysis was suggestive of pancreatic etiology. Conservative measures of treatment failed. Endosonography showed 3.6 cm communicating pseudocyst with immature wall. Leak from head region of pancreatic duct into pseudocyst was evident on pancreatogram. From the cyst cavity the dye was noted tracking up retroperitoneally on the right side, demonstrating the fistulous communication to right pleural cavity. Also, another leak from the cyst was noted inferiorly indicating the possible cause for ascites. Transpapillary drainage of the cyst was done by inserting a 7 French double pigtail stent. In the post-procedure period, patient improved symptomatically and on imaging.

eP319 Flap & Win: western data on endoscopic resection of gastric subepithelial lesions

Authors Bravi I[1], Maregatti M[1], Galtieri A[1], Giunta M[1], Soru P[1], Ravizza D[1], Trovato C[1], De Roberto G[1]

Institute **1** European Institute of Oncology, Milan, Italy

DOI 10.1055/s-0046-1821646

Aims In Western countries, endoscopic resection (ER) of gastric subepithelial lesions (SELs) is emerging as an alternative to either surveillance for lesions < 20 mm or surgical resection in cases with suspected malignant potential (such as GISTs > 20 mm or type 1 neuroendocrine neoplasms > 10 mm). Several endoscopic resection techniques have been proposed. This study reports a cohort of patients with gastric SELs who underwent endoscopic resection using a modified-STER (submucosal tunneling endoscopic resection) approach, defined as "FLAP technique"

Methods Data from consecutive patients with gastric SELs who underwent ER were collected. All patients underwent endoscopic ultrasonography (EUS) prior to the ER. Patients' characteristics, SELs features, and endoscopic procedure details were collected. The "FLAP technique" consists in creating a short submucosal access, less than 1 cm proximal to the lesion (closer than the originally tunnel described at 5 cm), followed by careful dissection of the lesion while preserving the capsule and the overlying mucosal flap. If the lesion is deeply adherent to muscolaris propria (MP), a transmural resection is performed, resulting in a controlled and intentional perforation of the MP and serosa. After removal and retrieval of the specimen, hemostatic gel is applied and the defect is completely closed with clips using the mucosal flap. Technical success was considered as complete endoscopic resection and retrieval of the specimen; clinical success as an en-bloc and R0 resection. Intraprocedural, short term and long-term adverse events (AEs) and complication have been registered.

Results A total of 6 patients (50 % male, mean age 60 yr) with 6 SELs were included. Median SELs size was 16.5 mm (IQR), 50 % located in the antrum and 50 % located in gastric body. In 83 % cases MP involvement was described at EUS. Technical success was achieved in 5/6 patients. The technical unsuccessful procedure, a 30 mm SELs of the grater curvature of the gastric body with a predominant extraluminal extension, was suspended due to the impossibility to endoscopic retrieve the lesion, with a high risk of lesion migration into the peritoneum.; the patient underwent laparoscopic wedge resection. Clinical success (en bloc and R0) was achieved in 5/5 patients with preservation of the capsule in 100 % of the cases. To achieve complete tumor removal a transmural resection was required in 60 % of cases. Total closure of the defect using the mucosal flap and clips was achieved in 100 % of the patients. Histopathology showed a low-risk GIST and benign lesions in other cases. Median total procedure time was 100 minutes. No AEs occurred during or after the procedure.

Conclusions In selected cases, endoscopic resection of SELs is feasible, efficient and safe, also in a Western setting. In our experience preserving the mucosal flap is usefull to allow easy and complete endoscopic closure. Creation of a shorter submucosal access did not compromise the integrity of mucosal flap. More data or comparative studies are needed to assess endoscopic resectability and retrival criteria and optimal removal techniques for SELs.

DOI 10.1055/s-0046-1821647

Aims Sedative medication is commonly used to improve patient comfort and tolerability during colonoscopy. Standards for colonoscopy sedation are known to vary across countries, while different types of sedation are also associated with differences in clinical outcomes, as well as different economic and environmental burdens. In the Netherlands, insights into sedation practices across endoscopy units were lacking. This study aimed to evaluate national trends in colonoscopy sedation, inter-unit variability in sedation practices, and associations between type of sedation and various colonoscopy performance measures in the Dutch population.

Methods All colonoscopies recorded in the Dutch Gastrointestinal Endoscopy Audit (DGEA) registry between January 1, 2020, and January 1, 2025, were eligible for inclusion. Sedation was classified as none, mild sedation (midazolam and/or opioids), or deep sedation (propofol). Trends and variability in colonoscopy sedation were analyzed across predefined indication categories: positive fecal immunochemical test for the colorectal cancer (CRC) screening program; post-polypectomy or CRC surveillance; familial CRC risk; inflammatory bowel disease (IBD); IBD surveillance; therapeutic procedures; and symptoms/other indications. The association between sedation type (none, mild, deep) and midazolam dosage (< 2.5 mg, 2.6-5 mg, > 5 mg) with the incidence of successful cecal intubation and polyp detection was assessed using generalized estimating equation Poisson regression.

▶ **Table 1** Percentual differences in incidence rate (95 % confidence interval) of successful cecal intubation and polyp detection for different types of sedation

	No sedation	Mild sedation, midazolam < 2.5 mg	Mild sedation, midazolam 2.6-5 mg	Mild sedation, midazolam > 5 mg	Deep sedation
Successful cecal intubation	-2.5 % (-3.5 to -1.5 %)	Reference	+ 0.6 % (+ 0.4 to + 0.8 %)	-0.2 % (-0.7 to + 0.3 %)	-0.9 % (-1.4 to 0.5 %)
Polyp detection	+ 1.1 % (-5.8 to + 8.4)	Reference	+ 1.7 % (+ 0.4 to + 3.0 %)	+ 2.2 (-1.5 to + 6.0 %)	+ 4.9 % (+ 1.1 to 8.9 %)

Results A total of 260,316 colonoscopies were included. Mild sedation was used in the majority of colonoscopies (ranging from 88.9 % to 92.6 % over the years). Meanwhile, the use of deep sedation increased progressively from 5.8 % in 2020 to 10.0 % in 2024. The most notable increase in deep sedation was observed for IBD colonoscopies (11.6 % to 23.2 %; annual change 2.7 % [95 % CI 2.0-3.3]) and therapeutic colonoscopies (28.2 % to 51.7 %; annual change 5.3 % [95 % CI 4.3-6.3]). For procedures with mild sedation, the mean midazolam dosage varied by indication category, with the lowest dosage for colonoscopies for post-polypectomy or CRC surveillance (3.44 ± 1.29 mg) and the highest for IBD colonoscopies (4.26 ± 1.55 mg). Significant inter-unit variability in the overall mean midazolam dosage was observed (range: 2.13 ± 1.17 to 5.62 ± 1.70 mg), indicating considerable differences in midazolam dosing regimens across units. Compared to mild sedation with < 2.5 mg midazolam (reference), a dosage of 2.6-5 mg was associated with a slightly higher incidence of successful cecal intubation (+ 0.6 % [95 % CI 0.4-0.8 %]) and polyp detection (+ 1.7 % [95 % CI 0.4-3.0 %]). Midazolam dosages > 5 mg and propofol sedation did not improve cecal intubation, although they were associated with higher polyp detection rates (▶ **Table 1**).

Conclusions In the Netherlands, the use of deep sedation for colonoscopy is rising. Besides, sedation practices were illustrated to vary considerable across units, particularly in terms of midazolam dosing regimens. While a midazolam dosage of 2.6-5 mg was associated with slight improvements in cecal intubation and polyp detection compared to dosages < 2.5 mg, the gain for daily practice seems very small. Therefore, the benefits of routinely administering doses > 2.5 mg should be carefully weighed considering the associated greater risks, costs and environmental burdens of higher dosing. The findings of this study can be used to inform the development of guidelines for more standardized colonoscopy sedation.

Conflicts of Interest E. eP321 "Predicting precancerous gastric lesions using Helicobacter pylori infection and serum pepsinogen levels

Authors Baatar G[1], sergelen SG[1], Altangerel P[1], Altangerel A[1], Erdene E[1], Buyanbat Y[1], gantuya GB[2]

Institutes **1** ShinonMed Hospital, Ulaanbaatar, Mongolia; **2** Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia

DOI 10.1055/s-0046-1821648

Aims

To perform upper gastrointestinal endoscopy on the study participants and determine Helicobacter pylori infection and serum pepsinogen I and II levels.

To establish cutoff values for serum markers of precancerous gastric lesions.

To classify all cases into gastric cancer risk groups according to the serum marker–based ABCD classification.

Methods This study was conducted using a hospital-based cross-sectional study design. Among individuals aged 32 years and older, upper gastrointestinal endoscopy was performed, stool antigen testing was used to detect H. pylori infection, and serum pepsinogen I, pepsinogen II, and anti-H. pylori antibodies were measured

Results A total of 94 participants were included in the study, with a male-to-female ratio of 1:1. The cutoff value for pepsinogen I indicating precancerous gastric lesions was PG I ≤ 33 ng/mL, with a sensitivity of 80 %, specificity of 64.1 %, and a p-value of 0.005. The cutoff value for detecting H. pylori infection was an H. pylori antibody level ≤ 7.85 U/mL, with a sensitivity of 75.4 %, specificity of 72 %, and a p-value < 0.005. Based on serological markers, 25.5 % (n = 23) of cases were classified as group A, 38.6 % (n = 36) as group B, 34 % (n = 32) as group C, and 3.2 % (n = 3) as group D [1–8].

Conclusions According to the ABCD classification, 25.5 % of the individuals in the study (Group A) require repeat endoscopy and gastric cancer screening after 5 years, 38.6 % (Group B) after 3 years, and 37.2 % (Groups C and D) after 1 year.Establishing the serological marker–based ABCD classification helps prioritize gastric cancer risk groups in endoscopic screening practice. By reducing unnecessary repeated endoscopies and ensuring that high-risk individuals undergo closer endoscopic surveillance, this approach contributes significantly to improving the early detection of gastric cancer.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821649

Aims The impact of non-anesthesiologist-administered propofol (NAAP) sedation on colonoscopy performance remains elusive. We aimed to assess the impact of NAAP on colonoscopy quality metrics published in recent literature.

Methods A systematic review across MEDLINE and Cochrane Central Register for all types of trials was performed, evaluating the impact of NAAP compared to AP sedation on colonoscopy quality measures. The primary endpoint was Adenoma Detection Rate (ADR), while cecal intubation rate (CIR) and procedure length comprised the secondary endpoints. The effect size on study outcomes is presented either as the event rate or as the Risk Ratio (RR) with 95 % confidence interval (CI). We assessed the quality of evidence using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

Results Two RCTs and nine cohort studies with 3769 patients (NAAP 1959, AP 1810), published between 2019 and 2024, were included. NAAP resulted in similar ADR compared to AP [RR 1.06, 95 % CI (0.94-1.19); $I^2 = 0$ %]. Similarly, no difference in terms of CIR [RR 1.01, 95 % CI (0.98-1.04), $I^2 = 10$ %] as well as procedure length [MD -0.94, 95 % CI (-2.79-0.91), $I^2 = 74$ %] was evident. Overall, the certainty of evidence was very low.

Conclusions The ADR and CIR colonoscopy quality indicators are comparable between NAAP and AP sedation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP323 Five-day waste audit in a tertiary endoscopy department: quantifying waste streams and carbon footprint

Authors Vegting B[1], Izci CB[1], Diehl JC[2], Van Den Heuvel W[3], Hunfeld NGM[4, 5], Van Raaij EM[6], Tietschert MV[6], Siersema PD[1], De Jonge PJF[1]
Institutes **1** Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; **2** TU Delft Faculty of Industrial Design Engineering, Design for Sustainability, Delft Netherlands; **3** Erasmus University Rotterdam, Erasmus School of Economics, Econometrics Institute, Rotterdam, Netherlands; **4** Erasmus University Medical Center, Department of Adult Intensive Care, Rotterdam, Netherlands; **5** Erasmus University Medical Center, Department of Hospital Pharmacy, Rotterdam, Netherlands; **6** Erasmus University Rotterdam, Erasmus School of Health Policy & Management, Rotterdam, Netherlands
DOI 10.1055/s-0046-1821650

Aims Endoscopy units are the third largest emitters of carbon dioxide (CO_2) within hospitals. A substantial part of these emissions results from waste. Improving waste segregation and reducing waste in endoscopy units requires detailed insights into current waste streams. We aimed to quantify waste generation in an academic endoscopy department and to estimate the associated carbon footprint (▶ **Table 1**).

Methods We performed a five-day waste audit of the pre-, post- and procedure phases of an eight-room gastrointestinal endoscopy department. Waste from the reprocessing area was excluded. All waste streams were collected twice daily and subsequently weighed and categorized into preidentified waste streams. The total mass (kg) per waste stream and per procedure was calculated. Procedure numbers during the study period were recorded, and waste-related carbon emissions (carbon dioxide equivalents (CO_2e)) were estimated using national carbon emissions factors.

Results Over the five-day period, 243 endoscopic procedures were performed: 64 colonoscopies, 107 esophagogastroduodenoscopies, 13 endoscopic retrograde cholangiopancreatographies, 31 endosonographies, and one video capsule endoscopy. In addition, 27 procedures were pulmonary endoscopies. Given that gastrointestinal endoscopy constituted nearly 90 % of activity during the audit, these findings mainly reflect waste patterns in gastrointestinal endoscopy workflows. On average, 49 procedures were performed per day (range 44-54). A total of 317.6 kg of waste was generated. Most waste consisted of general waste (184.9 kg, 58 %), followed by hazardous waste including sharps (78.6 kg, 27 %), and recycled materials (47.5 kg, 15 %). Each procedure generated approximately 1.3 kg of waste. Waste-related carbon emissions amounted to 1,465 kg CO_2e over the 5-day period, corresponding to 6 kg CO_2e per procedure and an estimated 58,820 kg CO_2e annually of endoscopy waste in this center, which is equivalent to driving a conventional car for 266,000 km, or six times around the earth.

Conclusions This is the first 5-day comprehensive waste audit of pre-, post- and procedure phases in an endoscopy department in a Dutch academic hospital, providing a baseline for targeted sustainability interventions. It highlights substantial opportunities for waste reduction and segregation, improved recycling, and can guide environmental improvement efforts in endoscopy units.

▶ Table 1

Waste stream	Total waste in kg (%)	Waste per day, kg	Waste per procedure, kg	Total CO2e, kg
General hospital waste	184.90 (58)	36.98	0.75	893.8
Hazardous waste	78.59 (25)	15.72	0.31	442.9
Sharps	6.64 (2)	1.33	0.03	28.9
Recycled paper	24.83 (8)	4.97	0.10	23.2
Recycled plastic	22.63 (7)	5.86	0.12	76.1
Total	317.59 (100)	63.52	1.31	1464.9

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP324 Outcomes of Endoscopic Balloon Dilatation in Benign Luminal Obstruction

Authors Davaadorj E[1], Otgondemberel B[2], Khurelshagai A[2], Duurenjargal B[2], Batsaikhan A[2], Tumendemberel B[2], Zoljargal U[2], Batbayar B[2], batsuren B[2], Dorjsuren M[2]
Institutes 1 IGIC endoscopic center, Ulaanbaatar, Mongolia; 2 IGIC Endoscopic Network, Ulaanbaatar, Mongolia
DOI 10.1055/s-0046-1821651

Aims Benign luminal obstruction of the gastrointestinal tract and airway arises from multiple causes, including peptic ulcer disease, caustic injury, postoperative strictures, inflammatory disorders, and tuberculosis-related airway stenosis [1–3]. Endoscopic balloon dilatation (EBD) is a minimally invasive, organ-preserving treatment with reported success rates of 81–100 % for benign gastrointestinal strictures [12] and 65–89 % for benign airway stenosis, avoiding surgery in ~65 % of pediatric cases [13]. However, long-term EBD outcomes have not been reported in Mongolia, where gastric cancer (~20.3/100,000) [8], esophageal cancer (~18.5/100,000) [10], and *Helicobacter pylori* prevalence (~80 %) [9] remain high. This study evaluates EBD technical and clinical success, refractory stricture rates, balloon-diameter progression, and safety (▶ **Table 1**).

▶ **Table 1** Balloon Dilation Parameters and Outcomes

Parameter	Value
Median initial diameter	20 mm (IQR 18–20)
Median final diameter	20 mm (IQR 19.5–20)
Increase across sessions	Median 2 mm; mean 1.35 mm
Incremental dilation	2–3 mm steps [4,6,12]
Procedural success	100 % (51/51)
Clinical success	100 % (51/51)

Methods A retrospective review was conducted on patients who underwent EBD for benign gastrointestinal or airway/anastomotic strictures from January 2022 to December 2025. Data collected included demographics, etiology, stricture location, balloon diameters (first and last), number of sessions, interval between dilatations, and adjunctive therapy use [4]. Procedural success was defined as successful passage of the endoscope after dilation [5]. Clinical success was defined as symptom resolution lasting > 1 month with easy passage of a standard gastroscope [1]. Refractory strictures were defined as failure to achieve procedural success after five sessions [3].

Results Fifty-one patients were included (mean age 55.6 years; 51 % male). Etiologies were peptic/ulcer-related disease (n = 13), postoperative strictures (n = 12), iatrogenic injury (n = 10), radiation injury (n = 3), and other benign causes such as TB-related airway/anastomotic stenosis (n = 13). Stricture locations included the esophagus (n = 15), gastric outlet (n = 8), duodenum (n = 2), and anastomotic or airway-related sites (n = 26). Procedural and clinical success were achieved in all patients (100 %) [6, 7, 11].

Seven patients (13.7 %) had refractory strictures, but all responded after adjunctive therapy. One perforation occurred (1.96 %). The median initial and final balloon diameters were 20 mm (IQR 18–20) and 20 mm (IQR 19.5–20), respectively. Median diameter gain was 2 mm (mean 1.35 mm), with most patients undergoing conservative 2–3 mm incremental dilations consistent with safety-based protocols [4, 12, 13].

Conclusions EBD is a safe and highly effective treatment for benign luminal obstruction of both gastrointestinal and airway structures, achieving excellent technical and clinical success. Gradual balloon expansion using 1–3 mm increments was well tolerated and aligned with internationally recognized safety protocols. Although refractory strictures occurred in a minority of cases, most responded to adjunctive modalities such as repeated dilation, steroid injection, incisional therapy, or temporary stenting. Further investigation is needed to determine optimal management strategies and to compare the effectiveness of each adjunctive modality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP325 Endoscopic characteristics of Metastatic Colorectal Lesions: A 38-case institutional Analysis

Authors Misato S[1], Takahito T[1], Yoshikazu H[1], Hiroaki I[1], Eriko I[1,2], Yuka K[1], Tomonori Y[1], Yamamoto H[1]

Institutes **1** Department of Medicine, Division of Gastroenterology, Jichi Medical University, Shimotsuke, Japan; **2** Comprehensive Pathology Division, Department of Pathology, Jichi Medical University, Shimotsuke, Japan

DOI 10.1055/s-0046-1821652

Aims Primary colorectal cancer has been extensively studied due to the large number of cases, allowing for substantial insights into its clinical characteristics and treatment strategies. In contrast, metastatic colorectal cancer remains poorly understood because of its rarity and limited number of reports. With recent advancements in chemotherapy, accurately diagnosing metastatic lesions has become increasingly important and has significant implications for treatment planning. Here, we report the characteristics of 38 cases of metastatic colorectal lesions encountered at our institution.

Methods We reviewed 38 patients who underwent colonoscopy at our institution between January 1, 2015, and October 31, 2025, and were diagnosed by biopsy pathology as having colorectal cancer originating from other organs. We analyzed the mode of invasion or metastasis, age and sex at diagnosis, indications for colonoscopy, cecal intubation status, lesion location, number of lesions, and endoscopic findings. Cases involving direct invasion from adjacent advanced tumors were classified as direct invasion, while those involving non-adjacent tumors were defined as distant metastasis.

Results The cohort consisted of 17 men and 21 women, with a mean age of 69.2 years. Indications for colonoscopy included screening in 15 cases, abnormal CT findings in 12 cases, bowel obstruction in 6 cases, and other reasons in 4 cases. Of the 38 cases, 17 were classified as direct invasion and 21 as distant metastasis. The cecal intubation rate was lower in the direct invasion group (9/17, 53 %) than in the distant metastasis group (16/21, 76 %). The most common primary tumor was of gynecological origin (15 cases), followed by gastric cancer (9 cases). Among gynecological cancers, 9 of 15 cases (60 %) were direct invasion, whereas gastric cancer more commonly presented as distant metastasis (7 of 9 cases, 78 %). Endoscopic findings in the direct invasion group mainly consisted of non-epithelial strictures or submucosal tumor–like protrusions. In contrast, the distant metastasis group displayed a wide variety of findings, including strictures, elevated lesions, flat lesions, and ulcers.

Conclusions In cases of direct invasion, endoscopic findings predominantly consisted of strictures or SMT-like protrusions, and the cecal intubation rate was low. In contrast, distant metastasis demonstrated more diverse endoscopic appearances, ranging from protruding lesions to flat elevated lesions, and some cases were difficult to detect even on CT. When atypical endoscopic findings are observed in the colon of patients with another primary malignancy, we should consider the possibility of metastatic colorectal lesions.

eP326 Bipolar Fragmentation Forceps as a Last Resort Tool: An Innovative Strategy for Dismantling Entrapped Metal Instruments in the Distal CBD

Authors Aliosin O[1], Justas B[2], Mindaugas S[3], Michail K[4]

Institutes **1** Klaipeda University Hospital, Klaipėda, Lithuania; **2** Klaipeda university Hospital, Liepojos, Klaipeda, Lithuania; **3** Klaipeda University Hospital, Klaipeda, Lithuania; **4** Conquest hospital, East Sussex, Healthcare NHS Trust, Hastings, UK, United Kingdom

DOI 10.1055/s-0046-1821653

Problem to solve A young patient was scheduled for the removal of a covered metallic stent (cSEMS) from the Common Bile Duct (CBD), which had been placed nine months earlier. The first removal attempt failed due to significant stent ingrowth. During the second attempt, a critical error occurred: the special grasping forceps got stuck, and its internal wire core broke off, leaving the closed forceps tip trapped inside the stent mesh. When we tried to free the trapped forceps with a Dormia basket, the basket also got stuck. This created a complex, multi-layered metal blockage deep in the CBD, a situation that usually means immediate surgery is necessary.

Innovation To solve this unusual and severe problem without surgery, we used a non-standard method. We decided to use bipolar fragmentation forceps, which are usually designed to cut other large metal structures. The technique involved using the bipolar current to cut the metal parts of the stuck instruments (the forceps shaft and the basket wires). The goal was to dismantle these instruments in the distal CBD, showing an innovative and highly unusual way to use this specialized tool for a major mechanical failure.

Results The bipolar cutting technique worked technically: we successfully cut the metallic parts. The core of the broken forceps and all the stuck Dormia basket wires were cut near the main bile duct opening (papilla of Vater). However, the smaller, cut metal fragments of both instruments remained firmly trapped inside the deeply ingrown stent mesh. Following these complications and the partial endoscopic result, we decided to stop the procedure and plan for a definite surgical repair later.

Conclusions Our case shows that specialized bipolar fragmentation forceps have high potential for dealing with very unusual and difficult complications, like having metal instruments stuck in a critical area. This highlights that successful advanced endoscopy sometimes requires creative, "out-of-the-box" thinking and using existing tools in new ways. The remaining metal fragments show the limit of this technique, especially when the main problem is a deeply ingrown stent. We believe that adding a scope for direct viewing inside the bile duct (cholangioscopy) could significantly help manage such deeply ingrown stents in the future.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP327V LAMS dislodgement during EDGE: not all about anchoring

Authors Yepishkina K[1], Hucl T[1], Kučera M[1], Vašátko M[1]

Institute **1** Institute of Clinical and Experimental Medicine, Prague, Czech Republic

DOI 10.1055/s-0046-1821654

Abstract Text

We present a case of a 36-year-old woman post gastric bypass who underwent EDGE for suspected CBD stones. After LAMS placement, the tract was left to mature for four weeks. During the subsequent ERCP, a perpendicular axis of the endoscope to the axis of a distally placed LAMS was encountered. Further attempts at scope advancement, despite severe friction, resulted in LAMS dislodgement. The absence of wire introduction made endoscopic salvage impossible. Intraoperative ERCP during emergency surgery ultimately revealed no stones. This case highlights the importance of factors other than LAMS anchoring in preventing stent dislodgement.

eP328 Optimal recording time to avoid incomplete wireless video capsule endoscopy of the small bowel

Author Moreels T[1]

Institute **1** Cliniques universitaires Saint-Luc (UCLouvain), Avenue Hippocrate, Brussels, Belgium

DOI 10.1055/s-0046-1821655

Aims Assessment of optimal recording time to reduce incomplete wireless capsule endoscopy (WCE) due to functional gastrointestinal (GI) motility disorders.

Methods Single-centre retrospective study of consecutive WCE examinations using different types of capsules: EndoCapsule S10, Pillcam SB3, OMOM and

ANKON. Daytime (between 9h00 and 16h00) and overnight recordings were performed. All WCE were read in the conventional modus with a reading speed between 5 and 10 images/sec without the use of artificial intelligence.

Results A total of 210 consecutive WCE examinations were analysed in 117 male (69 ± 1y) and 93 female (65 ± 2y) patients (age range 14-92y). Suspected small bowel bleeding was the leading indication (97 %), except for n = 7 patients. Bleeding presented as iron deficiency anaemia (66 %), melena (26 %) or unexplained rectal bleeding (8 %) after normal upper and lower GI endoscopy. In 17 % of all WCE active GI bleeding was diagnosed and in 41 % potentially bleeding lesions like arteriovenous malformations, blue rubber bleb naevi, erosions or polypoid and tumoral lesions. In 29 % the (potentially) bleeding lesions were located in the upper GI tract and in 6 % in the lower GI tract within the reach of conventional endoscopy. In 34 % WCE turned out to be normal. 37 % of patients were referred for device-assisted enteroscopy based on the WCE findings. A total of 28 WCE (13 %) were incomplete with the capsule not reaching the colon, with 7 because of technical failure (n = 2) or mechanical stricture (n = 5). The remaining 21 incomplete WCE were due to short recording time relative to the transit time (23 % incomplete WCE when < 10h recording time vs 3 % incomplete WCE when < 15h vs 1 % incomplete WCE when > 15h; p = 0.0012 Chi-square).

Conclusions WCE is an important first-line examination for suspected small bowel bleeding, with 17 % of active bleeding recorded and an additional 41 % of potentially bleeding lesions. However, those lesions are often found in the upper (29 %) and in the lower (6 %) GI tract despite prior normal upper and lower GI endoscopy. To avoid incomplete WCE due to slow GI transit a recording time of at least 15h seems mandatory.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP329 Clinicopathological Features, Endoscopic diagnosis and Treatment strategies for gastric epithelial neoplasm of fundic-gland mucosa lineage: A multicenter, retrospective, observational study in China

Authors Xiaobei L[1], Xiyu W[2]
Institutes 1 Nanfang Hospital, Southern Medical University, Guangzhou, China; 2 Department of Gastroenterology, Nanfang Hospital, Southern Medical University, Guangzhou, China
DOI 10.1055/s-0046-1821656

Aims Gastric epithelial neoplasm of fundic-gland mucosa lineage (GEN-FGML) is a rare pathological type of gastric cancer, first reported by Tsukamoto et al. in 2007 [1]. Based on cellular differentiation and submucosal invasion, GEN-FGML can be classified into oxyntic gland adenoma (OGA), gastric adenocarcinoma of fundic-gland type (GA-FG), and gastric adenocarcinoma of fundic-gland mucosa type (GA-FGM) [2]. Prior research primarily consists of small-scale case reports from Japan [3, 4]. Data on the incidence, detection rate, treatment strategies, and clinical prognosis of GEN-FGML in other countries remain scarce, so we conducted the first comprehensive, large-scale study on GEN-FGML in China. This study retrospectively collected data on GEN-FGML from multiple Chinese hospitals, aiming to compare the clinicopathological features, endoscopic characteristics, treatment strategies, and prognoses of different GEN-FGML subtypes.

Methods This retrospective study collected data from nine medical centers in China between 2018 and 2025. A total of 351 patients with GEN-FGML were enrolled. The clinicopathological features, endoscopic characteristics, treatment modalities, and prognoses of different GEN-FGML types were analyzed and compared (▶ **Table 1**).

Results A total of 351 GEN-FGML patients were included, including 225 OGA, 116 GA-FG, and 6 GA-FGM. These three types of lesions showed some similar characteristics: most lesions were located in the gastric fundus/cardia, with II-a as the predominant macroscopic type and most patients had no H. pylori infection. Endoscopic Submucosal Dissection (ESD) was the primary treatment. All patients were followed up for an average of 17.3 months, during which no tumor recurrence or metastasis was observed, and all patients survived. Some patients underwent indigo carmine chromoendoscopy, which revealed a granular appearance of the surface mucosa in 3 OGA patients (11.5 %), 7 GA-FG patients (30.4 %), and 2 GA-FGM patients (100 %), showing a statistically significant difference between groups (p = 0.010). Among the GA-FG and GA-FGM groups, some patients underwent Magnifying Narrow-Band Imaging (M-NBI) endoscopy. Irregular microvascular pattern (IMVP) was positive in 18 GA-FG patients (20.2 %) and 3 GA-FGM patients (50.0 %) (p = 0.097), suggesting a potential trend towards difference.

Conclusions This is the largest clinical investigation of GEN-FGML conducted globally to date. The combination of indigo carmine chromoendoscopy and magnifying narrow-band imaging endoscopy may be effective in differentiating

▶ **Table 1** Clinical and endoscopic features of different GEN-FGML types

	OGA(n = 225)	GA-FG(n = 116)	GA-FGM(n = 6)	p value

eP330 Peroral Endoscopic Myotomy for Achalasia: Evidence of Efficacy and Safety Based on a Retrospective Analysis in a Private Clinical Setting

Authors Abdiyev N[1], Акниет У[2], Aizat O[2]

Institutes 1 Private Clinic Almaty, Almaty, Kazakhstan; 2 Asfendiyarov Kazakh National Medical University, Almaty, Kazakhstan

DOI 10.1055/s-0046-1821657

Aims Achalasia cardia is an idiopathic neurodegenerative disorder of the esophagus characterized by impaired relaxation of the lower esophageal sphincter and loss of normal peristalsis. Although rare (2.92 per 100,000 adults and 0.11 per 100,000 children), achalasia has a significant clinical and social burden. Progressive dysphagia, regurgitation, chest pain, and weight loss substantially reduce patients' quality of life and lead to nutritional deficiencies, while the risk of esophageal carcinoma remains elevated. Conservative therapy provides only limited and short-term relief.Peroral endoscopic myotomy (POEM) has emerged as a modern, minimally invasive treatment demonstrating high efficacy and safety. In Kazakhstan, POEM is primarily performed in national research centers; however, experience from private hospitals remains underreported, highlighting the relevance of this study.

Methods Diagnosis of achalasia was established buy barium x-ray esophagography, EGD and symptom assessment Eckardt score. The study included 19 patients (7 men and 12 women) with stages I–III achalasia. The mean age was 43.5 years (range: 23–59), and the mean body mass index (BMI) was 24.6 kg/m² (16.9–26.4). Hospitalization lasted 4–7 days. The mean procedure time was 50 minutes (range: 45–120), with an average myotomy length of 6 cm (5–9 cm).

Results In a private clinic setting without government funding, POEM was successfully performed in all 19 patients. The preoperative mean Eckardt score was 7.85, reflecting marked dysphagia, regurgitation, chest pain, and weight loss. The average body weight before surgery was 58 kg (48–85 kg), with weight loss ranging from 2 to 30 kg.Following POEM, the mean Eckardt score decreased to 1.26. All patients reported significant symptom resolution, including improved swallowing, chest comfort, and normalization of sleep. No serious complications occurred. A complete regression of dysphagia, regurgitation, and chest pain was achieved in all cases, with only one patient experiencing recurrence within one year postoperatively.

Conclusions Our findings confirm that POEM can be safely and effectively performed not only in national or academic centers but also in private clinical settings, provided adequate endoscopic expertise and equipment are available. The outcomes in this study are comparable to international data, underscoring that procedural success depends primarily on adherence to technical standards rather than institutional status.This experience demonstrates that private hospitals can play a pivotal role in expanding access to innovative, minimally invasive treatments for achalasia, ultimately improving healthcare quality and reducing disparities in care availability.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP331 Inpatient vs Outpatient Endoscopic Retrograde Cholangiopancreatography: Patient Characteristics and Outcomes in a Cohort Study

Authors Quaunine M[1], Parmar A[1], King W[1], Khan R[1], Haberston K[1], Bradley R[1], Kerwat R[1]

Institute 1 Queen Elizabeth Hospital, London, United Kingdom

DOI 10.1055/s-0046-1821658

Aims Endoscopic Retrograde Cholangiopancreatography (ERCP) is a key therapeutic procedure in gallstone disease. Outpatient ERCP may reduce inpatient pressures and costs, but patient selection is challenging due to post-procedure complications. No validated criteria currently guide suitability for outpatient ERCP. This study aimed to identify factors associated with inpatient versus outpatient ERCP and to determine patient characteristics predictive of post-ERCP complications [1–7].

Methods A retrospective cohort study included demographic variables, comorbidities, Clinical Frailty Scale (CFS), ASA classification, presenting diagnosis, and biochemical markers, including initial and peak bilirubin. Logistic regression assessed factors associated with inpatient ERCP; variables with $p < 0.10$ on univariate analysis were included in multivariate models. ERCP-related complications were recorded, and univariate and multivariate regression analyses identified predictors of complications. Predictive performance was evaluated using Receiver Operating Characteristic (ROC) curves and reported as area under the curve (AUC) (▶ **Table 1**).

▶ **Table 1** Logistic Regression Analysis for Factors Predicting Complications after ERCP. Variables with $p < 0.1$ in the initial univariate model were included in the multivariant regression analysis.

Multivariate regression analysis	P value	Estimate (95 % CI)
Age	**<0.001**	-0.143 to −0.034
CFS	**<0.001**	0.391 to 1.693
ASA	**0.010**	-2.755 to −0.329
Initial Bilirubin	**<0.001**	-0.100 to −0.0278
Gallstone Pancreatitis	0.125	-3.871 to 0.388
Inpatient ERCP	0.109	-3.297 to 0.2777

Results Over a one-year period, 112 patients met inclusion criteria, with 67 % undergoing outpatient ERCP. On univariate analysis, elevated initial and peak bilirubin levels, ASA grade, and a diagnosis of ascending cholangitis were significantly associated with inpatient ERCP ($p < 0.05$). Following multivariate adjustment, none of these factors remained statistically significant (all $p > 0.05$), indicating the absence of independent predictors for the choice of inpatient versus outpatient ERCP. Post-ERCP complications were observed more frequently in the outpatient cohort. Multivariate analysis identified age, Clinical Frailty Scale, ASA grade, and initial bilirubin as independent predictors of complications. ROC analysis demonstrated limited discriminative performance,

with AUC ≤ 0.65; age and initial bilirubin had the highest predictive accuracy, though discrimination remained poor to fair (▶ **Table 2**).

▶ **Table 2** Area Under the Curve (AUC) for variables outlined from the results of multivariate regression analysis, with their confidence intervals (CI) and p value.

Predictor	AUC	95 % CI	P value
Age	0.64	0.509-0.779	0.048
ASA	0.63	0.488-0.765	0.083
CFS	0.56	0.419-0.705	0.396
Initial Bilirubin	0.65	0.519-0.782	0.039

Conclusions In conclusion, there were no specific patient characteristics which correlated with the setting of ERCPs (inpatient vs outpatient). Initial bilirubin level, age, ASA and frailty were predictors of post-ERCP complications. Complications occurred more frequently in our outpatient setting, suggesting that a guideline for patient selection could be useful in deciding who is safe for an outpatient ERCP. Further work on a larger scale is required to establish a set criteria for patients who are best suited to outpatient ERCP.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP332V Cholangioscope-assisted balloon dilation of sequential esophageal strictures in Crohn's disease: A minimally invasive innovative technique

Authors Neonaki A[1], Papadakos S[1], Tampaki M[1], Papatheodoridi M[1], Karatzas P[1], Papatheodoridis G[1], Koutsoumpas A[1]
Institute **1** 1st Academic Department of Gastroenterology, General Hospital of Athens "Laiko", Athens, Greece
DOI 10.1055/s-0046-1821659

Problem to solve Upper gastrointestinal (GI) tract involvement in Crohn's disease is increasingly recognized due to improved endoscopic techniques [1]. However, data on managing esophageal strictures endoscopically is limited due to their rarity and the complexity of the disease, which often requires surgery [2]. Endoscopic balloon dilation (EBD) is the cornerstone for short fibrotic strictures management [3]. Nevertheless, many strictures cannot be traversed with a conventional gastroscope, making interventions challenging. In these cases, ultra-slim endoscopes may offer a feasible, minimally invasive alternative [4].

Innovation We describe a case where a digital cholangioscope was used, enabling successful dilation of two non-passable (with conventional gastroscopes) esophageal strictures. A 32-year-old woman with Crohn's disease (Montreal A2/L3 + L4/B2), on 4-week intensified intravenous infliximab therapy, presented with progressive dysphagia. Upper GI Endoscopy revealed two short esophageal strictures at 21 cm and 30 cm from the incisors, both non-traversable with a standard gastroscope. A digital cholangioscope with adaptation for air insufflation was used to assess both strictures that looked fibrostenotic without inflammatory component. The cholangioscope easily traversed the proximal stricture, allowing guidewire placement through the distal, tighter stricture (estimated diameter:3-4 mm). With gentle manipulation, the cholangioscope reached the stomach and guidewire was left in place. The cholangioscope was then withdrawn and reinserted alongside the guidewire. Finally, over-the-wire balloon dilation of the distal stricture was performed under direct endoscopic visualization, with biliary balloons at 4mm and 6mm, with superficial therapeutic mucosal tear at 5o'clock.

Results Following that, the patient underwent two more EBD sessions, in steps, at 6-7-8mm and 8-9-10mm respectively, finally allowing the standard gastroscope to pass through. She experienced significant improvement of her symptoms, was able to resume oral intake, and did not encounter any post-procedural complications.

Conclusions This case illustrates an innovative and minimally invasive technique for managing tight and complex esophageal strictures in patients with Crohn's disease. The off-label use of a digital cholangioscope allowed for access and real-time visualization of previously non-passable strictures, enabling safe and delicate EBD without the need for obsolete and rough fluoroscopic guidance.

eP333 Therapeutic Pancreatic Duct Stenting in Severe Post-ERCP Pancreatitis: Clinical Effectiveness and Institutional Experience

Authors Tiunov O[1], Melnik D[2], Bykov M[3]
Institutes **1** City Hospital №4 Sochi, Tuapsinskaya 1, Sochi, Russia; **2** City Hospital №4, Sochi, Tuapsinskaya, 1 , Sochi, Russia; **3** Regional Clinical Hospital №1 Krasnodar, Krasnodar, Russia
DOI 10.1055/s-0046-1821660

Aims To evaluate the feasibility and clinical outcomes of early therapeutic PD stenting in patients with severe PEP.

Methods From 2020 to 2024, **879** retrograde interventions on the major papilla were performed. Severe PEP occurred in **14** patients, divided into:

- **Group 1 (n = 7):** conservative management;

- **Group 2 (n = 7):** attempted therapeutic PD stenting within 24 hours.

Therapeutic stenting was successful in **5/7** patients. Straight plastic stents **5 Fr × 5 cm** without flaps were used.

Results All successfully stented patients demonstrated:

- significant pain reduction within **48 hours**,
- normalization of laboratory parameters within **48–72 hours**,
- no development of peripancreatic fluid collections.

In the conservative group, fluid collections developed in **3/7** patients, requiring drainage.No mortality was observed in either group [1–7].

Conclusions Early therapeutic PD stenting appears feasible and clinically beneficial in selected patients with severe PEP, resulting in faster symptom resolution and fewer complications.These findings support the need for prospective controlled studies to clarify indications, timing, and the potential role of therapeutic PD stenting in the management of severe PEP

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP334 Efficacy of endoscopic full-thickness resection (eFTR) in colorectal lesions therapy: outcomes from a single tertiary center

Authors Brodyuk N[1], Grega T[1, 2], Vackova Z[1], Kuzko I[1], Urbanek P[1], Suchanek S[1, 2]

Institutes **1** Deparment of Medicine, 1st Faculty of Medicine, Military University Hospital, Prague, Czech Republic; **2** Department of Gastrointestinal Oncology, 1st Faculty of Medicine, Military University Hospital, Prague, Czech Republic

DOI 10.1055/s-0046-1821661

Aims This analysis aimed to evaluate the technical success, histological results, and safety profile of all eFTRs in the treatment of colorectal lesions in a tertiary referral center.

Methods We retrospectively analyzed all consecutive colorectal eFTR procedures conducted between 2018 and 2025 at a single tertiary endoscopy center (Military University Hospital Prague, Czech Republic), using the full-thickness resection device (FTRD; Ovesco Endoscopy, Tübingen, Germany). Patient demographics, lesion characteristics, procedural data, histopathology, and adverse events (AEs) were extracted from a prospectively maintained database. Technical success was defined as en-bloc removal of the target lesion using the FTRD system. R0 resection required histologically tumor-free lateral and deep margins. Curative resection of invasive cancer followed ESGE low-risk criteria (R0, absence of lymphovascular invasion, and limited submucosal infiltration). AEs were defined as complications requiring endoscopic or surgical treatment. Proportions are reported with 95 % confidence intervals (CI) using the Wilson or Clopper–Pearson method.

Results A total of 88 eFTR procedures were performed in 86 patients, 41 men (48 %), and 45 women (52 %); age range 26–86 years. The median lesion size was 20 mm (range, 10–30 mm). Lesion location was right colon 37 (42 %), left colon 28 (32 %), and rectum 23 (26 %). Main indications were lesions suspicious for invasive cancer (36; 41 %), non-lifting adenomas (21; 23.8 %), recurrent adenomas (14; 16 %), subepithelial tumors (5; 5.6 %), scar after non-curative resection of T1sm1 cancer (9; 10.2 %), and appendiceal lesions (3; 3.4 %). En-bloc resection was achieved in 74/88 (84.1 %; 95 % CI, 75.0–90.3) and histological R0 in 71/88 (80.7 %; 95 % CI, 71.2–87.6). Invasive cancer was present in 34/88 (38.6 %; 95 % CI, 29.1–49.1). Among these cancers, R0 resection was achieved in 23/34 (67.6 %; 95 % CI, 50.8–80.9), with curative resection in 7/23 (30.4 %; 95 % CI, 15.6–50.9). AEs occurred in 11/88 (12.5 %; 95 % CI, 7.1–21.0): perforation (n = 4), acute appendicitis (n = 2), and bleeding (n = 5). Three patients (3.4 %) with delayed perforation required surgery.

Conclusions In this single-center cohort, eFTR achieved high en-bloc and R0 resection rates with acceptable morbidity; most AEs were managed non-operatively. eFTR represents a valuable minimally invasive option for selected colorectal lesions, including non-lifting or recurrent adenomas and early cancer.

eP335 Comparative evaluation of AI systems for endoscopic detection of gastric precancerous conditions

Authors Ligato I[1], De Magistris G[2], Dilaghi E[1], Panzuto F[1], Lahner E[1], Annibale B[1], Giagu S[3], Esposito G[1]

Institutes **1** Department of Medical-Surgical Sciences and Translational Medicine, Sapienza University of Rome, Rome, Italy; **2** Department of Computer, Control and Management Engineering, Sapienza University of Rome, Italy, Rome, Italy; **3** Physics Department, Sapienza University of Rome, Rome, Italy

DOI 10.1055/s-0046-1821662

Aims Intestinal metaplasia (IM) is a gastric precancerous condition. Patients with advanced stages of IM are considered at higher risk for developing gastric cancer (GC), and endoscopic surveillance in this population has proven beneficial. The diagnosis of IM is histological; however, electronic chromoendoscopy enables targeted biopsies through real-time detection. Artificial intelligence (AI) can support IM detection, particularly in cases with patchy distribution, and for endoscopists who are not specialized in upper gastrointestinal (GI) endoscopy. Our previous pilot study demonstrated that a machine learning (ML) system based on EfficientNet-B0 achieved approximately 90 % accuracy in recognizing IM using blue light imaging (BLI) in the gastric corpus [1]. The present study aimed to compare different ML systems for the identification of IM using BLI endoscopic images of the antrum and corpus.

Methods We retrospectively analyzed a dataset of prospectively collected endoscopic images from gastroscopies performed at Sant'Andrea Hospital, Sapienza University of Rome, between January 2020 and March 2024. Several ML approaches were tested and compared to develop an automated multi-task model: binary image classification into healthy vs. non-healthy categories (EfficientNet-B0), detection of IM-affected areas (YOLOv5 and HistologyYOLO), and interpretability assessment (Gradient-weighted Class Activation Mapping, GradCAM).

Results The dataset comprised 2017 images from 279 patients. EfficientNet-B0 achieved a test accuracy of 0.90, precision of 0.92, and recall of 0.91. The HistologyYOLO model showed an accuracy of 0.52, precision of 0.47, and perfect recall (1.00), while YOLOv5 achieved a precision of 0.32 and recall of 0.29. GradCAM provided satisfactory qualitative interpretability by highlighting the regions influencing the network's decisions, complementing the classifier despite the absence of quantitative validation.

Conclusions EfficientNet-B0 showed optimal performance, which can be further enhanced by the application of GradCAM to identify the most influential image regions guiding the model's decision-making process.

eP336 Intestinal Behçet's Disease as a Distinct Phenotype of Behçet's Disease

Authors Subum P[1], Woojin K[1], Cheolwoong C[1], Jinook J[1], Cheolmin L[1]
Institute 1 Pusan National University Yangsan Hospital, Yangsan-si, Republic of Korea

DOI 10.1055/s-0046-1821663

Aims Behçet's disease (BD) is a multisystem inflammatory vasculitis presenting with recurrent mucocutaneous ulcers, ocular inflammation, and skin lesions. Although gastrointestinal symptoms may appear in a substantial number of patients, true intestinal BD is relatively uncommon. This study assessed the clinical characteristics and treatment patterns of intestinal BD at a tertiary center in Korea [1–5].

Methods Medical records of 327 patients who fulfilled the ISG or ICBD criteria for BD and were followed between November 2008 and September 2023 were reviewed. Among them, 261 had BD without gastrointestinal involvement, while 66 patients (20.2 %) were diagnosed with intestinal BD. Demographic data, clinical symptoms, laboratory markers, imaging results, and treatment modalities were compared between the two groups (▶ **Table 1**).

Results Intestinal BD accounted for 20.2 % of all BD patients. Abdominal pain (74.2 % vs. 10.0 %, p < 0.001) and gastrointestinal bleeding (19.7 % vs. 0.8 %, p < 0.001) were significantly more frequent in intestinal BD, whereas uveitis, skin lesions, and arthritis were more common in non-intestinal BD. CRP levels were higher in intestinal BD (2.35 vs. 1.23 mg/dL, p < 0.001), while HLA-B51 positivity was markedly lower (13.0 % vs. 50.4 %, p = 0.001). Treatments such as 5-ASA, azathioprine, and adalimumab were used more often in intestinal BD. Hospitalization (54.5 % vs. 8.4 %) and surgery rates (16.7 % vs. 0.8 %) were also significantly higher. Multivariate analysis identified abdominal pain (adjusted OR 54.1) and HLA-B51 negativity (adjusted OR 0.20) as independent predictors of intestinal involvement (▶ **Table 2**).

Conclusions Intestinal BD shows a distinct phenotype characterized by predominant gastrointestinal symptoms, higher inflammatory activity, and reduced HLA-B51 positivity. Abdominal pain and HLA-B51 negativity may help early diagnostic suspicion. More intensive therapy and higher complication rates highlight the need for timely recognition and individualized management.

eP338 When AI Meets Expertise: Adoption and Reinvention of Computer-Aided Polyp Detection (CADe) in Endoscopy

Authors von Renteln D[1], Barkun A[2], Oleksiw M[3], Vieru D[4], Shuraida S[4]
Institutes 1 CHUM, Montreal, Canada; 2 McGill University, Montréal, Canada; 3 CHUM – Centre hospitalier de l'Université de Montréal, Montréal, Canada; 4 Université TÉLUQ, Montreal, Canada

DOI 10.1055/s-0046-1821665

Aims While clinical trials show that computer-aided detection (CADe) has the potential for increasing adenoma detection rates, real-world practice has produced inconsistent improvements. Many endoscopists report frustration with false positive notifications and workflow disruptions yet remain optimistic about its future use. This paradox challenges established information systems theories of post-adoption use. This study explores: (1) The role of expertise in endoscopists' adoption of CADe technologies, and (2) How expertise influences the reinvention of CADe in practice.

Methods We adopt a qualitative research design based on 13 semi-structured interviews with Canadian endoscopists having used a CADe platform. Participants represent a spectrum of experience levels from early-career to senior clinicians. Interviews explored motivations for adoption, experiences with CADe integration, perceptions of reliability, and workflow adaptations. Data were transcribed and coded using NVivo, with analysis guided by abductive reason-

ing. Themes include cognitive learning, and information systems (IS) use. The analysis draws on absorptive capacity, exploratory vs. exploitative technology use, and technology reinvention theories to examine how expertise influences post-adoption adaptation.

Results 1) The influence of clinical expertise on CADe adoption and application: More experienced endoscopists tend to be more resistant to using CADe with only 1/5 with > 20 years practice continuing to use the system versus 7/8 with < 15 years. Moreover, the 3 novice endoscopists (< 3 years practice) are more likely to follow AI-generated prompts rigidly (including unnecessary resections of diminutive rectosigmoid hyperplastic polyps). In contrast, the 5 more experienced endoscopists (> 10 years) adapt the system to fit their own needs and workflows, demonstrating a process of "reinvention" in practice. Overall, those with less experience use CADe as prescribed in their practice, while more experienced endoscopists envisioned different roles for the technology than its principal intended use. Clinicians also actively modulate the influence of CADe, negotiating a balance between trust in AI and professional judgment.

Conclusions These findings will refine technology reinvention theory by foregrounding expertise as a key determinant of user-driven adaptation, contributing to post-adoption information systems research, technology reinvention theory, and provides actionable insights in attempting to optimize CADe integration into practice.

eP339 Conditional inference decision trees to support colonoscopy scheduling after positive FIT in the Emilia-Romagna colorectal cancer screening program

Authors Baldacchini F[1], Giuliani O[1], Fuccio L[2], Frazzoni L[3], Fabbri C[4], Gibiino G[4], Falcini F[1, 5]

Institutes **1** Cancer Registry, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) Dino Amadori, Meldola, Italy; **2** Gastroenterology Unit, Department of Medical and Surgical Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy; **3** Gastroenterology and Digestive Endoscopy Unit, AUSL Romagna, Rimini, Italy; **4** Gastroenterology and Digestive Endoscopy Unit, Forlì-Cesena Hospitals, AUSL Romagna, Forlì-Cesena, Italy; **5** Oncological Prevention Unit, AUSL Romagna, Forlì, Italy

DOI 10.1055/s-0046-1821666

Aims The effectiveness of faecal immunochemical test (FIT)–based colorectal cancer (CRC) screening programs relies heavily on the timely completion of colonoscopy following a positive FIT result, enabling the detection and removal of early-stage cancers and precancerous lesions. However, due to limited endoscopic capacity and organizational constraints, many programs struggle to meet the recommended target of performing colonoscopy within 31 days of a positive FIT. This study aimed to evaluate the potential of a Conditional Inference Decision Tree (CIDT) model as a supportive tool to classify the risk of CRC among FIT-positive participants in the Emilia-Romagna regional screening program.

Methods Study data were obtained from the Information System for the Surveillance of Colorectal Screening of the Regional Department of Health. The analysis included all individuals aged 50–69 years with a positive FIT result recorded between 2005 and 2024. Candidate predictors included age, sex, haemoglobin concentration at FIT, cumulative haemoglobin concentration for repeat participants, and screening round (first vs subsequent).

A Conditional Inference Decision Tree was applied to identify the most relevant predictors of CRC. Internal validation was performed using cross-validation, and model performance was assessed through the area under the ROC curve (AUC). Weighted analyses were applied to account for the low prevalence of CRC (4 %).

Results Among 201,065 FIT-positive participants, 4 % were diagnosed with colorectal cancer at colonoscopy. Although CRC was a relatively rare outcome, the Conditional Inference Decision Tree (CIDT) identified clear patterns of risk within the screened population. Haemoglobin concentration at FIT was the dominant predictor and constituted the first splitting variable in the tree, effectively distinguishing participants with very low probabilities of CRC from those at substantially higher risk. Increasing haemoglobin values showed a strong and progressive association with the likelihood of detecting colorectal cancer at colonoscopy.

Age and screening round provided additional discriminatory information, refining risk estimates within haemoglobin-based strata. Individuals undergoing their first screening round and those in older age groups had higher probabilities of CRC, whereas cumulative haemoglobin across previous FIT rounds contributed to differentiating risk among repeat participants. Sex did not substantially influence the structure of the tree.

Participants with lower haemoglobin values showed markedly lower risk across all branches of the tree, with final estimated probabilities of CRC ranging from 1.4 % to 4.6 %, depending on age and screening round. Within this group, the lowest observed risks were found among participants with low haemoglobin values who were younger (≤ 59 years) and in subsequent screening rounds, with estimated probabilities as low as 1.4 %. In contrast, participants with higher FIT haemoglobin concentrations exhibited substantially greater probabilities of CRC. Within this group, age and screening round further stratified risk: older individuals (> 57 years) undergoing their first screening round formed the highest-risk terminal nodes, with estimated CRC probabilities reaching 19.9 %. The CIDT had an AUC of 0.71.

Conclusions The moderate discriminative performance of the tool, which is consistent with the low-prevalence nature of the endpoint and the real-world heterogeneity of FIT-positive populations, suggests that it needs to be improved with additional patient information. Our findings indicate that the CIDT has a potential to become a simple, interpretable, and data-driven approach to assist clinicians in the management of colonoscopy workload by identifying higher-risk subgroups of FIT-positive patients, particularly in settings with constrained resources or waiting list pressures.

eP340 Results of Endoscopic-Ultrasound Tissue Acquisition (EUS-TA) for Solid Pancreatic Lesions: 13 years' real-world experience of academic oncological center

Authors Lenz L[1], Matuguma S[2], Martins B[3], Andrade De Paulo G[1], Almeida R[4], Cesar C[5], Pombo A[5], Machado A[6], Nobre R[7], Felipe L[1], Safatle-Ribeiro A[7], Maluf-Filho F[7]

Institutes **1** Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil; **2** Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil; **3** Instituto do câncer do estado de São Paulo – ICESP, São Paulo, Brazil, São Paulo, Brazil; **4** Universidade Federal de Sao Paulo – UNIFESP, São Paulo, Brazil; **5** Instituto do Câncer do Estado de são Paulo – ICESP, São Paulo, Brazil; **6** Instituto do cancer do, andressa.machado@hc.fm.usp.br, Brazil; **7** Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil, Sao Paulo, State of Sao Paulo, Brazil, Brazil

DOI 10.1055/s-0046-1821667

Aims Aims: to provide a comprehensive description of the diagnoses and the results of EUS-TA (adequacy, sensitivity, specificity, and accuracy) for solid pancreatic lesions that have been referred due to clinical and radiological findings in a tertiary oncological referral center.

Methods Methods: a retrospective analysis was conducted on consecutive patients who underwent EUS-FNA or EUS-FNB procedures. These procedures were performed by advanced fellows under direct supervision of expert endoscopists. The material obtained was subsequently analysed by a pathologist specializing in the gastrointestinal tract. However, the pathologist was not in the endoscopy room during the procedure, i.e., without rapid-on-site-evalua-

tion (ROSE). Final diagnosis was based on histology or clinical/radiological follow-up [1–3].

Results Results: From April 2013 to February 2025, a total of 491 EUS pancreatic punctures were conducted on 433 patients, of whom 50.3 % were female. The mean age of the patients was 62 years, with a range of 25 to 86 years. The mean size of the lesions was 36 mm, with a range of 2 to 120 mm The majority of lesions were found to be localized in the pancreatic head region (72.7 %). The final diagnoses revealed that 70.8 % of cases were confirmed to be ductal adenocarcinoma, 9.6 % were neuroendocrine tumours, 8.6 % were benign lesions, and 4.8 % exhibited pancreatic metastases from other organs. Lymphoma was diagnosed in 4 patients (0.8 %), while 29 patients had other diagnoses. A total of 85.7 % (95 % CI 82.3–88.6 %) of the samples were deemed adequate. The sensitivity was 84.7 % (95 % CI 81.0–87.9 %), the specificity was 94.3 % (95 % CI 84.3–98.8 %), and the accuracy was 85.7 % (95 % CI 82.3–88.6 %).

Conclusions Notwithstanding its designation as an oncological referral center, a significant proportion of cases, amounting to nearly 10 %, were found to be benign lesions. Despite the predominance of adenocarcinoma, accounting for over 70 % of cases, other rare neoplasms, including neuroendocrine tumors, metastases, and lymphomas, can also be diagnosed through EUS-TA. Given the significant management disparities among neoplasms, histological confirmation is imperative. Current guidelines stipulate that a diagnostic rate of at least 85-87 % is a pivotal quality marker for eligible samples in all solid lesions undergoing EUS-TA. The ASGE suggests that a diagnostic rate of 70 % should be maintained and a sensitivity of 85 % or higher for malignancy on EUS-TA of pancreatic lesions. Our results demonstrated the achievement of these quality indicators even when the procedures were done by fellows and without ROSE. However, the all EUS-TA were supervised by experienced endoscopists and analyzed by expert GI pathologists. Continuous monitoring of quality indicators related to the diagnostic performance of ultrasound-guided biopsy should be carried out by all centers that perform this procedure, aiming to identify potential failures and further improve results.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821668

Abstract Text

We present the case of a 28-year-old female referred via the 2-week-wait colorectal cancer pathway for urgent colonoscopy following episodes of significant rectal bleeding with passage of large blood clots. She described fluctuating bowel habits with a baseline tendency toward constipation, intermittent watery stools, and tenesmus associated with bleeding episodes. Additional symptoms included bloating, fatigue, and nausea. She denied urgency, mucus discharge, weight loss, or systemic symptoms. Her past medical history was unremarkable; she was a non-smoker, took no medications, and had a WHO performance status of 0. Routine blood tests, including haemoglobin and iron studies, were normal, and no FIT test had been performed.

Colonoscopy demonstrated a solitary 15 mm Paris IIa flat-elevated lesion in the rectum, exhibiting a JNET type 1 and Kudo type I pit pattern. En bloc resection was performed using submucosal lift and hot snare polypectomy. The remainder of the colonoscopy was unremarkable. Histopathological analysis of the resected specimen demonstrated gastric heterotopia composed of fully differentiated gastric mucosa without dysplasia or features of neoplasia [1–3].

Gastric heterotopia is defined as the presence of mature gastric mucosa outside its normal anatomical location. It is most commonly found in the upper gastrointestinal tract, and its occurrence in the colon, particularly in the rectum, is exceedingly rare[1]. Although often asymptomatic, gastric heterotopia can be clinically significant due to local acid secretion, which may lead to ulceration, bleeding, mucosal irritation, and, in rare cases, stricture formation[2].

Rare complications reported in the literature include chronic inflammation, polyp formation, and although extremely uncommon, dysplastic change. Although rare, dysplasia has been identified in around 4–5 % of rectal gastric heterotopia cases in the literature, highlighting the importance of thorough evaluation and definitive resection[3]. Endoscopic resection is considered the treatment of choice, offering both definitive diagnosis and resolution of symptoms. In this case, complete resection was achieved, thereby eliminating the risk of further bleeding and avoiding the need for additional therapy.

This case emphasizes the importance of maintaining a broad differential diagnosis in young patients presenting with alarming lower gastrointestinal symptoms, as uncommon benign conditions such as gastric heterotopia may mimic more serious pathology. Accurate endoscopic assessment combined with histological confirmation remains central to appropriate management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP342 Challenges to Discontinuation of Long-Term Palliative Chemotherapy in Advanced Cholangiocarcinoma: Insights from Two Cases

Authors Woojin K[1], Cheolwoong C[1], Cheolmin L[1]

Institute 1 Pusan National University Yangsan Hospital, Yangsan-si, Republic of Korea

DOI 10.1055/s-0046-1821669

Background Cholangiocarcinoma is a rare but aggressive malignancy, often diagnosed at an advanced stage where curative resection is not feasible. First-line palliative chemotherapy with gemcitabine and cisplatin remains the standard of care. However, the optimal timing for treatment discontinuation following response remains uncertain. We report two cases of advanced cholangiocarcinoma in which chemotherapy was discontinued after achieving a metabolic complete response (CR) confirmed by PET-CT [1–3].

Method We retrospectively reviewed two patients with advanced cholangiocarcinoma who underwent prolonged first-line palliative chemotherapy with gemcitabine and cisplatin. Chemotherapy was discontinued upon confirmation of metabolic CR via PET-CT, and the patients were subsequently monitored for disease progression and overall clinical course.

Result

Case 1: A 70-year-old man was diagnosed with cholangiocarcinoma with liver metastases. He received gemcitabine-cisplatin chemotherapy for 66 cycles over six years. PET-CT showed metabolic CR, and chemotherapy was discon-

tinued. However, progressive disease developed. Despite multiple subsequent lines of systemic treatment, the patient transitioned to best supportive care two years later.

Case 2: A 71-year-old man presented with epigastric discomfort and was diagnosed with intrahepatic cholangiocarcinoma. He underwent 41 cycles of gemcitabine-cisplatin over four years. PET-CT confirmed metabolic CR, leading to treatment discontinuation. Recurrence was observed one year later. Several lines of systemic therapy were administered thereafter, but the patient ultimately transitioned to supportive care.

Conclusion These cases highlight the risk of early recurrence following chemotherapy discontinuation, even after achieving metabolic CR in advanced cholangiocarcinoma. Careful consideration is needed in determining the timing of treatment cessation and the role of maintenance strategies. Further research is warranted to define the optimal treatment duration and to identify patients who may benefit from discontinuation or continuation of therapy.

eP343 Case Report: Peripancreatic Low-Grade Nerve Sheath Tumor (Neurofibroma) Mimicking Pancreatic Malignancy in a 32-Year-Old Male

Authors Calda DA[1], Caburnay A[1]
Institute 1 St. Luke's Medical Center – Global City, Taguig, Philippines
DOI 10.1055/s-0046-1821670

Abstract Text

Neurofibromas are benign peripheral nerve sheath tumors commonly associated with Neurofibromatosis Type 1 (NF1). Sporadic, solitary neurofibromas arising in the peripancreatic region are exceedingly rare and may present diagnostic challenges due to their resemblance to pancreatic malignancies on imaging. Accurate diagnosis is essential to guide management, as treatment strategies differ significantly between benign neurogenic tumors and aggressive pancreatic neoplasms. A 32-year-old male with no known comorbidities and no family history of malignancy underwent a routine annual wellness examination, during which an abdominal ultrasound was performed. The study incidentally revealed a few lobulated, heterogeneous, predominantly hypoechoic masses in the peripancreatic region, measuring 1.9 × 1.4 cm and 7.5 × 6.6 × 3.5 cm, with internal calcifications. The masses appeared to encase vascular structures, including the celiac trunk and portal confluence, raising concern for a malignant pancreatic process. Further evaluation with MRCP demonstrated an exophytic, peripherally enhancing lobulated mass arising from the pancreatic head and uncinate process. The lesion appeared T1 hypointense and T2 iso- to hyperintense and measured 5.4 × 6.5 × 7.1 cm (AP × T × CC). It encased the celiac trunk and superior mesenteric artery, compressed the portal confluence and superior mesenteric vein, and was intimately related to the inferior vena cava and the inferior margin of hepatic segment 4B and the caudate lobe. Due to these suspicious features, endoscopic ultrasound with fine needle biopsy was performed. Histopathologic evaluation revealed a spindle cell lesion, and immunohistochemical staining demonstrated negativity for CD117, DOG1, SMA, and desmin, with CD34 positivity highlighting perineural cells and diffuse S100 positivity. These findings were diagnostic of a low-grade, benign nerve sheath tumor, favoring neurofibroma. Peripancreatic neurofibromas are rare tumors, particularly in patients without neurofibromatosis type 1 (NF1), and they present a significant diagnostic challenge due to their ability to mimic pancreatic malignancy on imaging. In this case, the large size of the mass, its heterogeneous appearance, presence of calcifications, and particularly the encasement of major vascular structures created a strong radiologic impression of an aggressive pancreatic neoplasm such as pancreatic ductal adenocarcinoma or a malignant neuroendocrine tumor. These imaging features often prompt consideration of unresectable disease, and without tissue confirmation, patients may be subjected to unnecessary radical surgery or deemed inoperable. This case illustrates a rare presentation of a sporadic peripancreatic neurofibroma masquerading as a malignant pancreatic tumor due to its size and extensive vascular involvement. Comprehensive evaluation—including advanced imaging and EUS-guided biopsy with immunohistochemistry—is essential to avoid misdiagnosis and unnecessary radical surgery [1–3].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP344 Pancolonic Intestinal Schistosomiasis Masquerading as Ulcerative Colitis: A Case Report

Author Banga R[1]
Institute 1 Vicente Sotto Memorial Medical Center , Cebu City Philippines
DOI 10.1055/s-0046-1821671

Aims To report a rare case of diffuse intestinal schistosomiasis involving the entire colon, mimicking ulcerative colitis, and to emphasize the importance of considering parasitic infections in the differential diagnosis of pancolitis in endemic regions.

Methods A 31-year-old male from Consolacion, Cebu, presented with painless hematochezia and was initially admitted for planned hemorrhoidectomy. Due to persistent bleeding, colonoscopy was performed, which revealed continuous mucosal ulceration and inflammation from the rectum to the cecum. An initial endoscopic impression of ulcerative colitis was made. Systematic biopsies were obtained from all colonic segments, and stool microscopy for ova and parasites was performed [1, 2].

Results Stool microscopy was negative for parasitic ova. However, histopathological examination of colonic biopsies demonstrated numerous *Schistosoma* ova embedded within the lamina propria throughout all sampled segments, confirming extensive intestinal schistosomiasis. The patient was treated with praziquantel and subsequently underwent hemorrhoidectomy. Complete resolution of hematochezia was observed, with no recurrence on follow-up. This case illustrates the significant diagnostic challenge posed by diffuse egg deposition producing a pancolitis pattern that closely mimics inflammatory bowel disease.

Conclusions Pan-colonic involvement in intestinal schistosomiasis is exceedingly rare, as the disease typically localizes to the rectum and sigmoid colon. In endemic regions, schistosomiasis should be strongly considered in cases of diffuse colitis, even when stool examinations are negative. Mucosal biopsy remains the diagnostic gold standard. Early recognition allows effective treatment with praziquantel and prevents misdiagnosis and unnecessary long-term immunosuppressive therapy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP345 Endoscopic Resection of Previously Incomplete Resected Colorectal Lesions: A Retrospective Observational Cohort Study

Authors Khalaf K[1], Li H[1], Bucheeri MAGA[1], Jugnundan S[1], Nishimura T[1], Hanna Y[1], Devloo R[1], Abu Shawish W[1], Brar G[1], Gupta S[1], He T[1], Zhang L[1], Harb M[1], Fujiyoshi Y[1], Clancy J[1], Calo N[1], May G[1], Teshima C[1], Mosko J[1]
Institute 1 St. Michael's Hospital, Toronto, Canada
DOI 10.1055/s-0046-1821672

Aims Incomplete resection of colorectal polyps predisposes to local recurrence and technical difficulty in subsequent interventions. Prior resection attempts create fibrosis in the submucosal space, limiting lifting and snare capture, and may necessitate advanced techniques. Real-world data comparing outcomes for incompletely resected versus naive lesions are limited, particularly within an "all-comers" unselected referral population. Our aim was to compare procedural success, safety, and recurrence between previously incompletely resected and naive complex colorectal lesions, and to describe the efficacy of advanced resection and adjunctive techniques for previously resected lesions [1].

Methods All consecutive patients who underwent resection of complex colorectal polyps at St. Michael's Hospital, Toronto, Canada, between 2019 and 2025 were included. Prior resection was defined as any lesion with a prior incomplete resection (not including biopsy or tattoo) attempt identified endoscopically and/or through referral chart review (▶ **Table 1**).

▶ **Table 1**

	No Prior Resection (n = 1359)	Prior Incomplete Resection (n = 187)	p-value
EMR technique	1175 (86.5 %)	130 (69.5 %)	**< 0.0001**
En Bloc	137 (10.1 %)	6 (3.2 %)	
Hot Piecemeal	888 (65.3 %)	108 (57.8 %)	
Cold Piecemeal	150 (11.0 %)	16 (8.6 %)	
Hybrid technique	37 (2.7 %)	22 (11.8)	**< 0.0001**
ESD technique	147 (10.8 %)	35 (18.7 %)	**< 0.0001**
Adjunctive methods			
CAST	421 (31.0 %)	82 (43.9 %)	**0.0004**
Hot avulsion	79 (5.8 %)	38 (20.3 %)	**< 0.0001**
Snare-tip Submucosal release	108 (8.0 %)	75 (40.1 %)	**< 0.0001**
Technical success	1302 (95.8 %)	183 (97.9 %)	0.18
Curative Resection	1243 (91.5 %)	176 (94.1 %)	0.22
Recurrence at first surveillance	61 (9.2 %)	11 (13.1 %)	0.25

Results Among 1,546 lesions, 1,359 had no prior resection and 187 had prior incomplete resection. In the no prior resection group, 86.5 % were treated with EMR, 2.7 % with hybrid EMR and 10.8 % with ESD, whereas in the prior incomplete resection group 69.5 % underwent EMR, 11.8 % hybrid EMR and 18.7 % with ESD. When EMR was performed in the no prior resection group, en-bloc EMR was performed 10.1 % of the time, hot-snare piecemeal EMR in 65.3 %, cold-snare piecemeal EMR in 11.0 %,, compared with 3.2 %, 57.8 %, and 8.6 % respectively in the prior incomplete resection group ($p < 0.0001$). Adjunctive methods were required more in the prior incomplete resection group. CAST was used in 31.0 % vs 43.9 % ($p = 0.0004$), hot avulsion in 5.8 % vs 20.3 % ($p < 0.0001$), and submucosal release in 8.0 % vs 40.1 % ($p < 0.0001$). Technical success was achieved in 95.8 % vs 97.9 % ($p = 0.18$) in the no prior resection versus prior incomplete resection groups. For adverse events, intra-procedural perforation occurred in 0.8 % vs 1.1 % ($p = 0.38$), delayed bleeding in 2.2 % vs 1.6 % ($p = 0.59$), and delayed perforation in 0.4 % vs 0 % ($p = 0.36$) in the no prior resection versus prior incomplete resection groups. Recurrence at first surveillance was 9.2 % vs 13.1 % in the no prior resection versus prior incomplete resection groups ($p = 0.25$).

Conclusions Lesions with prior incomplete resection were associated with markedly greater technical complexity, reflected by increased use of advanced and adjunctive techniques. Despite this, technical success, curative resection, adverse events, and early recurrence were similar between groups. In contrast to prior literature [1], when adjunctive therapy consisted almost exclusively of CAST/hot avulsion and outcomes for previously attempted lesions were inferior, a more nuanced and deliberately aggressive adjunctive strategy can largely overcome the historical disadvantage of previously manipulated, fibrotic colorectal lesions.

eP346 Role of bedside glucometry in differentiating mucinous vs non mucinous cystic lesions of pancreas

Author Mishra A[1]
Institute 1 Medanta – The Medicity, Gurugram, India
DOI 10.1055/s-0046-1821673

Aims To study the sensitivity,specificity and accuracy of bedside glucometry in diagnosing nature of cystic lesions of pancreas.

Methods Study was conducted in Medanta,The Medicity hospital Gurgaon-,India and total number of patients were 56 and all patients with age more than 18 years and with pancreatic cystic lesions were included [1, 2].

EUS was done in each patient and FNA was performed and pancreatic cystic fluid was collected immediately and glucose was checked using commercial glucometer ie Accu Check.

Results Glucose level less than 60 mg/dl correctly differentiated mucinous from non mucinous pancreatic cystic lesions among 42.9 % patients with sensitivity and specificity of 82.8 % and 81.5 % respectively.The area under curve was high (0.88,p = 0001).The positive predictive value,negative predictive value and accuracy was 82.8 %,81.5 % and 82.1 % respectively.The mean CEA level was significantly (p = 0.0001) higher among patients with mucinous (4844.5 + /- 90.24) compared to non mucinous (262.9 + /- 366.9).

CEA level more than 100 correctly differentiate mucinous from non mucinous cysts with sensitivity and specificity of 82.8 % and 70.4 % respectively.The positive predictive values,negative predictive value and accuracy was 75 %,79.2 % and 76.8 % respectively.

Conclusions Glucose level less than 60 mg/dl correctly differentiated mucinous from non mucinous pancreatic cystic lesions among 42.9 % patients with sensitivity and specificity of 82.8 % and 81.5 % respectively.The area under curve was high (0.88,p = 0001).The positive predictive value,negative predictive value and accuracy was 82.8 %,81.5 % and 82.1 % respectively.The mean CEA level was significantly (p = 0.0001) higher among patients with mucinous (4844.5 + /- 90.24) compared to non mucinous (262.9 + /- 366.9).

Abstract Text

Duodenal stenosis is commonly caused by peptic ulcer disease, Crohn's disease, neoplasms, extrinsic compression, or, rarely, infections. Standard management of benign stenosis includes endoscopic balloon dilation; however, success may be limited in refractory or anatomically complex strictures. Lumen-apposing metal stents (LAMS), such as the AXIOS stent, have emerged as a novel therapeutic option in these challenging cases.

We report the case of a 20-year-old male with a history of para-aortic paraganglioma requiring extensive resection and subsequent radiotherapy, who later developed recurrent disease and retroperitoneal fibrosis. He presented with elevated liver enzymes and was found on MRCP to have intrahepatic biliary dilation and intrabiliary cast formation. Attempts at ERCP were unsuccessful due to a severe intrinsic duodenal bulb stenosis that limited passage of a standard endoscope despite multiple sessions of stepwise balloon dilation up to 15 mm. Given persistent failure to traverse the stricture, a multidisciplinary decision was made to deploy a 20 mm × 10 mm AXIOS (Boston Scientific) LAMS across the stenosis under combined endoscopic and fluoroscopic guidance. The stent remained in place for 10 days without adverse events, allowing successful duodenoscope passage and ERCP, with partial extraction of biliary stones and sludge and subsequent cholangioscopic evaluation.

This case highlights the effective use of LAMS as a bridge to ERCP in benign, refractory duodenal stenosis. The stent dwell time was 10 days with no stent migration or adverse event reported with no recurrence of biliary stenosis up to 3 months follow up.

Current literature demonstrates high technical and clinical success rates for LAMS in benign gastrointestinal strictures, with acceptable adverse event rates. Our case adds to growing evidence supporting LAMS as a safe and effective option when standard dilation fails.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP348 Safety and efficacy of 10 mm self-expandable metallic stent placement for malignant esophageal stricture after radiotherapy

Authors Kawata N[1], Masao Y[1], Kazunori T[1], Ito S[1], Imai K[1], Matsubayashi H[1], Hotta K[1], Ono H[1]

Institute **1** Shizuoka Cancer Center, Shizuoka, Japan

DOI 10.1055/s-0046-1821675

Aims Self-expanding metal stents (SEMS) are effective in relieving dysphagia caused by malignant tumors and are considered an important palliative option for patients with unresectable esophageal cancer. However, SEMS placement after radiotherapy has been associated with an increased risk of serious adverse events (AEs), including bleeding, perforation, and mediastinal infection. Smaller-diameter SEMS may reduce the risk of AEs, but their clinical utility in patients after radiotherapy has not been fully elucidated. The aim of this study was to evaluate the safety and efficacy of esophageal SEMS with a 10 mm shaft diameter (10 mm SEMS) in patients with malignant esophageal stricture after radiotherapy.

Methods This was a prospective observational trial conducted at Shizuoka Cancer Center. We included patients with malignant esophageal stricture after radiotherapy for esophageal squamous cell carcinoma, in whom a standard endoscope could not pass the stricture, and who underwent placement of a 10 mm SEMS. The primary endpoint was the incidence of esophageal bleeding, perforation, and mediastinal infection of grade ≥ 3, according to the Common Terminology Criteria for Adverse Events (CTCAE). Secondary endpoints included best dysphagia score (DS), duration of DS ≤ 2, all AEs, and overall survival (OS) after 10 mm SEMS placement.

Results A total of 20 patients (17 men, 3 women; median age 71.5 years, range 46–87 years) were enrolled from March 2018 to March 2024. According to the Eastern Cooperative Oncology Group Performance Status, 7 patients had PS 0–1 and 13 had PS ≥ 2. Stricture locations were upper, middle, and lower esophagus in 8, 9, and 3 patients, respectively. The median radiation dose was 60 Gy (range: 30–60 days), and the median interval from completion of radiotherapy to 10 mm SEMS placement was 149 days (range: 7–965 days). No CTCAE grade ≥ 3 bleeding, perforation, or mediastinal infection was observed after 10 mm SEMS placement. Dysphagia improved in 95 % (19/20) of patients, with DS improving from 3.45 ± 0.76 to 1.20 ± 0.83 ($P < 0.001$). Best DS values of 3, 2, 1, and 0 were observed in 2, 3, 12, and 3 patients, respectively. The median duration of DS ≤ 2 after 10 mm SEMS placement among 18 patients was 44 days (range: 3–126 days). Stent migration occurred in 7 patients (35 %) and occlusion in 1 patient (5 %). Among those with migration, 5 underwent additional placement of a 16–18 mm SEMS, and 1 required gastrostomy. The median OS after 10 mm SEMS placement was 103 days (range: 47–607 days).

Conclusions Placement of a 10 mm SEMS was safe and effective for malignant esophageal stricture after radiotherapy. Although no severe adverse events were observed, stent migration remains a significant limitation and further studies are needed to develop methods to prevent migration.

eP349 Pre-Endoscopic Anxiety: Determinants and Impact on the Patient Experience

Authors Hammouda L[1], Jlassi H[2], Ben Khalifa MO[3], Zaouga S[1], Soua S[1], Sabbah M[2], Bibani N[2], Gargouri D[4]

Institutes **1** Habib Thameur Hospital, tunis, Tunisia; **2** university of medicine of tunis , tunis Tunisia; **3** University of medicine of tunis, tunis, Tunisia; **4** Hôpital Habib Thameur, Tunis, Tunisia

DOI 10.1055/s-0046-1821676

Aims To identify the key determinants of pre-endoscopic anxiety and to examine how this anxiety influences procedural tolerance, symptom burden, and overall patient satisfaction.

Methods We conducted a cross-sectional observational study including 51 patients scheduled for digestive endoscopy. Anxiety levels were assessed using the Spielberger Anxiety Inventory. Sociodemographic features, medical and psychiatric history, personality traits, previous experiences with endoscopy, knowledge about the procedure, and willingness to undergo unsedated endoscopy were recorded.Per-procedural variables included pain intensity, bloating, nausea/vomiting, incontinence, and procedure duration. Statistical analysis used comparison tests and multivariate linear regression ($p < 0.05$).

Results Patients had a mean age of 59.7 years (29–82), with a male-to-female ratio of 1.32. The mean anxiety score was 44.3 (25–70).

Higher anxiety levels were more frequent among patients with an anxious personality (36 % vs. 7.7 %, $p < 0.01$), those who had previously had a negative endoscopic experience (45.5 % vs. 7.1 %, $p < 0.05$), those with limited knowledge of the procedure (40 % vs. 15.4 %, $p < 0.05$), and those who felt uncom-

fortable with the idea of undergoing the exam without sedation (24 % vs. 3.8 %, p < 0.05).Age, sex, and medical history showed no significant relationship with anxiety.

Patients with higher anxiety reported more abdominal pain during the procedure (p = 0.005), along with more bloating and more nausea/vomiting. Anxiety did not correlate with the duration of colonoscopy (p = 0.22).

Pain had a clear impact on patient satisfaction: 83 % of patients with no pain rated their experience as "very satisfactory", compared with 44 % among those who experienced pain. The same pattern was observed for willingness to repeat the procedure (83 % vs. 44 %). Nearly half of patients who felt pain wished for sedation during future exams.

Conclusions Pre-endoscopic anxiety mainly stems from psychological factors and lack of information. It increases discomfort during the procedure and reduces satisfaction. Recognizing and addressing anxiety beforehand could improve patient comfort and enhance their overall experience with endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP350 Cholangioscopy-guided management of intrahepatic stones and strictures in PSC–associated ulcerative colitis: beyond conventional ERCP

Authors Popa AM[1, 2], Pavel C[2, 3], Constantinescu G[3, 2]
Institutes **1** The Clinical Emergency Hospital of Constanta County, Constanța, Romania; **2** Spitalul Clinic de Urgență București, București, Romania; **3** Carol Davila University of Medicine and Pharmacy, 020021, Bucharest, Romania
DOI 10.1055/s-0046-1821677

Abstract Text

Primary sclerosing cholangitis (PSC) is a rare but clinically significant hepatobiliary complication of ulcerative colitis (UC), associated with complex biliary strictures and recurrent obstruction that can require advanced endoscopic assessment. In PSC–UC phenotype, multifocal strictures impair bile drainage and promote secondary intrahepatic stone formation, which may complicate ductal clearance with conventional ERCP. We present a long-term PSC–UC case illustrating the role of cholangioscopy in achieving effective management of recurrent intrahepatic obstruction that had persisted despite multiple ERCP interventions. A young woman with history of UC diagnosed, in overall sustained clinical and endoscopic remission aside from a single postpartum flare, presented with symptoms of acute cholangitis. MRCP revealed multifocal intrahepatic strictures with a beaded configuration, along with multiple stones predominantly involving the left ducts, consistent with PSC. Initial endoscopic management achieved extraction of common bile duct stones using standard techniques, although a markedly dilated left intrahepatic duct with residual lithiasis and inflammatory stricturing persisted, limiting adequate drainage and prompting interval cross-sectional reassessment. Later that year, the patient experienced a second clinically significant episode of cholangitis, again requiring ERCP with only partial clearance of intrahepatic lithiasis. One year later, MRCP demonstrated progressive disease evolution, with marked dilation of the left intrahepatic ducts and an infiltrative-appearing dominant stenosis at the hepatic confluence, warranting further evaluation to exclude malignancy. These findings supported the use of SpyGlass cholangioscopy to enable comprehensive intraductal inspection, lithotripsy-assisted stone retrieval and targeted biopsy of the stenotic segment. The stricture appeared inflammatory on direct inspection and was subsequently confirmed as non-malignant by histopathological report. Cholangioscopy allowed complete clearance of impacted left intrahepatic stones, direct evaluation of multifocal inflammatory strictures, and targeted biopsies confirming non-malignant disease, thereby restoring effective segmental ductal decompression. The intervention was completed without procedure-related complications. Follow-up imaging confirmed sustained improvement in left-sided biliary drainage, with complete clinical resolution and no recurrence of cholangitic symptoms. Cholangioscopy provided decisive diagnostic and therapeutic benefit in PSC–UC with complex intrahepatic obstruction, achieving complete ductal clearance and accurate intraductal tissue evaluation. This procedure demonstrates particular value when conventional ERCP alone fails to achieve adequate ductal evaluation or complete therapeutic management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP351 Closure of polypectomy scar with the XTACK endoscopic suture system

DOI 10.1055/s-0046-1821678

Introduction Endoscopic suturing is a complementary technique to the resection of lesions of the gastrointestinal tract mucosa, specifically applied in large gastric and colonic lesions resected by mucosal resection or submucosal dissection techniques. The objective of the technique is to perform suturing of the eschar after the procedure in order to reduce associated complications, mainly perforation and bleeding.

Clinical Case A 65-year-old male with a history of multiple cardiac and nephrological conditions underwent gastroscopy due to anemia. A large 6 cm polypoid formation was observed on the posterior wall of the gastric antrum, with a wide base of implantation that spared the pylorus, suggesting an inflammatory polyp as the first option (photo 1). Fragmentary resection of the lesion was performed after elevation with indigo-gelafundin-adrenaline dilution, with good endoscopic results (photo 2) and recovering fragments for pathological anatomy, which resulted in tubular adenocarcinoma on a hyperplastic polyp invading at least the muscularis mucosa without lymphovascular invasion, with margins that could not be assessed due to fragmented resection. Subsequently, it was decided to close the eschar with the X-Tack suture system without immediate or short-term complications (photos 3 and 4). This was discussed in a multidisciplinary session, and conservative treatment was decided upon due to the patient's history.

Conclusion The endoscopic suture system has established itself as an effective method for closing large mucosal defects. It guarantees closure in areas that cannot be covered by conventional clips, which has represented a breakthrough in advanced endoscopic management. The use of the endoscopic suture system has been widely accepted in the treatment of large mucosal defects, as it allows for the closure of defects that would otherwise be impossible to close with conventional clips.

DOI 10.1055/s-0046-1821679

Abstract Text

A 44-year-old male with a history of recent high-risk sexual exposure presented to the Gastroenterology clinic reporting constipation of four months' duration and distal rectorrhagia. A diagnostic colonoscopy was performed, which revealed multiple nonspecific, circular, non-elevated, whitish lesions (2-3 mm in diameter) in the last two centimeters of the rectum, suggestive of infectious proctitis (Images 1-3). Histopathological analysis identified interstitial spiro-

chetosis, and *Mycobacterium avium* was concurrently isolated in the microbiological specimen.

The patient was also assessed by Dermatology due to a generalized cutaneous rash, oral ulcers and the aforementioned symptomatology. PCR testing on the rectal ulcer sample confirmed Lymphogranuloma Venereum (LGV) due to *Chlamydia trachomatis* serovars L1-L3. Furthermore, PCR analysis of an oral ulcer sample yielded positive results for *Treponema pallidum*. Based on the strong suspicion of both oral and rectal luetic secondary disease, the patient received treatment consisting of Benzathine Penicillin G 2.4 million units IM and a 3-week course of Doxycycline for the management of lymphogranuloma venereum. This regimen resulted in an adequate serological response and favorable clinical evolution. A follow-up rectoscopy is scheduled to definitively exclude the persistence of the associated *Mycobacterium avium* infection and its indication to be treated [1–6].

Syphilitic proctitis—an uncommon manifestation of secondary syphilis—along with LGV proctitis (secondary to *C. trachomatis* L1-L3 serovars) both constitute infrequent causes of proctitis. Nevertheless, their incidence has demonstrably risen over the past decades, particularly within high-risk sexual cohorts (accounting for up to 23 % and 47 % of proctitis cases in men who have sex with men (MSM), a subgroup where LGV is the most prevalent cause of proctitis) and in patients co-infected with HIV. Clinical presentation is often asymptomatic or may mimic Inflammatory Bowel Disease (IBD) or colorectal carcinoma, frequently featuring nonspecific endoscopic findings. This mandates a high index of clinical suspicion, a rigorous differential diagnosis, serological assays, and the meticulous collection of biopsies and microbiological samples for definitive detection. Complete clinical and endoscopic resolution is typically achieved following appropriate antimicrobial therapy. Failure to treat can lead to severe complications, including progression to proctocolitis, strictures, fibrosis, fistula or abscess formation, or even colonic perforation.

It is paramount to systematically include syphilis and lymphogranuloma venereum in the differential diagnosis of proctitis, particularly within high-risk patient populations, in order to prevent misdiagnosis and mitigate the risk of subsequent morbidities.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP353 Full thickness resection device (FTRD) in pT1 colorectal cancer

Authors Pérez Urra C[1], Espinel Pinedo P[1], Bulnes Labrador CB[1], Martin Ibañez C[1], Cimavilla Román M[1], González de Castro E[1], Montero Moretón ÁM[1], Rizzo Rodríguez MA[1], Robles de la Osa D[1], Maestro Antolín S[1], Pérez Citores L[1], Santos Santamarta F[1], Rancel Medina FJ[1], Barcenilla Laguna J[1], Moreira Da Silva BA[1], Santos Fernández J[1], Pérez Millán AG[1]

Institute 1 General Hospital Río Carrión, Palencia, Spain

DOI 10.1055/s-0046-1821680

Aims Endoscopic resection of pT1 tumors is effective if certain histological criteria for a good prognosis are met, including a resection margin > 1 mm. The FTRD (Full Thickness Resection Device) system allows resection of the entire wall thickness, making it possible to assess the presence of residual tumor [1–5].

The aim is to evaluate the role of FTRD and its safety as a complementary treatment in pT1 with borderline histological margins.

Methods Observational, descriptive, retrospective study of patients with endoscopic scar resection using FTRD between March 2023 and June 2025.

Results A total of 8 FTRD resections were performed on scars from previously resected lesions with pT1 adenocarcinoma histology with a resection margin < 1 mm and no evidence of macroscopic residual lesion. The mean age was 67 years, with 88 % being male. In all cases except one, polypectomy (mean size 17 mm) was performed on a fragment. The histology was adenocarcinoma, and the risk factors for lymphatic metastasis (not assessable in fragmented resection) were: well or moderately differentiated, no vasculolymphatic involvement, and low tumor budding. For pedunculated polyps, the Haggitt score was ≤ 3, and for sessile polyps, the Kikuchi score was ≤ SM2. In the anatomy after FTRD, no foci of adenocarcinoma were observed except in the scar of the fragmented polyp. There were no complications or recurrences during follow-up.

Conclusions Scar resection using FTRD is an effective and safe technique that allows the treatment of pT1 tumors with positive resection margins and without high histological risk, avoiding the comorbidity and costs associated with oncological surgery. Our study shows that in the resection of the polyp in a single fragment, residual disease is 0 % despite a borderline resection margin.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP354 WHEN ERCP ALONE ISN´T ENOUGH: A Single-centre Experience with Cholangioscopy-guided Lithotripsy for Complex Biliary Stones

Authors Serrano M[1], Krishnan B[1], Williams E[1], Ayres L[1], Jalal M[1], Keen T[1], Mccrudden R[1]
Institute 1 University Hospitals Dorset NHS Foundation Trust, Bournemouth, United Kingdom
DOI 10.1055/s-0046-1821681

Aims Endoscopic Retrograde Cholangiopancreatography (ERCP) is the recommended procedure for the management of choledocholithiasis. Different modalities of cholangioscopy-assisted intraductal therapy, including laser lithotripsy and electrohydraulic lithotripsy (EHL), have been developed for managing difficult biliary stones 1. However, these have been associated with a higher risk of adverse events (6 %-15 %), mainly cholangitis 2. Difficult biliary stones are defined by their diameter (> 1.5 cm), number, unusual shape, and anatomical factors that can prevent their removal 3.

We aimed to evaluate the effectiveness of cholangioscopy-guided EHL using data collected prospectively at a single high-volume tertiary referral centre (450 – 500 ERCP procedures annually).

Methods We included all patients who underwent acholangioscopy-assisted EHL for choledocholithiasis from October 2018 to September 2025.

All procedures were performed by two expert endoscopists (> 50 procedures/year) with a single-operator cholangioscopic system. Technical success was defined as complete stone clearance. The primary endpoint was the number of cholangioscopy-assisted EHL sessions needed to achieve full stone clearance. Patient-related factors (e.g. stone burden) and procedure-related variables were analysed [1–4].

The complications recorded were post-ERCP pancreatitis (PEP), cholangitis, upper gastrointestinal haemorrhage (UGIH), and perforation (which were graded as mild, moderate, or severe[4]) occurring during or within 30 days post-procedure.

Results A total of 81 EHL procedures were performed in 75 patients (49 females, 65.3 %). The median age was 73 years (range 29-95). Complete stone clearance was achieved in a single session in 68 patients (90.7 %); one additional procedure was required in 6 patients (8 %), and two procedures were required in a single patient. Overall, the technical success rate was 100 %. EHL was used as the first-line therapy in 11 patients (14.7 %). Conversely, 44 (58.8 %) had undergone one prior ERCP, 14 (18.6 %) had undergone two, and 6 (8.0 %) had undergone three or more ERCP procedures before the EHL session. All procedures were done with anaesthetist-supported deep sedation or general anaesthesia.

Regarding the choledocholithiasis profile, the median size was 17mm (range 8-40mm). The number of stones varied, with one stone present in 45 interventions (55.6 %), and ≥ 2 stones in 36 (44.4 %). After EHL, the stone fragments were removed with a balloon catheter in all the procedures. In 42 procedures (51.9 %), sphincteroplasty was necessary to achieve complete clearance. Case-by-case analysis showed that EHL use was influenced not only by stone size/number but the shape (e.g. faceted), the location (e.g. cystic duct), the presence of a stricture, or Mirizzi syndrome.

Prophylactic intravenous antibiotics were given peri-procedure, followed by a 3- to 5-day oral course (except cases with active treatment due to infection). Rectal Diclofenac (100mg) was administered to all patients unless contraindicated.

There were complications in 8 procedures (9.9 %): One case of PEP (1.2 %), two cases of UGIH (2.5 %), four cholangitis (4.9 %), and one perforation (1.2 %). Five were mild, three were moderate. None of them had a native papilla.

Conclusions Overall, our data showed that EHL is an effective and safe technique for managing complex choledocholithiasis when conventional ERCP has failed. Our complication rate was comparable to that reported in the literature. Cholangitis was more frequent, as expected with intraductal therapy, but remained within reported ranges.

Given high success rates in achieving complete stone clearance with EHL, we would recommend performing cholangioscopy/EHL following an incomplete stone clearance attempt at index ERCP, particularly if failure is due to difficult stones.

Abstract Text

Oesophageal strictures are a recognised complication of radiotherapy treatment for head, neck and oesophageal cancers. Dilatation of the completely obstructed oesophagus may require combined antegrade and retrograde dilatation (CARD). Retrograde endoscopic access may be achieved by dilatation of an existing gastrostomy site. Whilst effective, complications have been reported from gastrostomy dilatation, and from passage of the endoscope.

This is the first video report of a radiologic retrograde approach for management of occlusive oesophageal stricture. We describe a case of a completely occluded oesophagus, post-radical chemoradiotherapy for mid-oesophageal squamous cell carcinoma, which was successfully recanalized by CARD using a novel, exclusively radiologic retrograde approach.

Background: Although breast cancer (BC) is the most common malignancy in women, metastatic involvement of upper gastrointestinal (UGI) tract is uncommon. UGI metastases may affect quality of life and overall survival, but presenting with nonspecific symptoms, diagnosis may be delayed.

Case Presentation: We describe the case of a 70-year-old woman with a history of invasive lobular breast carcinoma diagnosed and treated with left mastectomy and axillary dissection. Despite adjuvant chemotherapy, bones metastasis were diagnosed 7 years later. Chemotherapeutic agents were administered during the years with stability of the bones metastasis and no other organ involvement at the follow-up CT scans. 5 years after, she underwent

EGD for progressive dyspepsia, vomiting, and weight loss. Endoscopy revealed a gastric mucosa with granular-aspect, congestion, edema, redness and multiple confluent fibrotic ulcers of 1 to 2 cm. Moreover, multiple duodenal polypoid lesions, ranging from 3 to 10 mm, with central depression and non-adenomatous pattern at digital chromoendoscopy were identified. Biopsies were performed on gastric ulcers and polypoid lesions. Histopathology demonstrated localization of lobular breast carcinoma, with immunohistochemical expression of GATA3 and lack of E-cadherin, CDX2 and the receptors for estrogen, progesterone, and HER2 proteins. According to the metastatic involvement of UGI tract, supportive palliative care was proposed. The patient was still alive 3 month after endoscopy [1–3].

Conclusion: UGI metastasis from breast carcinoma are rare, but they should be considered in patients with history of BC presenting with persistent UGI symptoms. Early recognition is crucial for the appropriate oncological management.

eP357 Traditional and modified endoscopic mucosal resection techniques for colorectal polyps over 15mm: a systematic review and network meta-analysis

Authors Santo P[1], Meine G[2], Monteiro Delgado L[3], Nunes Arantes V[3], Gralnek I[4, 5]

Institutes **1** Texas Tech University Health Sciences Center, Lubbock, United States of America; **2** Feevale University – Campus II, Novo Hamburgo, Brazil; **3** Federal University Of Minas Gerais, Belo Horizonte, Brazil; **4** Ellen and Pinchas Mamber Institute of Gastroenterology and Hepatology at Emek Medical Center, Afula, Israel; **5** Rappaport Faculty of Medicine Technion Israel Institute of Technology, Haifa, Israel

DOI 10.1055/s-0046-1821684

Aims Traditional endoscopic mucosal resection (T-EMR) is the primary endoscopic technique for resecting large size sessile colorectal lesions. However, the potential for residual adenomatous tissue to be found at the EMR site at surveillance colonoscopy remains problematic. Therefore, more recently, several modified EMR techniques have been developed including underwater EMR (U-EMR), cold EMR (C-EMR), tip-in EMR (TI-EMR), cap-assisted EMR (CA-EMR), and the addition of thermal ablation of resection margins following T-EMR using snare tip soft coagulation (STSC) or argon plasma coagulation (APC). However, few randomized controlled trials (RCTs) directly compare these modified techniques with T-EMR, thus limiting clinical decision making.Therefore, to compare the effectiveness and safety of different EMR techniques, we conducted a systematic review and network meta-analysis [1–17].

Methods We searched PubMed, Embase, and the Cochrane Library from inception to April 2025 for RCTs comparing EMR techniques for the treatment of colorectal polyps ³15 mm. We estimated relative risks (RRs) with 95 % credible interval (CrI) for dichotomous outcomes using Bayesian network meta-analysis. To assess the credibility of each comparison, we used Confidence in Network Meta-Analysis (CINeMA).

Results We included 17 RCTs with 2,832 polyps resected, using seven different EMR techniques: T-EMR (16 studies, 1,263 polyps); U-EMR (6 studies, 303 polyps); C-EMR (4 studies, 437 polyps); CA-EMR (1 study, 143 polyps); TI-EMR (2 studies, 92 polyps); and thermal ablation of resection margins (STSC: 3 studies, 440 polyps and APC: 3 studies, 154 polyps). As compared to T-EMR, U-EMR, CA-EMR, and T-EMR plus thermal ablation were all associated with significantly lower residual adenomatous tissue rates at surveillance colonoscopy, while C-EMR showed higher residual adenomatous tissue rates. SUCRA values for risk of residual adenomatous tissue with each technique were (higher SUCRA values = lower risk of residual adenomatous tissue): CA-EMR: 0.836; T-EMR plus STSC: 0.826; TI-EMR: 0.687; T-EMR with APC: 0.544; U-EMR: 0.413; T-EMR: 0.189; C-EMR: 0.007. There was no statistically significant difference between T-EMR and TI-EMR for residual adenoma rates, but TI-EMR was associated with higher rates of R0 resection than T-EMR. As compared to T-EMR, en-bloc resection rates were superior using U-EMR, yet lower with C-EMR. Intraprocedural bleeding was lower with C-EMR, CA-EMR and T-EMR. C-EMR and T-EMR also had lower rates of delayed bleeding, and perforation rates were lower with C-EMR.

Conclusions As compared with T-EMR, all modified EMR techniques appear to be effective, except C-EMR, which consistently demonstrated higher residual adenomatous tissue rates at surveillance colonoscopy. However, these outcomes should be viewed with caution given the imprecision of TI-EMR outcomes and limited data for CA-EMR. Therefore, the choice of colorectal EMR technique should be individualized based on patient and lesion characteristics as well as endoscopist EMR technical experience.

eP358 Correlation between sMARIA Score and Simple Endoscopic Score (SES-CD) in Crohn's Disease

Authors Zarrouk S[1], Mrabet S[2], Harbi R[3], Bachraoui E[1], Trabelsi O[1], Akkari I[2], Ben JE[2]
Institutes 1 Hospital F. Hached, Sousse, Tunisia; 2 Hospital Farhat Hached, Sousse, Tunisia; 3 Hospital Farhat Hached, Sousse, Tunisia
DOI 10.1055/s-0046-1821685

Aims Thanks to recent technological advances enabling rapid acquisition and the acquisition ofhigh-resolution images, and given the absence of radiation, entero- MRI plays anessential role in the evaluation and monitoring of patients with Crohn's disease.The aim of our study was to compare the performance of entero-MRI to endoscopy inassessing disease severity in croh's disease.

Methods This is a retrospective descriptive study including patients followed for Crohn's disease.Disease activity was assessed using the sMARIA score on entero- MRI and the simpleendoscopic score (SES) on endoscopy.

Results 37 patients were included, with an average age of 39,1 ± 11,77 years. The sex ratio M/Fwas equal to 2. The disease location was ileal(L1) in 3 patients (14.3 %),colonic (L2) in 1patient (4.7 %), and ileo-colic (L3) in 17 patients (81 %). An inflammatory phenotype (B1)was observed in 7 patients (33.3 %), a stenosing phenotype (B2) in 13 patients (61.9 %)and a fistulizing/penetrating phenotype in 7 patients (33.3 %).A significant correlation was observed between the sMaRIA radiological score andendoscopic activity of Crohn's disease with a statistically significant difference (p = 0.020.Significant performance of the sMaRIA score was observed in predicting endoscopicdisease activity (AUC = 0.675; CI = 0.463–0.886, p = 0.119). An sMaRIA score greater than1 was correlated with severe endoscopic activity, with a sensitivity and specificity of 66 %and 54 %, respectively.

Conclusions In our study, there was a positive correlation between the sMARIA and the SES inassessing Crohn's disease activity. This radiological score should be used in practice tooptimize patient management.

eP359 Ileocolonoscopy versus Entero-MRI for detecting complications in Crohn's disease: a comparative study

Authors Bachraoui E[1], Mrabet S[2], Harbi R[3], Zarrouk S[1], Trabelsi O[1], Akkari I[2], Ben JE[2]
Institutes 1 Hospital F. Hached, Sousse, Tunisia; 2 Hospital Farhat Hached, Sousse, Tunisia; 3 Hospital Farhat Hached, Sousse, Tunisia
DOI 10.1055/s-0046-1821686

Aims Ileocolonoscopy is usually used in Crohn's disease to check flare-up of the disease.Yet, entero-MRI shows more – like the bowel wall and nearby areas – which mightspot inflammation missed during scopes. Our aim is to study the performance ofentero-MRI compared to ileocolonoscopy in assessing disease complications.

Methods We conducted a retrospective descriptive study including 37 patients havingconfirmed Crohn's;s disease. Patients done both an entero-MRI and a colonoscopy.thetime between the two explorations did not exceed one month. For every test, we notedif strictures, ulcers, or fistulas showed up. After that, we checked how accurate eachmethod was – also how closely their results matched.

Results 37 patients were included, with an average age of 39,1 ± 11,77 years. The sex ratioM/F was equal to 2. The disease location was ileal(L1) in 3 patients (14.3 %),colonic(L2) in 1 patient (4.7 %), and ileo-colic (L3) in 17 patients (81 %). An inflammatoryphenotype (B1) was observed in 7 patients (33.3 %), a stenosing phenotype (B2) in 13patients (61.9 %) and a fistulizing/penetrating phenotype in 7 patients (33.3 %).Comparison of endoscopic and MRI data revealed that these two techniques werenearly equivalent in detecting deep gastrointestinal ulcers (p = 0.100). Endoscopy hasallowed the detection of more superficial ulcerations than enterographyMRI(0.04).However,entero-MRI was more efficient than endoscopy in detectingstrictures, with a statistically significant difference (p = 0.001).Also, MRI appears to besuperior to endoscopy in detecting deep fistulas (p = 0.013).

Conclusions In our study, entero MRI was superior to endoscopy in detecting stricture andabdominal fistulas. Ileocolonoscopy was more effective for detecting superficialulcerations.These two investigations are complementary in order to obtain a completeassessment of the lesions, allowing for optimal management of patients with Crohn'sdisease.

eP360 Transesophageal EUS-Guided FNB for Diagnosis of Right Lower Lobe Lung Adenocarcinoma: A Case Report

Authors Madrigal Bayonas L[1], Arroyo Díaz N[1], Pastor Mena J[1], Bógalo Romero C[2], Sánchez Roncero FJ[1], Calatayud Vidal G[1], Gómez Gómez A[2], Romero Martínez M[2], Espuche Jiménez C[1], Jurado Hernández A[1], Egea Valenzuela J[2], Alberca De Las Parras F[2]
Institutes 1 Rafael Méndez University General Hospital, Lorca, Spain; 2 Virgen of Arrixaca University Clinical Hospital, El Palmar, Spain
DOI 10.1055/s-0046-1821687

Introduction: Lung mass biopsy is sometimes not feasible using EBUS, making a multidisciplinary approach essential; therefore, we present this case as a representative example.

Case report: A 74-year-old woman presented with a 27 × 16 mm pulmonary nodule in the right lower lobe on chest CT, adjacent to the esophagus [Image 1], suspicious for malignancy. As the lesion was not accessible by EBUS, she was referred to our Unit to evaluate the feasibility of a transesophageal lung biopsy using endoscopic ultrasound (EUS). EUS examination identified—at 30 cm from the dental arcade, near nodal station 8—a hypoechoic pulmonary lesion measuring 29 × 7 × 11 mm, in contact with the esophagus but without invasion of its wall, showing smooth borders on the esophageal side and irregular borders on the pulmonary side [Images 2 and 3].

Fine-needle biopsy (FNB) was performed using a 25G needle, with three passes employing fanning technique and 12–15 to-and-fro movements per pass [Image 4]. Prophylactic antibiotics (ciprofloxacin 400 mg IV) were administered beforehand. The procedure was completed without complications.

Histology demonstrated large cells with abundant cytoplasm, anisokaryosis, irregular nuclear contours, and heterogeneous chromatin, arranged in glandular structures, positive for TTF1 and negative for p53 and synaptophysin, consistent with pulmonary adenocarcinoma [Image 5 and 6].

Discussion Diagnosing central lung masses adjacent to the esophagus can be challenging, as they may not be accessible for biopsy via bronchoscopy or EBUS. In such cases, EUS has emerged as a complementary tool for tissue acquisition, allowing transesophageal sampling of central pulmonary lesions, with a diagnostic accuracy of 87.5–93.4 % and an adverse event rate of 0.7–5.36 %, mostly self-limited mild bleeding. These data support the role of EUS as a safe and effective alternative when conventional strategies cannot reach the lesion [1–4].

In our case, the pulmonary lesion was located near nodal station 8, which is not accessible via EBUS. EUS enabled direct, stable, and safe access, yielding sufficient material to confirm the diagnosis. We opted for a 25G needle to theoretically reduce bleeding risk, although no statistically significant differences in adverse event rates have been reported compared with 22G needles.

In conclusion, EUS-guided transesophageal biopsy is a valid alternative for central pulmonary lesions that are not accessible by EBUS.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP361 Comparative characteristics of changes in reflux disease in patients with morbid obesity after surgical treatment

Author Yaroshenko K[1]

Institute 1 Oxford Medical, Dnipro, Ukraine

DOI 10.1055/s-0046-1821688

Aims Comparison of the dynamics of metabolic effects of performing different methods of bariatric interventions on the course of reflux disease in patients with morbid obesity in the early and late postoperative period.

Methods 71 patients with morbid obesity, aged 21 to 65 years, were examined. Among the patients, there were 36 (50.7 %) women and 35 (49.3 %) men. The stratification of patients was carried out depending on the method of bariatric intervention: Group I – 30 (42.3 %) patients: biliopancreatic bypass in the Hess-Marceau modification; Group II – 41 (57.7 %) patients – sleeve gastrectomy. According to the body mass index, the patients were distributed almost evenly: Group 1 – 10 (33 % – obesity grade 2) and 20 (67 % – obesity grade 3), Group 2 – 14 (34.1 % – obesity grade 2) and 27 (65.9 % – obesity grade 3). Upper endoscopy was performed on all patients in the preoperative period: in group I, 12 (40 %) patients were diagnosed with reflux esophagitis (A, B and C according to the LA classification); in group II, 19 (46 %) patients (also mild and moderate GERD). Patients were treated for 2 weeks, endoscopic control was not performed before surgery [1–3].

Results In the postoperative period, not only the dynamics of changes in body weight of patients, but also the course of reflux disease were analyzed. Analysis of the dynamics of indicators within 3 years after bariatric interventions, both in general and in terms of different techniques and gender of patients, proved the fact of intensive reduction of body weight and, accordingly, BMI, within 12 months after BPS and in the period of 3-6 months in patients after sleeve gastrectomy. Achievement of statistical comparability of BMI indicators in both groups ($p > 0.05$) occurred already after 3-6 months in women, and after 1.5 years after surgery in men. Postoperatively, upper endoscopy was performed 3 years later: reflux disease was detected in 9 (30 %) patients in group I and in 8 (19.5 %) patients in group II (▶ **Table 1**).

▶ **Table 1** Distribution of patients with reflux disease after bariatric surgery

Severity of reflux esophagitis	Group 1: biliopancreatic bypass in the Hess-Marceau, number of studies (n = 30)	Group 2: sleeve gastrectomy, number of studies
(n = 41)		
A	3 (10 %)	4 (9,8 %)
B	5 (16,6 %)	4 (9,8 %)
C	1 (3,3)	-
D	-	
Total	9 (30 %)	8 (19,5 %)

Conclusions Bariatric surgical methods of treating obesity can be considered as a treatment for GERD: in patients who underwent biliopancreatic bypass in the Hess-Marceau, a decrease in the number of GERD episodes was observed in the postoperative period from 12 (40 %) to 9 (30 %) cases; after sleeve gastrectomy from 19 (46 %) to 8 (19.5 %). Better results are observed after sleeve gastrectomy, which also correlates with a decrease in BMI at an earlier stage after this intervention.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP362 Intestinal intussuspection as a capsule endoscopy finding in a patient with Crohn's disease: a case report

Authors Sánchez Roncero FJ[1], Madrigal Bayonas L[1], Bógalo Romero C[2], Romero Martínez M[3], Gómez Gómez A[4], Calatayud Vidal G[5]
Institutes 1 Rafael Méndez University General Hospital, Lorca, Spain; 2 Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain; 3 Virgen of Arrixaca University Clinical Hospital, El Palmar, Spain; 4 Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; 5 Rafael Méndez Hospital, Lorca, Spain
DOI 10.1055/s-0046-1821689

Abstract Text

Intussusception is defined as the invagination of one segment of the bowel into an immediately adjacent segment. In adults, it is uncommon and typically secondary to structural lesions such as tumors, polyps, Meckel's diverticulum, postsurgical changes, or inflammatory conditions affecting the small bowel [1, 2].

We present the case of a 19-year-old male followed in the Gastroenterology clinic for Crohn's disease with upper gastrointestinal involvement (A1L4B1), treated with intravenous infliximab 5 mg/kg every 8 weeks. He had a prior admission for acute pancreatitis the previous year, attributed to active duodenal disease causing biliary obstruction.

Since the pancreatitis episode, the patient had experienced at least three episodes of severe abdominal pain, although laboratory markers—including C-reactive protein and fecal calprotectin—remained within normal range. He reported no diarrhea or extraintestinal manifestations. Given the possibility of subclinical disease activity, follow-up endoscopic studies (colonoscopy and upper endoscopy) were performed, both without significant findings.

Capsule endoscopy was subsequently conducted, demonstrating prolonged capsule retention for over 90 minutes in the mid-jejunum, with an image suggestive of intestinal intussusception. The mucosa proximal and distal to the intussusception appeared normal, and no lesions compatible with active Crohn's disease were identified on the examination.

This case illustrates an exceptionally uncommon presentation of jejunal intussusception in a young adult with Crohn's disease, occurring in the absence of biochemical, clinical, or endoscopic evidence of active inflammation, underscoring its diagnostic relevance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP363 EUS-guided radiofrequency ablation for adrenal gland metastases: A rare therapeutic indication

Authors Espinel P[1], Pérez Urra C[1], Bulnes Labrador CB[1], Martín IC[1], González de Castro E[1], Robles de la Osa D[1], Pérez Citores L[1], Moreira Da Silva BA[1], Santos Fernández J[1], Santos Santamarta F[1], Cimavilla Román M[1], Maestro Antolín S[1], Barcenilla Laguna J[1], Montero Moretón ÁM[1], Rizzo Rodríguez MA[1], Rancel Medina FJ[1], Pérez Millán AG[1]
Institute 1 General Hospital Río Carrión, Palencia, Spain
DOI 10.1055/s-0046-1821690

Introduction Surgical resection remains the main therapeutic option for abdominal metastases. However, a considerable number of patients are not suitable candidates for surgery due to high operative risk, advanced age, comorbidities, or unresectable disease. In recent years, minimally invasive alternatives have been introduced, with endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) emerging as a valuable option for local tumor control. This technique enables targeted ablation of adrenal lesions while reducing morbidity, shortening hospital stay, and improving tolerance compared with conventional surgery. Although its use has been more extensively evaluated in pancreatic or peripancreatic lesions, evidence regarding adrenal gland metastases is still limited. Therefore, EUS-RFA may represent a particularly relevant approach in selected patients when curative or consolidative intent is pursued [1, 2].

Case Report A 77-year-old man was diagnosed with oropharyngeal squamous cell carcinoma and initially managed with chemoradiotherapy. Due to cervical oligoprogression during follow-up, salvage surgery was performed, and treatment continued with immunotherapy (nivolumab). 5 year later, surveillance PET-CT revealed a hypermetabolic lesion in the left adrenal gland (Figure 1), raising suspicion of metastatic disease. Endoscopic ultrasound revealed a solid adrenal mass, and fine-needle biopsy confirmed metastatic squamous cell carcinoma. Considering the patient's characteristics and underlying comorbidities, EUS-RFA was selected as a local therapeutic alternative. The procedure was performed one half year later without intra- or post-procedural complications. Subsequent imaging demonstrated complete resolution of the adrenal lesion. Immunotherapy was discontinued thereafter, and the patient has remained clinically stable without radiological evidence of recurrence to date.

Conclusion EUS-RFA represents a promising therapeutic alternative for patients with adrenal metastases who are not suitable for surgery. It offers a safe, effective, and well-tolerated option that allows satisfactory short- and mid-term oncologic control with low complication rates. However, existing evidence remains limited, and further prospective studies with larger sample sizes are required to better define standardized indications and confirm long-term outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP364V Endoscopic Findings of Ischemic Gastropathy in Cirrhotic Patients: Beyond Portal Hypertension

Authors García Ayuso M[1], Pérez Pérez J[1], Garrido Gallego F[1], Carlos VP[1], Prieto Doblado M[1], Escobar Ortiz J[1], Abdelkader Hamete I[1], Muñoz Naranjo JD[1], Ponferrada-Díaz Á[1]
Institute 1 Hospital Universitario Infanta Leonor, Madrid, Spain
DOI 10.1055/s-0046-1821691

Abstract Text

A 66-year-old man with alcoholic cirrhosis on anticoagulation for atrial fibrillation was admitted with anemia, melena, hypotension, dehydration, and acute renal failure. Labs showed coagulopathy and hypoperfusion. Urgent gastroscopy revealed superficial longitudinal gastric ulcers from the upper body to prepyloric region, without active bleeding or portal hypertension. Biopsies excluded infection and other causes. Findings were consistent with ischemic gastropathy, likely due to systemic hypoperfusion and cirrhosis. Endoscopic features include erythematous, congested mucosa with superficial ulceration. Early endoscopic recognition is essential for accurate diagnosis and management, preventing misdiagnosis in cirrhotic patients presenting with upper gastrointestinal bleeding [1].

eP365V Diagnosing Hepatocellular Carcinoma Through the Bile Duct: A Rare Presentation with Quincke's Triad

Authors Loo XY[1], Chew WD[1]

Institute 1 Tan Tock Seng Hospital, Singapore, Singapore

DOI 10.1055/s-0046-1821692

Abstract Text

Quincke's triad is a rare presentation of hepatocellular carcinoma (HCC). This case describes the use of endoscopic retrograde cholangiopancreatography (ERCP) and cholangioscopy in the diagnosis of HCC. An 83-year-old man presented with hypotension, right upper quadrant tenderness, and melena. Laboratory tests showed haemoglobin 8.7g/dL and obstructive jaundice. Oesophagogastroduodenoscopy revealed haemobilia. ERCP demonstrated no obvious structure or mass on cholangiogram. Cholangioscopy revealed bleeding from friable, ulcerated mucosa with frond-like projections in the third order of the right intrahepatic ducts. Targeted biopsies obtained and haemostasis achieved by catheter-directed infusion of diluted adrenaline and cold saline. Imaging showed two segment eight lesions with arterial phase enhancement and washout. Histology from the ERCP biopsy confirmed diagnosis of HCC [1, 2].

eP366 Integrating contrast-enhanced CT/MR and contrast-harmonic EUS into real-life management of solid pancreatic lesions in an emergency hospital

Authors Badiu S[1], Ochea F[1], Rosu AC[1], Dima S[1], Curte A[1], Tudose I[1], Tieranu CG[1], Olteanu OA[1], Calu V[1], Saftoiu A[1]

Institute 1 Spitalul Universitar de Urgență Elias, București, Romania

DOI 10.1055/s-0046-1821693

Aims ESGE and EFSUMB guidelines recommend multimodal imaging, including contrast-enhanced CT/MR (CE-CT/MR) and contrast-harmonic EUS (CH-EUS), for evaluation of solid pancreatic lesions. However, integration of these modalities into the workflow of a mixed emergency–endoscopy unit remains challenging. This study evaluated the diagnostic performance of CE-CT/MR, CH-EUS, and EUS-FNA/FNB against the final reference diagnosis, and assessed adherence to ESGE performance indicators for EUS tissue acquisition (EUS-TA).

Methods We retrospectively analyzed 124 consecutive patients with solid pancreatic lesions evaluated over 36 months. Final diagnosis was determined by histopathology and/or 6-month follow-up, yielding 104 cases with definitive malignant or benign outcomes (malignant 91.3 %). CH-EUS, CE-CT/MR, and EUS-FNA/FNB results were compared with the reference standard using standard diagnostic metrics. ESGE quality indicators (EUS-TA rate, diagnostic adequacy, and adverse events) were calculated from procedural data. Clinical and technical determinants of sampling performance were explored [1].

Results For ADK-only diagnosis, CH-EUS achieved a sensitivity of 97.5 % and a specificity of 72.5 %. CE-CT/MR yielded a sensitivity of 81.0 % and a specificity of 50.0 %. EUS-FNA/FNB demonstrated a sensitivity of 89.9 % and a specificity of 75.0 %. ESGE performance benchmarks were fulfilled, with EUS-TA performed in 95.2 % of lesions, a diagnostic adequacy rate of 90.3 %, and no recorded adverse events. Correct EUS-FNA/FNB diagnosis correlated with elevated CA19-9 and the presence of cholestasis, whereas needle type and number of passes did not significantly influence adequacy.

Conclusions These data are very consistent with the concept that CH-EUS is the best "rule-out" tool (do not miss malignancy), while EUS-FNA/FNB is the best "rule-in" tool (confirm malignancy and the specific type of malignancy when cytology/histology is positive). CT/MR remains important for staging and initial triage, but not for fine discrimination of benign vs malignant solid lesions.

In an emergency hospital environment, CH-EUS provides high diagnostic accuracy for solid pancreatic lesions compared with CT/MR, while EUS-FNA/FNB maintain full compliance with ESGE quality benchmarks for EUS-TA. Integrating CH-EUS early in the diagnostic pathway enhances real-world performance and supports the feasibility of guideline-concordant care even in busy emergency hospitals.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP367 Efficacy and Safety of Diclofenac versus Placebo in Preventing Post-ERCP Pancreatitis: systematic review and meta-analysis

Authors Hasanin E[1], Khelifa H[2]

Institutes 1 Faculty of Medicine, University of Tripoli, Tripoli, Libya; 2 University of Oran 1 – Ahmed Ben Bella, Es Senia, Algeria

DOI 10.1055/s-0046-1821694

Aims To evaluate the efficacy and safety of diclofenac compared with placebo for the prevention of post-ERCP (endoscopic retrograde cholangiopancreatography) pancreatitis.

Methods We conducted a comprehensive search of **PubMed, Scopus, Web of Science, Embase, and Cochrane** from their inception to **November 2025**, focusing on **randomized controlled trials (RCTs)** evaluating **diclofenac versus placebo in the prevention of post-ERCP pancreatitis.** Meta-analyses were performed using a **random-effects model**. Odds **ratios (ORs), hazard ratios (HRs), and mean differences (MDs)** were calculated with **95 % confidence intervals (CIs)** to assess the efficacy and safety of **diclofenac versus placebo.**

Results Four randomized trials assessing low-dose diclofenac for prevention of post-ERCP pancreatitis (PEP) were included (n = 708; diclofenac n = 353, control n = 355). Overall, diclofenac **did not significantly reduce** the incidence of PEP compared with control (pooled RR = 0.55; 95 % CI, 0.20–1.50; p = 0.24). However, there was **marked variability across studies (I^2 = 70.7 %, p = 0.02)**. Trials evaluating rectal diclofenac demonstrated substantial benefit, particularly Khoshbaten 2008 (RR = 0.15; 95 % CI, 0.04–0.65) and Otsuka 2012 (RR = 0.21; 95 % CI, 0.05–0.90). In contrast, studies using low-dose rectal diclofenac (Katoh 2020) or oral administration (Cheon 2007) showed no protective effect. These findings suggest that **clinical efficacy depends on dose and route of administration**, with higher-dose rectal diclofenac showing the greatest preventive effect.

Conclusions Rectal diclofenac is a safe and effective prophylaxis for post-ERCP pancreatitis, showing greater benefit than placebo, especially at higher doses. Its efficacy is route-dependent, as oral and low-dose formulations do not provide meaningful protection. Overall, rectal administration offers the most reliable preventive effect without increasing adverse events.

Abstract Text

A 75-year-old woman was admitted to our department for weight loss (25 kg in 10 months) and chronicdiarrhea (>6 months). In history: hypertension in Olmesartan 20 mg/day, multinodular goiter. The patient was already tested for anti-transglutaminase antibodies (negative, IgA in normal range) but EGDS showed severe duodenal villous atrophy. On suspicion of ARBsII-associated enteropathy, olmesartan was suspended with partial but not complete benefit on clinical. During hospitalization, the patient presented asthenic, occasionally soporific, severely malnourished (Table 1) and with a picture of pan-cytopenia (Table1). We excluded neurological (brain CT scan), infectious (blood cultures and co-cultures) and hematologic (bone marrow biopsy) causes. Ultrasound of the intestinal loops and ileo-colonoscopy were normal. Video capsule endoscopy showed marked scalloping of DII and jejunum with extensive ulcers (Figure1). Later, she performed at referral center anterograde double-balloon enteroscopy (DBE). DBE confirmed marked atrophy and map ulcers primarily suggestive of refractory celiac disease type II/EATL with ulcerative jejunum-ileitis. Histologic examination described findings referable to chronic exacerbated, erosive enteritis, not diagnostic for celiac disease. HLA search for celiac disease was negative therefore celiac disease was excluded. Hemotransfusions and nutritional supplementation were administered in consideration of anemia and nutritional deficiency. Empiric/ex juvantibus therapy with steroid was also set up with marked improvement in symptomatology. Following hospitalization, she was re-evaluated on an outpatient basis at enteropathy referral center. Here she was first imposed high-dose steroid therapy with marked improvement and weight gain, then Azathioprine in maintenance. She was therefore discharged with a diagnosis of autoimmune enteropathy with likely previous overlap with sartane enteropathy [1, 2].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Lower gastrointestinal bleeding poses a significant challenge, especially in patients receiving combined antithrombotic therapy. We report a 72-year-old patient who, following major surgery, developed a miocardial infarction and was started on dual antiplatelet therapy plus low molecular weight heparin. Then, he experienced severe rectal bleeding requiring transfusion. Colonoscopy revealed a circumferential rectal ulcer with a large adherent clot; after clot removal, active oozing from a visible vessel was noted. Argon plasma coagulation failed due to deeply located bleeding. Underwater snare-tip coagulation allowed stable vessel contact and precise energy delivery, achieving complete hemostasis. Self-assembling peptide hydrogel was applied to promote mucosal healing and reduce rebleeding risk. This case highlights the need for adaptable endoscopic strategies in heightened bleeding risk patients [1–3].

Abstract Text

Hepatic and perihepatic cystic lesions may present with heterogeneous radiologic characteristics that overlap with neoplastic, infectious, and biliary etiologies, posing a diagnostic challenge in the context of biliary obstruction[1]. We present the case of a 68-year-old woman who initially developed biliary colic and was diagnosed with chronic calculous cholecystitis and high-risk choledocholithiasis. CT scan demonstrated a choledochal stone at the intrapancreatic portion of the common bile duct, along with additional cholelithiasis [1–4].

ERCP was performed, revealing three filling defects measuring approximately 12 mm each. Complete ductal clearance was not achieved despite appropriate maneuvers and biliary stent was placed. Given the persistence of biliary obstruction, a magnetic resonance cholangiopancreatography study was obtained three days after ERCP. This demonstrated a large capsular lesion located in hepatic segment VIII, measuring 147 × 95 × 63 mm. Additionally, CA 19-9 was reported at 1366 U/mL, a finding that raised concern for a biliary or cystic neoplasm.[2]

Two weeks later, the patient was referred to our center for further evaluation. Endoscopic ultrasound revealed a well-defined, homogeneous hypoechoic mass exerting significant extrinsic compression on the gastric wall, measuring

121 × 77 mm. Because imaging alone could not provide a definitive diagnosis, a decision was made to perform fine-needle puncture using a 19-gauge needle.[3] Puncture of the lesion resulted in immediate drainage of purulent material, establishing the diagnosis of a hepatic abscess. Given the volume of purulent content and the mass effect on adjacent structures, an endoscopic drainage strategy was selected. A 20 × 10-mm lumen-apposing metal stent (LAMS) was deployed under EUS guidance, achieving rapid and effective internal drainage. Microbiologic evaluation confirmed infection with Escherichia coli. The patient completed targeted antibiotic therapy. Her clinical evolution was favorable, and a follow-up CT scan obtained one month after the procedure demonstrated near-complete resolution of the hepatic lesion. Subsequent ERCP and surgical gallbladder removal were performed.

This case illustrates the essential role of EUS in clarifying equivocal hepatobiliary lesions initially suspected to be neoplastic, and demonstrates the clinical effectiveness of LAMS-guided drainage as a minimally invasive therapy for large hepatic abscesses. The multidisciplinary evaluation and stepwise therapeutic decision-making allowed full patient recovery and resolution of both the abscess and the biliary obstruction.[4]

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Kaposi sarcoma (KS) is an HHV-8–associated vascular malignancy that most commonly occurs in the setting of HIV infection but may also develop in immunosuppressed, HIV-negative solid-organ transplant recipients. Post-transplant KS is rare, accounting for only 0.4–5 % of malignancies, and visceral involvement—particularly of the gastrointestinal (GI) tract—is highly uncommon. We describe a case of disseminated KS with gastric, duodenal, and colonic involvement in an HIV-negative renal transplant recipient presenting with chronic diarrhea [1–8].

We present the case of a 56-year-old HIV-negative woman with a history of renal transplantation who developed disseminated Kaposi sarcoma following prolonged immunosuppression. The patient had been receiving azathioprine after previous intolerance to mycophenolate. She presented with chronic diarrhea and progressive painful cutaneous lesions involving the genital, perineal, and perianal regions. Skin biopsy demonstrated spindle cell proliferation with HHV-8 positivity, confirming KS. Subsequent PET/CT imaging revealed extensive nodal, cutaneous, and pulmonary involvement, along with nonspecific FDG uptake in the stomach and colon.

Gastrointestinal evaluation was pursued due to persistent diarrhea and abnormal imaging findings. Laboratory studies, including thyroid function, fecal calprotectin, fecal elastase, celiac serology, and infectious GI PCR panel, were unremarkable. Endoscopic assessment revealed multiple raised, erythematous lesions throughout the stomach, duodenum, and colon. Histology from these sites confirmed Kaposi sarcoma with spindle cell proliferation and HHV-8 positivity.

This case reflects the role of chronic immunosuppression as the primary pathogenic driver of KS in HIV-negative transplant recipients. Calcineurin inhibitors and azathioprine are recognized to potentiate HHV-8 reactivation and tumor development. Conversely, mTOR inhibitors such as sirolimus and everolimus possess anti-angiogenic and antiproliferative properties and have been associated with regression of KS lesions. Based on this evidence, immunosuppression was modified by discontinuing azathioprine and transitioning to everolimus with low-dose tacrolimus. Systemic treatment with liposomal doxorubicin was initiated due to disseminated disease.

Although well documented in HIV-positive individuals, colonic Kaposi sarcoma remains rare in HIV-negative transplant recipients. Review of the literature demonstrates only a small number of comparable cases, emphasizing that gastrointestinal KS can present with nonspecific symptoms such as diarrhea and may only be diagnosed through endoscopic biopsy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821699

Abstract Text

Dieulafoy's lesion is an uncommon vascular abnormality characterized by a large-caliber, tortuous submucosal arteriole that fails to taper as it approaches the mucosal surface. This anomaly can lead to sudden and severe upper gastrointestinal bleeding despite the absence of a visible ulcer or mucosal defect. Although it accounts for less than 2 % of cases of acute gastrointestinal hemorrhage, it remains a potentially life-threatening condition. The stomach, par-

ticularly the proximal lesser curvature, is the most frequent location; however, esophageal involvement is extremely rare, making careful endoscopic assessment essential when the bleeding source is not immediately evident [1–3].

We present the case of a 79-year-old man who arrived at the emergency department with presyncope, generalized weakness, mucocutaneous pallor, melena, and coffee-ground vomiting. Initial laboratory tests demonstrated a hemoglobin level of 6 g/dL, requiring transfusion and urgent endoscopic evaluation. During gastroscopy, a small red clot was identified in the distal esophagus, approximately 3 cm above the cardia. When gently displaced with the endoscope, brisk pulsatile bleeding was observed without an evident underlying mucosal injury, suggesting a Dieulafoy's lesion (Forrest I). Immediate endoscopic therapy was performed using elastic band ligation, achieving complete hemostasis with no further bleeding events. The patient remained clinically stable with no recurrence during follow-up.

Esophageal Dieulafoy's lesions pose significant diagnostic challenges due to their subtle appearance and uncommon location. Awareness of this entity is crucial, since failure to recognize it may delay treatment and worsen outcomes. Endoscopic therapy is considered first-line management, with band ligation and hemostatic clips demonstrating high success rates. Given the possibility of rebleeding, close monitoring and follow-up are recommended. This case highlights the importance of maintaining a high index of suspicion for Dieulafoy's lesions in patients with severe upper gastrointestinal bleeding and emphasizes the effectiveness of early endoscopic intervention in ensuring hemostasis and preventing complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP373 One Marker for All Territories? Fecal Calprotectin Across the Different Locations of Crohn's Disease

Authors Qarch I[1], Lagdali N[2], Sabbah S[3], Kadiri M[4], Chabib FZ[5], Borahma M[6], Ajana FZ[2]

DOI 10.1055/s-0046-1821700

Aims Fecal calprotectin is a widely used non-invasive biomarker to assess intestinal inflammation in Crohn's disease (CD). However, its reliability may vary depending on the anatomical location of disease involvement.

The objective of this study was to investigate the correlation between disease location, fecal calprotectin levels, and endoscopic disease activity measured by the Crohn's Disease Endoscopic Index of Severity (CDEIS).

Methods We conducted a retrospective study including 172 patients with Crohn's disease who underwent both fecal calprotectin testing and ileocolonoscopy with CDEIS scoring.

Disease locations were classified according to the Montreal classification: L1 (ileal), L2 (colonic), L3 (ileocolonic), L4 (upper gastrointestinal), and L3L4 (combined ileocolonic and upper GI involvement).

Statistical analyses were performed using **Jamovi software**. Spearman's rank correlation was used to assess the relationship between fecal calprotectin and CDEIS scores, both globally and stratified by disease location. Comparisons of calprotectin and CDEIS values across locations were made using the **Kruskal-Wallis test**, as data were not normally distributed.

Results Among the 172 patients included, fecal calprotectin demonstrated a moderate and statistically significant correlation with endoscopic activity across the entire cohort (Spearman's $\rho = 0.53$, $p < 0.001$). When analyzed by disease location, the strongest correlations were observed in colonic disease (L2: $\rho = 0.62$) and combined ileocolonic and upper GI involvement (L3L4: $\rho = 0.76$). Ileal disease (L1) showed a moderate correlation ($\rho = 0.41$), while isolated ileocolonic (L3: $\rho = 0.30$) and upper GI disease (L4: $\rho = 0.26$) showed weaker associations. A perfect correlation in the L1L4 subgroup ($\rho = 1.00$) was noted but was limited by the very small sample size. Despite these differences, Kruskal-Wallis tests revealed no statistically significant differences in calprotectin levels ($p = 0.99$) or CDEIS scores ($p = 0.89$) across the various disease locations.

Conclusions Fecal calprotectin demonstrates a good overall correlation with endoscopic disease activity in Crohn's disease, reinforcing its usefulness as a monitoring tool regardless of disease location. Although stronger correlations were noted in colonic and extended disease forms, no statistically significant differences were found across locations. These findings suggest that fecal calprotectin can be reliably used as a location-independent marker of mucosal inflammation in Crohn's disease.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP374 Comparative Analysis of Endoscopic Ultrasound and PET-CT Findings in the Diagnosis and Characterization of Pancreatic Masses

Authors Telli P[1], Çavuş B[1], Çlfcibaşı ÖRmeci A[1], Genç Uluçeçen S[1], Dağcı G[1], Yağlı MA[1], Gurbanov A[1], Ağargün BF[1], Mammadov S[1], Bilgin E[1], Vurallı BD[1], Işık EG[1], ÖZlük Y[1], Demir K[1], Beşışık F[1], Kaymakoğlu S[1], Akyüz F[1]

Institute **1** Istanbul University Faculty of Medicine, Istanbul, Türkiye

DOI 10.1055/s-0046-1821701

Aims The diagnosis of pancreatic masses presents a significant clinical challenge due to their malignant potential. Endoscopic Ultrasound (EUS) and Positron Emission Tomography-Computed Tomography (PET-CT) are critical evaluation modalities. This study aimed to evaluate and compare EUS and PET-CT findings in a cohort of patients with pancreatic masses.

Methods Data from 94 consecutive patients evaluated with both EUS and PET-CT between 2020 and 2025 were retrospectively analyzed.

Results Histopathological examination revealed 84 malignant (89.4 %) and 10 benign (10.6 %) masses. EUS demonstrated a smaller median mass size in benign lesions (20 mm vs 30 mm; $p = 0.005$) and showed vascular invasion in 60.7 % of malignant cases. PET-CT detected a lower median SUV-max in benign lesions (6 vs 8; $p = 0.023$). Median CA 19-9 levels were higher in the malignant group (216 U/mL vs 45 U/mL; $p = 0.039$). The highest diagnostic accuracy was the EUS endosonographic impression, based on ROC analysis. The AUCs (95 % CI, p-value) were: EUS impression, 0.744(95 % CI: 0.583-0.905, $p = 0.002$); EUS size, 0.701 ($p = 0.011$); EUS vascular invasion, 0.647 ($p = 0.063$); PET-CT qualitative assessment, 0.601 ($p = 0.201$); and PET-CT SUV-max, 0.568 ($p = 0.399$). Kaplan-Meier analysis showed that median overall survival for patients with a benign EUS impression (49 months) was significantly longer than for those with a malignant impression (16 months) (log-rank $p = 0.001$). EUS-detected vascular invasion was associated with shorter median overall survival (6 months vs 24 months in its absence) (log-rank $p = 0.001$).

Conclusions These findings underscore the complementary roles of EUS and PET-CT. Integration of clinical information, imaging findings, and biomarker data is essential for optimal diagnosis and management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP375 From Rarity to Resection: Successful Endoscopic Full-Thickness Resection of Colonic Schwannomas

Authors Ribeiro H[1], Vidal Lima F[1], Santos L[1], Pimentel J[2], Gravito-Soares E[1,3], Gravito-Soares M[1,3], Amaro P[1], Narra Figueiredo P[1,3]
Institutes **1** Gastroenterology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; **2** Pathology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; **3** Faculty of Medicine, University of Coimbra, Coimbra, Portugal
DOI 10.1055/s-0046-1821702

Introduction Colonic schwannoma is an extremely rare neurogenic tumor of the gastrointestinal tract, often presenting as incidental finding or with non-specific gastrointestinal symptoms. The diagnosis can be challenging due to overlapping endoscopic and imaging features with other subepithelial lesions. Traditional management has relied on surgical resection, yet advances in endoscopic techniques have enabled minimally invasive alternatives. We report two cases of colonic schwannoma successfully managed by Endoscopic Full-Thickness Resection(EFTR).

Case Report 1 A 66-year-old man with a medical history of arterial hypertension and pacemaker under aspirin therapy was referred to our department due to an asymptomatic suspected subepithelial lesion, incidentally found during an outpatient screening colonoscopy, with inconclusive biopsy results. Endoscopy ultrasound showed a 12*10-mm heterogeneous hypoechoic lesion arising from the submucosal layer. After multidisciplinary discussion, a minimally invasive endoscopic resection was proposed by Endoscopic Submucosal Dissection (ESD). During colonoscopy, a 12-mm subepithelial lesion was identified at the proximal sigmoid colon with superficial erosion. During the clip-band traction-assisted ESD, the involvement of muscularis propria layer was observed leading to a switch for EFTR using the colonic FTRD system (Ovesco Endoscopy, Tubingen, Germany). A transmural en-bloc resection was achieved with no complication. Histopathological analysis revealed a R0-resection of a S-100 positive spindle-cell tumor, compatible with a reticular/microcystic-type schwannoma [1, 2].

Case Report 2 A 60-year-old woman with a medical history of arterial hypertension was referred to our department for evaluation of an asymptomatic subepithelial lesion, incidentally identified during an outpatient screening colonoscopy. It was decided for minimally invasive endoscopic resection at multidisciplinary meeting. A 10-mm yellowish and firm-elastic subepithelial lesion at the cecum with no involvement of appendix was observed in the therapeutic colonoscopy, with non-lifting sign. An EFTR was attempted with an en-bloc transmural resection of the lesion after being grasped into the cap using the colonic FTRD system, with no complications. A schwannoma was diagnosed on histopathological examination with positivity for S-100, SOX-10 and CD-68.

Conclusion EFTR proved to be an effective and safe minimally invasive approach for the management of small colonic schwannomas regardless colonic location. EFTR may represent a valuable alternative to conventional surgical resection for selected patients with subepithelial colonic tumors up to 20/25-mm, depending on the lesion consistency and the presence of fibrosis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP376 Enhancing Endoscopic Retrograde Cholangiopancreatography (ERCP) Care in a UK NHS District General Hospital – Successful modernisation of a Local Service

Authors Hwang S[1], Patel K[1], Dwivedi P[1], Marelli L[1], El Menabawey T[2]
Institutes **1** Homerton Healthcare NHS Foundation Trust, London, United Kingdom; **2** University College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1821703

Aims Endoscopic Retrograde Cholangiopancreatography (ERCP) is a complex therapeutic procedure often requiring temporary stent placement. While clinical success hinges on technical skill, the quality of the consenting process is equally imperative for patient understanding, satisfaction, procedural safety and reduces medicolegal risk. Furthermore, if not removed or exchanged in a timely manner, retained stents can cause serious sequelae such as cholangitis, biliary obstruction, ductal damage, or perforation, while increasing length of stay and need for further investigations. In many institutions, the consent for ERCP often occurs on the day of the procedure, occasionally under significant time pressure. This practice can limit the opportunity for meaningful patient discussion, potentially reducing understanding, satisfaction and concordance. The primary aim of this project was to ameliorate the ERCP process via pre-consenting, as well as to develop a robust, integrated stent tracking system within the electronic patient record (EPR).

Methods A retrospective review was conducted over an 8-month period across two years (April 2024 – July 2025). All ERCP procedures were included and data was extracted from EPR and local audit records. Baseline measurements assessed the proportion of patients pre-consented prior to the day of procedure, with inpatient (IP) and outpatient (OP) sub-analysis. Pre-consent clinic slots were made available weekly. OP identified for ERCP were offered an appointment in this clinic, during which consent discussions were held and educational material provided. For IP, registrars consented patients during the admission. An enhanced ERCP patient information leaflet that included simplified explanations of procedure indications, risks, recovery expectations and contact information. The leaflet was reviewed and approved by the local endoscopy user group prior to implementation. A multidisciplinary working group involving endoscopy and the digital informatics teams convened to formulate a stent tracking tool within our EPR. Temporary stents and relevant data (type, date of insertion, planned removal date) were inputted and extracted into a live Excel tracker (▶ **Table 1**).

Results A total of 116 procedures were analysed and a marked improvement in pre-consenting rates was observed post intervention with pre-consenting rates increasing from 26 % to 48 %. OP pre-consent rates doubled from 28 % to 55 %, while IP completion also upgraded from 22 % to 39 %. Qualitative feedback from clinicians highlighted improved workflow efficiency, reduction in on-the-day administrative delays and enhanced patient understanding. Patients were reported to be more informed and confident during pre-assessment, allowing more meaningful discussions about risks, alternatives and expectations.The EPR-linked stent tracking module was successfully embedded, ensuring that every temporary stent inserted was logged for follow-up. Early post-implementation audit confirmed 100 % accuracy of data capture for stent tracking fields, demonstrating the reliability of the digital workflow.

▶ Table 1

Period	Total ERCPs	Inpatients (IP)	Outpatients (OP)	Pre-consented (n)	% Pre-consented	% IP Pre-consented	% OP Pre-consented
Apr–Jul 2024	47	18	29	12	25.5 %	22.2 %	27.6 %
Apr–Jul 2025	69	31	38	33	47.8 %	38.7 %	55.3 %

Conclusions This service improvement initiative demonstrates that pre-consent can substantially improve preparedness for ERCP procedures. Pre-consenting represents more than an administrative step, it embodies patient-centred care. By providing information early, patients can reflect, discuss with family members and make informed decisions without time pressure. The redesigned pre-consent workflow and automated stent tracking support safer, more consistent pathways. Updates to the ERCP patient information leaflet, enhances access to clear, standardised information. The addition of automated stent tracking promotes continuity of care beyond the procedure and reduces risk associated with retained temporary stents, as well as being JAG mandated. Future steps include introducing patient-facing digital consent options and maintaining continuous audit cycles to ensure sustained improvement and patient-centred outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP377 Emphasizing outcomes: Systematic Review of EUS-Guided Radiofrequency Ablation Compared with Surgery for Pancreatic Insulinoma

Authors Haziri T[1], Driton S[1], Kushtrim M[1]
Institute 1 University Clinical Center of Kosovo, Pristina, Kosovo
DOI 10.1055/s-0046-1821704

Aims Objective Minimally invasive techniques, including endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA), have been proposed as potential alternatives to surgery for the treatment of pancreatic insulinomas (IP). The aim of this systematic review was to synthesize existing evidence on the safety, efficacy, and long-term outcomes of EUS-RFA compared with traditional surgical approaches [1].

Methods Methods A systematic search was conducted in PubMed, Scopus, and Embase databases up to 2024. Inclusion was limited to studies reporting on the treatment of IP with either EUS-RFA or surgery that provided data on complications, clinical response, recurrence, and long-term follow-up. Strict selection criteria were applied, and the PRISMA guidelines were followed for the review process. Data on follow-up duration (up to 24–36 months) and monitoring strategies (clinical and radiological) were analyzed as secondary outcomes.

Results Results Out of 742 identified articles, 22 studies met the inclusion criteria. Evidence indicated that EUS-RFA had a superior safety profile compared with surgery, with a low rate of adverse events. Effectiveness in normalizing glucose levels and controlling hypoglycemic symptoms was similar between the approaches. Long-term follow-up (24–36 months) in most studies showed stability of clinical response, with sporadic recurrences typically managed with repeat EUS-RFA procedures. However, methodological heterogeneity and the limited number of comparative studies remain significant limitations.

Conclusions Conclusion Current evidence suggests that EUS-RFA represents a safe and effective alternative to surgery for patients with pancreatic insulinoma, offering clear advantages in terms of invasiveness and recovery time. Long-term outcome data are promising, but the evidence remains fragmented. Prospective, comparative, and standardized studies are required to definitively establish the role of EUS-RFA as a first-line therapy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP378 Bridging the Disconnection: ERCP Management of Pancreatic Ascites and Pseudocysts in a High-Risk Patient Referred for TIPS

Authors Kerezova Z[1], Tishkov I[1], Radkova S[2], Stoichkov Y[1]
Institutes 1 University Hospital Sofiamed, Sofia, Bulgaria; 2 University Hospital "St. Anna", Sofia, Bulgaria
DOI 10.1055/s-0046-1821705

Abstract Text

Pancreatic ascites is a rare condition marked by high amylase ascitic fluid accumulation in the peritoneal cavity, often resulting from pancreatic duct disruption/ “disconnected pancreatic duct syndrome”/, due to necrotizing pancreatitis at most cases. Its rarity and unclear clinical presentation make diagnosis and treatment challenging. Conservative management, including nutritional support and therapeutic paracentesis, has a high failure rate. In contrast, interventional therapies like endoscopic pancreatic stenting have shown better outcomes. However, standardized management guidelines are lacking. We present a 56-year-old man, referred for TIPS placement due to refractory ascites. He was diagnosed with decompensated liver cirrhosis with portal hypertension and chronic pancreatitis with pseudocysts. Multiple paracenteses were conducted at various hospitals, utilizing maximal diuretic therapy; however, no significant reduction in the ascites was achieved. Upon physical examination, the patient exhibited severe tenderness in the epigastric region and periumbilical area, without signs of peritoneal irritation. The abdomen was distended due to ascites, and there was no peripheral edema. A diagnosis of pancreatic ascites was confirmed following diagnostic paracentesis, revealing high levels of amylase (963U/l) and lipase (359U/l). An MRI identified three pancreatic pseudocysts, dilatation of the main pancreatic duct up to 6cm, and discontinuity of the duct at the distal body and tail with pseudocyst formation measuring 12×8.3 cm leading to the diagnosis of disconnected pancreatic duct. An ERCP was performed with pancreatography, revealing contrast filling in the dilated proximal part of the main pancreatic duct with partial disruption and a contrast "leak" at the level of the pancreatic body/tail along with cyst formation. There was an absence of contrast filling downstream of the Wirsung, indicating a 10 mm long stenosis at the proximal part of the pancreatic duct, which precluded the passage of a standard sphincterotome and of a needle-knife. After selective pancreatic sphincterotomy, a 6-fr cystotome was utilized to traverse the distal ductal stricture, enabling pancreatic stenting with a 7fr/10cm plastic stent and bridging the disruption/leak/. Post-procedure, the patient experienced a decrease in abdominal pain. A CT scan demonstrated a reduction the volume of ascites and the size of the pseudocysts. Within four weeks, the abdominal fluid and pseudocysts completely resolved.

Endoscopy 2026; 58: S1–S1041

There are no established treatment protocols for pancreatic ascites, but early intervention is key for better outcomes. For patients with DPD, crossing the disconnection with a guidewire to the excluded segment is very difficult, with high failure rates of 50 % to 100 %. Sphincterotomy reduces outflow resistance, facilitating pancreatic drainage and promoting healing, effectively decreasing recurrence rates and reducing the need for repeated paracentesis [1–4].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A 42-year-old obese woman presented with severe postoperative sepsis and MODS ten days after sleeve gastrectomy. The condition was caused by a large dehiscence of the staple line beneath the GE junction. Despite multiple surgical revisions and negative-pressure wound therapy, she developed additional complications, including Aspergillus pneumonia and acute renal failure requiring hemodialysis. After three months of intensive care, follow-up imaging revealed a 12-cm retrogastric cavity containing purulence and necrotic tissue. Thirteen consecutive sessions of endoscopic vacuum therapy failed to achieve healing. We ultimately decided to perform endoscopic full-thickness gastric myotomy along the staple line to open and connect the cavity with gastric lumen. This intervention resulted in complete resolution of the cavity within five weeks.

DOI 10.1055/s-0046-1821707

Aims Peroral endoscopic myotomy (POEM) is emerging as a minimally invasive therapeutic option for achalasia. Data are limited in pediatric population. Aim: To compare the efficacy and safety of POEM between pediatric and adult patients with achalasia diagnosis

Methods A prospective study was conducted, including all patients who underwent POEM, since August/2022-October/2025, in a tertiary centre from Portugal. Patients aged under 18yo were included in the pediatric group and above 18yo in adult group. Procedural-related parameters, adverse advents, pre- and post-intervention clinical, manometric and radiologic outcomes were evaluated [1]

Results Sixty-four consecutive patients underwent POEM, including six pediatric patients aged 13–16 years (mean age: 14.5 ± 1.2 vs. 53.1 ± 18.6 years; male gender: 83.3 % (n = 5) vs. 50.0 % (n = 29); p = 0.12). According to Chicago classification v4.0, five children had type II achalasia and one had type I achalasia (adults: type I 6.9 % (n = 4), type II 86.2 % (n = 50), type III 6.9 % (n = 4)). No significant differences were observed between groups regarding pre-procedure Eckardt score (7.2 ± 1.7 vs. 8.0 ± 2.1; p = 0.39), symptom duration (26.2 ± 16.8 vs. 71.8 ± 95.3 months; p = 0.17), pre-POEM IRP (38.5 ± 6.5 vs. 27.1 ± 11.9 mmHg; p = 0.08), EGJ-CI or barium column height at 1/5 minutes (5.2/4.8 vs. 12.1/10.2 cm; p = 0.12/0.21). Technical success was 100 % with comparable procedure duration (82.5 ± 18.3 vs. 90.2 ± 39.1 min; p = 0.48) and exclusive posterior approach. At a mean follow-up of 8.3 in pediatric patients vs. 10.8 months in adults, clinical success was achieved in 100 % of pediatric and 94.8 % of adult patients (post-POEM Eckardt 0.3 ± 0.5 vs. 1.2 ± 1.5; p = 0.31). Minor intraprocedural adverse events occurred in 50 % vs. 32.8 % (p = 0.41); No major adverse events, perforation, or mortality occurred in either group. Symptomatic gastroesophageal reflux disease was significantly less frequent in pediatric patients (0/6, 0 %) than adults (10/58, 17.2 %) (p = 0.021, Fisher's exact test), all managed with proton pump inhibitors.

Conclusions POEM proved to be effective and safe for achalasia both in adults and pediatric patients, with no statistically significant differences regarding technical, clinical, manometric and imaging success or complications. Symptomatic post-POEM GERD was significantly lower in children. Early POEM appears to be equally effective and safe compared to late POEM, with less long-term symptomatic post-POEM GERD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims EUS-guided biliary drainage (EUS-BD) is emerging as a potential alternative to percutaneous transhepatic biliary drainage and ERCP in the management of malignant biliary and pancreatic strictures. This study aimed to analyze and detail the epidemiological, clinical, biological, and radiological profile of patients who underwent EUS-BD for malignant biliary obstructions, after failure retrograde drainage

Methods This was a retrospective, descriptive, and analytical study including all patients who underwent EUS-guided biliary drainage between 2021 and 2025.All procedures were performed using a therapeutic linear echoendoscope (Olympus).

Results Our study involved 16 patients, 8 women and 8 men, with a mean age of 64.3 years (range: 37–78 years). Clinically, all patients presented with jaundice, 6 suffered from hepatic colic, 7 from pancreatic-type pain, and 2 others

from diffuse and atypical abdominal pain. Radiologically, all had dilation of the common bile duct (CBD) and intrahepatic bile ducts (IHBD). All patients were in cholangitis.

The indication for EUS-BD was duodenal tumor invasion related to pancreatic head adenocarcinoma with failed ERCP for 7 patients , duodenal tumors invading the CBD for 2 patients, perihilar cholangiocarcinoma for 3 patients , for an afferent loop syndrome after Whippple surgery, and finally, 3 patient with an antral adenocarcinoma invading the lower common bile duct, who had previously undergone a gastrojejunostomy.

Regarding the procedure, three drainage approaches were used:

- Choledocho-bulbar drainage in 6 cases,
- Antegrade drainage in 4 cases,
- Hepatico-gastric drainage in 6 cases.

The procedure was technically successful in 87,5 % of cases. The targeted bile duct was punctured using a 19-. The creation of the tract was performed with different instruments: a 7 Fr cystotome for 7 cases, a 8.5 Fr cystotome for 3 cases, a Soehendra dilatation bougie for 2 cases, and a needle knife for 4 others. Post-operative follow-up showed clinical and biological improvement, with pain resolution and a reduction in total bilirubin (TB) of over 75 % after one week of drainage.

During follow-up, 10 patients died, mostly due to tumor progression, at intervals ranging from 2 to 5 months after drainage. 2 patients died two weeks after drainage due to septic shock related to an infectious pneumonia, and one other died due to combined respiratory and neurological failure. Five patients remained alive at the time of evaluation, maintaining good clinical and biological status

Conclusions EUS-guided biliary drainage constitutes a reliable and minimally invasive alternative to percutaneous drainage and ERCP in the management of malignant biliary obstruction, especially in cases of ERCP failure.The technique provides rapid relief of cholestasis and infection, with high technical and clinical success rates. Mortality in this series was primarily related to disease progression rather than the procedure itself highlighting the value of rigorous patient selection and appropriate follow-up

eP382 Saved by Ileoscopy: The Unexpected Around the Corner

Authors Ribeiro H[1], Vidal Lima F[1], Gravito-Soares E[1, 2], Gravito-Soares M[1, 2], Lopes S[1], Narra Figueiredo P[1, 2]

Institutes **1** Gastroenterology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; **2** Faculty of Medicine, University of Coimbra, Coimbra, Portugal

DOI 10.1055/s-0046-1821709

Introduction Neuroendocrine Tumors (NETs) are a heterogeneous group of neoplasms with distinct clinical, biological, and histological characteristics. Although rare, the incidence and prevalence of these tumors have increased over the past few decades, particularly in the gastrointestinal tract. NETs are predominantly asymptomatic and are often diagnosed incidentally [1].

Clinical Case A 66-year-old female patient with a history of duodenal peptic ulcer disease was referred for evaluation of an 8 mm sessile polyp (Paris 0-Is) located in the terminal ileum. The polyp was excised during a colonoscopy performed at a private facility in the context of colorectal cancer screening. Histological analysis revealed a well-differentiated NET (Grade 1) in the mucosal and submucosal layers of the terminal ileum, measuring 5.6 mm, with an endoscopic resection achieving R0 status (IVL0, 170 µm from the vertical margin). Following multidisciplinary discussion, staging was performed using CT of the abdomen and pelvis, enterography CT, and 68-Ga PET, which showed an ileocolic lymphadenopathy with high expression of somatostatin receptors and elevated serum Chromogranin A (238.7; N < 85). A decision was made to reevaluate with 68-Ga PET in four months to determine the course of action regarding surgery versus chemotherapy. Due to the persistence of findings and after further multidisciplinary discussion, a right hemicolectomy with laparoscopic lymphadenectomy was performed. The procedure revealed no mural lesions; however, 5 out of 20 ileocolic lymph nodes were positive for TNE invasion (ypT-1N1M0, Ki-67 < 1 %, mitotic index < 1/10 HPF, stage III). The follow-up at five months showed no recurrence.

Discussion This case underscores the importance of ileoscopy during colonoscopy, even in the absence of symptoms, in order to exclude lesions of the small intestine. Existing literature indicates that jejunoileal NETs are often diagnosed when symptomatic, with lymph nodal or distant metastasis occurring more frequently than in other locations and often associated with a poor prognosis. Approximately two-thirds of such tumors are found within 60 cm of the ileocecal valve. Given their aggressive nature, increasing incidence, and more frequent ileal location, the performance of ileoscopy during total colonoscopy offers significant clinical benefit without a substantial increase in procedure time, even in asymptomatic individuals.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP383 Type I Gastric Neuroendocrine Tumors and Autoimmune Gastritis: Experience of a Reference Centre in Northern Greece

Authors Georgiadou G[1], Stafylidou M[1], Mollagiousoufoglou B[1], Mpountouridis A[1], Athanasiadou E[1], Mamalis S[1], Axiaris G[1], Xatzopoulos E[1], Lazaraki G[1], Tzilves D[1]

Institute **1** Theageneio Anticancer Hospital of Thessaloniki, Thessaloniki, Greece

DOI 10.1055/s-0046-1821710

Aims Autoimmune gastritis (AIG) predisposes to type I gastric neuroendocrine tumors (NETs), which are usually well-differentiated and of low malignant potential. Early endoscopic recognition is critical for adequate management and follow-up. This study aimed to assess the prevalence of gastric NETs among patients with AIG and explore potential endoscopic and clinical correlations.

Methods A retrospective study was conducted including patients with histologically confirmed AIG diagnosed between 2010 and 2025 at a tertiary referral center in Northern Greece. Demographic, clinical, and endoscopic data were reviewed. Archived endoscopic images were re-evaluated and graded according to the Kimura–Takemoto classification to determine the extent of atrophy. The prevalence, localization, histological grade, and management of NETs were analyzed. The chi-square (χ^2) test was used to examine associations between atrophy severity and NET occurrence [1, 2].

Results A total of 210 patients were included (median age 61.8 years, range 34–84; 60.9 % female). Endoscopic atrophy distribution was: C-1, 18 %; C-2, 15.2 %; C-3, 31.4 %; O-1, 8 %; O-2, 8.5 %; and O-3, 18.5 %. Type I gastric NETs were diagnosed in 47 patients (22.3 %), with a median size of 0.5 cm (range 0.2–3 cm) and median age 56.6 years (range 34–75); 46.8 % were male. Most lesions were located in the corpus (85 %), and were graded as G1 in 70 % and G2 in 30 %. Endoscopic resection was performed in 51 %, and surgical resection in 4.2 % for lesions > 1 cm. Severe atrophy (C-3/O-3) was significantly associated with NET occurrence ($p = 0.007$). No other significant associations were observed.

Conclusions Type I gastric NETs were identified in 22.3 % of patients with autoimmune gastritis, predominantly as small, well-differentiated lesions. The severity of endoscopic atrophy correlated significantly with tumor development. These results support structured endoscopic surveillance and grading of atrophy in AIG as essential for early detection and timely management of type I gastric NETs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP384 Effect of a self-assembling peptide on delayed bleeding and healing of post-resection defects after advanced endoscopic therapy: a retrospective cohort study

Authors Kmochova K[1], Brodyuk N[1], Vackova Z[1], Grega T[1, 2], Urbanek P[1], Suchanek S[1, 2]

DOI 10.1055/s-0046-1821711

Aims The study evaluates the association of SAP use with delayed bleeding and endoscopic healing after advanced endoscopic therapy. The findings may support the integration of SAP into standard post-endoscopic care protocols.

Methods A retrospective analysis was conducted at a single tertiary endoscopy center including consecutive patients undergoing EMR or ESD. The primary outcome was delayed bleeding within 30 days, defined as clinically evident bleeding requiring medical attention. Secondary outcomes included endoscopic healing of the post-resection defect at 4, 8, and 24 weeks using the Sakita–Fukutomi classification. Defect size was measured during the index procedure using endoscopic forceps or a polypectomy snare as reference. Data were abstracted from medical records.

Results A total of 167 patients were included (65 women, 102 men). Procedures comprised ESD in 110 (66 %), piece-meal EMR in 47 (28 %), hybrid EMR + ESD in 8 (5 %), and en bloc EMR in 2 (1 %). Lesion locations were esophagus 19 (11 %), stomach 18 (11 %), duodenum 3 (2 %), colon 34 (20 %), and rectum 93 (56 %). Mean lesion size was 35.5 (SD 21.5) mm. Among 112 en bloc resections, R0 was achieved in 84 (75 %). Delayed bleeding occurred in 6 patients (4 %), with a median onset of 4 days (range 0–13). All cases were managed endoscopically: SAP alone (n = 3), SAP plus coagulation (n = 1), coagulation plus hemoclips (n = 1), and coagulation plus hemostatic powder (n = 1); 2 patients required transfusion. Mean post-resection defect size was 38.4 (SD 20.2) mm, decreasing to 20.4 mm, 13.7 mm, and 10.9 mm at 4, 8, and 24 weeks, corresponding to 47 %, 64 %, and 72 % reductions, respectively.

Conclusions In this single-center cohort, use of a self-assembling peptide was associated with a low rate of delayed bleeding and progressive endoscopic healing of post-resection defects after EMR/ESD. These findings support the selective use of SAP to enhance the safety of advanced endoscopic procedures; prospective controlled studies are warranted.

eP385 Acute abdominal pain resolved following gastroscopy

Author Hrabak P[1]
Institute **1** Všeobecná fakultní nemocnice v Praze, Prague, Czech Republic
DOI 10.1055/s-0046-1821712

Abstract Text

A 68-year-old male with a complex medical history, including chronic ischemic heart disease (seven prior myocardial infarctions), COPD, and previous duodenal ulcer perforation, presented to the surgical department with acute epigastric pain lasting approximately 24 hours. The onset of pain followed coffee ingestion. On first evaluation, he was hemodynamically stable, afebrile, with a soft, non-tender abdomen, normal bowel sounds, and no peritoneal signs. Laboratory tests revealed CRP 6 mg/L and leukocytes 11.8×10^3/µL, with otherwise normal liver, pancreatic, renal, and hematologic parameters. Initial abdominal ultrasound and native X-ray were unremarkable, including ECG. The patient was treated with intravenous analgesics and an increased dose of proton pump inhibitor (omeprazole) and discharged with instructions for outpatient follow-up.

Approximately 20 hours later, the patient returned due to persistent epigastric pain. Repeat examination revealed a soft, non-tender abdomen without peritoneal signs. Laboratory testing demonstrated CRP 19 mg/L and leukocytes 11×10^3/µL, while all other parameters remained within normal limits. Given ongoing symptoms, urgent gastroscopy was performed. During gastroscopy, two flat wooden sticks were noted in the gastric antrum, partially protruding from the mucosa. Upon careful extraction with a loop, they were identified as toothpicks approximately 40 mm in length, each embedded through two-thirds of the gastric wall. Post-procedure, the patient experienced immediate relief of pain. Upon discussion of the findings, the patient recalled having eaten small sandwiches but had not realized that he might have ingested toothpicks. The procedure was completed without mucosal perforation or bleeding. Despite recommendation for hospital observation due to comorbidities and antiaggregation therapy (acetylsalicylic acid + ticagrelor), the patient declined admission. He was discharged under close outpatient follow-up with continuation of omeprazole therapy and a soft diet, without any antibiotic therapy prescribed [1, 2]. Follow-up evaluation demonstrated complete resolution of symptoms, normal bowel movements, and no gastrointestinal complaints. Repeat abdominal ultrasound and native X-ray showed no abnormalities.

This case illustrates a rare cause of acute epigastric pain—ingestion of sharp foreign bodies—that is often not initially considered, particularly when the patient history does not suggest foreign body ingestion. Prompt recognition and endoscopic retrieval allowed safe management and complete symptom resolution, emphasizing the importance of maintaining a high index of suspicion for unusual etiologies in patients presenting with unexplained abdominal pain.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP386 Novel mototrized biopsy device for EUS-guided liver biopsy: a prospective matched-controlled study

Authors Van De Loo DJ[1], Reinartz Groba SN[1], Wang L[1], Meier JA[1], Peiffer KH[1], Laleman W[2], Trebicka J[1], Praktiknjo M[1], Braden B[1]
Institutes **1** Department of Medicine B, Münster University Hospital, Münster, Germany; **2** Department of Gastroenterology and Hepatology, University Hospitals Leuven, KU Leuven, Leuven, Belgium
DOI 10.1055/s-0046-1821713

Aims EndoDrill is a novel motorized biopsy tool for endoscopic ultrasound that is designed to collect high quality tissue cores with less blood contamination. This single use flexible biopsy device with a 17G rotating drill-tip cylinder is driven by a reusable electric motor unit, and the tip rotation is activated by pressing a foot pedal.

In this prospective matched-controlled study, we compared the diagnostic performance of the novel endodrill biopsy device and conventional 19G fine needle biopsy (FNB) needles for obtaining EUS-guided liver biopsies.

Methods Consecutive eligible patients scheduled for untargeted EUS-guided liver biopsy were biopsied using the endodrill.
These patients were matched 1:2 for age and indications with patients undergoing untargeted EUS-LB using conventional 19 G EUS-FNB needles in wet-suction technique with one pass and 3-6 actuations. EUS-guided liver biopsies were performed by two experienced endoscopists.
Primary outcomes were the number of complete portal tracts (CPT) and aggregate specimen length. Secondary outcomes were user experience scores (0-10) for tissue penetration, visibility during biopsy, flexibility, handling and preparation of the biopsy device, and adverse events.
Results Seven consecutive patients underwent EUS-guided liver biopsy with endodrill and 14 patients with 19G-FNB needles. Median age was 49 years with 57 % male and 43 % female patients. Aggregate sample length with endodrill and EUS-FNB was 14 mm ± 7 mm vs. 40 mm ± 16 mm, respectively($p < 0.001$). Adequate samples defined as more than 10 CPT were obtained in 2/7 (29 %) vs. 13/14 (93 %; $p < 0.01$) of cases with endodrill and 19G FNB, respectively. Number of CPT was 5 ± 4 vs. 16 ± 6 ($p < 0.003$), respectively.
The drill device was rated highly in flexibility (8.9 ± 0.4) and easiness of preparation (9.8 ± 0.4). Visibility was hampered by artefacts due to the rotation (5.1 ± 2.8), and tissue penetration was scored low (2.9 ± 2.3).
There was one bleeding from the gastric wall requiring endoscopic clip application in the drill biopsy group.
Conclusions For EUS-guided liver biopsies, the motorised biopsy device was not superior to the conventional 19G FNB needles regarding aggregate length of cores or count of portal tracts.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP387 Black Esophagus with Atypical Presentation

Abstract Text

Acute necrotizing esophagitis (ANE) is a rare and severe form of esophageal inflammation characterized by diffuse mucosal necrosis predominantly involving the distal esophagus. Its etiology is multifactorial and associated with hypoperfusion states, severe infections (pneumonia, sepsis, etc.), and diabetes mellitus, among others. It primarily affects elderly males and presents as upper gastrointestinal bleeding (UGIB) in up to 90 % of cases [1–3].
We present the case of a 78-year-old male with poorly controlled diabetes who presented to the emergency department with a 10-day history of odynophagia and dysphagia, without food impaction. Symptoms began concomitantly with a pneumonia episode treated with oral antibiotics. During this period, he also experienced episodes of hypotension.
Upper endoscopy revealed from the proximal esophagus an erythematous mucosa with confluent erosions involving the entire circumference from 20 cm to the cardia, with diffuse black plaques. The duodenal bulb was edematous and erythematous with fibrin-covered erosions. In the first portion of the duodenum, a 10-mm Forrest IIc ulcer was identified. Biopsies were not obtained due to poor tolerance.
The patient was admitted for supportive management and intravenous proton pump inhibitors. Follow-up endoscopy after one week demonstrated near-complete mucosal recovery, with erythematous areas undergoing re-epithelialization and minimal residual sloughing.
Although UGIB is the most common presentation, the presence of acute odynophagia and dysphagia should prompt consideration of this entity in the differential diagnosis. In our case, given the patient's recent antibiotic use, the initial suspicion was esophageal candidiasis, which can present with similar symptoms; however, ischemia and inflammation in ANE can also produce them. Obtaining biopsies may be useful in cases where diagnostic uncertainty exists. Patients with ANE benefit from early diagnosis and prompt supportive treatment, along with management of the underlying cause. This typically leads to favorable recovery, with complete or near-complete re-epithelialization of the esophageal mucosa within 1–2 weeks after initiating therapy.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP388 Environmental impact of digestive endoscopy: experience from a hospital-based endoscopy unit

Authors Lachkar Y[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2]
Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821715

Aims To quantitatively assess the environmental impact of a hospital-based digestive endoscopy unit, including waste production and water and electricity consumption, and to identify areas for improvement toward more sustainable practices.
Methods This descriptive study was conducted in the Hepato-Gastroenterology Department "Medicine B" at Ibn Sina University Hospital over a 12-month period (January–December 2024). Data were collected retrospectively from endoscopy registries and included the number and type of procedures (diagnostic or therapeutic), number of biopsies, and use of disposable or reusable devices. Direct observation was used to measure the average amount of waste generated per procedure, sorted and weighed by category, and annual waste production was extrapolated accordingly. Water and electricity consumption related to endoscope reprocessing and endoscopy equipment were calculated.
Results A total of 1282 digestive endoscopic procedures were performed, including 1078 diagnostic procedures (509 upper endoscopies, 381 colonoscopies, 126 sigmoidoscopies, 62 endoscopic ultrasounds) and 204 therapeutic procedures (102 ERCPs, 39 dilations, 38 polypectomies, 17 argon plasma coagulations, 6 gastrostomies, 2 stent placements). A total of 704 biopsies were performed. Single-use devices represented the majority of the material used, including personal protective equipment, anesthesia consumables, endoscopic accessories (biopsy forceps, polypectomy snares, catheters, sphincterotomes), device packaging and waste generated during endoscope reprocessing. Annual waste production was 2734 kg (2.73 tons), ranging from 1.5 kg to 5 kg per procedure depending on procedure type. (▶ **Table 1**) Water consumption for endoscope reprocessing was 64,100 L/year (≈ 50 L/procedure). Annual electricity consumption of endoscopy equipment (endoscopy tower, reprocessor, electrosurgical generators, room lighting) reached 3,575 kWh, corresponding to 1.95 tons of CO_2 emitted.

▶ **Table 1** Waste generated by procedure type

Procedure type	Waste generated (kg)
Simple diagnostic (no biopsy)	1.5 kg
Diagnostic with biopsy	2.0 kg
Simple therapeutic	2.0-2.5 kg
ERCP	5.0 kg

Endoscopy 2026; 58: S1–S1041

Conclusions These results confirm the substantial environmental footprint of digestive endoscopy, driven by extensive use of disposable devices and high resource consumption. Several improvement pathways emerge, including optimization of indications, reduction of unnecessary procedures, and limitation of non-essential biopsies through optical characterization and decision-support tools. The integration of innovative technologies, including artificial intelligence, and more efficient energy management (automatic standby systems, workflow planning) may contribute to a more sustainable endoscopy practice that balances diagnostic performance with environmental responsibility.

eP389 EFTR 2.0: Prospects for Improving Safety and Standardization of Full-Thickness Resections Using Hybrid Endoscopic Solutions

Author Dubrovin V[1]
Institute **1** Saint-Petersburg, Russia
DOI 10.1055/s-0046-1821716

Problem to solve Although EFTR has expanded therapeutic options for complex subepithelial and early neoplastic lesions, a significant unmet clinical need remains in European practice: achieving a safer, more reproducible, and standardized resection technique that is less dependent on operator experience and variability in center equipment. Current limitations and complication risks demonstrate that the existing EFTR model requires technological reinforcement.

The innovative contribution of this work is positioning hybrid EFTR approaches as a conceptual foundation for a "next-generation EFTR"- a technologically enhanced and methodologically standardized procedural model.

Full-thickness resection (EFTR) has expanded endoscopic options for complex subepithelial and early neoplastic gastrointestinal lesions. However, significant limitations remain in European practice: variability of technique between centers, differences in equipment availability, high dependence on operator experience, risk of perforation, and the need for surgical intervention in some cases.

ESGE Strategy 2025 highlights the need to improve safety, reproducibility, and standardization of advanced procedures.

These limitations emphasize the need for a technologically enhanced and methodologically standardized next-generation EFTR model.

Innovation Hybrid EFTR approaches combine full-thickness resection with additional endoscopic technologies, such as:

- advanced hemostasis modalities (advanced coagulation devices, vessel-sealing tools);
- enhanced defect closure systems (over-the-scope clips, full-thickness suturing systems, combined clipping);
- visual assist tools (optical magnification, digital filters, image stabilization);
- traction-assisted methods (suture-traction, clip-line traction);
- integration of EFTR with ESD- or STER-based elements to improve control of the resection layer.

These hybrid technologies are considered a pathway toward a safer, more standardized, and more reproducible EFTR model.

Results A structured review of PubMed, Embase, and Scopus literature (2018-2025) was performed, assessing EFTR for subepithelial and early neoplastic lesions of the stomach, small intestine, and colon.

Evidence shows that hybrid EFTR approaches contribute to:

Improved safety: Enhanced visualization, hemostasis, and closure tools provide more stable control of the resection field and reduce complications.

Higher R0 resection rates: Hybrid series report R0 rates consistently above 90 %, comparable to or higher than standard EFTR.

Reduced inter-operator variability: Hybrid tools provide more predictable resection trajectories and easier defect closure.

Better reproducibility and training potential: Combined technologies support modular education following the ESGE "train-to-standard" concept.

Foundations for EFTR 2.0 registries: Several studies highlight the need for multicenter registries as a basis for future guideline development.

Conclusions Hybrid endoscopic solutions have the potential to form the concept of EFTR 2.0 – a safer, more standardized, and more reproducible model for full-thickness resection in the gastrointestinal tract. They align with ESGE priorities by improving safety, visual control, complication reduction, and training standardization.

Contemporary evidence underscores the need for further prospective, multicenter studies aimed at establishing registries and developing standardized protocols under ESGE guidance.

eP390 AI Tools for Polypectomy Guidance: Talk or Transcribe?

Authors Oualaalou S[1], Karam I[1], Jioua C[2], Nejjari F[1], Berrag S[1], Adioui T[2], Tamzaourte M[2]
Institutes **1** Mohammed V Military Training Hospital, Rabat, Morocco; **2** Mohamed V Military training hospital, Rabat, Morocco
DOI 10.1055/s-0046-1821717

Aims Artificial intelligence tools such as ChatGPT and Gemini are increasingly used by trainee endoscopists for rapid access to guideline-based recommendations. During colonoscopy, endoscopists often encounter polyps requiring endoscopic resection. Rapid support from AI tools can be obtained either in voice mode (direct verbal interaction with vocal responses) or via audio-to-text (spoken input transcribed to text with written AI output), offering different levels of hands-free support.

The aim of our study is to evaluate the concordance of two commonly used AI tools with ESGE 2024 polypectomy recommendations, comparing audio-to-text and voice mode performance.

Methods Ten clinical scenarios covering different polyp types were submitted to ChatGPT and Gemini in both modalities. Responses were compared to ESGE 2024 colorectal polypectomy and endoscopic mucosal resection guidelines. For discordant responses, follow-up prompts ("Are you sure?") assessed each model's ability to self-correct. Descriptive analyses were performed using Jamovi.

Results For ChatGPT, audio-to-text responses achieved a concordance of 100 % (10/10) with ESGE guidelines, and minor transcription inaccuracies (40 %) did not affect the correctness of the answers. In voice mode, initial concordance was 50 % (5/10), and follow-up prompts corrected 2 of the discordant answers, yielding a final concordance of 70 %.

For Gemini, audio-to-text responses showed 60 % concordance, 20 % mixed answers (two techniques suggested, only one matching the guidelines), and 20 % discordance. Gemini's live voice mode showed a concordance of 70 %, which remained unchanged after prompting.

Conclusions AI tools can assist in selecting appropriate polypectomy techniques according to ESGE recommendations; however, their performance varies significantly between models and usage modes. ChatGPT provided consistently accurate responses via audio-to-text, offering an almost hands-free support tool during endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP391 Clinical Profiles and Outcomes of Patients Undergoing Endoscopic Retrograde Cholangiopancreatography in a Tertiary Care Center

Authors El Khattab A[1], Kadiri M[2], Lagdali N[3], Ajana FZ[3], Borahma M[4]
Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Rabat, Morocco; **3** Mohammed V University, Rabat, Morocco; **4** Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821718

Aims Endoscopic retrograde cholangiopancreatography (ERCP) is a cornerstone technique for the diagnosis and management of biliary and pancreatic obstructive diseases. Despite its widespread use, ERCP remains associated with potentially severe complications. In Morocco, few large-scale descriptive series have been reported.

This study aimed to describe the indications, cholangiographic findings, therapeutic interventions, and immediate complications of ERCPs.

Methods A retrospective descriptive monocentric study including all consecutive ERCP procedures performed from May 2019 to September 2025. Data collected from a structured Excel registry included demographics (age, sex), indication, presence of cholangitis, bilirubin level, type of biliary stenosis, bile appearance, therapeutic gestures, biopsies, and complications. Quantitative variables were analyzed using means, medians, and interquartile ranges; qualitative variables with frequencies and percentages.

Results A total of 759 ERCPs were analyzed. The mean age was 60.9 years (median 63; range 18–100). Sex was available for all patients: 55 % were female (n ≈ 420) and 45 % male (n ≈ 338), giving a sex ratio M/F of 0.80.

The main indications were: choledocholithiasis (38.5 %), pancreatic head tumors (15.4 %), cholangiocarcinoma (8.0 %), and complicated hydatid cysts (3.0 %). Documented cholangitis was present in 71.3 % of interpretable cases. Biliary stenoses were predominantly distal (61.1 % of characterized stenoses). Bile was purulent in 9.1 % of documented cases. The most common interventions were stone extraction (31.5 %), metallic stent placement (24.4 %), and plastic stent placement (18.2 %). Endobiliary biopsies with forceps were performed in 10 % of procedures. The overall complication rate was 8.3 %, mainly immediate hemorrhage (3.8 %), post-ERCP pancreatitis (1.2 %), infectious complications (0.9 %), and perforation (0.1 %). Two deaths (0.3 %) were recorded.

Conclusions This six-year descriptive series provides one of the largest Moroccan datasets on ERCP. The activity is dominated by lithiasic and malignant biliary obstruction, frequently in a context of acute cholangitis. The therapeutic profile relies mainly on stone extraction and stent placement. The complication rate remains comparable to international standards. Structured registries represent an essential tool for quality monitoring and clinical research, and their enrichment could enable multicentric national studies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP392 Long-term follow-up of Lumen-Apposing Metal Stent (LAMS) in benign pathology

Authors Pérez Urra C[1], Espinel Pinedo P[1], Bulnes Labrador CB[1], Martin Ibañez C[1], Montero Moretón ÁM[1], González de Castro E[1], Pérez Citores L[1], Maestro Antolín S[1], Rizzo Rodríguez MA[1], Robles de la Osa D[1], Moreira Da Silva BA[1], Cimavilla Román M[1], Santos Santamarta F[1], Santos Fernández J[1], Barcenilla Laguna J[1], Rancel Medina FJ[1], Pérez Millán AG[1]

Institute 1 General Hospital Río Carrión, Palencia, Spain

DOI 10.1055/s-0046-1821719

Aims Luminal apposing stents are used to treat digestive tract stenosis with better results than endoscopic dilation and with a better morbidity and mortality profile than surgery. Despite an increase in their use, there is no evidence regarding their long-term safety. Below is a series of patients who have had LAMS for more than twelve months at our center [1, 2].

Methods Observational, descriptive, and retrospective study of patients with LAMS for more than one year due to benign digestive pathology.

Results The sample consisted of five patients with a mean age of 68.8 years (SD: 25.23) and 60 % males. The indication in all cases was benign stenosis: three duodenal stenoses (two secondary to chronic pancreatitis and the third post-ulcerative) in which gastroenteroanastomosis was performed, one peptic pyloric stenosis in which a transpyloric LAMS was placed, and one gastrointestinal anastomotic stenosis in which a prosthesis was used in the anastomosis. The most commonly used Hot-Axios prosthesis (60 %) had a diameter of 10x10 mm; in both cases indicated for duodenal stenosis secondary to chronic pancreatitis, it presented as a complication of obstruction at 17 and 23 months, requiring replacement with a 20x10 stent, and in the third case, used for pyloric stenosis, it was removed at 17 months due to restenosis and requiring reinsertion. In post-ulcer duodenal stenosis, a 15x10 diameter was used and after 13 months of follow-up, no complications have been reported. Finally, in gastrointestinal anastomotic stenosis, a 20x10 Hot-Axios was used without incident after 26 months of follow-up.

Conclusions The placement of LAMS in benign stenoses has revolutionized the management of many digestive pathologies with good results and an acceptable complication rate, allowing other more aggressive therapies such as surgery to be avoided. In our experience with long-term prostheses, there were no serious complications, with prosthesis obstruction in those with a smaller diameter being the most frequent adverse effect (40 %).

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP393 EndoDrill-Assisted EUS Biopsy: Unmasking an extrinsic rectal mass

Authors Vera Garcia D[1], Osagiede O[1], Kinnucan JA[1], Wallace MB[1], Wagh MS[1]

Institute 1 Mayo Clinic, Jacksonville, United States of America

DOI 10.1055/s-0046-1821720

Abstract Text

EndoDrill is a novel electromechanical device designed for EUS-guided core biopsy, featuring a motorized handle and a flexible 17-gauge cylindrical tip that drills tissue rather than relying on conventional needle puncture. We report an unusual case where EndoDrill allowed easy one-step EUS-guided sampling of an extrinsic rectal mass. A 72-year-old man undergoing CT urogram for hematuria was found to have a pelvic mass extending toward the rectum. Colonoscopy revealed a 3-cm extrinsic lesion eroding into the rectal lumen, located 10 cm from the anal verge. EUS-guided EndoDrill biopsies provided ample core tissue without adverse events. Histopathology and immunohistochemistry confirmed high-grade urothelial carcinoma. This case highlights the diagnostic potential of the novel EUS biopsy device in complex pelvic tumors [1].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP394 Closer to Endoscopic Gastrectomy… Curative Endoscopic Submucosal Dissection of an extensive Early Gastric Cancer

Authors Ribeiro H[1], Vidal Lima F[1], Gravito-Soares E[1, 2], Gravito-Soares M[1, 2], Amaro P[1], Narra Figueiredo P[1, 2]

Institutes 1 Gastroenterology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; 2 Faculty of Medicine, University of Coimbra, Coimbra, Portugal

DOI 10.1055/s-0046-1821721

Introduction: Gastric carcinoma remains a significant cause of morbidity and mortality worldwide. Early detection allows for minimally invasive therapeutic options, including Endoscopic Submucosal Dissection (ESD), which enables en-bloc resection of superficial gastric neoplasms with curative intent regardless the lesion size. We report a case of an extensive early gastric carcinoma successfully treated with ESD, highlighting its role as a safe and effective alternative to conventional surgical resection [1].

Case Report: A 69 year-old woman with a medical history of gastroesophageal reflux disease, lactose intolerance and thyroidectomy was referred for evaluation of a gastric flat lesion with biopsies suggesting intestinal-type adenocarcinoma, identified during an outpatient upper gastrointestinal endoscopy performed for pyrosis. Repeat upper endoscopy using WLI (White Light Imaging), virtual chromoendocopy (Blue Laser Imaging, BLI) and magnification revealed a large flat lesion (Paris 0-IIb) extending from the cardia to pylorus at the lesser curvature and a large extension of anterior and posterior wall of the stomach. Imaging evaluation by endoscopic ultrasound and CT-scan showed a pre-resection staging of T1aN0M0. After multidisciplinary discussion, it was decided for a minimally invasive resection by ESD. ESD was performed using Flush Knife 2.0 (Fujifilm, Japan) with Endocut I 2.0/Swift Coag 4.5 mode (VIO3 ERBE, Germany), after prior marking of the entire lesion with Forceg Coag 2.0 mode using BLI and magnification. The procedure was performed in the operating theatre with the patient intubated and ventilated, with total procedure duration of 7 hours, without immediate complications. An en-bloc resection was achieved with a final resected specimen of 130*105mm. Histopathological analysis confirmed a R0-resection of a low-grade intramucosal tubular adenocarcinoma, without lymphovascular/perineural invasion, in the context of chronic atrophic gastritis with extensive intestinal metaplasia. On post-operative D1, peripheral bilateral pulmonary thromboembolism with pro-thrombotic risk was diagnosed on CT-angiography performed due to mild epigastric pain without respiratory symptoms. The patient was started on anticoagulation and a second-look endoscopy was decided for delayed bleeding prophylaxis due to high bleeding risk. Coagulation of potentially bleeding vessels using hot-biopsy forceps with Soft Coag mode 4.0 and eschar covering with EndoClot Adhesive 3g (Olympus, Japan) was performed. At 1-month follow-up after a very low-risk curative resection, the patient is asymptomatic and remains on anticoagulation due to a prothrombotic risk status (MTHFR A1298C and PAI 4G/5G mutation).
Conclusion: This case highlights the challenge of endoscopic resection limits for early gastric cancer as a minimally invasive and organ-sparing strategy. Despite the post-procedural complication of pulmonary thromboembolism treated conservatively, ESD has proven to be an effective and safe endoscopic technique in selected patients, regardless the lesion size, avoiding major surgery with associated mortality and morbidity and providing a better quality of life.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP395 C-Reactive Protein on Day 1 After Peroral Endoscopic Myotomy : Is It a Predictive Factor for Complications?

Authors Amine M[1], Mrabti S[2], Benhamdane A[1], Azammam S[1], Hiji C[1], Addajou T[1], Elkoti I[1], Fedoua R[3], Seddik H[1]
Institutes **1** Mohammed V Military Training Hospital, Rabat, Morocco; **2** Mohammed V Military Teaching Hospital Rabat, Morocco, Rabat, Morocco; **3** Mohamed V Military training hospital, Rabat, Morocco
DOI 10.1055/s-0046-1821722

Aims Peroral endoscopic myotomy (POEM) is now considered one of the reference treatments for achalasia. However, predictive factors for unfavorable postoperative outcomes remain insufficiently defined.C-reactive protein (CRP), a simple, rapid, and accessible inflammatory biomarker, could help early identify patients at increased risk of complications.The objective of this preliminary study is to assess the association between the CRP level measured on day 1 after POEM, the occurrence of postoperative complications, and the length of hospitalization.

Methods This is a prospective, descriptive, and analytical study conducted over **2 years and 10 months**, from January 2023, including **52 patients** who underwent POEM.We evaluated demographic data (age, sex), the type of achalasia, the Eckardt score, previous treatments (dilation or myotomy), the CRP level at day 1 post-POEM, and postoperative outcomes (complications and length of hospital stay). A prolonged hospitalization was defined as a stay longer than 4 days.Statistical analyses used Welch's t-test for continuous variables and χ^2 or Fisher's exact test for categorical variables. A ROC curve was constructed to determine the optimal CRP threshold predictive of complications.

Results The mean age of the patients was **43.7 years**, with a male predominance
(**53.8 %**).**11.5 %** of patients had previously undergone treatment. Type II achalasia was predominant, representing **52.1 %** of cases.Patients with postoperative complications had significantly higher CRP levels than those without complications (**82.6 mg/L vs. 52.5 mg/L; p = 0.003**).
Using a CRP threshold of **50 mg/L**, the sensitivity was **27.8 %** and the specificity **88.9 %**. The positive predictive value (PPV) was **83.3 %**, while the negative predictive value (NPV) was **38.1 %**. The area under the curve (AUC) for this threshold was **0.293**, indicating limited discriminative ability.
These results suggest that, although this threshold identifies at-risk patients with good precision (high PPV), its low sensitivity and limited AUC show that it cannot detect all cases of complications by itself. However, it could serve as a clinical **alert marker**, to be combined with other risk factors to optimize postoperative surveillance.
The overall rate of immediate postoperative complications was **17.3 %**, including:

- Mucosal breach: **3.85 %**
- Pneumoperitoneum: **5.77 %**
- Subcutaneous emphysema: **7.69 %**
- Pneumomediastinum: **1.92 %**
- Death: **1.92 %**

Moreover, a post-POEM CRP > 50 mg/L was strongly associated with a prolonged hospital stay ($\chi^2 = 4.98$, p = 0.026; Fisher's exact test p = 0.042), with an odds ratio of **10.1** (95 % CI: 1.04–98).

Conclusions Our **preliminary study** demonstrates that CRP at day 1 post-POEM is a **significant predictive factor** for postoperative complications (p = 0.003).A CRP level above **50 mg/L** is also associated with an increased risk of prolonged hospitalization, making CRP a simple and potentially valuable tool to enhance postoperative monitoring

DOI 10.1055/s-0046-1821723

Abstract Text

A 78-year-old woman with multiple comorbidities underwent screening colonoscopy. A 15-mm homogeneous granular laterally spreading tumour (LST) was detected straddling the lower lip of the ileocecal valve. The lesion showed regular surface and vascular patterns and was classified as NICE I on NBI, consistent with sessile serrated lesion (SSL). We adopted the "novel underwater" technique: after complete gas aspiration and water filling, submucosal injection of saline plus indigo carmine (IC) was performed directly under water immersion using a standard 23-G needle. The cushion created excellent lift and vivid blue demarcation of the flat borders. *En bloc* underwater endoscopic mucosal resection (UEMR) was then carried out using a diathermic stiff snare. Inspection of the resection bed revealed no residual lesion, bleeding, or perforation. One

prophylactic clip was applied. Histopathology confirmed a SSL without dysplasia and with negative margins [1–4].

Conventional EMR (CEMR) and UEMR show comparable technical success and adverse event rates, although recurrence is higher after CEMR. Most studies predominantly include adenomas, with SSLs representing a minority. SSLs remain challenging due to their subtle margins. While IC chromoendoscopy may assist in demarcation, its use before UEMR can impair visibility. Perforation has been reported when injection precedes water filling. Conversely, a recent Japanese study demonstrated that submucosal injection performed directly under water immersion ('novel underwater') is safe and effective.

This case study shows that the 'novel underwater' technique is safe and dramatically improves margin delineation in challenging SSLs. To our knowledge, this is the first reported use of this technique for treating colorectal lesions outside of Japan.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP397 Osseous metaplasia in duodenal nodule: A rare case report

Authors Slama E[1], Benzarti Z[1], Jerbi A[1], Abdelwaheb N[1], Bouchabou B[1], Ennaifer R[1]

Institute 1 Hôpital Mongi Slim, Marsa, Tunisia

DOI 10.1055/s-0046-1821724

Aims Heterotopic bone formation is an uncommon finding in the gastrointestinal tract. Mesenchymal metaplasia, particularly osseous metaplasia (OM), is occasionally reported in malignant tumors but remains rare in benign polyps. OM is more frequently described in colonic polyps, whereas its occurrence in gastric polyps is exceptional, with only about ten cases reported in the literature. It has also been described in juvenile polyps, either sporadically or in association with Peutz–Jeghers syndrome.The exact pathogenesis is not well established, although most hypotheses suggest an inflammation-driven mechanism leading to osteogenic stimulation.While heterotopic ossification has been documented in various benign and malignant intestinal lesions, its development in the duodenum is exceedingly rare.We report a case of OM occurring in a duodenal nodule in a 31-year-old woman.

Methods A 31-year-old female patient with no significant medical history presented with chronic epigastric pain. Laboratory investigations were within normal limits (Hb 13.9 g/dL).An esophagogastroduodenoscopy (EGD) was performed.

Results EGD revealed a sliding hiatal hernia, congestive antral gastropathy, and a millimetric duodenal nodule.Histopathologic examination showed inflammatory and edematous–congestive changes in the duodenal mucosa with clear evidence of osseous metaplasia. No Helicobacter pylori infection, dysplasia, or malignancy was identified.A follow-up EGD performed one month later was normal.Although OM is considered to have limited clinical significance, its recognition is important to avoid misdiagnosis. No endoscopic surveillance is recommended once the diagnosis is confirmed.

Conclusions Osseous metaplasia is a rare entity in the upper gastrointestinal tract and exceptionally uncommon in the duodenum. Increased awareness among endoscopists and histopathologists is essential for accurate identification and appropriate diagnosis, preventing unnecessary interventions or follow-up.

eP398 Same Success, Same Safety: Rethinking Needle-Knife Technique Selection in ERCP

Authors Payab Q[1], Mahmood S[2], Lekharaju V[2], Iqbal J[2], Baig D[3], korani M[2], Alvin S[1], Miran F[1], Enrica W[4]

Institutes 1 Manchester University NHS Foundation Trust, Manchester, United Kingdom; 2 Manchester University NHS Foundation Trust, Wythenshawe, United Kingdom; 3 Wythenshawe Hospital, Wythenshawe, United Kingdom; 4 Wythenshawe Hospital, Manchester, United Kingdom

DOI 10.1055/s-0046-1821725

Aims To compare the cannulation success, and complications of Needle Knife Papilotomy Vs Fistulotomy in both benign and malignant cases.

Methods We conducted a retrospective comparative analysis of patients undergoing papillotomy (n = 118) or fistulotomy (n = 52) in our local centre. Outcomes included success, failure, overall complications, and specific complications (bleeding and pancreatitis). Subgroup analyses were performed for both benign and malignant indications. Proportions were compared using Chi-square and Fisher's exact tests with Wilson 95 % confidence intervals, risk differences, and risk ratios.

Results Success rates were similarly high for both papillotomy and fistulotomy (88.1 % vs 90.4 %; p = 0.668). Differences in unsuccessful rates (11.9 % vs 9.6 %; p = 0.668) and overall complications rates (12.7 % vs 7.7 %; p = 0.434) were not statistically significant. Both rates of bleeding (5.1 % vs 7.7 %; p = 0.497) and pancreatitis (7.6 % vS 1.9 %; p = 0.286) also showed no meaningful disparity. Subgroup analyses of benign and cancer indications echoed these findings. All risk differences were minimal, and confidence intervals included zero.

Conclusions No statistically significant differences were acknowledged between papillotomy and fistulotomy in terms of success or complication profiles, indicating that both techniques are equally safe and effective. Fistulotomy demonstrated a numerically lower risk of pancreatitis; however, this difference did not achieve statistical significance. Therefore, real-world decision-making may hinge more on anatomy, case complexity, and operator judgment rather than relying on expected clinical outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP399 Endoscopic Full-Thickness Resection of a Challenging Upper Submucosal Lesion: An unexpected diagnosis

Authors Ribeiro H[1], Vidal Lima F[1], Madeira J[2], Gravito-Soares E[1, 3], Gravito-Soares M[1, 3], Amaro P[1], Narra Figueiredo P[1, 3]

Institutes 1 Gastroenterology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; 2 Pathology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; 3 Faculty of Medicine, University of Coimbra, Coimbra, Portugal

DOI 10.1055/s-0046-1821726

Introduction Subepithelial lesions (SELs) of the gastrointestinal tract are often incidentally found and can range from benign to potentially malignant tumors. Traditional management includes endoscopic surveillance or resection, but deeper lesions may be difficult to remove endoscopically. Endoscopic Full-Thickness Resection (EFTR) is a minimally invasive technique that allows complete removal of such lesions. We report a case of a subepithelial lesion successfully treated with EFTR, highlighting its diagnostic and therapeutic utility [1].

Case Description A 71-year-old man with a medical history of Schatzki ring, arterial hypertension, dyslipidemia, coronary artery disease and psoriasis, was referred for a subepithelial lesion on the greater curvature at the body-antrum junction, diagnosed during an outpatient upper gastrointestinal endoscopy performed for dyspepsia. An endoscopic ultrasound was performed, identifying a well-defined elongated subepithelial lesion, measuring approximately 16x6

mm in size, hypoechoic, heterogeneous, arising from the muscularis propria layer, with features that do not allow the potential malignancy of the lesion to be ruled out, including the distinction between Gastrointestinal Stromal Tumor (GIST) and leiomyoma. Considering these findings, it was decided to excise the lesion by a cap-assisted EFTR technique using the gastroduodenal FTRD system (Ovesco Endoscopy, Tubingen, Germany). An en-bloc resection was achieved without complications. Histopathological analysis revealed a R0-resection of a solitary inverted hamartomatous polyp. No other hamartomas were detected on colonoscopy, excluding hereditary polyposis syndromes. At 1-month follow-up, the patient remains asymptomatic with no complications.

Conclusion This case highlights the efficacy and safety of EFTR for the management of gastrointestinal subepithelial lesions allowing complete resection for histopathological purposes. Endoscopic resection as a minimally invasive approach allows for both definitive diagnosis and treatment, avoiding the need for ongoing surveillance, being the size of the lesion the main limitation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP400 Contribution of biliopancreatic endoscopic ultrasound in the evaluation of pancreatic masses: diagnostic performance and practical implications

Authors Lachkar Y[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2]

Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821727

Aims Pancreatic masses represent a major diagnostic challenge, requiring high-precision imaging to guide therapeutic decision-making. Biliopancreatic endoscopic ultrasound (EUS) has emerged as a reference technique owing to its high resolution and the ability to perform fine-needle aspiration/biopsy (FNA/FNB). It enables detailed lesion characterization and improves the distinction between benign and malignant processes. The aim of this study was to assess the diagnostic performance of biliopancreatic EUS in the evaluation of pancreatic masses [1].

Methods A retrospective descriptive and analytical study was conducted in the Hepato-Gastroenterology Department "Médecine B" of Ibn Sina University Hospital over a 3-year period (January 2022 – January 2025). All patients managed for a pancreatic mass and who underwent biliopancreatic EUS in the interventional endoscopy unit were included. Demographic, clinical, EUS, and histopathological data were collected and analyzed.

Results Fifty-six patients were included (31 men, 55.4 %, sex ratio 1.24), with a mean age of 64.3 ± 14.1 years. Thirty-one patients (55.3 %) were symptomatic, most commonly with cholestatic jaundice (42.9 %). EUS identified a cystic mass in 2 cases (3.6 %), a multilocular cystic lesion in 3 cases (5.4 %), and a mixed cystic–solid lesion in 2 cases (3.6 %), while 49 patients (87.5 %) had a solid mass, heterogeneous in 69.6 % and hypoechoic in 17.9 %. Most lesions were located in the pancreatic head (67.9 %), with a mean size of 40 × 30 mm. The EUS appearance suggested a pancreatic tissue process in 46 cases (82.1 %). Specific lesions were also identified, including 4 neuroendocrine tumors (7.1 %), 3 intraductal papillary mucinous tumors (IPMN, 5.4 %), along with isolated cases of pancreatic metastasis, pseudocyst, and cystic lymphangioma (▶ **Table 1**). EUS-guided tissue sampling was performed in 50 patients (89.3 %) using various needle calibers, predominantly 20G ProCore (45.6 %). Histopathological analysis was positive in 15 cases (26.8 %), including 14 pancreatic ductal adenocarcinomas (21.4 % moderately differentiated, 3.6 % well-differentiated) and one well-differentiated grade 3 neuroendocrine tumor (1.8 %).

▶ **Table 1** EUS Findings (N = 56)

EUS diagnosis	N (%)
Pancreatic head process	35 (62.5 %)
Uncinate process lesion	5 (8.9 %)
Neuroendocrine tumor	4 (7.1 %)
Cephalo-isthmic process	4 (7.1 %)
Intraductal papillary mucinous neoplasm	3 (5.4 %)
Corporo-caudal process	1 (1.8 %)
Pancreatic body process	1 (1.8 %)
Pancreatic metastasis	1 (1.8 %)
Pancreatic pseudocyst	1 (1.8 %)
Pancreatic cystic lymphangioma	1 (1.8 %)

Conclusions Biliopancreatic EUS is a reference technique for the evaluation of pancreatic masses, offering high-precision morphological characterization and targeted tissue acquisition. Caution remains necessary, as the pancreas is one of the organs most prone to cytopathological interpretation difficulties, sometimes requiring repeated sampling with multiple needle passes. Optimizing sampling techniques and integrating advanced EUS technologies may further enhance diagnostic performance and improve patient management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP401 Clinical performance of endoscopic intermuscular dissection for challenging rectal lesions

Authors Ichimasa K[1], Kudo SE[1], Hayashi T[1], Sakurai T[1], Minegishi Y[1], Miyata Y[1], Ide Y[1], Kuroki T[1], Shiina O[1], Kouyama Y[1], Maeda Y[1], Ogata N[1], Baba T[1], Nemoto T[1], Misawa M[1]

Institute 1 SHOWA Medical University Northern Yokohama Hospital, Yokohama, Japan

DOI 10.1055/s-0046-1821728

Aims Endoscopic intermuscular dissection (EID) is an emerging technique that exploits the anatomical plane between the circular and longitudinal layers of the rectal muscularis propria. [1, 2] By enabling dissection within this intermuscular space, EID has the potential to secure vertical margins more confidently than standard submucosal dissection (ESD) and to remove lesions that extend deeper than the conventional ESD indication range. To clarify the practical utility of this approach, we assessed our center's experience with EID for difficult rectal lesions.

Methods We retrospectively reviewed consecutive cases in which EID was attempted for suspected deeply submucosal invasive rectal cancinomas or submucosal tumors located in the Ra/Rb region between 2021 and 2023. Key endpoints included procedural success, histological completeness of resection, and procedure-related adverse events.

Results A total of 14 patients (median age 68 years; 79 % male) underwent EID. Median lesion diameter was 19 mm (IQR 12–20 mm). Technical success was achieved in all cases, and complete (R0) resection was obtained in 71.4 % (95 % CI 45.4 %–90.6 %). Final pathology revealed T1b carcinoma in six patients, T2 carcinoma in four, neuroendocrine tumors in three, and a gastrointestinal stromal tumor in one. No severe complications occurred; only one patient reported mild transient abdominal symptoms that resolved without additional intervention.

Conclusions Our early experience suggests that EID is a feasible and safe method for removing deeply situated rectal lesions while offering improved vertical margin control. Importantly, for individuals who are unsuitable for surgery, EID may provide a meaningful endoscopic alternative even for lesions traditionally categorized as non-curative by current guidelines. A demonstration video of the EID technique will be shown during the presentation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP402 Innovative Double-Tunneling D + E-Peroral Endoscopic Myotomy (POEM) Approach for Symptomatic Left-Side Esophageal Diverticula: Two-Patient Experience

Authors Ribeiro H[1], Vidal Lima F[1], Gravito-Soares E[1, 2], Gravito-Soares M[1, 2], Amaro P[1], Narra Figueiredo P[1, 2]

Institutes **1** Gastroenterology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; **2** Faculty of Medicine, University of Coimbra, Coimbra, Portugal

DOI 10.1055/s-0046-1821729

Problem to solve Two male patients, aged 83 and 74, both taking antithrombotic drugs (one under anticoagulation with edoxaban and the other patient under dual antiplatelet therapy with acetylsalicylic acid and ticlopidine) were referred to our department due to a large epiphrenic esophageal diverticulum (mean size of 45. ± 7.1mm) on outpatient upper gastrointestinal endoscopy, associated with achalasia-like symptoms (dysphagia, regurgitation and nonintentional weight loss) with a mean Eckardt score of 6.5 ± 2.1. High-resolution esophageal manometry revealed distal esophageal spasm in one of the cases. Esophageal motility disorders are often associated with esophageal diverticula, indicating the need for intervention to address not only the structural esophageal problem but also the associated motility disorder. Left-side esophageal diverticula (6–12 o'clock position), especially epiphrenic diverticula pose an additional major bleeding risk for Peroral Endoscopic Myotomy (POEM) due to the potential injury of the aorta and other major vessels [1, 2].

Innovation For this specific subtype of left-side esophageal diverticula, we propose a double tunneling approach in a single procedure: the left tunnel limited to septotomy (D-POEM) and the right tunnel for E-POEM from the diverticulum to the cardia, reducing the risk of major bleeding. For both cases, left tunnel in a posterior approach (7 o' clock position) for D-POEM was performed using a triangle-tip (TT) Knife J (Olympus, Japan) with Spray Coag 2.5 mode (VIO3 ERBE, Germany), starting 3cm proximal to the diverticular septum and extending 3cm distal to the septum. After isolating the septum, a complete septotomy was performed with TT-knife J with Endocut Q 2.0/Forced Coag 3.0 mode. Then, right tunnel in a posterior approach (5 o' clock position) and subsequently complete myotomy were performed for E-POEM, from the level of the diverticular septum to the cardia, using the same knife and electrosurgical parameters described for D-POEM. Both mucosotomies were closed with TTS clips. Mean procedure time was 97.5 ± 31.8min. One patient presented subcutaneous emphysema and capnoperitoneum requiring intraprocedural percutaneous drainage. No other complications were reported.

Results At a mean follow-up of 5.0 ± 4.2months, both patients remain completely asymptomatic (Eckardt score of 0), with no complications.

Conclusions We present a variant double tunneling technique combining D-POEM with a complete septotomy and limited esophageal myotomy at the left side of the esophagus and E-POEM with a complete myotomy up to the cardia at the right side of the esophagus, that has proven to be effective and safe for the treatment of symptomatic left-side epiphrenic esophageal diverticula, addressing both structural and motility abnormalities in a single procedure. This minimally invasive endoscopic approach highlights the effective treatment of symptoms associated with the diverticulum, the prevention of its recurrence, treating underling motility disorders, which are often associated with it, and avoiding potential injury of large vessels and major bleeding complication, given the diverticulum proximity to the aorta and other major vessels, even in patients under antithrombotic drugs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Institute **1** Chonnam National University Hwasun Hospital and Medical School, Hwasun-gun, Republic of Korea

DOI 10.1055/s-0046-1821730

Aims Endoscopic submucosal dissection (ESD) is an organ-preserving treatment for superficial esophageal neoplasm with the potential for high-quality resection and favorable outcomes. We described the clinical characteristics and analyzed outcomes and prognosis at a single tertiary center [1–8].

Methods We retrospectively reviewed 118 consecutive patients with 128 esophageal lesions treated by ESD from January 1, 2012 to December 31, 2024. Primary endpoints were en bloc resection rate, recurrence rate, all-cause mortality, and disease-free survival. Continuous variables are presented as median (IQR) and categorical variables as number (%) (▶ **Table 1**).

▶ **Table 1** Baseline characteristics of patients

Characteristics	Value
Age, median (IQR), years	68.0 (59.0-74.0)
Sex, n (%)	
Male	113 (88.3%)
Female	15 (11.7%)
BMI, mean ± SD	23.2 ± 3.2
Smoking history, n (%)	51 (39.8%)
Medical history, n (%)	
Head & Neck cancer	5 (3.9%)
Hypertension	54 (42.2%)
Diabetes	24 (18.8%)
Chronic kidney disease	2 (1.6%)
Liver cirrhosis	6 (4.7%)
COPD	4 (3.1%)
Hospital days, mean ± SD	5.8 ± 1.7

Results The median tumor long-axis size was 15.0mm (IQR 10.0-21.2) and 10.0mm (IQR 10.0-15.0) in the short axis. En bloc resection rate was 97.7 % (125/128) and curative resection rate was 80.5 % (103/128). In the histologic analysis, lesions comprised squamous cell dysplasia [low-grade, 11 cases (8.6 %); high-grade, 54 cases (42.2 %)], squamous cell carcinoma in situ (20 cases, 15.6 %), and squamous cell carcinoma (41 cases, 32.0 %). Procedural complications occurred in 10.9 % (14/128): bleeding requiring endoscopic therapy or transfusion 0.0 % (0/128), perforation 0.8 % (1/128) successfully managed with endoscopic clipping, and post-ESD stricture 10.2 % (13/128). Median follow-up duration was 27.6 months (IQR 12.3-58.0). During follow-up, recurrence occurred in 6.3 % and all-cause mortality in 2.3 %; median disease-free survival was 24.0 months (IQR 9.4-57.1), and overall survival was 97.7 % (▶ **Table 2**).

▶ **Table 2** ESD procedural and clinical outcomes

Clinical outcomes	Value
En bloc resection, n (%)	125 (97.7 %)
Curative resection, n (%)	103 (80.5 %)
Complications, n (%)	14 (10.9 %)
Bleeding	0 (0.0 %)
Perforation	1 (0.8 %)
Post-ESD stricture	13 (10.2 %)
Recurrence, n (%)	8 (6.3 %)
All-cause mortality, n(%)	3 (2.3 %)
Disease-free survival, median (IQR), months	24.0 (9.4-57.1)

Conclusions In this single center series, ESD achieved a high en bloc resection rate with low recurrence and mortality over mid-term follow-up, supporting its role as an effective organ-preserving therapy for superficial esophageal neoplasia.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP404 Challenging Diagnosis of Insulinoma: Endoscopic Ultrasound as a Clarifying Method

Authors Vasconcelos Patricio AL[1], Cardoso MCDB[2], Sakae TM[3], De Oliveira LB[1], Daminelli Eugenio F[1], Bresciani LS[1]

Institutes **1** Universidade do Extremo Sul Catarinense, Criciúma, Brazil; **2** Clinigastro Hospital Dia, Criciuma, Brazil; **3** UFSC Araranguá, Criciuma, Brazil

DOI 10.1055/s-0046-1821731

Introduction: Insulinomas are rare tumors, with an estimated incidence of 0.1–0.4 cases per 100,000 inhabitants, and are almost always functioning, causing limiting symptoms related to hypoglycemia. Initial imaging exams such as computed tomography (CT) and magnetic resonance imaging (MRI) usually identify the lesion; however, in a small percentage of cases they are inconclusive.

Case Report: A 36-year-old female patient presented with episodes of sweating, dizziness, and loss of consciousness, during which hypoglycemia was documented. She also exhibited weight gain due to an increase in both frequency and volume of meals in an attempt to avoid hypoglycemic episodes. After laboratory tests indicated elevated insulin and C-peptide levels, abdominal imaging studies were performed, but no lesions were identified on either CT or MRI. To further investigate the pancreas as the source of symptoms, endoscopic ultrasound (EUS) was performed, revealing a well-defined, heterogeneous, hypoechoic nodular lesion with firm consistency in the pancreatic tail, measuring approximately 23 × 16 mm. Fine Needle Biopsy was performed during the procedure, and subsequent histopathology and immunohistochemistry demonstrated a well-differentiated neuroendocrine neoplasm producing insulin, confirmed by positivity for Chromogranin A, Synaptophysin, beta-catenin, and insulin.

Discussion: The diagnosis of insulinoma can be challenging, especially when lesions are small and not detectable on traditional imaging modalities. In this case, Endoscopic Ultrasound proved fundamental—not only for localizing the lesion but also for obtaining tissue for analysis and confirming the diagnosis—thus enabling definitive treatment [1–9].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP405 Bibliometric Analysis of the 100 Most-Cited Articles on Endoscopic Band Ligation in Esophageal Variceal Bleeding

Authors Elnaggar M[1], Habib M[2], Omar A[3], Houman R[4]
Institutes **1** Hartford Hospital, Hartford, United States of America; **2** Beth Israel Deaconess Medical Center, Boston, United States of America; **3** Faculty of Medicine Al-Azhar University Boy's Branch in Cairo, Cairo, Egypt; **4** UConn School of Medicine, Farmington, United States of America
DOI 10.1055/s-0046-1821732

Aims To identify, characterize, and visualize trends among the top 100 most-cited articles on EBL in the treatment of gastrointestinal bleeding, with a focus on esophageal varices, using a comprehensive bibliometric approach.

Methods A systematic search was conducted in the Scopus database on April 11, 2025, using predefined keywords related to EBL and gastrointestinal bleeding. Only English-language review and original research articles were included. Data such as citation count, author affiliations, country of origin, journal, and keywords were extracted. Analysis and visualizations were performed using the Bibliometrix R-package and VOSviewer.

Results Out of 1,115 records screened, 100 articles were selected (71 original articles, 29 reviews), published between 1989 and 2021, and collectively cited 17,298 times (range: 43–1,046 citations). Spain, the UK, and the USA led in research output. Hospital Clínic (Spain) and Royal Infirmary of Edinburgh (UK) were the most productive institutions. *Gastrointestinal Endoscopy* and *Hepatology* were leading journals in terms of publication count and citation impact. The most cited authors included Bosch J. and García-Pagán J.C., with strong collaborative networks visualized. Co-occurrence analysis of keywords identified key research themes and evolving trends over time.

Conclusions This bibliometric analysis provides a comprehensive overview of the most impactful literature on EBL for esophageal variceal bleeding. It highlights key contributors, institutions, and journals, offering insights into historical progress and emerging directions in this critical area of gastroenterology.

eP406 Risk Factors and Prediction Model for False Negative Results in Repeated EUS-FNA/B of Pancreatic Solid Lesions

Authors Ma J[1], Jiang W[1], Wang K[1], Jin Z[1]
Institute **1** Department of Gastroenterology, ChangHai Hospital, Shanghai, China
DOI 10.1055/s-0046-1821733

Aims Repeat endoscopic ultrasound-guided fine-needle aspiration/biopsy (rEUS-FNA/B) is recommended in solid pancreatic lesions (SPLs) with inconclusive initial results. However, even rEUS-FNA/B cannot completely eliminate false negatives in challenging cases. This study aims to identify risk factors of false-negative results in rEUS-FNA/B and develop a prediction model.

Methods Data of patients who had initial inconclusive diagnosis and underwent rEUS-FNA/B for SPLs across eight Chinese medical centers from January 2013 to June 2024 were retrospectively reviewed. Logistic regression was performed to identify the risk factors of false-negative results in rEUS-FNA/B. A clinical prediction model using random forest (RF) algorithm was developed with leave-one-hospital-out cross validation [1].

Results A total of 230 patients were enrolled in this study. Among them,159 patients (69.1 %) were diagnosed with malignancies, while 71 patients (30.8 %) had benign lesions. The diagnostic accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of rEUS-FNA were 75.00 %, 62.63 %, 100 %, 100 %, and 56.98 %, respectively, whereas those of rEUS-FNB were 84.15 %, 78.33 %, 100 %, 100 %, and 62.86 %. At multivariate analysis, lesion size 20-40mm (OR 0.26), lesion size ≥ 40mm (OR 0.20), ≤ 2 needle passes (OR 3.1), no liquid-based cytology (LBC) examination (OR 3.95) were found to be independently associated with false-negative results. A final RF model with 4 features (lesion size, rEUS-FNA/B needle type, LBC, smear cytology) showed moderate ability to distinguish false-negative results in both training (AUC = 0.78) and validation sets (AUC = 0.68).

Conclusions To minimize false-negative outcomes during rEUS-FNA/B, LBC is strongly recommended. Additionally, SPLs with a maximum diameter of ≤ 20 mm exhibit a higher probability for producing false-negative results during rEUS-FNA/B procedures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Zollinger-Ellison syndrome (ZES) is a rare condition, characterized by acid hypersecretion, due to a gastrin-secreting neuroendocrine tumour (NET) – gastrinoma, linked to multiple endocrine neoplasia type 1 (MEN-1) syndrome in 25 % of the cases. Surgical resection is the standard treatment for localized gastrinomas, but Endoscopic Ultrasound–Guided Radiofrequency Ablation (EUS-RFA) is emerging as a minimally invasive alternative for selected pancreatic NETs, supported mainly by experience with insulinomas [1–6].

We report a 33-year-old male with end-stage kidney disease and history of Wilms and parathyroid tumors, who presented with gastrointestinal bleeding from erosive esophagitis, esophageal ulcer, complicated by stricture, and peptic ulcers. Computed tomography showed a 1,2cm solid nodule between the distal duodenum and the pancreatic uncinate process. Serum gastrin level was 4982 pg/ml (normal: < 115 pg/ml). EUS revealed a 14-mm homogeneous, hypoechoic, round peripancreatic nodule adjacent to the uncinate process and close to the superior mesenteric vein. Fine-needle biopsy (22G-FNB) confirmed a well-differentiated NET (CD56 + , chromogranin + , synaptophysin + , Ki-67 < 2 %), establishing the diagnosis of ZES and MEN1.

Given his comorbidities and high-surgical risk, after a multidisciplinary team reunion, it was opted for EUS-RFA. After esophageal balloon dilation (12 mm), EUS-RFA was successfully performed (30 W for 25 seconds, impedance > 500 Ohms) without adverse events. The patient was discharged after 48 hours. Serum gastrin decreased to 311 pg/ml within six days. Upon follow-up, the patient remained asymptomatic.

This case highlights the potential role of EUS-RFA as a therapeutic option for gastrinomas, particularly in patients who are poor surgical candidates. Further studies are warranted to better define its role, long-term outcomes, and ideal clinical indications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP408 Organ Preservation and Escalation-Free Palliation in Rectal Cancer Using Endoscopic Electroporation: A Prospective Observational Cohort Study

Authors Adeyeye A[1], Bhoday J[1], Olabintan O[1], Lim A[1], Campion J[1], Emmanuel A[1], Hayee B[1], Haji A[1]
Institute 1 King's College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1821735

Aims Rectal cancer is challenging to manage in elderly or frail patients, for whom chemoradiotherapy, brachytherapy, radical surgery, and local endoscopic excision may be poorly tolerated. Existing organ-preservation and palliative strategies often provide limited or short-lived benefit with significant toxicity. Early work with endoscopic electroporation (EE) has shown feasibility for palliation, but its structured role in organ preservation for stage II–III disease and escalation-free palliation in stage IV rectal cancer has not been established.The aim of this study was to evaluate the role of dual EE in supporting organ preservation, palliation, and salvage therapy in frail or medically unfit patients with treatment-naïve, residual, or recurrent rectal cancer.

Methods Eighteen consecutive patients with rectal or rectosigmoid cancer (below the peritoneal reflection) were treated with combined calcium electroporation and irreversible electroporation between October 2023 and September 2025. Demographics, oncological history, symptoms, clinical response, complications and survival were obtained from a prospectively maintained database. Organ-preservation (stage II–III) was defined as avoidance of any rectal surgical resection after EE. Successful palliation (stage IV) required documented symptom control (bleeding, pain, obstruction) and absence of escalation of care (no new stoma, stenting, haemostatic-endotherapy, transfusion, or iron infusion). Follow-up and overall survival (OS) were calculated from first EE to death or data cut-off. All procedures were performed as day-case treatments under sedation using CE-approved equipment.

Results Median age was 84.9 years (range 54–93), with a male: female ratio of 2:1. Baseline symptoms included bleeding in 77.8 %, pain in 61.1 %, and subacute obstruction in 22.2 %. Disease stages were II (11.1 %), III (66.7 %), and IV (22.2 %). Fifteen tumours (83.3 %) were mismatch-repair proficient. Eleven patients (61.1 %) had residual or recurrent tumours after prior therapy (short-course radiotherapy 8/11; chemoradiotherapy 3/11), with additional brachytherapy (3/11), attempted endoscopic resection (3/11), or systemic therapy (2/11). Seven patients (38.9 %), including all four rectosigmoid tumours, were treatment-naïve. Nine (50 %) patients received a single EE session, and nine received multiple sessions (2–6). Median follow-up was 6.9 months (range 2.9–24.9). Median OS was 6.4 months (range 2.9–25.9), with 88.9 % (16/18) alive at data cut-off. Organ-preservation occurred in 100 % (14/14) of stage II-III patients at 6 months, with a 28.6 % (4/14) complete clinical response rate. Among stage IV patients, 75 % (3/4) achieved successful palliation, and 100 % avoided invasive escalation of care. Overall symptomatic response was 88.9 % (16/18), and tumour response was 77.8 % (14/18). No procedure-related severe adverse events occurred.

Conclusions Dual EE enabled universal organ preservation in stage II–III rectal cancer and meaningful escalation-free palliation in stage IV disease, with high symptomatic response and excellent safety in a frail, elderly cohort. EE may represent a versatile option for organ preservation, salvage therapy, and palliation in selected patients. Larger prospective comparative studies are warranted.

eP409 What factors are associated with post ERCP pancreatitis(PEP) among patients undergoing endoscopic retrograde pancreatic duct drainage (ERPD) ?

Author Lee JH[1]
Institute 1 Chosun University, Gwangju, Republic of Korea
DOI 10.1055/s-0046-1821736

Aims Post-ERCP pancreatitis(PEP) is the most common complication following endoscopic retrograde cholangiopancreatography (ERCP) and represents a frequent clinical challenge. Placement of an endoscopic retrograde pancreatic duct drainage (ERPD) stent has been recognized as an important preventive measure against post-ERCP pancreatitis. The aim of this study was to identify factors associated with post-ERCP pancreatitis in patients who underwent ERPD placement

Methods This single – tertiary center retrospective study was conducted at Chosun University Hospital and included patients who underwent ERCP between January 1, 2024, and December 31, 2024. A total of 576 ERCP procedures were performed during the study period, of which 60 cases involved the placement of an ERPD. Among patients who received an ERPD, potential risk factors associated with post-ERCP pancreatitis (PEP) were evaluated, including age, sex, naïve cannulation, cannulation time, procedure time, endoscopic papillary balloon dilation (EPBD), and trainee involvement.

Results Among the 60 patients who received an ERPD, the incidence of post-ERCP pancreatitis (PEP) was 21 cases (35 %), which was higher compared with the overall ERCP population. The mean cannulation time was longer in patients who developed PEP compared with those who did not (637 seconds vs. 516.6 seconds), although the difference did not reach statistical significance ($P = 0.343$). Similarly, the mean procedure time tended to be longer in the PEP group (34.1 minutes vs. 30.69 minutes), but this difference was also not statistically significant ($P = 0.242$). No risk factors evaluated in this study demonstrated a statistically significant association with the development of PEP.

Conclusions Among patients who received an ERPD, no procedure-related factors were identified as predictors of increased risk for PEP. These findings suggest that ERPD placement itself may be the most important procedural measure for preventing PEP.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP410 Risk of pancreatitis for combined EUS ERCP in distal malignant biliary obstruction may be lower than previously reported

Authors Paladiya R[1], Karthik M[1], Dharan M[1]
Institute 1 UConn Health, Farmington, United States of America
DOI 10.1055/s-0046-1821737

Aims A recent meta-analysis (Beran et al., 2024) showed that overall risk of post-ERCP pancreatitis is approximately 5.4 %. Previous studies comparing same-session EUS tissue acquisition and ERCP with separate procedures did not show a significant difference in the incidence of Post-Procedure Pancreatitis (PPP). However, the absolute incidence of PPP was high, at 19 % in the same session arm and 12 % in the separate session group (Gorris et al., 2022). Hence, we analyzed our database to ascertain the risk of PPP in same-session interventions [1, 2].

Methods Single center retrospective analysis of all patients undergoing the same session EUS ERCP for head of pancreas mass from July 2019 to November 2025. All procedures were performed by single endoscopist (MD). Outcomes, including technical success, clinical success, FNA results, and immediate and long-term adverse events (AE), were analyzed.

▶ **Table 1**

Category	Data
Age	Mean ≈ 75.7 years
Sex (M/F)	16 : 21
Fine Needle Aspiration Performed	100 %
Needle Gauge Usage	• 22G only: 43.2 % (16/37) • 25G only: 35.1 % (13/37) • Both 22G & 25G: 21.6 % (8/37)
Total Passes (by Gauge)	• 22G: 67 passes (54.5 %) • 25G: 57 passes (45.5 %)
Average Number of Passes per Gauge	• 22G: 67 ÷ 24 = 2.79 • 25G: 57 ÷ 21 = 2.71
Endoscopic Ultrasound Route	• Transduodenal (TD): 35/37 (94.6 %) • Transgastric (TG): 3/37 (8.1 %)
Same-session Biliary Cannulation	28/37 (75.7 %)
Percutaneous Transhepatic Catheter with Drain	10/37 (27 %)
Stent Placement	• Stent placed: 27/37 (73 %) • No stent placed: 10/37 (27 %)
Type of Biliary Stent (Among 27 placed)	• Plastic: 11/27 (40.7 %) • Uncovered metal: 7/27 (25.9 %) • Covered metal: 11/27 (40.7 %)
Prophylaxis	• NSAIDs: 33/37 (89.2 %) • IV fluids: 24/37 (64.9 %)
Complication	Post-ERCP Pancreatitis: 1/37 (2.7 %)

Results 37 patients with pancreatic head masses underwent index EUS ERCP as part of the diagnostic workup. FNA was performed on all patients (100 %), with a 25-gauge needle in 13 patients (35 %), a 22-gauge needle in 16 patients (43 %), and both needles in 8 patients (22 %). FNA access was transduodenal (TD) in 35 patients (95 %) and transgastric (TG) in 3 patients (8 %). On average, three passes were performed per patient. Rapid on-site evaluation (ROSE) for preliminary cytologic exam and specimen adequacy was available for all patients. Same-session biliary cannulation was successful in 28 patients (76 %), while the rest underwent Percutaneous Transhepatic catheter with drain. Prophylactic rectal NSAID were administered to 33 patients (89 %), and 24 patients (65 %) received periprocedural IV hydration with lactated Ringer's solution. Overall, the incidence of AE was low, and the specific incidence of PPP was 2.7 % (1/37). (▶ **Table 1**)

Conclusions Same session EUS guided tissue acquisition and ERCP for the head of pancreas mass may have lower risk for PPP than previously reported. The availability of ROSE, appropriate number of FNA passes, endoscopist with advanced technical expertise, case complexity, prophylactic rectal NSAIDs, and IV fluids could have positively impacted the risk of PPP in our study.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP411 Guideline-Optimized Large-Language Models for Colonoscopy and Pathology Interpretation: A Three-Model Comparative Study Revealing Distinct Performance Behaviors

Authors Kahwagi A[1], Wehbe P[1], Rita A[2], Boustani B[2], Haddad R[2], Njeim M[2], Mahfouz E[1], Amara J[1], Honein K[1], Slim R[1], Yaghi C[1]
Institutes 1 Gastroenterology Department, Hotel Dieu de France, Beirut, Lebanon; 2 Hôtel-Dieu de France, Beirut, Lebanon
DOI 10.1055/s-0046-1821738

Aims Large-language models (LLMs) are increasingly used to support colonoscopy report interpretation, but their diagnostic reliability and behavior before and after guideline optimization have not been systematically evaluated. This study compared the accuracy and completeness of ChatGPT, DeepSeek and Copilot when interpreting colonoscopy and corresponding anatomopathology reports, assessed the effect of structured evidence-based prompting, examined cost-related practical considerations and identified performance domains in which any model surpassed ChatGPT.

Methods Ninety-one colonoscopy reports combined with their available anatomopathology results were processed by each LLM in two conditions: before and after receiving standardized guideline-based instructions. Each model was asked to interpret the full clinical sequence, integrating both endoscopic findings and pathology outcomes. The dataset was derived from real-world procedures performed at Hôtel-Dieu de France, Beirut, Lebanon, ensuring clinically authentic case representation. Two binary outcomes were recorded: accuracy, defined as correct interpretation of report and pathology correlation, and completeness, defined as inclusion of all essential reporting elements. Paired analyses used the McNemar test. Comparisons were conducted within each model pre- vs post-guidelines and between models at each timepoint.

Results Across all three LLMs, the most frequent pre-guideline error was incorrect assignment of surveillance intervals, reflecting insufficient integration of evidence-based follow-up rules before structured prompting. ChatGPT demonstrated the largest improvement after guideline optimization, with accuracy increasing from 56.0 % to 92.3 % ($p < 0.001$) and completeness from 79.1 % to 92.3 % ($p < 0.001$). DeepSeek showed a moderate increase in accuracy (53.8 % to 70.3 %, $p < 0.01$) but a significant decline in completeness (46.1 % to 29.7 %, $p < 0.001$), suggesting a restrictive or “restorative” behavior where structured prompting leads the model to remove rather than expand essential descriptors. Copilot improved in both domains, with accuracy rising from 57.1 % to 86.8 % and completeness from 57.1 % to 81.3 % ($p < 0.001$).

Before guidelines, accuracy did not differ significantly between models. Completeness, however, differed markedly, with Copilot achieving the highest

pre-guideline completeness at 95.6 %, outperforming both ChatGPT and DeepSeek. This was the only performance domain in which ChatGPT was surpassed. After guideline prompting, ChatGPT achieved the highest overall performance. Its accuracy significantly exceeded DeepSeek's and was comparable to Copilot's, while its completeness remained significantly higher than DeepSeek and borderline higher than Copilot.

Practical considerations included the fact that ChatGPT was the only paid model, whereas DeepSeek and Copilot were freely accessible. Although ChatGPT delivered the best overall post-guideline performance, cost differences may influence accessibility, equity and feasibility in low-resource settings. Copilot, as a free tool demonstrating strong accuracy and completeness after optimization, represents a scalable alternative when paid models are not feasible.

Conclusions Guideline prompting markedly enhanced LLM performance in the interpretation of colonoscopy and anatomopathology findings. ChatGPT showed the most consistent and robust improvements and was significantly superior to DeepSeek in all post-guideline comparisons. Copilot outperformed ChatGPT in pre-guideline completeness and remained a strong free alternative after optimization. DeepSeek's decline in completeness highlights functional limitations and a restrictive response to structured guidance. Overall, ChatGPT was the most reliable model, while Copilot offers a promising cost-accessible option for endoscopic reporting support. As LLMs become increasingly accessible to lay people seeking guidance after their colonoscopy, our findings highlight the importance of directing them toward models that prioritize accuracy and completeness, ensuring that patient self-education remains aligned with evidence-based recommendations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP412 Beyond the Obvious: Analyzing Demographic Trends and Predictive Factors for Successful Endoscopic Retrieval of Foreign Bodies from Gastrointestinal tract

Authors Banerjee A[1], Sarkar R[2], Banerjee S[2], Ray G[2]
Institutes **1** Manipal Hospitals Broadway, Kolkata, India; **2** Institute of Post Graduate Medical Education & Research, Kolkata, India
DOI 10.1055/s-0046-1821739

Aims Studies exploring demographic factors associated with foreign body (FB) ingestion are typically uncommon in adults, resulting in limited information available in the current literature.We aimed to identify demographic factors associated with FB ingestion and to evaluate predictors of successful endoscopic removal (ER).

Methods This descriptive cross-sectional study was conducted at the SDLD OPD and Endoscopy Suite, Department of Gastroenterology, SDLD, IPGMER & SSKM Hospital, Kolkata, India, from July 2021 to December 2022. Consecutive patients of all ages presenting with clinical and/or radiological evidence of FB ingestion were included. Data on demographic, clinical, and socio-economic factors were collected. All patients underwent evaluation and endoscopic management as per standard protocols. Descriptive statistical analysis was performed using MS Excel and Epi Info 7.2.2.2, and $p < 0.05$ was considered significant.

Results The patients who met the inclusion criteria had a median age of 6.25 years (range 0.2-75.0) and 58.6 % males. Socio-economic status distribution was predominantly lower-middle (40.23 %) and upper-lower (31.05 %). Most patients (88.5 %) presented with FB ingestion via the oral route. The time since ingestion varied, with 44.83 % presenting after > 72 hours. The most common FBs were coins (34.48 %) and meat bones/dentures (11.49 % each). A significant ($p = 0.00058$) association between the individuals' denture ingestion and the endoscopic outcome was observed. Sharp objects accounted for 35.63 % of cases. Dysphagia and odynophagia were reported in 29.89 % and 21.83 %, respectively, showing a strong association ($p < 0.0001$). Logistic regression analysis identified age as the only significant predictor of successful ER (odds ratio [OR] 0.96, $p = 0.0008$), indicating a slight decrease in removal success with increasing age. Socio-economic status, sex, time since ingestion, and size of the food bolus were not significantly predictive. The predictive model integrating multiple factors demonstrated good discrimination with an area under the ROC curve (AUC) of 0.79 (sensitivity- 65.5 %, specificity-83.3 %). Models with socio-economic status or sex alone had poor predictive power (AUC 0.52 and 0.51, respectively). Age alone as a predictor showed an AUC of 0.73 (sensitivity-70.5 %, specificity-72.2 %), comparable to the full model. Endoscopic success in old patients (> 50 years) was significantly lower (46.7 %). Logistic models exhibited modest discriminatory capacity (AUC 0.75 and 0.589), suggesting restricted prognostic significance for endoscopic outcomes in the older population.

Conclusions In this cohort, younger age was the sole significant predictor of successful ER of FBs, with removal success decreasing slightly with increasing age. The predictive model demonstrated good discrimination (AUC 0.79), with age alone performing comparably well (AUC 0.73). These findings highlight the importance of age as a clinical factor in endoscopic management of FB ingestion and suggest that ER is a generally effective procedure regardless of other demographic variables.Further research may focus on strategies to enhance timely presentation and optimize management protocols in diverse patient populations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP413V Early Detection and Successful Endoscopic Submucosal Dissection of a Superficial Hypopharyngeal Cancer

Authors Fortes Fonseca Y[1], Nobre Moura R[2], Lenz L[2], Costa Martins B[2], Mansilla Gallegos M[1], Lima A[2], Morganti Ferreira Dias M[2], Gustavo ADP[3], Simas Lima M[2], Vaz Safatle Ribeiro A[2], Maluf-Filho F[4]
Institutes **1** Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil; **2** Cancer Institute of the State of São Paulo, São Paulo, Brazil; **3** Cancer Institute of the State of São Paulo, Brazil, São Paulo, Brazil; **4** Cancer Institute of the State of São Paulo, Brazil, Sao Paulo, State of Sao Paulo, Brazil, Brazil
DOI 10.1055/s-0046-1821740

Problem to solve Oesophageal squamous cell carcinoma (ESCC) increases the relative risk of developing head and neck cancer by up to 34.9-fold [1]. This association is explained by the *field cancerization* phenomenon, in which the entire epithelial surface of the upper aerodigestive tract becomes susceptible to malignant transformation after chronic exposure to shared carcinogens such as alcohol and tobacco. Consequently, multiple synchronous or metachronous squamous cell carcinomas may arise throughout this region [2]. Despite their clinical relevance, pharyngeal cancers are frequently missed on standard white-light endoscopy. Even with advances such as magnification and digital chromoendoscopy, early detection remains challenging, and many cases continue to be diagnosed at advanced stages [3–6].

Early identification of superficial pharyngeal cancers enables curative resection, improving survival and reducing the long-term functional consequences associated with advanced disease and its treatments, including swallowing and voice impairments [6]. Endoscopic submucosal dissection (ESD) has emerged as a minimally invasive, organ-preserving, and safe therapeutic option with excellent outcomes and low complication rates [3–6]. Although well established for early gastric, rectal, and colonic tumors, its use for superficial pharyngeal cancers is relatively recent. Most evidence originates from Asian centers, and limited global exposure may be hindering widespread familiarity and adoption of this promising technique [4, 7].

Innovation We describe the case of a 71-year-old male patient with a history of oesophageal squamous cell carcinoma (ESCC) who had previously undergone subtotal esophagectomy. During follow-up endoscopy, and considering the field cancerization theory, a meticulous examination of the oral cavity and upper gastrointestinal tract was performed. On the right wall of the hypopharynx, an extremely subtle flat area with only minimal erythema was noted so discreet

that it was barely visible on white-light endoscopy. Under NBI chromoendoscopy, this area showed mildly brownish, raising suspicion. The biopsy, confirmed high-grade dysplasia. After multidisciplinary discussion with the head and neck surgeon, ESD was indicated.

First, the patient was anesthetized with orotracheal intubation, and no accessory device for laryngeal elevation was required. During the procedure, the lesion margins were difficult to identify, making 1.25 % Lugol chromoendoscopy necessary to clearly delineate the affected area, revealing a flat lesion of approximately 40 x 20 mm. Circumferential marking and the submucosal dissection was performed using the Orise™ProKnife. Submucosal lifting with 6 % hydroxyethyl starch and indigo carmine was then carried out, followed by submucosal dissection. Near the end of the procedure, the clip-with-line traction technique was employed to enhance lesion exposure and facilitate submucosal dissection. Complete *en bloc* resection of the lesion was successfully achieved. The procedure was completed in approximately 40 minutes.

Results The lesion was successfully resected *en bloc* using ESD, without intraprocedural or postprocedural adverse events. Histopathological evaluation confirmed *in situ* squamous cell carcinoma, with both lateral and deep margins free of neoplasia. No lymphovascular invasion was detected. The patient recovered uneventfully. Food intake was resumed on day 1 post-ESD, and the patient was discharged on day 2 post-ESD. Endoscopic follow-up was scheduled at 6 months after the procedure (not done yet).

Conclusions This case illustrates the importance of meticulous oral cavity and pharynx evaluation in patients with a history of ESCC, given their high risk of developing secondary neoplasia due to field cancerization. Even minimal subtle pharyngeal lesions may correspond to early carcinoma and can be easily missed on white-light endoscopy**.** Adjunctive imaging techniques significantly enhance lesion detection and margin delineation. Wider adoption of systematic screening protocols and pharyngeal ESD in Western centres could improve early detection rates and survival, while preserving laryngeal function in this population.

eP414V Balloon-Assisted Redirection: A Novel Endoscopic Technique for Complex Biliary Injury Post-Cholecystectomy

Authors Chavan R[1], Maindad D[1], Rawal R[1]
Institute 1 Bharati Vidyapeeth Deemed University Pune, Pune, India
DOI 10.1055/s-0046-1821741

Abstract Text

A 52-year-old woman developed persistent high-output bile leak after a difficult open cholecystectomy, with imaging revealing a long proximal CBD–CHD stricture and upstream non-opacified ducts. Repeat ERCP attempts failed as the guidewire repeatedly entered the large defect. A novel balloon-assisted redirection technique was used, wherein a biliary balloon catheter was advanced through the percutaneous drain and inflated at the defect, creating a temporary barrier that enabled successful guidewire entry into the left hepatic duct. Bilateral stents were placed, achieving internal drainage. Drain output decreased rapidly, collections resolved, and the patient improved without requiring surgery. This minimally invasive method offers an effective alternative for complex bile duct injuries where standard endotherapy fails.

eP415 EUS-FNA Diagnosis of Pancreatic Lymphangioma: A Rare Chylous Cyst of the Pancreas

Authors Ortolani A[1], Ridolfi F[1], Serio M[1], Ferrarini A[1], Scarcelli A[1]
Institute 1 AST Pesaro Urbino UOC Gastroenterologia ed Endoscopia Digestiva Pesaro – Fano, Pesaro, Italy
DOI 10.1055/s-0046-1821742

Background: Pancreatic lymphangioma is an uncommon benign cystic lesion that may closely resemble mucinous or serous cystic neoplasms on imaging. EUS-FNA with biochemical and cytological assessment is critical for establishing a definitive diagnosis.

Case Description:A 50-year-old woman with hypothyroidism and thalassemia minor was evaluated for persistent dyspepsia and abdominal pain. Abdominal ultrasound identified a 25 × 35 mm cystic structure adjacent to the pancreatic head. MRI demonstrated a well-defined 3.6 × 2.7 cm cystic lesion arising exophytically from the pancreatic body–tail, showing T1 hypointensity, marked T2 hyperintensity, thin septations, and no mural nodules or ductal dilatation. Linear EUS revealed a 37 × 26 mm anechoic lesion at the head–isthmus junction, without communication with the main pancreatic duct and without internal solid components or Doppler signal. Initial sampling was performed with a 22G FNA needle, followed by a FNB pass with a 22G FNB Franseen-tip needle, resulting in aspiration of milky-white chylous fluid.

Biochemical analysis demonstrated marked hypertriglyceridemia (6250 mg/dL), low CEA (2.2 ng/mL), and low amylase and lipase levels (221/412 U/L). Cytology showed fibrino-leukocytic material with a lymphocyte-rich background and no epithelial cells. These findings were consistent with pancreatic lymphangioma.

Conclusion: EUS-FNA enabled definitive distinction between pancreatic lymphangioma and other cystic pancreatic lesions. The biochemical profile of the aspirate—chylous fluid with markedly elevated triglycerides, low CEA, and low amylase and lipase levels—is characteristic of lymphangioma and effectively excludes mucinous or other neoplastic cysts, supporting a conservative, non-operative approach.

eP416 Does Extent-Integrated Colonoscopic Scoring Better Predict Ulcerative Colitis Relapse Than Severity Alone?

Authors Kuroki T[1], Kudo SE[1], Maeda Y[1], Ogata N[1], Kawabata Y[1], Kawashima J[1], Ichimasa K[1], Misawa M[1], Hayashi T[1], Baba T[1], Kazuo O[2]
Institutes 1 SHOWA Medical University Northern Yokohama Hospital, Yokohama, Japan; 2 Institute of Science Tokyo Hospital, Tokyo, Japan
DOI 10.1055/s-0046-1821743

Aims The Mayo Endoscopic Subscore (MES) is widely used to assess endoscopic inflammatory activity in ulcerative colitis (UC). More recently, additional indices such as the Modified MES (MMES) and Dublin index have been proposed to improve the prediction of clinical outcomes. However, real-world evidence directly comparing these scoring systems remains limited. Therefore, we evaluated the predictive performance of MES, Modified MES(MMES) [1], and the Dublin index [2] in patients with clinical remission UC undergoing colonoscopy.

Methods Consecutive patients who had maintained sustained corticosteroid-free remission for at least 6 months, had a partial Mayo score ≤ 1, and underwent colonoscopy at our institution between August 2022 and February 2023 were prospectively enrolled. Following index colonoscopy, patients were followed every 8 or 12 weeks for 24 months or until clinical relapse occurred. Clinical relapse was defined as a partial Mayo score > 2. The area under the receiver operating characteristic curve (AUC). of each endoscopic index was compared. The sensitivity, specificity, and risk ratio (RR), were also assessed. MMES was calculated by multiplying the sum of MES across five colonic segments (MS) by the maximal evaluated extent of the colon measured in decimetres during withdrawal, and dividing the resulting EMS by the number of segments with MES > 0. The DUBLIN score was calculated as the product of the highest MES (0–3) observed during colonoscopy and disease extent classified according to the Montreal system (E1–E3).

Results A total of 166 patients were included. Ten patients were lost the follow up. The remaining 156 patients were analysed. Among them, 21 patients experienced clinical relapse.The AUCs were 0.766, 0.754, and 0.787 for MES, MMES, and the Dublin index, respectively.The best cut-off values for predicting clinical relapse were 1, 4, and 2 for MES, MMES, and the Dublin index, respectively.At the best cut off, the sensitivity, specificity, and relative risk were 0.857, 0.556, and 6.000 for MES; 0.857, 0.474, and 4.517 for MMES; and 0.429, 0.933, and 5.750 for the Dublin index, respectively.

Conclusions Both the MMES and Dublin index showed no clear advantage over the conventional MES in predicting clinical relapse. Although these indices provide more detailed segmental assessment, they did not yield improved discriminative performance. In this post hoc analysis, the results suggest that the conventional MES may also have potential for predicting relapse risk in routine clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP417 Comparing the Efficacy and Adverse Outcomes of Plastic Versus Metallic Stents in Patients with Malignant Distal Biliary Obstruction: A Retrospective Study

Author Althahabi R[1]
Institute 1 King Hamad University Hospital, Al Sayh, Bahrain
DOI 10.1055/s-0046-1821744

Aims Endoscopic retrograde cholangiopancreatography (ERCP) with stent placement remains the cornerstone of palliation for patients with malignant distal biliary obstruction (MDBO). The choice between plastic stents (PS) and self-expanding metallic stents (SEMS) continues to ignite debate due to their varying patency duration, complication rates and cost effectiveness. While PS are less expensive and suitable for short term drainage, SEMS are favored for longer term management owing to their wider diameter and reduced occlusion rates. Nevertheless, clinical decisions are often influenced by patient survival, local resources, and anticipated need for reintervention. This study was conducted at King Hamad Univerity Hospital, a tertiary care center in Bahrain to compare outcomes of PS versus SEMS in patients with MDBO [1–19].

Methods A retrospective cohort study was conducted at King Hamad University Hospital between January 2019 and May 2024. Demographic data, comorbidities, malignancy type, biochemical parameters, and post ERCP complications were reviewed. Comparative analyses between PS and SEMS groups were performed using appropriate statistical tests. Primary outcomes included improvement in bilirubin levels and liver enzymes post ERCP. Secondary outcomes assessed adverse events, reintervention and readmission rates.

Results A total of 54 patients with MDBO underwent ERCP with stenting for palliation (24 metallic, 30 plastic). Both groups demonstrated significant reductions in total and direct bilirubin, AST, and ALT following ERCP ($p < 0.001$). There were no statistically significant differences in cholangitis, migration or readmission rates. Reintervention was less frequent among PS recipients (58 % vs. 43 %), though not statistically significant. Addtionally, time to reintervntion was longer with patients who received SEMS compared to PS. Overall, both stent types achieved comparable biochemical improvement and palliation.

Conclusions In this retrospective study, both PS and SEMS provided effective biliary drainage and comparable biochemical improvement in patients with MDBO. Complications and readmission rates were similar, while SEMS demonstrated a longer time to reintervention. Overall, either stent type can be used effectively and stent selection should remain individualized based on prognosis, cost, and institutional resources.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP418 Patient Satisfaction Among Individuals Undergoing Endoscopic Procedures at Naimat Begum Hamdard University Hospital: A Prospective Pareto-Based Evaluation

Author samad A[1]
Institute 1 Department of Gastroenterology, Hamdard University Hospital Karachi Pakistan, karachi, Pakistan
DOI 10.1055/s-0046-1821745

Aims To assess patient satisfaction following outpatient endoscopic procedures at Naimat Begum Hamdard University Hospital and to identify the major contributors to dissatisfaction using Pareto analysis to guide quality improvement strategies.

Methods This prospective observational study enrolled 300 consecutive outpatients undergoing endoscopic procedures from the Gastroenterology Department. After undergoing the procedure, all patients filled a structured satisfaction questionnaire assessing the following domains: (1) pre-endoscopy guidance and booking communication, (2) interaction with staff on the day of the procedure, (3) waiting time, (4) technical aspects of the procedure, (5) discomfort during endoscopy, (6) sedation-related concerns, and (7) post-procedure recovery. Procedures included 210 upper gastrointestinal (GI) endoscopies and 90 colonoscopies. The study population consisted of 180 males and 120 females. All participants completed the satisfaction form.

Dissatisfaction responses were categorized and quantified. A Pareto analysis was applied to identify the most frequent contributors to dissatisfaction and to determine the "vital few" domains responsible for the majority of negative feedback. Descriptive statistics were used to calculate proportions and cumulative percentages [1, 2].

Results A total of 62 dissatisfaction events were reported across all domains. Pre-endoscopy communication issues were the leading source of dissatisfaction, reported by 22 patients (35.5 %), primarily relating to booking confirmation delays or inadequate instructions. Sedation-related anxiety was the second most common issue, reported by 14 patients (22.6 %), predominantly among younger female patients. Endoscopy-related discomfort was noted in 12 patients (19.4 %); discomfort was higher among colonoscopy patients (n = 8) compared with upper GI endoscopy (n = 4). Other issues contributed smaller proportions, including waiting time (6 patients, 9.7 %), staff interaction concerns (4 patients, 6.5 %), technical/information-related issues (2 patients, 3.2 %), and delayed recovery discharge (2 patients, 3.2 %).

Pareto analysis showed that the top three dissatisfaction categories—communication issues, sedation-related anxiety, and procedural discomfort—accounted for **77.4 %** of all dissatisfaction events. This aligns with the 80/20 principle, indicating that addressing these three domains would yield the greatest improvement in overall patient satisfaction. The remaining categories collectively contributed only 22.6 % of dissatisfaction, indicating relatively minor impact.

Conclusions Communication gaps, sedation-related anxiety, and procedural discomfort were the main contributors to dissatisfaction, accounting for most negative feedback. Focusing on improving pre-procedure counselling, appointment communication, and patient reassurance may significantly enhance overall satisfaction.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP419 Clinical Profile and Treatment Outcomes in Patients with Solitary Rectal Ulcer Syndrome: A Three-Year Prospective Study from a Tertiary Care Centre

Author samad A[1]
Institute 1 Department of Gastroenterology, Hamdard University Hospital Karachi Pakistan, karachi, Pakistan
DOI 10.1055/s-0046-1821746

Aims To evaluate the frequency, clinical presentation, and treatment response of patients diagnosed with solitary rectal ulcer syndrome (SRUS) among individuals presenting with bleeding per rectum

Methods This prospective observational study was conducted from January 2022 to January 2025 at a tertiary care hospital. A total of 250 patients presenting with bleeding per rectum underwent colonoscopic assessment. Individuals diagnosed with SRUS were followed as a focused cohort. Standardized management included dietary and lifestyle modification, careful use of laxatives, sucralfate enemas, and biofeedback therapy. Patients were assessed during follow-up visits for clinical improvement, symptom persistence, treatment compliance, and psychosocial impact [1, 2].

Results Among the 250 patients evaluated, 42 (16.8 %) were diagnosed with SRUS. Only 6 patients (14.3 %) showed significant improvement with lifestyle modification and judicious laxative use. The remaining 36 patients (85.7 %) remained symptomatic despite adherence to conservative treatments, including sucralfate enemas and biofeedback therapy. Of these non-responders, only 3 patients consented to undergo surgical rectopexy. Although the procedure was technically successful, all three patients reported significant post-procedure psychological distress, including heightened anxiety, fear of symptom recurrence, and impaired confidence in daily functioning. The majority of the overall non-responder group required frequent outpatient visits, continued to experience bleeding and discomfort, and reported marked deterioration in quality of life with associated personal, professional, and emotional challenges.

Conclusions SRUS remains a difficult condition to manage, with poor response to conventional conservative therapies. While surgical rectopexy was accepted by only a small subset of refractory patients, postoperative psychological issues further complicated their recovery. These findings highlight the need for more

effective therapeutic strategies, early psychological support, and a multidisciplinary approach to improve long-term outcomes and quality of life in patients with SRUS.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP420 Use of a Modified Condom Catheter as a Protective Cap During Endoscopic Retrieval of Ingested Needles: A Case Series of 10 Patients

Author Ozercan M[1]

Institute 1 Fırat University, Elâzığ, Türkiye

DOI 10.1055/s-0046-1821747

Aims Endoscopic removal of foreign bodies from the stomach is among the most common emergency indications in gastrointestinal endoscopy. Needle ingestion is a particularly common among women who secure their headscarves with needles. The main complications that may occur during the extraction procedure are mucosal injury, bleeding, laceration, or perforation of the stomach and esophagus. In this study, we evaluated the presence and severity of esophageal injury during the removal of a swallowed needle using an easily accessible and low-cost modified condom catheter attached to the tip of the gastroscope.

Methods Fourteen female patients who accidentally swallowed a needle were admitted to the emergency department. After radiologic imaging confirmed that the foreign body was located in the stomach, endoscopic removal was performed under sedation with midazolam and meperidine. Before the procedure, a condom catheter with 35 mm diameter was modified by cutting and adapted to the tip of the gastroscope. Since swallowed needles could not be found in 2 patients, 12 patients were evaluated. During the procedure, the proximal one-third of each needle was grasped with a snare, and once the modified condom catheter cap at the gastroscope tip completely enclosed the needle at the esophagogastric junction, the instrument was withdrawn. Post-procedure endoscopic examinations were performed to assess possible esophageal mucosal damage, and the lengths of the removed needles were measured. Descriptive analysis was performed.

Results The mean age of the 12 female patients was 27.7 ± 8.7 years. All reported accidental needle ingestion while wearing a headscarf. The mean length of the extracted needles was 24.7 ± 6.2 mm (range: 15–35 mm). Follow-up endoscopic evaluations revealed no mucosal injury or laceration in any patient. All patients were discharged following the procedure.

Conclusions In this small case series of 12 patients with ingested needles, the use of a modified condom catheter attached to the gastroscope tip in conjunction with a snare was associated with successful retrieval without any endoscopically detectable esophageal mucosal injury. This easily accessible and low-cost modification may represent a useful adjunct in selected cases; however, larger comparative studies are needed to confirm its safety and efficacy.

eP421 Let it snow: a novel hemostatic agent to prevent delayed bleeding after duodenal adenoma resection

Authors Gerritsen D[1], Maan ADI[1], Kemper G[2], Rijckborst V[1], Koch A[1], Siersema PD[1]

Institutes 1 Erasmus MC Cancer Institute, University Medical Center, Rotterdam, Netherlands; 2 Radboud University Medical Center, Nijmegen, Netherlands

DOI 10.1055/s-0046-1821748

Problem to solve Endoscopic mucosal resection (EMR) is a standard technique for removing duodenal adenomas but carries a relatively high risk of clinically significant delayed bleeding (CSDB), reported in 8–18 % of cases. CSDB contributes to patient morbidity and increased healthcare utilization. Preventive measures such as clip closure and prophylactic coagulation can reduce this risk but are technically demanding and time-consuming. In contrast, topical hemostatic agents are quick and easy to apply. Novel hemostatic powders may therefore offer a simpler and more efficient strategy to reduce CSDB following duodenal EMR.

Innovation A Polysaccharide Hemostatic System (PHS (Endoclot); Olympus, Tokyo, Japan) is a hemostatic powder applied to the resection site using controlled air pressure. The powder consists of absorbable modified polymers (AMP), which degrade naturally. By absorbing water from blood, AMP particles concentrate platelets, red blood cells, and coagulation proteins, thereby accelerating the clotting cascade. An air compressor ensures consistent air pressure, allowing uniform powder application to the resection site, forming a protective layer over the resection plane (▶ **Table 1**).

▶ **Table 1** (Post-)Procedural and histologic characteristics

Characteristic	Duodenal EMR (n = 34)
Sedation	
Propofol	32 (94.1)
Midazolam	2 (5.9)
Non-lifting sign (yes), n (%)	8 (23.5)
Piecemeal EMR (yes), n (%)	30 (88.2)
*If piecemeal, number of pieces, median (IQR)**	4 (3)
Macroscopic complete resection (yes), n (%)	30 (88.2)
Successful application of hemostatic agent (yes), n (%)	33 (97.1)
Bleeding (yes), n (%)	
Intraprocedural	2 (5.9)
Post-procedural (delayed)	6 (17.6)
Timing of post-procedural bleeding (hours after EMR), median (IQR)	19 (110)
Perforation (yes), n (%)	0 (0)
Histology	
Tubular adenoma	16 (47.1)
Tubulovillous adenoma	17 (50 %)
Sessile serrated adenoma	1 (2.9)

EMR: endoscopic mucosal resection; IQR: interquartile range*: *unknown for 12 patients*

Results A total of 34 duodenal EMRs were performed using the novel hemostatic powder. Of these patients, 55.9 % were male, with a mean age of 61 years (95 % CI: 47.3-74.7). Most polyps were located in the second part of the duodenum (D2; 41.2 %) and had a median size of 20 mm (IQR 20). Piecemeal resection was performed in 88.2 % of cases. Application of the hemostatic agent was successful in 33 procedures (97.1 %). Delayed bleeding occurred in 6 patients (17.6 %) at a median of 19 hours post-EMR (IQR 110). Among these, a hemoglobin drop of ≥ 1.5 mmol/L was observed in 3 patients (8.8 %), hematemesis in 2 (5.9 %), hematochezia in 3 (8.8 %), and melena in 5 (14.7 %). Three patients were treated conservatively, and three underwent successful endoscopic hemostasis with clip placement.

Conclusions Compared with previous studies, this novel hemostatic agent does not appear to reduce the risk of CSDB. However, definitive conclusions cannot yet be drawn, as the study is ongoing and aims to include a total of 53 cases.

eP422 Protective Effects of Escin Against Ethanol-Induced Gastric Mucosal Injury in Rats via Regulation of the TNF-α/NF-κB Signaling Pathway

Authors Yao S[1], Xiaoyi Z[1], Zhou Z[1], Han J[1], Huazhen Z[1], Jie Y[1], Shuping S[1], Lijia D[1], Lin J[1], Yunan Z[1], Zhifa L[1], Tian W[1], Lv J[1], Qiang Z[1], An F[1]
Institute 1 Wuxi People's Hospital, Wuxi, China
DOI 10.1055/s-0046-1821749

Aims Therapeutic options for ethanol-induced gastric mucosal injury remain limited. To provide new drug options, this study investigated the protective mechanisms of Escin—a compound known for its anti-inflammatory and anti-edematous properties—against this condition, which are currently unreported.

Methods Male SD rats were divided into Control, Ethanol, Escin, and Omeprazole groups. Gastric ulcer index and histopathological scores were compared. Network pharmacology predicted Escin targets. Apoptosis proteins, NF-κB inflammatory pathway proteins, inflammatory factors, and related mRNA expression were analyzed. An Ethanol-induced GES-1 cell injury model was established to evaluate the protective effect of Escin. Genes positively regulating the TNF-α/NF-κB signaling pathway were identified through transcriptome sequencing and validated.

Results The study found that Escin significantly alleviated the damage of Ethanol to gastric mucosal tissue. Network pharmacology predicted that Escin was closely related to inflammation-related pathways such as NF-κB in the action of gastric ulcers. Escin significantly mitigated ethanol-induced damage by restoring MUC5AC, TFF2, Occludin, suppressing NF-κB activation, downregulating IL-1β, IL-6, and TNF-α at both protein and mRNA levels, and modulating apoptosis by inhibiting Bax/Caspase-3 while promoting Bcl-2 expression Escin's protection against ethanol-induced injury was further validated in cell proliferation assays. Finally, Transcriptomics revealed 27 inflammation-related genes upregulated by ethanol, of which 9 genes including Birc3, Bcl3, SOCS1, SOCS3, CCL2, CX3CL1, Pim1, SGK1, and OSMR positively regulated the TNF-α/NF-κB signaling pathway. Western blot confirmed seven of these are modulated by Escin during its protective action.

Conclusions The study found that Escin significantly alleviated the damage of Ethanol to gastric mucosal tissue. eP423 Significance of D-LECS in Introducing Duodenal ESD for Superficial Non-ampullary Duodenal Epithelial Tumors in a Japanese Regional Hospital

Authors Koyoshi N[1], Sasaki F[1], Maeda N[1], Hidehito M[1], Tanaka A[1], Kanmura S[1]
Institute 1 Kagoshima University Hospital, Kagoshima, Japan
DOI 10.1055/s-0046-1821750

Aims Endoscopic submucosal dissection (ESD) for superficial non-ampullary duodenal epithelial tumors (SNADETs) has been reported to be effective, but the unique anatomical and physiological features of the duodenum are associated with a higher incidence of severe complications compared with other sites. In addition, SNADETs requiring ESD are relatively rare, making it difficult, especially in regional hospitals, to accumulate sufficient cases and gain experience. To ensure safety while building experience with duodenal ESD, we introduced duodenal laparoscopic and endoscopic cooperative surgery (D-LECS), in which ESD is followed by laparoscopic suturing of the mucosal defect. We then gradually shifted to standalone duodenal ESD after stepwise training, including endoscopic closure techniques in colorectal ESD. This study aimed to clarify the role of D-LECS in the introduction of duodenal ESD in a Japanese regional hospital.

Methods We retrospectively reviewed 37 patients with 37 SNADETs treated by D-LECS between September 2016 and November 2024, and 6 patients with 6 SNADETs treated by ESD alone from January 2025 onwards at our institution.

D-LECS cases were divided into an early phase (before national insurance reimbursement) with 12 lesions and a late phase (after reimbursement) with 25 lesions. Patient characteristics and treatment outcomes were compared between phases, including en bloc resection rate, R0 resection rate, dissection speed, intraoperative perforation, delayed bleeding, delayed perforation, and postoperative fever.

Treatment outcomes of standalone ESD cases were evaluated descriptively.

Results Patient characteristics, including age, sex, tumor size, tumor location, and malignancy rate, did not differ between the early and late D-LECS phases. En bloc resection was achieved in 100 % of lesions in both phases. R0 resection rates were 16.7 % in the early phase and 8.0 % in the late phase, with no significant difference. Intraoperative perforation occurred in 41.7 % and 12.0 % of cases, respectively, showing a non-significant trend toward reduction in the late phase ($p = 0.083$). Postoperative fever occurred in 16.7 % of early-phase cases and in none of the late-phase cases.

All 6 standalone ESD cases achieved R0 resection. One patient **developed a perforation** during clip closure of the mucosal defect; free air worsened on the following day, and surgical suturing of the defect was required. The remaining 5 patients experienced no major complications and were discharged on postoperative day 4.

Conclusions In a Japanese regional hospital where case accumulation is challenging, stepwise skill acquisition through D-LECS for duodenal ESD, combined with training in endoscopic closure after colorectal ESD, appears useful for safely introducing standalone duodenal ESD. However, the risk of emergency surgery due to complications remains and requires careful attention. Close collaboration with surgeons is essential, and D-LECS may contribute to both technical training of endoscopists and improvement of treatment outcomes during the introductory phase of duodenal ESD.

DOI 10.1055/s-0046-1821751

Aims Endoscopic intermuscular dissection (EID) is an emerging, organ-preserving technique for rectal tumors; however, its clinical value necessitates further evidence. This study aimed to evaluate the efficacy and safety of EID for rectal tumors using multicenter data (▶ **Table 1**).

▶ **Table 1** Patients basline charceteristics and endoscopic findings

Outcomes		Results
Number		33
Gender, male, n(%)		20(60.61)
Age, mean(SD), years		45.30 ± 13.00
Location, n(%)	Upper	4(12.12)
	Middle	2(6.06)
	Low	27(81.82)
Diameter, mean(SD),(mm)		
Subepithelial lesion		9.86 ± 3.86

	White	5(15.15)
	Red	2(6.06)

Methods This retrospective cohort study included patients who underwent EID for rectal tumors at two tertiary centers between January 2019 and January 2025. Inclusion criteria were: (1) pathological confirmation of rectal tumor; (2) no distant metastasis on preoperative imaging (contrast-enhanced CT/MRI, endoscopic ultrasound, or 68Ga PET-CT); and (3) complete follow-up of ≥ 3 months. The primary outcome was R0 resection rate. Secondary outcomes included en bloc resection rate, procedure time, complication rate, and postoperative hospital stay.

Results A total of 31 patients (mean age 45.3 ± 13.0 years; 58.1 % male) were analyzed. Most tumors (87.1 %) were located in the middle/lower rectum. Preoperative diagnoses were predominantly submucosal tumors (93.6 %). EID achieved 100 % technical success and en bloc resection rates. The median procedure time was 60 minutes (IQR 42.3–68.0). Final pathology identified neuroendocrine tumors (G1, 87.1 %), leiomyoma (3.2 %), stromal tumor (3.2 %), and pT1 adenocarcinoma (6.5 %). The mean tumor diameter was 9.00 ± 3.86 mm. R0 resection was achieved in all cases (100 %), with no lymphovascular or perineural invasion. The complication rate was 9.7 % (3/31; fever: 2, pain: 1), all managed conservatively without re-intervention or surgery conversion. Median hospital stay was 5 days (IQR 5–6). Over a median follow-up of 22.5 months (IQR 11–62), no recurrence or metastasis was observed.

Conclusions EID is an effective and safe treatment for selected rectal tumors, offering high rates of R0 and en bloc resection with minimal complications. It represents a promising organ-preserving option for submucosal and early-stage rectal lesions. Larger prospective studies are warranted to confirm its long-term oncologic outcomes.

eP425 Top Linear Incision–Assisted Endoscopic Submucosal Enucleation for the Resection of Large Subepithelial Lesions at the Esophagogastric Junction: A Multicenter Retrospective Study

Authors Liao S[1], Huang S[2], He M[2], Li T[3]
Institutes **1** South China Hospital, Medical School, Shenzhen University, Shenzhen, China; **2** South China Hospital, Medical School, Shenzhen University. No 1 Fuxin Road, Longgang District, Shenzhen, China; **3** The First People's Hospital of Yunnan Province No. 157 Jinbi Road, Xishan District Kunming, Shenzhen, China
DOI 10.1055/s-0046-1821752

Aims Endoscopic submucosal excavation (ESE) for large subepithelial lesions (SELs) at the esophagogastric junction (EGJ) often faces challenges of large mucosal defects and difficult wound closure. This study aimed to preliminarily investigate the efficacy and safety of a modified technique—top linear incision-modified ESE (TLI-ESE)—for treating large SELs in this specific location.

Methods This multicenter retrospective study enrolled 7 consecutive patients with EGJ-SELs who underwent TLI-ESE between May 2024 and August 2025 at three tertiary centers. Inclusion criteria were lesions originating from the muscularis propria layer with a long diameter > 2 cm. Primary outcomes were technical success rate, en bloc resection rate, and R0 resection rate. Secondary outcomes included procedure time, complication rate, and follow-up results (▶ **Table 1**).

Results Seven patients (3 males, 4 females) with a mean age of 43.4 years were included. All lesions were successfully resected using TLI-ESE, achieving both a technical success rate and an en bloc resection rate of 100 %. The median procedure time was 65 minutes (range: 27-90 minutes). Postoperative pathology confirmed all lesions as leiomyomas with negative horizontal and vertical margins, resulting in an R0 resection rate of 100 %. No intraoperative bleeding or perforation occurred. Postoperatively, there were no instances of delayed bleeding, perforation, infection, or pneumothorax. During a median follow-up of 3-24 months, all patients recovered well, and endoscopic review showed no local recurrence.

▶ **Table 1** Baseline Characteristics and Treatment Outcomes of Patients Undergoing TLI-ESE for EGJ-SELs

Case No	Geder	Age (years)	Lesion Size (cm)	Procedure Time(min)	En Bloc Resection	RO Resection	Pathological Result	Follow-up (months)	Postoperative Complications				Recurrence or Metastasis
									Bleeding	Perforation	Infection	Pneumothorax	
1	M	53	8	60	yes	yes	Leiomyoma	3	no	no	no	no	no
2	M	54	2.4	70	yes	yes	Leiomyoma	5	no	no	no	no	no
3	F	24	2	90	yes	yes	Leiomyoma	12	no	no	no	no	no
4	F	36	3.5	60	yes	yes	Leiomyoma	24	no	no	no	no	no
5	F	33	3	27	yes	yes	Leiomyoma	4	no	no	no	no	no
6	M	33	3.2	70	yes	yes	Leiomyoma	4	no	no	no	no	no
7	F	70	2.8	66	yes	yes	Leiomyoma	3	no	no	no	no	no

Conclusions This preliminary study suggests that TLI-ESE is a technically feasible, safe, and effective treatment strategy for large SELs in the EGJ region, achieving high en bloc and R0 resection rates with a low complication profile. This technique offers a novel approach to addressing the challenge of post-resection wound closure for large lesions, although its long-term efficacy requires further validation through larger prospective studies.

eP426 Automated tumor documentation using a large language model

Authors Schulz D[1], Messmann H[1]
Institute 1 University Hospital Augsburg, Augsburg, Germany
DOI 10.1055/s-0046-1821753

Aims Tumor documentation for example for the Bavarian cancer registry to date is still done by typists, manually filling the information from the medical report to the cancer registry form. In this work, we explored the potential of a large language model based system (LLM) for automated tumor documentation.

Methods We developed an LLM based method, to read, output and fill in 10 typical tumor documentation related items from medical reports. We anonymized and modified potential identifying information of 10 physician letters. All patients had stage II or III colorectal cancer. We then measured the time it takes a typist to read and copy/paste the information from the medical report to the tumor documentation form. We compared and measured the time it takes for the LLM model alone. Finally, we measured the time it takes a typist to check for errors when the form was already prefilled by the LLM.

Results The typists manual fill in time was 14:45 minutes, the LLMs time was 0:45 minutes (-94.9 %). The typist error check time with LLM prefill was 06:28 minutes (-56.2 %). The LLM correctly extracted 100/100 items.

Conclusions State of the art large language models offer huge potential time saving benefits for automated tumor documentation. Larger studies are needed for evaluation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP427 A Tight Spot: EndoFLIP as a Diagnostic and Intra-POEM Compass in Type I Achalasia

Authors Chen ELY[1], Ong LWL[1], Ng YK[1], Yeung BPM[1]
Institute 1 Sengkang General Hospital, Singapore, Singapore
DOI 10.1055/s-0046-1821754

Introduction/Background Achalasia is a primary oesophageal motility disorder characterised by impaired lower oesophageal sphincter (LES) relaxation and absent peristalsis. While high-resolution manometry (HRM) remains the diagnostic gold standard, the functional lumen imaging probe (EndoFLIP) has emerged as a valuable adjunct in the evaluation of LES distensibility, hence aiding diagnosis[1]. In addition, EndoFLIP can provide real-time, intraoperative feedback during peroral endoscopic myotomy (POEM) in assessing procedural adequacy [1]. We present a case of type I achalasia in which EndoFLIP was used both for diagnostic clarification and intra-procedural assessment of myotomy effectiveness during POEM.

Case Presentation A 32-year-old male was referred to Gastroenterology from his primary care physician for progressive dysphagia to solids and liquids, regurgitation and significant loss of weight over the past year (Eckardt score 6 points). A computed tomography (CT) scan of the chest and abdomen were unremarkable. Oesophagogastroduodenoscopy (OGD) revealed a dilated oesophagus with retained food residue up until the proximal oesophagus and a puckered gastro-oesophageal junction. A high-resolution manometry (HRM) was unsuccessful due to difficulty traversing the catheter beyond the LES. An EndoFLIP was then performed which found a low esophagogastric junction (EGJ) distensibility index (DI) of 1.7 mm^2/mmHg at 60 mL fill volume and an absent contractile response during volumetric distension, confirming severe EGJ outflow obstruction and supporting a diagnosis of type I achalasia. He subsequently underwent a POEM, during which an intra-procedure EndoFLIP was performed post-myotomy to assess adequacy prior to mucosal incision closure – this revealed a DI of 6.3 mm^2/mmHg at 60 mL fill volume, indicating adequate disruption of the LES muscle fibres. The patient had significant improvement in symptoms and was discharged 2 days post-POEM.

Conclusion This case report highlights the utility of EndoFLIP as a diagnostic tool in patients with underlying oesophageal motility disorders, especially in circumstances where HRM is challenging to perform. Furthermore, its use as an intra-procedure guide in providing objective, real-time physiological feedback in the setting of POEM has great potential in guiding and optimising therapeutic outcomes.

eP428 Single-center experience with endoscopic management of demarcated walled-off pancreatic necrosis (WOPN)

Authors Horváth D[1], Brand T[1], Vass V[2], Dobszai D[2], Tari K[1], Lázár B[1], Sahin P[1], Mészáros B[1], Pálné BK[1], Erőss B[1, 2], Hegyi PJ[1, 2]
Institutes **1** Institute of Pancreatic Diseases, Semmelweis University, Budapest, Hungary; **2** Centre for Translational Medicine, Semmelweis University, Budapest, Hungary
DOI 10.1055/s-0046-1821755

Aims The revised Atlanta Classification delineates the local complications of acute pancreatitis, categorizing them as acute (peri)pancreatic fluid collections (PFCs), acute necrotic collections, pancreatic pseudocysts, and walled-off pancreatic necrosis (WOPN). Various endoscopic interventions are employed for the management of WOPN, notably including direct transluminal endoscopic necrosectomy (DEN) following the placement of an endoscopic ultrasound-guided (EUS) lumen-apposing metal stent (LAMS). This study aims to assess the clinical outcomes and safety profile of DEN in patients diagnosed with pancreatic WOPN.

Methods Between October 2021 and October 2025, we performed a total of 3337 endoscopic procedures, including 1705 EUS examinations. During this period, a total of 75 WOPN cases were identified, comprising 40 LAMS insertions, 11 conventional double pigtail plastic stent insertions, and 24 cases of spontaneous regression.This single-center retrospective analysis encompasses patients with pancreatic WOPN who underwent DEN at Semmelweis University between May 2022 and Oct 2025. The procedures were performed by three seasoned specialists in EUS. Comprehensive data on patient demographics, procedural specifics, and follow-up outcomes were collected, with adverse events classified according to the AGREE criteria.

Results We successfully placed LAMS in 40 patients (65,0 % female, average age 55,9 years, SD 15,41). The primary indications for intervention included the dimensions of WOPN, exacerbation of gastric outlet obstruction, and signs of infection. The mean dimensions of WOPN were recorded as 104 mm in the anteroposterior direction (SD 54,0), 96,7 mm laterolateral (SD 46,6), and 104,9 mm craniocaudal (SD 53,0), with a predominant occurrence in the head of the pancreas (60 %). Biliar reasons (42,3 %) and alcohol consumption (38,5 %) emerged as the leading etiological factors for WOPN in male patients and biliary causes were identified in 85,7 % of female patients. In total, we conducted 111 DEN procedures across the 40 patients (26 males and 14 females). The average number of DEN sessions was three for both male and female groups (range: 0-7). The technical success rate achieved was 100 %, accompanied by a clinical success rate of 97 %. Six of the 40 patients required intensive care. Four of these six patients needed surgical intervention due to complications from endoscopic necrosectomy, including bleeding and perforation. Unfortunately, one patient succumbed to multiorgan failure. To enhance the resolution of infection between DEN sessions, we employed 7 Fr/250 cm nasocystic tubes for irrigation of the WOPN with a saline solution in 36 patients, with no adverse events reported as a result of this intervention.

Conclusions DEN can be performed safely in experienced medical centers and demonstrates a high success rate in the treatment of infected WOPN, effectively alleviating symptoms and decreasing enzyme levels.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP429 A Rare Cause of Gastric Outlet Obstruction: Post-Caustic Pyloric Stenosis in an Adult Filipino Female

Authors Mancao FD[1], Gargaritano J[2]
Institutes **1** Vicente Sotto Memorial Medical Center (VSMMC), Cebu City, Philippines; **2** Vicente Sotto Memorial Medical Center, Cebu City, Philippines
DOI 10.1055/s-0046-1821756

Abstract Text
Caustic ingestion is an important global health problem that is largely underreported. In adults, it is typically associated with suicide attempts, with alcohol or recreational drug use, or in those with other mental health problems. The extent of injury following caustic ingestion depends on the type of product (alkali or acid), the amount ingested, and length of contact time. It is an emergent condition that may lead to serious morbidity, with deleterious complications, and even death. This paper aims to give awareness on the possible complications of such cases; and what may be done. This is to report on a singular case of a 32-year-old, Filipino, female, who intentionally ingested hydrochloric acid, approximately 50ml in volume. She was diagnosed with epilepsy at 12 years old, maintained on Phenobarbital, and had associated developmental delay. She is mainly dependent on her mother and elder sister. An immediate endoscopy was done within 24 hours of ingestion, which showed circumferential erosions and ulcerations throughout the length of the esophagus, and necrotic and friable stomach mucosa (Zargar IIIB). She was maintained on nothing-per-orem, given intravenous hydration, parenteral nutrition and proton pump inhibitor drip. A re-look endoscopy was done after 96 hours post-acid ingestion, which revealed a mid-esophageal stricture at 25cm from the incisors occupying about 10 % of the lumen; still with circumferential erosions and friable mucosa throughout the length of the esophagus; the stomach had linear brownish black ulcers in the entire stomach; and the pylorus was distensible and intubated, revealing friable and erythematous mucosa involving the first and second portion of the duodenum (Zargar IIIA). In coordination with the General Surgery service, patient was observed for progressive feeding from liquids to soft diet, which was generally tolerated. Patient was discharged and advised for repeat endoscopy after 2 months post-injury when stricture formation commonly occurs. However, at 5 weeks post-ingestion, patient consulted at the out-patient department due to episodes of post-prandial vomiting following intake of food or liquids. Repeat endoscopy was then advised, which still revealed an esophageal stricture occupying 10 % of the lumen, esophagitis LA grade A, and now with a stenotic pylorus with a linear clean-based ulcer. Biopsy taken revealed mucin-secreting columnar epithelium with chronic active inflammation. The duodenum was no longer accessible. Patient then underwent laparoscopic gastrojejunostomy under the General Surgery service, and re-started on progressive diet. With multidisciplinary coordination, patient was stabilized and discharged with ongoing monitoring and rehabilitation. Endoscopy is a reliable technique for assessing the extent of caustic injury and the presence of complications, such as stricture formation and stenosis. These may occur earlier or even years thereafter, and timing is of the essence. Early, and individualized, surgical intervention may also result in excellent long-term outcome for such instances [1–4].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP430 Performance of Colorectal Endoscopic Vacuum Therapy in Anastomotic Dehiscence Using the Tube-in-Tube Endoscopic Vacuum Therapy Method (CR TT-EVT)

Authors Franco F[1], De Lima M[2], Lenz L[2], Pombo A[2], Gustavo ADP[2], Martins AV[2], Oliveira C[2], Machado A[2], Geiger S[2], Pennacchi C[2], Martins B[2], Moura R[2], Clemente C[2], Fortes Fonseca Y[2], Lima A[2], Safatle-Ribeiro A[2], Maluf-Filho F[2]

Institutes 1 Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil; 2 Cancer Institute of the State of São Paulo, São Paulo, Brazil

DOI 10.1055/s-0046-1821757

Aims Anastomotic dehiscence remains one of the most severe and potentially fatal complications following colorectal surgery. Despite technical advances and improved perioperative care, its incidence remains around 11 % and is associated with high morbidity (2-16 %) and mortality rates (20-35 %). [1]

In recent decades, endoscopic vacuum therapy (EVT) has become a minimally invasive and effective option for managing anastomotic fistulas and leaks, preserving anastomosis and reducing the need for reoperations. [2]

The conventional EVT method, described in 2001, uses a sponge attached to a catheter inserted transanally and positioned intraluminally or intracavitary, connected to a continuous, controlled negative-pressure system. [3]

In 2019, the Tube-in-Tube Endoscopic Vacuum Therapy (CR TT-EVT) technique was introduced, allowing vacuum system placement without sponge, transanally or throught transparietal access. Its structural features eliminate the need for frequent device exchanges and allow cavity irrigation, improving infectious control and wound healing. [4]

The aim was to evaluate technical success, clinical success, and adverse events associated with the CR TT-EVT method in the management of colorectal anastomotic dehiscence.

Methods This retrospective observational study was conducted at the São Paulo Cancer Institute and included patients with colorectal anastomotic dehiscence treated with CR TT-EVT between 2019 and 2024.

Results Thirty patients with colorectal anastomotic dehiscence were treated using CR TT-EVT, 70 % were male and the mean age was 58 years. Twenty-six were operated for colorectal cancer, three for diverticulitis, and one for endometriosis.Diagnosis was predominantly established by computed tomography (93 %), and the mean volume of associated collections was 203mL.

CR TT-EVT was used as primary therapy in 21 patients and as rescue therapy after failure of initial treatment in nine. Seventeen had a protective ostomy at the time of diagnosis. Treatment access was mainly throught transparietal (20 patients), followed by transanal (nine) and intraluminal via colostomy (one).

The median interval between surgery and diagnosis of dehiscence was 8 days, and between diagnosis and CR TT-EVT initiation, 5 days. Technical and clinical success were 100 % and 87 %, respectively, with median time therapy of 21 days, and an average of three rectoscopies per patient. Eleven patients required additional therapy, but none required reoperation. Thirteen patients underwent treatment without an ostomy.

The most frequent complication was device displacement when positioned transanally (27 %). Three patients developed anastomotic stenosis – two successfully treated with endoscopic dilation. One patient developed complete anastomotic stenosis requiring permanent colostomy. One patient died during late therapy, without evidence of pelvic infection.

Conclusions CR TT-EVT demonstrated high efficacy and safety in the management of colorectal anastomotic dehiscence, with no need of surgery. Adverse events were infrequent, mainly limited to device displacement, and anastomotic stenosis, mostly endoscopically manageable. The relationship between time for defect to closing and the limited need for device exchanges, highlights the potential advantages of CR TT-EVT.

These findings support CR TT-EVT as an effective minimally invasive strategy, that optimizes the management of colorectal fistulas and anastomotic leaks, avoiding unnecessary surgical interventions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP431 Endoscopic Ultrasound Guided FNA and FNB Are Both Safe And Effective Modalities In Diagnosis Of Focal Liver Lesions – A Prospective Comparative Study

Authors bopanna S[1], Jain M[1], Lamba GS[1], Madaan K[1], Rafiq M[1]

Institute 1 Sri Balaji Action Medical Institute, New Delhi, India

DOI 10.1055/s-0046-1821758

Aims Ultrasonography(USG) guided tissue acquisition has been the modality of choice for diagnosis of focal liver lesions. EUS- TA has now become the mainstay for tissue diagnosis of various intraabdominal mass lesions. EUS guided liver biopsy is also slowly gaining acceptance. But,the safety and efficacy of EUS TA for focal liver lesion is largely unknown. In this study we looked as safety and efficacy of this modality and also compared the diagnostic accuracy of EUS FNAC and EUS FNB.

Methods In this prospective observational study, we included patients with focal liver lesions who underwent EUS – TA. Size of the lesion and number of passes taken were recorded. EUS guided FNAC followed by EUS guided FNB was done back -to- back during the same endoscopic session. The safety,sample adeqauacy,technical success and diagnostic yield of both FNA and FNB specimens was calculated based on the final diagnosis and compared.

Results Of the 40 patients included,42.5 % of patients were females with a mean age of 57.5 ± 12.84 years.9 adenocarcinoma (22.5 %),4 hepatocellular carcinoma(10 %)4 poorly differentiated carcinoma(10 %) 4 regenerating nodule(10 %), 3 liver abscess(7.5 %),2 small cell carcinoma(5 %),3 squamous cell carcinoma(7.5 %),3 non hodgkins lymphoma(7.5 %),2 inflammatory granuloma(5 %),2 high grade carcinoma(5 %),1 adenosquamous carcinoma(2.5 %),1 cholangiocarcinoma(2.5 %),1 NET was diagnosed(2.5 %).3 samples in EUS-FNA group and 1 sample in EUS-FNB was reported inconclusive. It was possible to obtain tissue from lesions in all patients,technical success 100 %. Number of passes were significantly more in the EUS FNA group compared to EUS FNB. The diagnostic yield of EUS-FNB was 97.5 % as compared to 92.5 %. Although diagnostic yield of EUS-FNB was higher than that of EUS-FNB, the difference was not statistically significant.

Conclusions EUS TA is safe and has a high diagnostic yield in focal liver lesions. In resource constraint settings, either EUS FNA or EUS FNB alone may be sufficient for diagnosis, with EUS FNB being done judiciously when maintained tissue architecture is required.

eP432 EUS guided drainage versus ERCP in Malignant Distal Biliary Obstruction: A Single-Center Retrospective Study

Authors Donato G[1], Mosconi M[2], Porta P[1], Fantasia S[3], Ferraro R[1], Impellizzeri G[1], De Angelis C[4], Pagano N[1]

Institutes **1** Gastroenterology Unit, Ospedale Maggiore di Novara, Novara, Italy; **2** Hospital of Foligno, Foligno, Italy; **3** Gastroenterology Unit – University Hospital of Parma, Italy, Parma, Italy; **4** Digestive Endoscopy Unit, Azienda Ospedaliero Universitaria di Torino, Turin, Italy

DOI 10.1055/s-0046-1821759

Aims Endoscopic ultrasound (EUS)-guided biliary drainage is an alternative technique for biliary decompression when ERCP fails. This study aims to compare the efficacy, safety, and clinical outcomes of EUS-guided biliary drainage versus ERCP in patients with distal malignant biliary obstructions (MBO).

Methods A single-center retrospective study was conducted on patients undergoing biliary drainage for MBO via EUS or ERCP between 2018 and 2024. Outcomes included technical success, clinical success (symptom resolution or bilirubin reduction ≥ 50 % at 14 days/ ≥ 75 % at 28 days), adverse events (AEs), reintervention rates, and long-term outcomes (survival, oncology treatment access). Continuous variables were compared using the Student's t-test, while categorical variables were analyzed using the Chi-square or Fisher's exact test. Survival rates were estimated using the Kaplan-Meier method. A p-value < 0.05 was considered statistically significant.

Results A total of 84 patients were enrolled in the study (31 EUS-group and 53 ERCP-group), with a combined total of 93 procedures (34 EUS and 59 ERCP). Technical success was achieved in 100 % of EUS-BD and 94.9 % of ERCP cases (p = 0.181), with clinical success rates of 92.9 % and 94.1 %, respectively (p = 0.816). No significant differences were found in total hospital stay (7.3 vs 6.6 days, p = 0.484) or post-procedural stay (4.6 vs 3.4 days, p = 0.094). Peri-procedural adverse events occurred in 11.8 % (EUS) vs 5.1 % (ERCP) (p = 0.207), while post-procedural complications were recorded in 5.9 % vs 11.9 % (p = 0.642). Regarding long-term outcomes, mortality during follow-up was significantly lower in the EUS group (64.5 % vs 73.6 %, p = 0.008), although mean survival time did not differ significantly (189 vs 285 days, p = 0.205). Access to chemotherapy was similar between groups (39.1 % vs 55.8 %, p = 0.196).

Conclusions Both methods proved effective, with a slight but not statistically significant advantage for EUS-BD in technical success and for ERCP in clinical success. Both EUS-BD and ERCP are effective options for biliary drainage in patients with malignant biliary obstructions. The choice of procedure may depend on the patient's clinical profile and the availability of experienced operators, considering individual characteristics and the specific risks associated with each technique.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP433 EUS-guided choledochoduodenostomy using LAMS with or without double pigtail stents for malignant biliary obstruction. A meta-analysis

Authors Teoh A[1], Chan SM[2], Hau V[3], Mahoney C[4], Ahrens J[4], Gupta K[4]

Institutes **1** Hong Kong Sanatorium & Hospital, HONG KONG, Hong Kong; **2** The Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong; **3** The Chinese University of Hong Kong, Hong Kong, Hong Kong; **4** Boston Scientific Corporation, Marlborough, United States of America

DOI 10.1055/s-0046-1821760

Aims In patients with distal malignant biliary obstruction (MBO) and failed endoscopic retrograde cholangiopancreatography, the American Society for Gastrointestinal Endoscopy and European Society of Gastrointestinal Endoscopy recommend endoscopic ultrasound-guided choledochoduodenostomy (EUS-CDS) EUS-guided hepaticogastrostomy. [1, 2] Retrospective studies report technical and clinical success rates as high as 96 % for EUS-CDS by transduodenal placement of a lumen-apposing metal stent (LAMS) into an extrahepatic bile duct. [3] Placement of double pigtail plastic stents (DPPS) has been described to reduce LAMS dysfunction. We conducted a meta-analysis of the efficacy and safety of EUS-CDS using a LAMS without or with DPPS to reduce stent dysfunction in the treatment of MBO.

Methods An expert librarian conducted searches of Embase and the MEDLINE full file (via Ovid) to identify studies published in English between January 1, 2011, and January 1, 2025. Clinical studies of EUS-CDS using the AXIOS LAMS (Boston Scientific Corporation, Marlborough, Massachusetts, USA) including more than 10 patients were eligible. Efficacy and safety outcomes were assessed using a random-effects meta-analysis to estimate the proportion of patients with the outcome. Efficacy outcomes were technical success, clinical success, and reinterventions. The safety outcome was the proportion of patients with ≥ 1 serious adverse event (SAE).

Results Eighteen eligible studies (96.7 % retrospective, 54.5 % male patients with mean or median age ≥ 68 years if reported) were conducted at 89 centers in 12 countries (US 1, APAC 3, Europe 8). Analyses included "cold" or "hot" (electrocautery-enhanced) LAMS without (15 studies, N = 905 patients) or with (4 studies, N = 141) concomitant placement of DPPS at the initial procedure. The estimated pooled proportions of patients with technical success and clinical success of EUS-CDS using the LAMS were 97.4 % (95 % CI 95.1–99.0 %) and 94.2 % (95 % CI 91.4 %–96.5 %), respectively. Reinterventions were performed in 11.3 % (95 % CI 7.0 %–16.4 %) of patients. The estimated pooled proportion of patients with ≥ 1 SAE during the study period was 12.6 % (95 % CI 8.0 %–18.0 %). Estimates were similar for EUS-CDS using LAMS with DPPS, including 96.4 % (95 % CI 88.0–99.9 %) clinical success, 98.6 % (95 % CI 94.1 %–100 %) technical success, 13.7 % (8.0 %–20.5 %) reinterventions, 15.7 % (9.5 %–23.2 %) patients with ≥ 1 SAE.

Conclusions EUS-CDS using a LAMS without or with DPPS had similarly high technical and clinical success and comparable safety to treat MBO in adults.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP434 Bovine Esophagus as an In Vitro Animal Model for Endoscopic Submucosal Dissection Training: Feasibility and Performance Improvement in 20 Procedures

Author Ozercan M[1]

Institute **1** Fırat University, Elâzığ, Türkiye

DOI 10.1055/s-0046-1821761

Aims The ESGE guideline, published in 2019, does not recommend performing the procedure directly on humans. It recommends performing procedures on at least 20 animal models before starting ESD procedures on humans, and performing en bloc resection without perforation in eight of the last ten procedures. Most animal models used today use pig organs due to their similarity to human organs. However, due to legal restrictions on pig production and slaughter in our country, access to pig models is difficult compared to other countries. Therefore, an animal model from the bovine esophagus, which is much more readily available in our country, was used as the first step of endoscopic submucosal dissection training. Twenty ESD procedures on the model were evaluated in terms of procedure time and muscle layer damage. Furthermore the first procedures performed by the endoscopist on humans were also

evaluated, considering that they could provide insight into the effects of these procedures on humans.

Methods The bovine esophagus, which was first 6 hours post-slaughter, was cleaned with tap water and 10 % acetic acid (white vinegar) and placed in the prepared apparatus with a shoe box, 5-liter plastic bottle adjusted by cutting, 10 mililiter injection syringe, and gloves. An endoscopist who has not performed ESD before marked approximately 2-cm-diameter area with a Fujinon 530W gastroscope using a flexknife. The marked area was lifted with methylene blue and saline solution. Submucosal dissection was performed using the flexknife using the ERBE 300 cautery device, using the cut mode: effect 2 and watt 40, and the Swift coagulation mode: effect 4 and watt 40. In 20 procedures, the procedure time from the beginning of the marking to the completion of the dissection was assessed. After the procedure, the esophagus was dissected lengthwise to assess the presence of muscle damage at the procedure site. The presence of muscular damage in 20 ESD procedures performed on humans by the endoscopist were assessed retrospectively

Results In the bovine esophageal ESD animal model, the first dissection lasted 63 minutes, and two punctate superficial muscle damage was present. The mean time of the procedure was 30,15 ± 14.8 min. After 10 procedures, a dissection of the same size took 23 minutes, and no muscle damage was detected. No muscular damage was detected in the 15 procedures following the 6th procedure. By the 20th procedure, dissection time had decreased to 14 minutes. In all procedures, the planned dissection area was extracted en-bloc. In the first 20 ESD procedures performed on humans by the endoscopist, who had used the bovine model 20 times, no complications were noted in 18 procedures. The mean diameter of the lesions was 25,1 ± 12,6 mm and the time of the procedures (range 22-275 min) were variable according to the size, localization and fibrotic amount of tissue Muscular damage of 3 mm and 7 mm in diameter occurred in two patients. The damaged areas were closed with hemoclips.

Conclusions In vitro and in vivo animal models constitute the first step in ESD training. The fact that the procedure time was reduced by two-thirds after 10 procedures and nearly 50 minutes after 20 procedures in the study suggests that it may be particularly useful for developing muscle memory with the use of the endoscope for mucosal incision and submucosal dissection. The in-vitro nature of the model and the absence of bleeding risk clearly played a role in this. While the presence of only one endoscopist in the study suggests that this model is not sufficient to determine its usefulness, similar findings have been obtained in in vitro porcine models.

eP435 Glycemic Control as a Predictor of Advanced Colorectal Neoplasia

Authors Wehbe P[1], Kahwagi A[1], Abi Khalil L[1], Honein K[1], Amara J[1], Mahfouz E[1], Slim R[2], Yaghi C[1]

Institutes 1 Gastroenterology Department, Hotel Dieu de France, Beirut, Lebanon; 2 Gastroenterology Department, Hotel Dieu de France, Beirut, Lebanon, Beirut, Lebanon

DOI 10.1055/s-0046-1821762

Aims Colorectal cancer (CRC) remains a major global health burden, and its rising incidence in younger adults underscores the limitations of age-based screening alone. Increasing evidence suggests that metabolic exposures, particularly diabetes and chronic hyperglycemia, may contribute to earlier and more aggressive colorectal neoplasia. This reinforces the need for metabolic risk–based stratification to identify high-risk individuals.This study aimed to assess the association between glycemic control and the presence of colorectal adenomas or cancers, and to develop a simple combined risk score [1].

Methods We conducted a single-center retrospective study at Hôtel-Dieu de France in Beirut, including 462 patients who underwent colonoscopy between 2020 and 2025 and had available HbA1c measurements. Demographic, cardiovascular, and metabolic data (age, sex, BMI, hypertension, diabetes, dyslipidemia) were extracted from medical records. The closest HbA1c to colonoscopy and the highest recorded HbA1c were collected. All lesions and cancers were confirmed histologically. Advanced neoplasia was defined as lesions ≥ 10 mm, villous histology, or high-grade dysplasia or invasive cancer.Statistical analysis included χ^2 testing, logistic regression (OR, 95 % CI), ROC curve analysis for HbA1c discrimination, and Youden-based optimal threshold selection. A multivariable risk score was built using the strongest predictors (age, sex, BMI, diabetes, HbA1cMax).

Results Among the 462 patients, colorectal lesions were present in 80.7 %, and advanced neoplasia in 7.4 %. ROC analysis identified an optimal HbA1c cut-off of 5.9 % (AUC 0.62, $p < 0.05$).Advanced colorectal lesions were more frequent in patients with HbA1c ≥ 5.9 % for both the closest HbA1c (12.2 % vs 5.7 %; OR 2.31, 95 % CI 1.13–4.71) and HbA1cMax (11.1 % vs 5.3 %; OR 2.22, 95 % CI 1.10–4.48).The final score was:0.35 × (Age) + 0.071 × (Male sex) + 0.042 × (BMI ≥ 30) + 0.054 × (Diabetes) + 0.488 × (HbA1cMax)Model performance was satisfactory (AUC 0.708, 95 % CI 0.629–0.786). Sensitivity was 88.2 % and specificity was 47.2 %.A score ≥ 25 identified high-risk patients (OR 6.70, 95 % CI 2.32–19.36, $p < 0.001$).

Conclusions In this cohort, HbA1c ≥ 5.9 % was associated with approximately double the risk of advanced neoplasia or colorectal cancer. Simple metabolic markers, particularly HbA1c, may improve pre-colonoscopy risk stratification and guide personalized screening intervals. Prospective multicentric studies are needed to validate this metabolic-based risk score.

eP436 Clinical Characteristics of Superficial Esophageal Cancer Detected After Gastrectomy

Authors Horio T[1], Ishiyama A[1]

Institute 1 Japanese Foundation for Cancer Research, Koto City, Japan

DOI 10.1055/s-0046-1821763

Aims After gastrectomy, endoscopic evaluation of superficial esophageal cancer can be challenging due to refluxed digestive fluids and changed background mucosa, making diagnosis of tumor margin difficult. To clarify factors associated with unclear tumor margin in endoscopic resection (ER) for superficial esophageal cancer after gastrectomy by classifying cases into clear (C) and unclear (U) groups.

Methods A total of 130 patients who underwent ER for superficial esophageal cancer after gastrectomy were retrospectively analyzed. 73 patients were classified into the C group and 57 into the U group. The U group was defined by at least one of the following: requirement of repeat preoperative endoscopy, horizontal margin classified as HMx or HM1 after ER, or piecemeal resection. Clinical variables were compared between groups.

Results In univariate analysis, the U group showed a significantly lower one-piece complete resection rate (82.5 %, $p < 0.001$). The background mucosa with multiple Lugol-voiding lesions (referred to as LVLs Grade C) ($p = 0.010$), type of gastrectomy ($p = 0.033$), and reconstruction method ($p = 0.012$) were identified as factors associated with unclear tumor margin. In multivariate analysis, LVLs Grade C ($p = 0.026$) was identified as an independent factor, and the frequency of unclear tumor margin was lower with gastro-gastro anastomosis compared with Billroth-I reconstruction ($p \leq 0.005$) as well as with pylorus-preserving gastrectomy (PPG) compared with distal gastrectomy (DG) ($p \leq 0.039$).

Conclusions In superficial esophageal cancer after gastrectomy, the changed background mucosa and gastrectomy procedure and the type of reconstruction may influence tumor margin diagnosis during endoscopic evaluation.

eP437 Jejunal Lymphangioma: An Extremely Rare Cause of Obscure Gastrointestinal Bleeding – A Two-Case Series from a Resource-Limited Setting

Authors Banga R[1], Gabriel E[2]
Institutes 1 Vicente Sotto Memorial Medical Center , Cebu City Philippines; 2 Vicente Sotto Memorial Medical Center (VSMMC), Cebu City, Philippines
DOI 10.1055/s-0046-1821764

Aims To describe two rare cases of jejunal lymphangioma presenting as obscure gastrointestinal (GI) bleeding and to highlight the diagnostic challenges of small bowel vascular–lymphatic lesions in patients with persistent anemia and negative conventional endoscopy.

Methods We report two adult patients with recurrent melena and severe iron-deficiency anemia who underwent extensive evaluation for obscure GI bleeding. Both had nondiagnostic esophagogastroduodenoscopy and colonoscopy. The first patient, a 45-year-old male Jehovah's Witness, had a 2-year history of melena and was initially managed conservatively due to refusal of blood transfusion. Capsule endoscopy demonstrated an ill-defined bleeding lesion in the small bowel, prompting surgical exploration. The second patient, a 71-year-old female with transfusion-dependent anemia and recurrent melena, underwent repeated endoscopic and radiologic investigations including CT angiography and mesenteric angiogram, which were non-diagnostic. Due to limited access to capsule endoscopy, she underwent exploratory laparotomy with intraoperative enteroscopy [1].

Results Surgical exploration in both cases revealed actively bleeding jejunal masses. In the first patient, a 3 × 5 cm mass located approximately 120 cm from the ligament of Treitz was resected with primary anastomosis. In the second patient, an actively bleeding nodular jejunal lesion was similarly resected. Histopathologic examination confirmed jejunal lymphangioma in both cases, with one specimen showing associated Brunner gland adenomatous changes. Complete surgical excision resulted in resolution of overt bleeding and correction of anemia, with no recurrence on follow-up. These cases illustrate that jejunal lymphangioma is an exceptionally rare cause of obscure GI bleeding and can remain undetected despite exhaustive standard investigations.

Conclusions Jejunal lymphangioma is an extremely rare but important cause of obscure gastrointestinal bleeding. In patients with persistent or transfusion-dependent anemia and negative upper and lower endoscopy, rare small bowel lymphatic lesions should be considered. Diagnostic delays are common, particularly in resource-limited settings where capsule endoscopy and device-assisted enteroscopy may be unavailable. Surgical resection remains definitive and curative. Increased awareness of this entity is critical to prevent misdiagnosis and reduce morbidity.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP438 Comparison Between Endoscopic Retrograde Cholangiopancreatography Guided Brush Cytology(Ercp-Bc) And Single Operator Cholangioscopy (Soc) Guided Biopsy In Diagnosis Of Indeterminate Hilar Biliary Strictures

Authors bopanna S[1], Jain M[1], Lamba GS[1], Rafiq M[1], Parmar A[1]
Institute 1 Sri Balaji Action Medical Institute, New Delhi, India
DOI 10.1055/s-0046-1821765

Aims Indeterminate biliary strictures pose a diagnostic challenge. The main reason for this has been the inability to obtain adequate tissue from the site of the biliary stricture. ERCP along with brush cytology has been the traditional method of obtaining cytology specimens, but has been found to have poor sensitivity. Cholangioscopy provides the ability to obtain biopsies under direct visualisation from these strictures. We aimed to compare the diagnostic utility of ERCP and brush cytology with cholangioscopy and biopsy. We also correlated visual findings on cholangioscopy with benign and malignant strictures

Methods In this prospective observational study, we included patients with indeterminate biliary strictures who underwent ERCP from April 2020 to April 2021.Indeterminate biliary stricture was defined as absence of diagnosis following cross sectional imaging and MRCP. Patients underwent back-to-back ERCP with brush cytology followed by cholangioscopy with biopsy during the same session. Data regarding biochemical, imaging, ERCP-BC and SOC guided biopsy were recorded. The appearance of the stricture on cholangioscopy was recorded. The final diagnosis of malignancy vs benign stricture was ascertained on positive pathology or on follow up for 3 months. The diagnostic accuracy of each modality was then calculated.

Results A total of 25 patients with indeterminate biliary strictures were included in the study, with a median age of 58.84 ± 15.69 years with 36 % being females. The sensitivity, specificity, positive predictive value,negative predictive value and accuracy of ERCP-BC and SOC guided biopsy was 55.6 %,100 %,100 %, 80 %, 84 % (p-value = 0.002) and 77.8 %,100 %,100 % ,88.8 %, 92 % (p-value < 0.001) respectively.Nodularity,presence of mass like appearance and irregular dilated vessels seen on cholangioscopy best predicted malignancy. Adverse events were similar in both groups

Conclusions SOC guided biopsy had better sensitivity and diagnostic accuracy when compared to brush cytology in diagnosis of malignancy in indeterminate hilar biliary strictures. SOC had a added advantage of direct visualisation of the stricture for features of malignancy

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP439 Endoscopic Detorsion of Sigmoid Volvulus: Outcomes, Predictive Factors, and Surgical Implications

Authors Ghrab F[1], Cherif D[1], Yacoub H[1], Debbabi H[1], Hassine H[1], Kchir H[1], Maamouri N[1]
Institute 1 Department of Gastroenterology B, Rabta Hospital, Tunis, Tunisia
DOI 10.1055/s-0046-1821766

Aims Sigmoid volvulus (SV) is an abdominal emergency for which the optimal management strategy remains debated. Endoscopic detorsion (ED) offers an effective alternative to immediate surgery, allowing decompression and improving operative conditions. This study aimed to assess the outcomes of ED, identify predictors of its success, and evaluate its impact on surgical strategy and postoperative results.

Methods This retrospective study spanned 15 years (2005–2020) and included patients presenting with uncomplicated SV who underwent an attempt of ED. Successful detorsion was followed by elective resection, whereas emergency surgery was performed in cases of ED failure or complicated recurrence. Clinical, radiological, and operative data were analyzed. Predictive factors for ED success were assessed using statistical analysis (SPSS, Chi-square test, p < 0,05).

Results Thirty patients were included (mean age 64.3 ± 11 years), with a male predominance (70 %). All presented with signs of distal bowel obstruction, including abdominal distension (100 %), diffuse abdominal pain (90 %), and cessation of stool and gas passage (87 %). Diagnosis was confirmed by imaging in all cases.

ED successfully relieved obstruction in 75 % of patients (n = 23). The mean interval before elective surgery was 22 days. Among these patients, 90 % underwent scheduled sigmoidectomy with single-stage primary anastomosis, performed under optimal conditions and associated with low morbidity and no mortality.

Conversely, 7 patients (25 %) required emergency surgery due to initial ED failure or complicated recurrence. Most underwent resection with stoma forma-

tion (Bouilly-Volkmann in 88 %, Hartmann's procedure in 12 %). This group showed higher postoperative morbidity (30 %) and included one death.
Predictive factors of ED success included consultation delay < 72 hours, endoscopic intervention < 77 hours, caecal diameter < 10 cm, typical radiographic appearance, and history of subocclusive episodes ($p < 0.001$). Conversely, prior abdominal surgery, caecal diameter > 10 cm, and delayed management (> 77 hours) were significantly associated with ED failure. Successful ED significantly increased the likelihood of single-stage surgery with primary anastomosis ($p = 0.025$).

Conclusions Endoscopic detorsion represents a key step in the management of uncomplicated SV. It enhances operative conditions, reduces the need for emergency surgery, and facilitates elective resection with primary anastomosis, ultimately improving prognosis. Early identification of patients at high risk of ED failure is essential to guide optimal therapeutic strategy and reduce morbidity and mortality.

eP440 Combined ligation-assisted and underwater endoscopic mucosal resection for gastric and duodenal neuroendocrine tumours in a single session

Authors Dias M[1], Lenz L[1], Lima A[1], Mansilla Gallegos M[1], Fonseca Y[1], Pombo A[1], De Lima M[1], Geiger S[1], Ferreira M[1], Oliveira C[1], Moura R[1], Andrade De Paulo G[1], Costa Martins B[1], Machado A[1], Clemente C[1], Pennacchi C[1], Safatle-Ribeiro A[1], Maluf-Filho F[1]
Institute 1 Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil
DOI 10.1055/s-0046-1821767

Abstract Text

Endoscopic resection of upper gastrointestinal neuroendocrine tumours (NETs) remains challenging, particularly in the duodenum, where positive vertical margins are frequent with conventional snare resection. Ligation-assisted endoscopic mucosal resection (EMR-L) and underwater EMR (UEMR) have emerged as valuable techniques to improve R0 resection rates and to manage recurrent lesions [1–4].
Here we describe the first reported case of simultaneous use of EMR-L and UEMR for multiple gastric and duodenal NETs during the same endoscopic procedure.
A 60-year-old woman with dyspepsia and obesity was referred to our unit after endoscopic resection of a duodenal NET performed elsewhere with positive lateral margins. Repeat oesophagogastroduodenoscopy in our center revealed intense gastric body atrophy, three reddish sessile polyps (3–6 mm) in the gastric body, and two 6-mm sessile lesions in the posterior wall of the duodenal bulb (one corresponding to the previously resected recurrent lesion).
All three gastric NETs and the non-recurrent duodenal lesion were removed *en bloc* using EMR-L. The recurrent duodenal NET was resected using the UEMR after complete immersion of the duodenal bulb. Prophylactic clips were placed on all resection sites. No immediate or delayed adverse events occurred.
Histopathological examination confirmed well-differentiated G1 NETs in all five lesions, all with negative lateral and vertical margins (R0 resection).
The combined application of EMR-L and UEMR in the same session proved safe and effective for achieving complete resection of multiple upper NETs, including a recurrent duodenal lesion. This is, to our knowledge, the first reported case employing both techniques simultaneously in a single procedure.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP441 Evaluation of a Novel Through-the-Scope Full-Thickness Suturing Device for Endoscopic Sleeve Gastroplasty: An Animal Feasibility Study

Authors Kim S[1], Bomee L[2], Choi HS[3], Jeen YT[3]
Institutes 1 Korea University, Seoul, Republic of Korea; 2 Korea University College of Medicine, Seoul, Seoul, Republic of Korea; 3 Korea University Anam Hospital, Seoul, Republic of Korea
DOI 10.1055/s-0046-1821768

Aims Endoscopic full-thickness suturing has multiple therapeutic applications, including bariatric interventions and gastrointestinal (GI) wall defect closure. However, currently available suturing devices are often complex, difficult to use, or lack robust efficacy data. This study aimed to evaluate the feasibility and performance of a newly developed through-the-scope full-thickness suturing device compatible with a standard 3.2-mm working channel.

Methods A total of six animal experiments were performed to assess the device's utility for endoscopic sleeve gastroplasty (ESG). All procedures were conducted using a conventional endoscope equipped with the novel suturing system. Procedural success, technical performance, and post-procedural recovery were monitored. Two animals were maintained for 28 days for survival and histologic assessment.

Results All six ESG procedures were successfully completed using the new device. Animals demonstrated favorable clinical recovery during the observation period. Histologic examination of the two long-term survival animals confirmed the formation of durable full-thickness sutures.

Conclusions This novel through-the-scope suturing device enables effective full-thickness suture placement and supports successful performance of ESG in an animal model. These results suggest potential utility for bariatric and therapeutic endoscopic applications. Further evaluation in human clinical trials is warranted.

eP442 Effective prevention of post-ERCP pancreatitis by selective 4-Fr prophylactic pancreatic stent insertion

Authors Ishihara T[1], Takashi T[1], Yuto S[1], Hiromu M[1], Takahiro S[1], Yuki K[1], Yamashita Y[1], Itonaga M[1], Reiko A[1], Kitano M[1]
Institute 1 Second Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan
DOI 10.1055/s-0046-1821769

Aims Post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP) remains the most common adverse event associated with ERCP and is particularly frequent in high-risk patients. Unintentional guidewire insertion into the pancreatic duct is recognized as a major procedure-related risk factor for PEP. Although prophylactic pancreatic stent (PPS) placement has been shown to reduce the incidence of PEP, identifying appropriate candidates before ERCP is often difficult, and unnecessary PPS insertion may introduce technical challenges or stent-related complications. Since January 2017, our institution has performed immediate insertion of a 4-Fr PPS in patients who experienced unintentional pancreatic duct guidewire insertion. The present study aimed to evaluate the effectiveness of this selective PPS strategy.

Methods This retrospective single-center cohort study included consecutive patients who underwent ERCP for biliary indications between January 2015 and December 2023. Eligible patients had intact papillae and experienced unintentional pancreatic duct guidewire insertion during the procedure. Patients with surgically altered anatomy, acute pancreatitis, main pancreatic duct obstruction, or intraductal papillary mucinous neoplasm were excluded.

At our institution, immediate placement of a prophylactic pancreatic stent is actively attempted whenever possible in patients with unintentional pancreatic duct guidewire insertion.

Accordingly, patients were categorized into two groups based on whether a stent was actually placed. The PPS group consisted of patients in whom a 4-Fr, 3-cm pigtail pancreatic stent (Advanix, Boston Scientific) was successfully inserted immediately after biliary cannulation, whereas the non-PPS group consisted of patients in whom PPS placement was not performed despite unintentional pancreatic duct guidewire insertion.

The primary endpoint was the incidence of post-ERCP pancreatitis (PEP). Secondary endpoints included PEP severity, serum amylase concentrations measured the day after ERCP, ERCP-related adverse events, and identification of independent risk factors for PEP using multivariate logistic regression analysis. PEP and its severity were defined according to established consensus criteria.

Results Of the 2,930 ERCP procedures performed during the study period, 366 patients met the eligibility criteria and were included in the final analysis (PPS group, n = 206; non-PPS group, n = 160). Although no major differences were observed in baseline characteristics, the frequencies of endoscopic sphincterotomy (EST), endoscopic biliary drainage (EBD), and biliary biopsy were higher in the PPS group. In contrast, there were no significant differences between the groups in the time required to achieve successful biliary cannulation or in the total procedure time.

Serum amylase levels measured on the day after ERCP were significantly lower in the PPS group. The incidence of post-ERCP pancreatitis was significantly lower in the PPS group than in the non-PPS group (14.8 % vs. 29.4 %, $p < 0.001$). The incidence of moderate or severe PEP was also significantly reduced in the PPS group (3.4 % vs. 10.6 %, $p = 0.009$).

Furthermore, univariate and multivariate logistic regression analyses demonstrated that PPS insertion ($p = 0.008$) and a history of cholangitis ($p = 0.008$) were independent protective factors associated with a reduced risk of PEP.

Conclusions Immediate insertion of a 4-Fr prophylactic pancreatic stent following unintentional pancreatic duct guidewire insertion significantly reduced both the incidence and severity of PEP. This selective strategy demonstrated a high technical success rate and was not associated with increased procedure time or additional adverse events. These findings indicate that selective prophylactic pancreatic stenting may be a practical and effective approach to reducing the risk of PEP in patients who experience unintentional pancreatic duct guidewire insertion during ERCP.

eP443 From Detection to Decision: Impact of Guideline-Guided Reasoning on the Performance of AI Models in Upper GI Endoscopy

Authors Wehbe P[1], Kahwagi A[1], Rita A[2], Barakat C[2], Amara J[1], Mahfouz E[1], Honein K[1], Slim R[1], Yaghi C[1]

Institutes **1** Gastroenterology Department, Hotel Dieu de France, Beirut, Lebanon; **2** Hôtel-Dieu de France, Beirut, Lebanon

DOI 10.1055/s-0046-1821770

Aims Artificial intelligence (AI) is increasingly used in upper gastrointestinal endoscopy (UGIE), particularly for early detection of esophageal and gastric neoplasia. However, its ability to integrate clinical reasoning and generate management recommendations has not been formally evaluated. Recent work suggests that next-generation AI should move beyond visual detection toward contextual interpretation supported by hybrid architectures combining computer vision with large language models (LLMs) aligned with evidence-based guidelines.This study aimed to evaluate the capacity of ChatGPT and DeepSeek to interpret UGIE reports and issue follow-up or treatment recommendations before and after the structured integration of international guideline frameworks [1].

Methods A comparative analysis was conducted at Hôtel-Dieu de France in Beirut using ninety-five UGIE reports and corresponding pathology results. Both ChatGPT 5.0 and DeepSeek interpreted each report under two independent conditions: (1) without guidelines, and (2) after structured integration of AGA, ACG, ASGE, and ESGE recommendations. Interpretation accuracy and completeness were assessed using a binary scoring system (1 = correct, 0 = incorrect). Statistical analysis was performed in R using McNemar's test with continuity correction, with significance set at $p < 0.05$.

Results Before guideline integration, both models demonstrated identical accuracy (57.9 %), while completeness reached 41.1 % for ChatGPT and 46.3 % for DeepSeek ($p < 0.05$). Recurrent errors involved inappropriate surveillance recommendations, particularly for sporadic non-dysplastic fundic gland polyps and focal antral intestinal metaplasia, potentially exposing patients to unnecessary procedures.After guideline integration, performance improved significantly for both models ($p < 0.001$): ChatGPT reached 97.9 % accuracy and 95.8 % completeness, while DeepSeek achieved 81.1 % accuracy and 72.6 % completeness. ChatGPT remained significantly superior across all parameters ($p < 0.001$), and most initial systematic errors were corrected after guideline incorporation.

Conclusions Without guideline guidance, AI models show major limitations and tend to over-recommend surveillance, failing to account for procedure-related risks. The initially similar performances of DeepSeek (free) and ChatGPT 5.0 (paid) indicate that commercial access alone does not ensure reliability without validated guideline integration, illustrating the bias that may arise when patients interpret their own reports using unguided AI.Integrating evidence-based recommendations dramatically improves accuracy and consistency, with ChatGPT showing clear post-guidance superiority. This approach may support clinicians in standardizing decisions and enhancing safety and quality throughout the endoscopic care pathway.

eP444 Endoscopic Intermuscular Dissection – A Case Series

Authors Birzle L[1], Nagl S[1], Probst A[2], Ayoub M[3], Ebigbo A[1, 3], Messmann H[4]

Institutes **1** University Hospital Augsburg, Augsburg, Germany; **2** University Hospital of Augsburg, Augsburg, Germany; **3** St. Josef-Hospital, Ruhr-University Bochum, Bochum, Germany; **4** Internal Medicine III – Gastroenterology, University Hospital Augsburg, Augsburg, Germany

DOI 10.1055/s-0046-1821771

Aims To explore the feasibility and outcomes of endoscopic intermuscular dissection (EID), a new endoscopic approach, we present a case series of EID in patients with suspected deep submucosal invasive T1 rectal cancers based on pre-interventional assessment. This series aims to describe the potential role of EID in risk-adapted treatment strategies for early rectal cancers.

Methods EID was performed in sixteen patients at the endoscopy departments of the University Hospitals Augsburg and Bochum. Procedures were carried out using the Olympus CZ-1500 gastroscope and the Olympus EVIS X1 system. En bloc resection of the lesion was achieved in all cases. In six patients, the resection site was closed using the Olympus SutuArt hand-suturing device.

Results Sixteen patients underwent EID. In all cases, the lesions were removed without significant complications. Histopathological examination confirmed low-grade adenocarcinomas with deep submucosal invasion, low tumor budding, and no lymphovascular invasion in six cases and low-grade adenocarcinoma with superficial submucosal invasion, low tumor budding and no lymphovascular invasion in one case. In one case the adenocarcinoma was

previously treated with TNT. Histology showed a low grade T1 carcinoma with intermediate tumor budding and histological evidence of perineural invasion. In one case histology confirmed a T2 carcinoma with poor differentiation (G3). The other cases showed tubular adenoma with high-grade dysplasia in three cases and low-grade dysplasia in another two cases. Furthermore, there was one neuroendocrine tumor and one vascular malformation removed with EID. Fourteen of the sixteen resections achieved clear margins. In one patient with confirmed deep-submucosal invasive cancer (D-SMIC), an R1 resection had to be presumed at the deep margin due to a specimen tear. This patient subsequently underwent a surgical transanal full-thickness resection. Histopathological analysis of the surgical specimen revealed no residual tumor cells.
In the specimen of the rectal carcinoma previously treated with total neoadjuvant therapy, histological examination identified infiltration of smooth muscle fibers. Consequently, an R1 resection had to be assumed.

Conclusions This case series demonstrates that endoscopic intermuscular dissection is a promising approach for the management of rectal D-SMIC. The technique allowed for successful resection in all cases, with no significant complications.
Recognizing the potential of EID as an alternative to radical surgery, we are actively engaged in collecting and structuring additional data to strengthen the evidence base for its use. Ongoing analysis will aim to assess its outcomes in larger patient cohorts and refine patient selection criteria to maximize safety and effectiveness.

DOI 10.1055/s-0046-1821772

Aims Pancreas divisum (PD) is one of the causes of recurrent acute pancreatitis (RAP). Its diagnosis may be missed that would result with chronic pancreatitis and even duktal adenocarcinoma in a rare case. Treatment aims to provide a sustained dilation of minor papillary orifice. We aimed to assees the eficacy of multiple plastic stenting of main pancreatic duct through minor papilla in PD cases.

Methods We evaluated the data of 24 PD patients with RAP treated between 2011 and 2023, with multiple plastic stenting with at least 24 months of follow up.

Results There were 11 females and 13 males with median age of 44 (Range:17-65). The patients underwent pancretic sphincterotomy with plastic stents 7-10 F. After 6 months we either incresed the size of the stent tor increased the number of stents according to the size of the main pancreatic duct. We continued 6 monthly intervals until a satisfactory calibration is obtained. Median number of plastic stents were two (1-3). Median number of sessions was 4 (3-6). We did baloon dilation with 4-8 mm ballons for some patients as well. The maximal size of stents was two 10 F plus one 7 F. After retrieveal of the stents, while nor RAP happened in 19 patients, RAP happened with stricture of minor papillary orifice in 5 patients who required further endoscopic treatment. All recurrences happened in the second year follow up: median 17 months (range 15-23). No serious side-effect happened.

Conclusions Management of pancreas divisum with multiple stenting is safe and has long-term benefit in 79.1 % (19/24) of patients. However in longer term follow up more recurrences may be expected. Recently we treated some patients with SEMS and data arising from small numbers are encouraging with less sessions (Unpublished observation).

eP446 Prophylactic Pancreatic Duct Stenting as the Most Effective Strategy for Preventing Post-ERCP Pancreatitis

Authors Tiunov O[1], Melnik D[2], Bykov M[3]
Institutes **1** City Hospital №4 Sochi, Tuapsinskaya, Sochi, Russia; **2** City Hospital №4, Sochi, Tuapsinskaya, 1 , Sochi, Russia; **3** Regional Clinical Hospital №1 Krasnodar, Krasnodar, Russia
DOI 10.1055/s-0046-1821773

Aims To evaluate the clinical effectiveness of prophylactic pancreatic duct stenting in reducing the incidence and severity of post-ERCP pancreatitis in patients undergoing high-risk endoscopic retrograde interventions.

Methods From January 2020 to August 2023, a total of 1034 retrograde endoscopic interventions were performed at City Clinical Hospital No. 4 (Sochi). Prophylactic PD stenting was applied in 42 patients (4.1 %). Plastic 5Fr stents (3–5 cm) were used. Main indications included: repeated guidewire passage into the pancreatic duct (> 2 times) and contrast reflux into the duct. The majority of patients had obstructive jaundice caused primarily by choledocholithiasis (64.3 %). All planned interventions were successfully completed [1–4].

Results Among the 42 stented patients, PEP developed in 6 (14.3 %), including 4 mild (9.5 %) and 2 severe cases (3.75 %); asymptomatic hyperamylasemia occurred in 3 patients (7.1 %) /Severe cases demonstrated transient marked hyperamylasemia (> 1000 mg/L) and ultrasound-confirmed pancreatic changes; all responded to conservative therapy. One death occurred due to unrelated advanced rectal cancer, without signs of pancreatitis. Pain relief and decrease of amylase levels were observed within 24–48 hours in most cases.

Conclusions PEP prevention remains essential due to high morbidity and frequent occurrence after technically challenging ERCPs.

Prophylactic PD stenting is effective in high-risk situations such as repeated pancreatic duct access or contrast reflux.

In our cohort, stenting contributed to limiting the severity of PEP, with rapid clinical recovery in most cases.

Combined with other preventive measures, prophylactic PD stenting remains the most reliable and evidence-based strategy for PEP prevention.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims The aims of this cross-sectional study are to determine the rate and predictors of endoscopic mucosal healing among IBD patients on non-biologic therapy in a resource-limited setting. We hypothesize that specific clinical and treatment-related factors are associated with the likelihood of achieving endoscopic mucosal healing in patients with IBD, and that clinical remission correlates poorly with endoscopic mucosal healing [1–27].

Methods A cross-sectional study was carried out at Tikur Anbesa Specialized Hospital in Addis Ababa, Ethiopia, from January 2023 to September 2023. The study included all consecutive IBD patients on treatment for at least 6 months who attended follow-up at the GI clinic during the study period, were willing to give consent, and agreed to undergo follow-up colonoscopy. Data was collected using a structured, pre-tested questionnaire directly from patients and from electronic medical records. Endoscopic mucosal healing was evaluated with SES-CD for Crohn's disease and the Mayo endoscopic sub-score for ulcerative colitis (▶ **Table 1**).

Results Out of the 106 patients included in this study, 69 (65.1 %) were in clinical remission. Thirty-five IBD patients (33 %) achieved endoscopic mucosal healing. More patients with ulcerative colitis achieved endoscopic mucosal healing compared to those with Crohn's disease (47 % vs. 29 %). Ten out of 32 (31.25 %) CD patients with a history of bowel resection achieved endoscopic healing. Of the 69 patients in clinical remission, only 27 achieved endoscopic mucosal healing (39.1 %). Higher ESR values (P = 0.040, AOR 0.946 with 95 % CI 0.898-0.997) and younger age at diagnosis (P = 0.046, AOR 1.322 with 95 % CI 1.005-1.739) predicted the absence of endoscopic mucosal healing.

Conclusions Clinical remission did not consistently indicate endoscopic mucosal healing in this cohort: only 39 % of patients in clinical remission showed mucosal healing, whereas 21.6 % of those not in clinical remission achieved mucosal healing. These results reinforce the evidence that relying solely on clinical assessment to evaluate disease control among inflammatory bowel disease patients has limitations; therefore, including follow-up colonoscopy in routine care—even in resource-limited setting, will improve treatment decisions and may lead to better patient outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP448 Relevance and Applicability of EPAGE (European Panel on the Appropriateness of Gastrointestinal Endoscopy) Criteria in the Prescription of Upper Gastrointestinal Endoscopy

Authors Aboullait A[1], Cherkaoui Malki M[2], Mechhor S[2], Mghyly F[2], Cherkaoui Malki O[2], Nadia B[3], Errabih I[3], El Bacha H[3]
Institutes **1** chu Ibn Sina , Rabat, Morocco; **2** CHU Ibn Sina, Rabat, Morocco; **3** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821775

Aims The prescription of esophagogastroduodenoscopy (EGD) has been steadily increasing over the years. However, some indications may be excessive, highlighting the need to rationalize its use. The EPAGE criteria, developed by a panel of European experts, provide a validated tool for assessing the appropriateness of indications for upper gastrointestinal endoscopy.
The aim of this study was to evaluate these criteria in validating indications for upper gastrointestinal endoscopy and to examine the correlation between the appropriateness of the indication and endoscopic findings.
Methods We conducted a retrospective descriptive study including all patients who underwent EGD in the digestive endoscopy unit of our Department : Hepato-Gastroenterology and Proctology "Medicine B" at Ibn Sina Hospital, Rabat between January 2023 and October 2025.
The appropriateness of the EGD indication was assessed according to the EPAGE criteria and classified as necessary and appropriate, appropriate, uncertain, inappropriate, or not applicable, using the software available at http://www.epage.ch.
EGDs with indications not covered by the EPAGE criteria were excluded from the analysis.
Results A total of 410 upper gastrointestinal endoscopies were performed during the study period, of which 88 (21.4 %) were excluded. Overall, 352 patients were included, with a mean age of 48.6 years (16–92 years). There was a marked female predominance, with a F/M ratio of 1.6.
The most frequent indications for EGD were: persistent epigastric pain despite adequate medical therapy in 106 patients (32.9 %),upper gastrointestinal bleeding in 80 patients (24.8 %), iron-deficiency anemia in 52 patients (16.14 %). According to the EPAGE criteria, the indication was classified as necessary and appropriate in 152 patients (47.2 %), appropriate in 73 patients (22.6 %), inappropriate in 33 patients (10.2 %), and uncertain in 64 patients (19.87 %). In 21.46 % of cases, the EPAGE criteria were not applicable.
A significant endoscopic lesion was identified in 165 patients (73.3 %) when the indication was deemed necessary and appropriate/appropriate.
There was a statistically significant association between the appropriateness of the indication and the presence of significant endoscopic findings ($p<0.001$). When the indication was considered inappropriate/uncertain, a significant lesion was detected in 17.5 % of cases, including 9 cases of gastric or duodenal ulcers and 4 cases of neoplastic lesions.
Conclusions In our study, 73 % of upper gastrointestinal endoscopies were judged to have an appropriate indication. However, 17.5 % of EGDs performed for inappropriate or uncertain indications revealed significant findings. These results underscore the need to update and refine the EPAGE criteria to better guide clinical decision-making.

eP449 Liver biopsy guided by endoscopic ultrasound: is the number of passes and the punctured lobe relevant?

Authors Artero A[1], Salvador I[1], Fernandez S[1], Raga A[1], Rifà R[1], López B[1], Bordoy L[1], González C[1], Ferrer C[1], Esteve M[1, 2], Loras C[1, 2]
Institutes **1** Hospital Universitari MútuaTerrassa, Terrassa, Spain; **2** Centro de Investigación biomédica en Red de Enfermedades hepáticas y Digestivas (CIBERehd), Madrid, Spain
DOI 10.1055/s-0046-1821776

Aims Liver biopsy guided by endoscopic ultrasound (EUS-LB) is an effective and safe technique for the study of liver diseases. However, there is limited scientific evidence regarding the technique (number of passes) and the difference in biopsy between the two lobes. Objective: To compare: 1) diagnostic yield, histological quality, and safety based on the number of passes, and 2) histological quality between the right liver lobe (RLL) and left liver lobe (LLL).
Methods This is a retrospective, single-center study based on a prospective cohort of patients who underwent EUS-LB with a 19G-FNB needle between October 2020 and March 2025. For Objective 1, patients were divided into two groups: 3-4 passes (Group A) vs 2 passes (Group B). All patients were analyzed for the second objective [1–3].
Results A total of 168 patients were included (113 in Group A and 55 in Group B), with a median age of 57 years (range 45.25–66), and 109 women (64.9 %). The overall diagnostic yield was 97.6 %, with a median number of portal tracts (NPT) of 16.5 (range 10–24) and a median specimen length (SL) of 10 mm (range 10–15). The overall adverse events rate was 6.5 %. No differences were observed in diagnostic yield or adverse events between Group A and B: (98.2 % vs. 96.4 %) and (6.2 % vs. 7.3 %), respectively. Regarding histological quality, no differences were found between the two groups in terms of total NPT, total SL, or NPT in the RLL/LLL. However, SL in the LLL was significantly shorter in Group B (median 10 (range 7.25–15) vs 7 (range 5–10) in group A; $p = 0.014$). No histological differences were found between the two lobes; NPT/SL in the RLL: 7 (range 5–12)/10 (range 7–13) vs NPT/SL in the LLL: 8 (range 5–12)/10 (range 7–12.5).
Conclusions Performing 2 passes by EUS-LB would be enough to achieve a high diagnostic yield. In cases of difficulty and/or technical impossibility, puncturing a single lobe would not affect the histological quality of the sample.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821777

Aims Digestive angiodysplasia is an acquired superficial vascular malformation developing in the mucosa or submucosa of the gastrointestinal tract. It may present with overt gastrointestinal bleeding or chronic anemia. An effective therapeutic intervention is required to improve symptoms and limit long-term complications. Argon plasma coagulation (APC) is considered the reference technique, providing a simple, rapid, precise, and reliable treatment option with minimal adverse effects and complications.The aim of this study was to evaluate the efficacy of APC in the management of digestive angiodysplastic lesions

Methods We conducted a retrospective study including 29 patients with digestive angiodysplasias treated with APC in the Department of Hepato-Gastroenterology and Proctology "Medicine B" at Ibn Sina Hospital, Rabat, between 2020 and November 2025.

Results A total of 29 cases were collected. All patients were admitted with either overt gastrointestinal bleeding or chronic anemia. A complete endoscopic evaluation was performed for each patient to determine the source of bleeding.Among the patients, 19 (65.5 %) were male and 10 (34.5 %) female, with an sex ratio F/M: 1.9. The mean age at diagnosis was 69 years (range 31–90).Most patients had at least one associated comorbidity, mainly cardiovascular disease in 14 cases (48.3 %) and end-stage chronic kidney disease requiring hemodialysis in 2 cases (6.7 %). The most common clinical presentation was overt bleeding in 26 patients (89.6 %): melena in 13 cases (44.8 %), hematemesis associated with melena in 5 cases (17.2 %), and rectorrhagia in 8 cases (27.5 %). Only 3 cases (10.3 %) were diagnosed during evaluation for anemia.Lesions were located in the stomach in 8 cases (27.5 %), small bowel in 4 cases (13.7 %), colon in 16 cases (55.2 %), and duodenum in 1 case (3.4 %).Treatment consisted of argon plasma coagulation in all cases (100 %). A favorable clinical and biological response after a single session was observed in 75.8 % of patients.Recurrence occurred in 7 patients (24.2 %), who required additional APC sessions (2 sessions), without the need for surgery.

Conclusions Digestive angiodysplasias are a condition with increasing incidence and can be life-threatening due to gastrointestinal bleeding. Argon plasma coagulation is an effective treatment option, with a success rate of up to 95 % after one or two sessions.

eP451 Esophageal stent placement: a single-center experience

Authors Neonaki A[1], Papadakos S[1], Markakis G[1], Papatheodoridi M[1], Mouziouras D[1], Argyrou A[1], Stratigakis L[1], Tampaki M[1], Lekakis V[1], Alexopoulos T[1], Bouga G[1], Fytili P[1], Kamberoglou D[1], Papatheodoridis G[1], Koutsoumpas A[1]
Institute **1** 1st Academic Department of Gastroenterology, General Hospital of Athens "Laiko", Athens, Greece
DOI 10.1055/s-0046-1821778

Aims Esophageal stent placement is a widely used endoscopic option for the management of both malignant and benign esophageal diseases. We aimed to evaluate the efficacy and safety of esophageal stent placement at a tertiary referral center.

Methods We retrospectively included all consecutive patients who underwent esophageal stenting between 05/2023 and 05/2025 at our hospital. Data on indications, stent type, use of fixation techniques, technical success, complications and outcomes were collected [1].

Results Overall, 32 patients were included [women: 36 %, age: 64 (58–72) years]. The indication was malignancy in 20 (64 %) patients [esophageal cancer (EC): 14 (69 %), non-EC extrinsic malignant compression: 4 (19 %), EC anastomotic recurrence: 2 (12 %)], and benign in 12(36 %) [anastomotic leak: 4 (34 %), post-radiation stricture: 3 (22 %), postoperative anastomotic stricture: 1 (11 %), caustic injury: 1 (11 %), variceal bleeding: 1 (11 %), intubation-related esophageal perforation: 1 (11 %)]. All patients received a self-expandable metal stent (partially or fully covered), placed endoscopically only, without any need for X-ray. Technical success with uneventful stent deployment was 100 %. Stent fixation (through-the-scope clips or StentFix OTSC) was used in 9 patients. Stent migration occurred in 3 patients, all without prior fixation, and was managed by restenting (n = 2) or with stent-in-stent placement (n = 1). Elective stent removal at 6–8 weeks was successfully performed in 8 patients with benign strictures or anastomotic leaks. During a mean follow-up of 110 ± 76 days, 18 patients with malignant indications died,with a mean survival of approximately 3.5 months (106 ± 21 days) after stenting.

Conclusions Esophageal stenting is a safe and effective therapeutic option for a broad spectrum of malignant and benign esophageal diseases. The use of fixation techniques appears to reduce the risk of stent migration and should be considered, especially in high-risk scenarios.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP452 Acute Cholangitis: A Retrospective Evaluation Based on International Guidelines

Authors Lamaachi H[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2, 3]
Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco; **3** Faculty Of Medicine And Pharmacy Of Rabat, Rabat, Morocco
DOI 10.1055/s-0046-1821779

Aims Acute cholangitis is a common diagnostic and therapeutic emergency resulting from biliary tract infection, most often secondary to obstruction. The Tokyo Guidelines 2018 (TG18) were established to provide standardized recommendations for the diagnosis, treatment, and management of acute cholangitis. However, few studies have assessed the extent to which these guidelines are implemented in real-world clinical practice.The aim of this study was to conduct a retrospective evaluation of the management of acute cholangitis by comparing therapeutic approaches with the recommendations of the Tokyo Guidelines 2018.

Methods This retrospective descriptive study was conducted in the Department of Hepato-Gastroenterology and Proctology. The study included all patients diagnosed with acute cholangitis between 2021 and 2025. Diagnostic criteria were based on three components: signs of inflammation, cholestasis, and imaging findings .Collected data included demographic characteristics (age, sex), clinical presentation, laboratory results, and both medical and endoscopic therapeutic interventions.Compliance with the guidelines was assessed based on diagnostic criteria, time to biliary drainage, antibiotic adaptation, and the use of drainage techniques.

Results A total of 160 cases of acute cholangitis were recorded. The mean age of the patients was 63 years (range: 17–88), with a predominance of males (M/F ratio 1.25).Diagnosis was established according to the Tokyo criteria: among the 160 patients, 142 (89 %) presented with systemic inflammatory signs, including fever and/or chills. All patients (100 %) had biological evidence of infection and cholestasis, with a mean CRP of 114.50 mg/L, a mean white blood cell count of 14,084/mm³, and a mean total bilirubin level of 101 mg/L. Etiologies were distributed as follows: lithiasis in 98 patients (61.25 %), neoplastic obstruction in 55 patients (34.38 %), and other causes including ruptured hydatid cyst or ampullary tumors in 7 patients (4.38 %).Severity assessment showed that 38 patients (23.75 %) had grade I cholangitis, 72 patients (45 %) grade II, and 50 patients (31.25 %) grade III according to the Tokyo Guidelines classification.

Therapeutic management consisted of early biliary drainage and systemic antibiotic therapy. Broad-spectrum intravenous antibiotics, including third-generation cephalosporins and metronidazole, were administered to 158 patients (98.75 %) upon admission. Antibiotic regimens were adjusted in 90 patients (56 %) based on blood or bile culture results.Endoscopic management was performed as the first-line treatment in 156 patients (97.5 %). Two patients (1.25 %) required surgical intervention, and none required radiologic drainage. Regarding compliance with drainage timing: among the 50 grade III patients, 27 (54 %) underwent biliary decompression within the recommended 24 hours. For grade II patients, 43 (60 %) received drainage within 72 hours, and 21 grade I patients (56 %) underwent drainage within the same timeframe.The rate of early complications following endoscopic intervention was 12.5 % (n = 20), including recurrent infections and post-Endoscopic Retrograde Cholangiopancreatography pancreatitis. Complications correlated with the severity of cholangitis: patients with grade III disease exhibited the highest complication rate (20 %, n = 10), followed by grade II (11 %, n = 8), while grade I patients had a complication rate of 5.3 % (n = 2).

Conclusions Acute cholangitis remains a severe condition requiring rapid management in accordance with the Tokyo Guidelines. Strict adherence to these recommendations is essential to optimize clinical outcomes, reduce complications, and improve patient survival. Continuous updating of institutional protocols and strengthened monitoring of guideline compliance are necessary to ensure optimal management of acute cholangitis.

eP453 Extra-Anatomical Biliary Drainage: Results

Authors El Hiouy H[1], Cherkaoui Malki M[1], Amrharhe EM[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2]
Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821780

Aims Extra-anatomical biliary drainage is an effective alternative to relieve biliary obstruction in cases of failed ERCP. Two endoscopic access routes are currently used : hepatogastric drainage and choledochoduodenal drainage. The aim of our study is to evaluate the indications, techniques used, and outcomes of extra-anatomical drainage in our center.

Methods This is a retrospective, descriptive, monocentric study conducted in the Medicine B Department of the Ibn Sina University Hospital in Rabat, between January 2019 and November 2025. All patients presenting with malignant biliary obstruction and who underwent extra-anatomical biliary drainage after failed ERCP were included.

The collected data included demographic, clinical, biological, radiological, and endoscopic parameters. Two techniques were used :

- Choledochoduodenal drainage (placement of a stent between the common bile duct and the duodenal bulb).
- Hepatogastric drainage (placement of a stent between a left intrahepatic bile duct and the stomach).Post-drainage follow-up included clinical and biological monitoring at day 0, day 2, day 7, and one month.**Results** 10 patients were included. The median age was 53.6 ± 17 years, mostly between 45 and 75 years. The sex ratio M/F = 1. Half of the patients (5 cases, 50 %) had no comorbidities. Type 2 diabetes was present in 3 patients (30 %), arterial hypertension in 2 patients (20 %), and heart disease in 1 patient (10 %).The most frequent etiologies were pancreatic cancer in 7 patients (70 %), followed by hilar cholangiocarcinoma in 2 cases (10 %), and ampullary carcinoma in 1 case (10 %). The main cause of ERCP failure was tumoral infiltration of the papilla, found in more than half of the cases (n = 6, 60 %). Other causes included anatomical abnormalities of the papilla (n = 2, 20 %), duodenal stenosis (n = 1, 10 %), and failure of intrahepatic bile duct cannulation (n = 1, 10 %).The main indication for drainage was cholangitis, found in half of the patients, followed by drainage for chemotherapy preparation (2 patients, 20 %). The remaining patients (n = 3, 30 %) presented with cholestatic jaundice with severe pruritus or general deterioration.Two techniques were performed:
- Choledochoduodenal drainage in 6 patients (60 %), using a fully covered metal stent.
- Hepatogastric drainage in 4 patients (40 %), using a “dumbbell-type” stent in 2 cases (20 %) and a partially covered metal stent in the remaining 2 cases (20 %).Initial evaluations showed a median total bilirubin level of 274 mg/L (predominantly conjugated), an average CRP of 52 mg/L, and an average prothrombin rate of 57 %.Regarding technical performance, hepatogastric drainage achieved 100 % technical and clinical success. Choledochoduodenal drainage also had 100 % technical success, but one case of biliary leak causing peritonitis reduced its clinical success to 83 %.Biological outcomes showed a clear and progressive improvement after the procedure :
- Bilirubin: 274 mg/L before drainage → 180 mg/L at 48 h → 121 mg/L at day 7 → 50.5 mg/L at one month.
- CRP: 52 mg/L before drainage → 27 mg/L at day 7 → 11 mg/L at one month.
- Prothrombin rate: 57 % before drainage → 62 % at 48 h → 69 % at day 7 → 88 % at one month.

Regarding follow-up, 4 patients (40 %) died in a context of terminal tumor progression, with a mean post-procedure survival of 6 months. Four patients (40 %) are still being followed in oncology palliative care, and 2 patients (20 %) were lost to follow-up after discharge.

Conclusions Extra-anatomical biliary drainage is an effective alternative after failed ERCP, particularly in cases of altered anatomy or tumoral involvement. Hepatogastric and choledochoduodenal techniques showed excellent technical success rates and significant biological improvement. The choice of method depends on patient characteristics, the etiology of the obstruction, and the expertise of the center.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP454 Relevance of Colonoscopy Indications According to EPAGE II Criteria

Authors El Hiouy H[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2]
Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821781

Aims In recent years, the indications for diagnostic colonoscopy have increased considerably; however, their prescription must be adjusted by considering the benefit–risk ratio. The EPAGE II criteria (European Panel on the Appropriateness of Gastrointestinal Endoscopy) provide an objective tool to assess the appropriateness of these indications.

The aim of our study was to evaluate the application of these criteria in clinical practice and to identify any potential correlation between the appropriateness of the indication and the endoscopic findings.

Endoscopy 2026; 58: S1–S1041

Methods This is a retrospective analytical study conducted over a 14 months, from September 2024 to November 2025, within the Department of Hepato-Gastroenterology and Proctology "Medicine B". It included all patients who underwent colonoscopy with or without intubation of the terminal ileum.
Patients with incomplete colonoscopy or indications not listed in the EPAGE II criteria were excluded.
Collected data included age, sex, medical history, indication, endoscopic findings, and the EPAGE score obtained through the official software (available at http://www.epage.ch).
Statistical analysis was performed using Jamovi software, with a significance threshold of < 0.05. For a more relevant analysis, the categories "appropriate" and "appropriate and necessary" were combined.
Results A total of 205 patients were included, all of whom underwent a complete ileocolonoscopy. The cohort comprised 112 women (54.6 %) and 93 men (45.4 %), with a female-to-male ratio of 1.2. The mean age was 51 ± 16.5 years, with 114 patients (55.6 %) older than 50 years and 91 patients (44.3 %) aged 50 years or younger.
More than half of the patients, 112 (54.6 %), had no medical history. 37 patients (18 %) had inflammatory bowel disease (including 23 Crohn's disease [11.2 %] and 14 ulcerative colitis [6.8 %]), and 14 patients (6.8 %) had cardiac disease.
The most frequent indications for colonoscopy were chronic diarrhea in 41 patients (20 %), rectal bleeding in 36 patients (17.6 %), constipation in 33 patients (16.1 %), therapeutic assessment in 25 patients (12.1 %), screening in 20 patients (9.8 %), iron-deficiency anemia in 19 patients (9.3 %), and abdominal pain in 16 patients (7.8 %).
According to the EPAGE score, indications were classified as: appropriate and necessary in 90 cases (43.9 %), appropriate in 58 cases (28.2 %), uncertain in 40 cases (19.5 %), and inappropriate in 17 cases (8.3 %).
Endoscopic lesions were detected in 90 patients (43.9 %), most commonly colonic polyps (27 cases; 13.2 %), neoplastic processes (14 cases; 6.8 %), and endoscopic recurrence of IBD (10 cases; 4.9 %).
Univariate and multivariate analyses showed that constipation and chronic diarrhea were significantly associated with an appropriate EPAGE indication for colonoscopy, with p-values of 0.019 and $< .001$, respectively.
Age over 50 years was also significantly associated with an appropriate EPAGE II score compared with younger patients (95 [83.3 %] vs. 53 [58.2 %], $p < .001$).
Conclusions Our study demonstrates that the EPAGE II score is a simple and effective tool for determining the appropriateness of colonoscopy indications. It not only allows for a better classification of patients based on their clinical indication but also contributes to improving the cost-effectiveness of endoscopic procedures.

eP455 Cholecysto-duodenal Fistula Complicated with Gallstone Ileus, Liver Abscess, and Common Bile Duct Stones: A Case Report of an Elderly Patient

Authors Feifan H[1], Chen K[1], An F[1]
Institute 1 Wuxi People's Hospital, Wuxi, China
DOI 10.1055/s-0046-1821782
Abstract Text
An 87-year-old female with a 10-year history of type 2 diabetes presented with upper abdominal pain, yellow urine, and fever for 5 days. Physical examination showed upper abdominal tenderness without rebound tenderness or muscle guarding. Imaging revealed a liver abscess, distal common bile duct stone, gallbladder stones, and intrahepatic and extrahepatic bile duct dilatation with pneumobilia, suggesting a cholecystoenteric fistula. Ultrasound-guided percutaneous drainage of the liver abscess was performed. Endoscopic examination confirmed a cholecystoduodenal fistula. ERCP revealed common bile duct stones, which were removed via ERC + EST + EPBD + stone retrieval + ENBD . Two days post-procedure, the patient experienced intermittent vomiting of bile-like fluid. Repeat abdominal CT suggested gallstone ileus due to gallstone migration into the small intestine. Surgical removal of the stones was performed due to poor response to conservative treatment. Given her advanced age and poor physical condition, no further treatment was pursued for the cholecystoduodenal fistula. The patient was monitored in the ICU postoperatively and later transferred to a general ward, eventually improving and being discharged. Cholecystoduodenal fistula is an internal fistula between the gallbladder and duodenum. Gallstone ileus, a rare cause of mechanical intestinal obstruction (0.3–0.5 % of cases), occurs when gallstones block the intestine after passing through a cholecystoenteric fistula. It is more common in elderly females. Treatment is primarily surgical, including enterotomy for stone removal or combined with cholecystectomy and fistula repair. However, there are few reported cases of gallbladder internal fistula complicating with hepatic abscess. In this case, the patient's type 2 diabetes likely facilitated retrograde bacterial infection, leading to hepatic abscess formation after the gallbladder internal fistula developed.This case report documents the complete clinical course of a patient who developed gallstone ileus caused by the spontaneous passage of stones through a cholecystoduodenal fistula during hospitalization [1–3].
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP456 Analysis of gastroscopy quality indicators during examinations with and without the participation of a trainee

Authors Pelczar M[1], Paks K[1], Nowotarska A[1], Zielińska K[2], Budzyń K[3, 4], Rak A[5], Wybrańczyk Ł[1], Prosowski J[1], ŁęCka M[1], Ostrowski B[1], Marek T[1], Wosiewicz P[1], Kurek K[2], Romańczyk M[4, 3]
Institutes 1 Medical University of Silesia, Katowice, Poland; 2 Medical University of Białystok, Białystok, Poland; 3 Endoterapia, H-T. Centrum Medyczne, Tychy, Poland; 4 Department of Gastroenterology, Academy of Silesia, Katowice, Poland; 5 King's College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1821783
Aims Esophagogastroduodenoscopy is crucial for early detection of upper gastrointestinal neoplasms (UGN) and preneoplastic lesions. With growing demand, training new endoscopists is essential. We aimed to evaluate the impact of trainee involvement in gastroscopy on key quality indicators and the detection of upper gastrointestinal abnormalities, and to assess how endoscopic training settings may influence diagnostic performance.
Methods We retrospectively analyzed 6,540 gastroscopies performed between January 2019 and December 2021 at two academic centers (663 with trainee participation). Quality indicators included Endoscopist Biopsy Rate (EBR), Composite Detection Rate (CDR), and UGN. Group comparisons used Mann–Whitney, χ^2, or Fisher's exact tests. Logistic regression identified factors associated with upper GI pathology and EBR, UGN, and CDR; variables with $p < 0.1$ entered multivariate models. Analyses used IBM SPSS Statistics.
Results Overall, 57.89 % of procedures were outpatient, the median patient age was 61 years (IQR 23), and 54.86 % of patients were female. A high-definition (HD) endoscope was used in 62.92 % of all procedures. The presence of a trainee did not significantly affect UGN (OR = 1.24; 95 % CI: 0.90-1.72; $p = 0.192$), EBR (OR = 1.05; 95 % CI: 0.88-1.25; $p = 0.614$), or CDR (OR = 1.01; 95 % CI: 0.85-1.21; $p = 0.872$). Similarly, no significant differences were ob-

served in the detection rates of cancers (p = 0.53), dysplasia (p = 0.198), and gastric precancerous conditions (p = 0.234) between procedures with and without trainee involvement. In the multivariate analysis, the factors associated with higher odds of UGN included age (OR = 1.02; 95 % CI: 1.01-1.02; p < 0.001), use of an HD endoscope (OR = 1.62; 95 % CI: 1.09-2.55; p = 0.017), sedation (OR = 1.22; 95 % CI: 0.80-1.87; p < 0.001), alarm symptoms (OR = 3.66; 95 % CI: 2.90-4.62; p < 0.001), and outpatient setting (OR = 1.57; 95 % CI: 1.41-1.75; p < 0.001), while female sex was associated with a lower risk of UGN (OR = 0.70; 95 % CI: 0.57-0.87; p = 0.001). Regarding EBR, multivariate regression analysis demonstrated that age (OR = 1.00; 95 % CI: 1.00-1.01; p < 0.001), female sex (OR = 1.20; 95 % CI: 1.08-1.34; p < 0.001), use of an HD endoscope (OR = 2.86; 95 % CI: 2.28-3.58; p < 0.001), and outpatient setting (OR = 1.44; 95 % CI: 1.28-1.61; p < 0.001) were associated with higher odds of EBR, while sedation was associated with lower (OR = 0.78; 95 % CI: 0.63-0.98; p = 0.033). For CDR, multivariate regression analysis indicated that age (OR = 1.02; 95 % CI: 1.01-1.02; p < 0.001), female sex (OR = 1.29; 95 % CI: 1.16-1.44; p < 0.001), use of an HD endoscope (OR = 1.57; 95 % CI: 1.23-2.00; p < 0.001), sedation (OR = 1.69; 95 % CI: 1.32-2.16; p < 0.001), and outpatient setting (OR = 1.44; 95 % CI: 1.28-1.61; p < 0.001) were significantly associated with higher CDR, whereas the presence of alarm symptoms was significantly associated with lower CDR (OR = 0.74; 95 % CI: 0.63-0.87; p < 0.001).

Conclusions These results indicate that trainee involvement does not compromise the quality of gastroscopy, supporting the safe integration of training into routine practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP457 Predictors of Biliary Cannulation Failure

Authors Dkhissi M[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2, 3]

Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco; **3** Faculty Of Medicine And Pharmacy Of Rabat, Rabat, Morocco

DOI 10.1055/s-0046-1821784

Aims Biliary cannulation is an important step in the management of biliary disorders. Despite being a widely performed procedure, cannulation failure remains a significant clinical challenge. Identifying predictive risk factors for failed biliary cannulation is therefore crucial for optimizing endoscopic strategies, improving success rates, and minimizing procedure-related complications. This study aims to evaluate the clinical, biological, anatomical, and technical determinants associated with biliary cannulation failure.

Methods This retrospective, descriptive, single-center study was conducted in our department between November 2020 and November 2025. A total of 74 patients were included, divided into two groups: 37 patients with failed biliary cannulation and 37 patients with successful cannulation.

Statistical analysis was performed using Jamovi. Univariate analysis was based on the χ^2 test, and multivariate analysis was conducted using a logistic regression model.

Results A total of 74 patients were included. The mean age was 65.5 ± 12.7 years (range: 27–85), with a slight female predominance (female-to-male ratio: 1.3). The leading indication for ERCP was acute cholangitis (36 patients, 48.6 %), followed by cholestatic jaundice (23 patients, 31.1 %).

Univariate analysis identified several predictors of biliary cannulation failure, including: cholestatic jaundice as the primary indication for ERCP (p = 0.007); history of hepatobiliary surgery (p = 0.012); bilirubin ≥ 250 mg/L (p = 0.009); leukocytosis ≥ 15,000/mm³ (p = 0.006); moderate-to-severe cholangitis (p < 0.001); presence of a main bile duct stricture (p = 0.004); malignant etiology of the stricture (p = 0.010); tumor type—particularly cholangiocarcinoma and pancreatic malignancies (p = 0.028); and papillary abnormalities, especially peri-diverticular papillae (p = 0.038).

In multivariate analysis, two factors remained independently associated with cannulation failure: history of hepatobiliary surgery (OR = 8.97; p = 0.033) and papillary abnormalities (OR = 31.68; p = 0.009).

Among the 37 patients with failed biliary cannulation, 28 (75.7 %) underwent second-line intraprocedural salvage techniques, primarily infundibulotomy (25 patients, 67.6 %) and, less frequently, precut sphincterotomy (3 patients, 8.1 %). These rescue techniques were successful in 75 % of cases (21 patients).

Conclusions Biliary cannulation failure is influenced by a combination of anatomical, biological, and disease-related factors. Early identification of these risk factors may help tailor endoscopic strategies, improve cannulation success rates, and reduce procedure-related complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP458 High-Grade Dysplasia Predicts Recurrence After Piecemeal EMR of Large Colorectal Lesions: Real-Life Data from an Italian Non-Tertiary Centre

Authors Kostandini A[1], Cocomello L[2], Todeschini C[1], Iasci AL[1], Rando G[2], Antonio DS[1]

Institutes **1** Senigallia Hospital, Senigallia, Italy; **2** Pescara Hospital Unit, Pescara, Italy

DOI 10.1055/s-0046-1821785

Aims Recurrence after piecemeal endoscopic mucosal resection (pEMR) of large colorectal lesions remains a significant clinical concern. Several lesion-related factors, including morphology, high-grade dysplasia (HGD), lesion size and use of snare-tip soft coagulation (STSC) have been proposed as potential predictors [1, 2].

Methods We conducted a retrospective study including 84 consecutive patients undergoing piecemeal EMR for colorectal lesions ≥ 20 mm at an Italian non-tertiary centre. Demographic, endoscopic and histological variables were collected. Time-to-recurrence was assessed using Kaplan–Meier curves and the log-rank test. Independent predictors were evaluated using multivariate Cox regression (p < 0.05).

Results Eighty-four lesions were analysed. Recurrence was significantly higher in lesions with HGD (p = 0.00091) and in those ≥ 25 mm (p = 0.022). No significant differences were observed between lesions treated with STSC and those without STSC (p = 0.057), between granular and non-granular LSTs (p = 0.84), or between serrated and non-serrated lesions (p = 0.48). In multivariate Cox regression, HGD was the only independent predictor of recurrence (HR 3.5; 95 % CI 1.19–10.5; p = 0.023). Lesion size ≥ 25 mm showed no statistically significant association with recurrence (HR 3.5; 95 % CI 0.78–16.1; p = 0.102). STSC was also not independently associated with recurrence (HR 1.6; 95 % CI 0.39–6.3; p = 0.522), a result likely reflecting its selective use in larger, higher-risk lesions.

Conclusions High-grade dysplasia was the strongest predictor of recurrence. Lesion size and STSC were not independently associated with relapse. Interpretation of the effect of STSC is limited by the small number of treated cases and their concentration in higher-risk lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP459 Endoscopic and histological aspects of colorectal lesions in IBD

Authors khalifa O[1], Mechhor S[1], Cherkaoui Malki M[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], El Bacha H[2, 3], Errabih I[2]
Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco; **3** Faculty Of Medicine And Pharmacy Of Rabat, Rabat, Morocco
DOI 10.1055/s-0046-1821786

Aims Endoscopy has an essential role in the diagnosis, assessment of inflammatory activity, and follow-up of IBD. It allows direct visualization of mucosal lesions, which can range from simple erosions to deep ulcerations, inflammatory pseudopolyps, or strictures.
In addition, histological examination, which complements endoscopy, is crucial for confirming the diagnosis and differentiating IBD from other inflammatory or neoplastic diseases of the colon.
The aim of this study is to analyze the endoscopic and histological aspects of colorectal lesions observed in patients with IBD.
Methods This is a retrospective descriptive study conducted between January 2023 and January 2025 in the Hepatology, Gastroenterology, and Proctology Department (Medicine B) at Ibn Sina Hospital – Ibn Sina University Hospital.
We included all patients aged over 16 years old who were being treated for chronic inflammatory bowel diseases, namely Crohn's disease and ulcerative colitis, and who had undergone ileocolonoscopy with staged colorectal biopsies.
Patients with incomplete data or normal colonoscopies were excluded from our study.
Results We included 75 cases of IBD collected over a period of 2 years, including 40 cases of Crohn's disease and 35 cases of ulcerative colitis.
Among patients with Crohn's disease, the average age was 38.5 years, ranging from 18 to 72 years, and the sex ratio (M/F) was 0.4.
Ulcerations were found in 40 % of cases (including aphthoid ulcerations in 53 % of cases, superficial linear ulcerations in 35 % of cases, and deep ulcerations in 12 % of cases), pseudopolyps in 21 % of cases, a sessile polyp in 14 % of cases, a pedunculated polyp in 4 % of cases, stenosis in 16.5 % of patients, and colonic erythema in 4.5 % of cases.
Histological examination revealed: nonspecific interstitial colitis in 48.5 % of cases, subacute colitis in 35 % of cases, granuloma without caseous necrosis in 5.5 % of cases, subacute proctitis in 5.5 %, and interstitial proctitis in 5.5 %.
Among patients with UC, the average age is 45 years and the sex ratio (M/F) is 0.54.
Ulcerations were found in 20 % of cases, pseudopolyps in 42.5 % of cases, a sessile polyp in 20 % of cases, a pedunculated polyp in 5.5 % of cases, colic erythema in 6 % of patients, and erosions in 6 % of cases. In addition, the vascular pattern disappeared in 16 cases, partially disappeared in 5 cases, and remained intact in 4 cases.
Histological examination revealed: nonspecific interstitial colitis in 57 % of cases, subacute colitis in 20 % of cases, subacute proctitis in 23 % (of which 70 % was ulcerative proctitis and 30 % was non-ulcerative).
Conclusions Ulcerations are the most common lesions in Crohn's disease, while pseudopolyps and polyps are more common in ulcerative colitis. Thus, there is a predominance of nonspecific interstitial colitis and subacute colitis in both diseases.
Our study highlights the distinct endoscopic and histological features of CD and UC, which are essential for the diagnosis and follow-up of patients.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP460 Patient Satisfaction Survey in the Endoscopy Unit

Authors El Hiouy H[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2]
Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821787

Aims Digestive endoscopy (DE) is an essential diagnostic and therapeutic procedure.Patient satisfaction is an important measure of performance standards and a key indicator of the quality of DE. Measuring the satisfaction index is a crucial component for improving the quality of care and optimizing medical practices.
The objective of this study is to determine the level of patient satisfaction in our endoscopy unit and to identify the factors associated with this satisfaction.
Methods This is a prospective, descriptive, and analytical study conducted over a period of 5 months from 01/10/2023 to 01/03/2024 within the Department of Hepato-Gastroenterology and Proctology “Medicine B,” including patients who underwent DE.
Patient satisfaction was assessed using the Likert scale.
The studied parameters included sex, age, previous endoscopic examination, type of endoscopic procedure, and indication.
Data analysis was performed using Jamovi software version 2.2.5.
Results A total of 220 patients were included in our study, including 113 men (51.4 %) and 107 women (48.6 %), with a male/female ratio of 1.05. The mean age was 48.4 ± 15.8 years.Regarding endoscopic procedures: an upper GI endoscopy (EGD) was performed in 147 patients (66.8 %), a total ileocolonoscopy in 113 patients (51.4 %), and a rectosigmoidoscopy in 6 patients (2.7 %).
A total of 164 patients (74.6 %) underwent a single examination, while 56 patients (25.5 %) underwent two simultaneous procedures.
These examinations were performed for the following indications: abdominal pain in 39 cases (17.7 %), IBD in 30 cases (13.6 %), bowel habit disorder in 24 cases (10.9 %), portal hypertension in 22 cases (10 %), and gastrointestinal bleeding in 21 cases (9.5 %).
The distribution of satisfaction levels was as follows : very satisfied 55 (25 %), satisfied 53 (24.1 %), neither satisfied nor dissatisfied 73 (33.2 %), slightly satisfied 26 (11.8 %), very dissatisfied 13 (5.9 %).
For statistical analysis, levels 1: very satisfied and 2: satisfied were combined.
Patient age and the presence of music in the room were the only factors associated with high satisfaction on both univariate and multivariate analysis, with p-values of 0.005 and < .001 respectively.
Total ileocolonoscopy was also found to be a factor of patient dissatisfaction with a p-value of 0.019.
Conclusions Satisfied patients are more likely to regularly adhere to screening and endoscopic surveillance programs.
In our study, age and the auditory environment appear to play a significant role as predictors of satisfaction.
Assessing satisfaction helps identify patient needs and guide necessary improvements to optimize their care.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP461 Biliary aspiration in ERCP: clinical relevance and impact on antibiotic therapy

Authors Chafif O[1], Cherkaoui Malki M[2], Mechhor S[2], Mghyly F[2], Cherkaoui Malki O[2], Nadia B[3], Errabih I[3], El Bacha H[3]
Institutes **1** CHU IBN SINA RABAT, RABAT, Morocco; **2** CHU Ibn Sina, Rabat, Morocco; **3** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821788

Aims Cholangitis is a potentially serious infection of the bile ducts, the treatment of which relies on appropriate antibiotic therapy and rapid biliary decompression, primarily achieved by endoscopic retrograde cholangiopancreatography (ERCP). Among the possible complementary procedures during ERCP, bile aspiration for bacteriological analysis can be performed. However, this procedure remains underutilized and is not always systematically included in international guidelines due to a lack of robust data on its clinical impact. The objective of this study is to evaluate the clinical benefit of bile aspiration performed during ERCP in the treatment of cholangitis.

Methods This retrospective, descriptive, single-center study was conducted within the Hepatology and Gastroenterology Department "Medicine B" of the Ibn Sina University Hospital in Rabat, covering a period of 2 years and 10 months, from January 2023 to October 2025. The medical records of patients treated by ERCP with biliary aspiration for acute cholangitis in the interventional endoscopy unit were collected and analyzed. Demographic, clinical, paraclinical, therapeutic, and outcome data were collected and analyzed.

Results A total of 90 patients who underwent ERCP with biliary aspiration for cholangitis were included. The mean age was 52 years [22–82], with a slight female predominance (56.7 %). Twelve patients (13.3 %) had previously undergone ERCP, and 10 patients (11.11 %) had a biliary stent. The severity of cholangitis, assessed using the Tokyo score, was distributed as follows: grade I in 20 cases (22.2 %), grade II in 53 cases (58.9 %), and grade III in 17 cases (18.9 %). The mean total bilirubin level was 172.1 mg/L before ERCP and decreased to 95.4 mg/L 48 hours after the procedure. The indications for ERCP were distributed as follows: neoplastic causes in 42 cases (46.7 %), lithiasis in 37 cases (41.1 %), and other etiologies in 11 cases (12.2 %). Empirical antibiotic therapy was primarily based on a combination of third-generation cephalosporins and metronidazole, prescribed in 80 cases (88.8 %). Biliary aspiration revealed a positive culture in 53 cases (58.9 %) (▶ **Table 1**), with *Escherichia coli* and *Pseudomonas spp* . as the predominant pathogens (▶ **Table 2**), identified in 13 cases (24.5 %) and 12 cases (22.6 %), respectively. Among the positive samples, the bacteria were susceptible to empirical antibiotic therapy in 30 cases (56.6 %). In cases of resistance, a change of antibiotic was necessary in 18 patients (33.9 %) , while 5 (9.4 %) progressed favorably without any change in treatment. The average length of hospital stay was 11.0 days. The 30-day recurrence rate was 4.5 %, and the mortality rate was 4.5 %.

▶ **Table 1** Biliary culture N = 90

Biliary culture	N (%)
Positive	**53 (58.9 %)**
Negative	**30 (33.3 %)**
Polymicrobial	**7 (7.8 %)**

▶ **Table 2** Main pathogens N = 53

Main pathogens	N (%)
Escherichia coli	**13** (**24.5 %**)
Pseudomonas spp	**12** (22.6 %)
Enterococcus spp .	**8** (**15.1** %)
Enterobacter spp	**6** (**11.3** %)
Klebsiella Pneumoniae	**7** (**13.2** %)
Streptococcus spp .	**2** (**3.8** %)
Others	**5** (**9.4** %)

Conclusions Biliary aspiration during ERCP is a valuable tool for identifying pathogens and tailoring antibiotic therapy, particularly in the context of increasing antibiotic resistance. This study highlights its clinical value in optimizing microbiological management and improving therapeutic outcomes for patients with cholangitis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP462 Evaluation of the SPART-App application dedicated to recording endoscopic procedures and assess improvement of hepatogastroenterology interns

Authors Gonzalez JM[1], Debordeau A[2], Maximilien B[3], Barthet M[4], Guillo L[1]
Institutes **1** Hôpital Nord, Marseille, France; **2** CHU de Montpellier, France, Montpellier, France; **3** Cochin Hospital, Paris, France; **4** Hospital Nord, Marseille, France
DOI 10.1055/s-0046-1821789

Aims Monitoring the technical progress of endoscopy trainees is essential to ensure the quality of care in hepatology and gastroenterology. The cumulative sum learning curve (LC-CUSUM) method allows for dynamic assessment of skill acquisition. Launched in 2022, the SPARTApp application, promoted by the University of Montpellier and supported by the SFED, aims to improve the collection of procedures, performance monitoring and access to educational tools (Figure A). This study evaluates its use, limitations, and the impact of LC-CUSUM on the perception and monitoring of interns' technical progress in endoscopy.

Methods A national survey was conducted between March and June 2025 among French interns registered on the SPART-App application. They were contacted by email via an emailing list extracted from the application's database. The questionnaire focused on the use of SPART-App, its comprehensiveness, obstacles encountered, suggestions for improvement, and perceptions of the integrated LC-CUSUM progression curve. Participation was voluntary and anonymous.

Results Of the 307 interns contacted, 102 responded in 20 university towns (Figure B). Almost all of them were familiar with the application (98 %) and 92.2 % reported using it to record their endoscopic procedures. The completeness of the data collection was rated as high to perfect by 43.6 % of users, and average to perfect by 63.8 % (Figure C). In centres where data collection was considered mandatory, these figures rose to 67.7 % and 83.9 % respectively (Figure C). The main obstacles reported were forgetting to enter data (67.7 %), lack of time (39.4 %), technical malfunctions (34.3 %) and the absence of institutional requirements (32.3 %). Among the 55 interns who suggested improvements, the majority of suggestions concerned offline operation, the user interface and educational enrichment. Finally, 63.7 % (65/102) used the LCCUSUM feature to track their technical progress, and 55.8 % (48/86) considered the curve to be consistent with their own perception of learning.

Conclusions SPART-App is widely and satisfactorily adopted among French interns. However, data collection is still uneven due to various organisational, technical and practical obstacles. This survey suggests that the LCCUSUM assessment is relevant for tracking technical progress in endoscopy, offering real-time monitoring of skills.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP463 Innovative Education Strategies: Non-physician medical staff facilitating the education of undergraduate medical students through practicable experiences

Authors Olsen B[1], Cadden I[2]
Institutes **1** HSCNI , Belfast, United Kingdom; **2** Belfast trust, Belfast, United Kingdom
DOI 10.1055/s-0046-1821790

Endoscopy 2026; 58: S1–S1041

Aims There are 10,000 undergraduate medical student places filled in the UK yearly (Bolton, 2024), the practical education of which is typically assigned to consultants, general practitioners and other physicians. This can be difficult, as these professions are often already under pressure from long patient lists, attending emergency situations, completing appropriate charting and other patient care responsibilities. This study explores facilitating undergrad learning with other high quality options, such as postgraduate nurses that have experience in the consultant's department.

Methods A convenience sample of 3rd year medical students was utilised to obtain feedback to an anonymised survey regarding knowledge attainment. These surveys follow 3rd year UK medical students' attendance at 1 hour in-person modules directed by a postgrad Endoscopy nurse. The topics of this module were cirrhosis, oesophageal varices, and Variceal Band Ligation endoscopic treatment and included up to 10 medical students each. These classes occurred for 28 weeks (September 2024 to May 2025) and included a hands on introduction to the gastroscope and the mechanics of variceal band ligation [1–3].

Results Out of 240 potential students, 110 responded to the anonymised link that was provided via email upon their completion of the training. Of these, 6 were removed for only responding to demographic questions, leaving 104 students who completed the survey in its entirety (43 % response rate). 72 % of respondents chose 'Strongly Agree' and 26 % 'Somewhat Agree' (total: 98 %) that the lecture was useful; 69 % chose 'strongly agree' and 27 % 'somewhat agree' (total: 96 %) in response to the statement 'I feel more confident that before the class in my knowledge on oesophageal varices'; and 78 % chose 'strongly agree' and 21 % chose 'somewhat agree' with the statement 'I feel more confident than before the class on the role of endoscopy in cirrhosis patients'.

Conclusions The education of the next generation of medical professionals can be problematic for physicians who are already under strain. One of the tools that could be considered going forward to address these barriers, is the utilisation of RNs with postgraduate degrees as ad-hoc educators. This case study demonstrates that when done successfully, undergraduate medical students can access knowledge of diseases and procedures without requiring physicians to be further overburdened. Educating the next generation of medical providers can emerge from numerous sources and it may be time we look to those to ensure that there are enough physicians to meet the medical demand that the future requires.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP464 Outcomes of Endoscopic Mucosal Resection of Large Colorectal Polyps Referred to a Single Tertiary Centre

Authors Ashrafinia N[1], Umar N[1], Issa T[1], Sultanian R[1], Zepeda-Gomez S[1]

Institute 1 University of Alberta, Edmonton, Canada

DOI 10.1055/s-0046-1821791

Aims Endoscopic mucosal resection (EMR) is widely used for removing large colorectal polyps (≥ 20mm). The goal is complete resection with minimal adverse events and a low adenoma recurrence rate (ARR). Optimal initial evaluation of the polyps and subsequent resection by a therapeutic endoscopist is of crucial importance to achieve good outcomes.

The study aims to evaluate the accuracy of the initial evaluation of large polyps referred for EMR to a tertiary center. Subsequently, we analyzed EMR technical success, complications, recurrence rate, final histology, appropriate follow-up, and the need for surgery in patients referred for EMR of large colonic polyps.

Methods This was a retrospective review of prospectively collected data of patients referred for EMR of colorectal polyps ≥ 20mm between 2017 and 2024. The procedures were performed by two therapeutic endoscopists.

Results A total of 170 patients (median age 66; 52.3 % female) with 187 polyps (median size 30mm) were included. Among referred polyps, 89 (48 %) had accurate descriptions; 50 (27 %) underestimated size, 41 (22 %) overestimated size, 16 (8.6 %) misclassified Paris type, and the location description was not accurate in 9 (5 %). Initial manipulation of polyps at the first endoscopy was done in 58 % of polyps; this included biopsies of the polyp (6.4 %), tattooing nearby (8.4 %), lifting (7.5 %), and attempted resection in 15.7 %. Median time to first EMR was 30 days. Median polyp size was 30 mm (range 20-80 mm). After EMR, high-grade dysplasia (HGD) was reported in 28 polyps (15 %) and invasive carcinoma in 7 (3.7 %). EMR could not be completed in 2 cases (1.1 %) due to suspicion of submucosal invasion. Complications included mild intra-procedural bleeding in 37 patients (20 %), post-polypectomy bleeding in 3 (1.7 %), perforation in 1 (0.5 %), which was managed conservatively and one case of post-polypectomy syndrome. Average time to follow-up was 7 months. Residual adenomatous tissue was present in 33 cases (18 %), with HGD in 9 (5 %). ARR increased according to polyp size (11.5 % for 20-29mm, 13.5 % for 30-39mm, and 29.0 % for ≥ 40mm).

Conclusions Initial polyp description was inaccurate in around 50 % of cases before referral for EMR, and around 58 % of polyps had some form of previous endoscopic manipulation as well. EMR is a safe and effective treatment for large colorectal polyps when performed by expert endoscopists. Subsequent follow-up met recommended guidelines, and ARR correlated significantly with polyp size.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP465 Quality of Life in Patients with Anal Stenosis in Crohn's Disease Following Dilatation Procedures

Authors Lamaachi H[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2, 3]

Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco; 3 Faculty Of Medicine And Pharmacy Of Rabat, Rabat, Morocco

DOI 10.1055/s-0046-1821792

Aims Anal stenosis is a frequent complication of Crohn's disease and is associated with a significant impairment in patients' quality of life. Endoscopic, manual, or surgical anal dilatations are commonly employed as therapeutic interventions; however, their impact on quality of life remains insufficiently explored. The aim of this study was to assess the improvement in quality of life among patients with Crohn's disease–related anal stenosis following dilatation, based on clinical symptomatology and Inflammatory Bowel Disease Questionnaire (IBDQ) score before and after the procedures.

Methods We conducted a retrospective descriptive study between 2018 and 2025 in the Department of Hepato-Gastroenterology and Proctology. All adult patients (aged > 16 years) with anal stenosis secondary to Crohn's disease who underwent dilatation (manual, endoscopic, or surgical) were included. Patients who received other therapeutic modalities for stenosis or who had incomplete medical files were excluded.Quality of life was assessed using the IBDQ before and after the procedure. Clinical data were collected regarding stenosis progression, type of dilatation, average number of sessions, success and failure rates, and recurrence.

Results Among the 33 patients with Crohn's disease related anal stenosis, 15 (45.45 %) underwent a dilatation procedure. The male-to-female ratio was 1.14

(8 men, 7 women), with a mean age of 47 years (range: 24–74). The mean interval between Crohn's disease diagnosis and the need for dilatation was 11 years.Five patients (33.3 %) underwent endoscopic dilatation, ten (66.7 %) manual dilatation, and four (26.7 %) surgical intervention.

Before dilatation, clinical symptoms included: spontaneous proctalgia in 4 patients (12.1 %), defecation induced proctalgia in 7 patients (21.2 %), and fecal incontinence in 6 patients (18.2 %). One patient (3 %) was asymptomatic, while 7 patients (21.2 %) reported a sensation of incomplete evacuation.

Among the 15 patients, 13 (86.67 %) expressed satisfaction and reported a significant improvement in quality of life after dilatation, along with reduction of symptoms.Analysis of IBDQ score showed an overall mean improvement of 33 points following dilatation. A Student's t-test confirmed that this difference was highly statistically significant ($p < 0.001$).When comparing dilatation techniques, endoscopic dilatation resulted in a mean IBDQ increase of 47 points ($p = 0.003$), whereas manual dilatation showed a mean increase of 20 points, which did not reach statistical significance ($p = 0.102$).

Disease progression after dilatation was marked by recurrence of stenosis in 13 patients (86.67 %), with a mean recurrence interval of 129 days. Recurrence was particularly frequent among those who underwent manual dilatation, accounting for 80 % of cases.

Conclusions According to our study, dilatation of anal stenosis in Crohn's disease leads to a significant short-term improvement in patients' quality of life. However, recurrence management remains challenging. Prospective multicenter studies with long-term follow-up are needed to better elucidate the sustained effects of this procedure and refine therapeutic strategies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP466 Which myotomy procedure should be used to treat refractory gastroparesis by endoscopic pylorotomy (G-POEM): Single? Double? Or resection?

Authors Djellouli W[1], Debourdeau A[2], Vitton V[3], Barthet M[3], Gonzalez JM[1]
Institutes 1 Hôpital nord, Marseille, France; 2 University Hospital of Nîmes, Nîmes, France; 3 Hospital Nord, Marseille, France
DOI 10.1055/s-0046-1821793

Aims Endoscopic pylorotomy (G-POEM) is a recent technique that has already proven its effectiveness in the management of gastroparesis refractory to medical treatment. However, the procedure differs from one center to another, particularly with regard to whether a single, double or myectomy myotomy is performed. Furthermore, to date, no study has compared the different techniques in terms of efficacy and, above all, recurrence. The aim of this multicenter study is to compare these different methods in order to standardize the procedure in favor of the most effective one.

Methods This is a retrospective multicenter study conducted in two expert centers in France, including patients treated with G-POEM for refractory gastroparesis between September 2015 and April 2025, with a comparison of three techniques: simple myotomy (SM), double myotomy (DM), or loop myectomy (LM).

The main objective was to evaluate clinical success according to the techniques used, defined by a one-point decrease in the Gastroparesis Cardinal Symptom Index (GCSI) score.

The primary objective was to evaluate clinical success according to the techniques used, defined by a decrease in the GCSI (Gastroparesis Cardinal Symptom Index) score of one point associated with a 50 % decrease in one of the three subscores at 6 months.

The secondary objectives included clinical success at 12 and 24 months, improvement in the severity stage of gastroparesis assessed by scintigraphy, and the rate of recurrence of gastroparesis.

Secondary objectives included clinical success at 12 and 24 months, improvement in the severity of gastroparesis as assessed by gastric emptying scintigraphy, the rate of symptomatic recurrence, and adverse events in each group.

Results A total of 122 patients were included, of whom 31 (25.4 %) were treated with simple myotomy (SM), 73 (59.8 %) with double myotomy (DM) and 18 (14.8 %) with myectomy (MC).

The groups were comparable in terms of demographics, etiology and disease severity (preoperative GCSI). Clinical success at 6 months was not significantly different in the 3 groups, despite a trend in favor of myectomy: 46 % for SM, 50 % for DM and 77 % for MC. However, the mean GCSI was significantly higher in the MS group (2.28 ± 1.14) compared to the other groups (1.79 ± 1.12 for MD and 1.46 ± 0.872; $p < 0.026$).

Importantly, the recurrence rate (not evaluated in the MC group) was significantly higher in the MS group, where it was 71 % compared to 12 % in the MD group ($p < 0.005$).

The improvement in gastric emptying, of at least 1 grade of scintigraphic severity, was similar in the 3 groups, ranging from 40 to 66 %. Finally, the complication rate was not different in the 3 groups, ranging from 0.5 to 5 %, mostly minor to moderate.

Conclusions G-POEM remains an effective and safe technique for the management of refractory gastroparesis. No significant difference in clinical success was observed between the three myotomy approaches, but myectomy tends to offer better symptomatic results at 6 months. Double myotomy appears to significantly reduce the risk of recurrence compared to single myotomy, without increasing the complication rate.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP467 Striking out on your own: Clinical and technical outcomes of EUS-Guided Hepatico-gastrostomy (EUS-HGS) for Malignant Biliary Obstruction (MBO) performed by a single operator with limited access to expert supervision

Authors Bălintescu A[1], Voiosu AM[1, 2], Bengus A[1], Rimbas M[1, 2], Mateescu RB[1, 2], Dumea E[1], Birligea M[1], Burlacu Zainea BA[1], Voiosu T[1, 2]
Institutes 1 Colentina Hospital, București, Romania; 2 Carol Davila University of Medicine and Pharmacy, București, Romania
DOI 10.1055/s-0046-1821794

Aims EUS-HGS has become an established technique either as a primary or salvage treatment modality for MBO. However, it remains a technically challenging procedure associated with a high risk of procedure related morbidity and mortality in a frail patient population. Current guideline recommendations recommend a gradual approach to performing EUS-guided therapy, suggesting that an endoscopist undertaking this new technique should perform a minimum of 25 procedures under expert supervision [1]. However, real life data about learning curves and upskilling in EUS-guided therapy are lacking. Furthermore, there are significant limitations in access to expert supervision for such advanced techniques as EUS-HGS. We aimed to assess the clinical and technical outcomes of the initial series of EUS-HGS performed by an experienced bilio-pancreatic endoscopist with limited access to expert supervision.

Methods We performed a retrospective analysis of a prospectively updated endoscopy database at a tertiary referral center where this technique was recently introduced. All consecutive patients who underwent EUS-HGS for malignant biliary obstruction either as a primary or as a rescue drainage procedure between June 2024 and November 2025 were included in the analysis. The primary outcome was technical success, defined as placement of a metal stent between the intrahepatic bile ducts and the stomach. Secondary outcomes included clinical success, defined as a decrease of > 25 % in bilirubin levels at 14 days after the procedure and procedure-related adverse events (AEs). EUS-HGS was performed using an Olympus linear scope. Access to the intrahepatic bile ducts was obtained with a 19G FNA needle and a hydrophilic guidewire (0.025 or 0.035i) was used for deep access after obtaining a cholangiogram. Tract dilation was performed with a 6Fr cystotome. Finally, an 8cm FC or PC SEMS (Boston Wallflex) was deployed into the stomach from the left intrahepatic

Endoscopy 2026; 58: S1–S1041

ducts to achieve adequate biliary drainage, which was confirmed through endoscopy and fluoroscopy.

Results Seventeen patients (64.7 % male; median age 69 years) underwent EUS-HGS during the study period. Underlying malignancies included duodenal and pancreatic cancers (4 each), cholangiocarcinoma, gastric and colonic cancers (2 each) and other tumor types (3). Indications for EUS-HGS were duodenal obstruction in 9/17 (52.9 %), failed ERCP in 5/17 (29.4 %), and altered anatomy in 3/17 (17.6 %) cases. Technical failure occurred in 5/17 (29.4 %). The causes included an unfavourable puncture window in surgically altered anatomy (1 patient), loss of echoendoscope position after adequate puncture in the bile ducts with subsequent loss of wire access (2 patients), inability to advance the guidewire despite adequate injection of ducts (2 patients). 4 out of these 5 patients underwent alternative drainage: one via EUS-guided choledochoduodenostomy and three through external percutaneous biliary drainage. In one case, no further endoscopic drainage was feasible and the patient was referred for palliative end of life care. We recorded a total of 5 procedure-related adverse events (2 early – 1 self-limited intraprocedural bleeding and 1 biliomа treated by percutaneous drainage and 3 late AEs – stent dysfunction with cholangitis).

Conclusions Our findings suggest that EUS-HGS can be safely attempted as an alternative drainage procedure by experienced bilio-pancreatic endoscopists proficient in both EUS and ERCP, even if no expert supervision is available. Further studies are required to better define the learning curves and milestones required for achieving efficient and safe independent practice of advanced EUS procedures, but autonomous upskilling seems to be feasible in certain scenarios.

eP468 Complete Endoscopic Healing: A New Therapeutic Target in Crohn's Disease?

Authors Dkhissi M[1], Mechhor S[1], Cherkaoui Malki M[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], El Bacha H[2, 3], Errabih I[2]

Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco; **3** Faculty Of Medicine And Pharmacy Of Rabat, Rabat, Morocco

DOI 10.1055/s-0046-1821795

Aims Crohn's disease is a chronic inflammatory bowel disorder characterized by an unpredictable clinical course. For many years, the therapeutic target was limited to achieving clinical remission associated with normalization of inflammatory biomarkers. To improve long-term outcomes, the STRIDE II recommendations introduced endoscopic healing as a therapeutic target, defined by an SES-CD < 3 (Simple Endoscopic Score for Crohn's Disease) or a CDEIS < 3 (Crohn's Disease Endoscopic Index of Severity).

Today, the concept of complete endoscopic healing is emerging as a potentially more relevant therapeutic goal.

The aim of the present study is to determine whether complete endoscopic healing is associated with improved long-term outcomes.

Methods This observational, cross-sectional, retrospective, monocentric study was conducted in our department between 2021 and 2025. We included patients with Crohn's disease who demonstrated endoscopic healing with a CDEIS ≤ 3 on their most recent assessment colonoscopy. Patients with a CDEIS ≥ 4, those lost to follow-up, or those without an evaluation colonoscopy were excluded.

Complete endoscopic healing was defined as a CDEIS score of 0, and partial endoscopic healing as a CDEIS score of 1–3. Relapse was defined as the occurrence of a clinical flare.

Statistical analysis was performed using the Jamovi software, and associations between variables were assessed using the χ^2 test.

Results A total of 60 patients in endoscopic remission were included, equally divided into 30 with complete healing and 30 with partial healing. The mean age was 45.7 ± 13.5 years (range: 18–78), with a marked female predominance (female-to-male ratio: 2.75).

According to the Montreal classification, phenotype distribution was as follows: 34 patients in A2 (56.7 %), 21 in A3 (35 %), and 5 in A1 (8.3 %). Disease location was predominantly L3 (43 patients, 71.7 %), followed by L2 (13 patients, 21.7 %) and L1 (4 patients, 6.7 %). The B2 phenotype was most frequent (25 patients, 41.7 %), followed by B1 (20 patients, 33.3 %). Perianal disease was present in 27 patients (45 %).

Regarding treatment, 41 patients were initially treated with immunosuppressants (68.3 %), while 19 received biologics (31.7 %), including 18 on infliximab (30 %) and 1 on adalimumab (1.7 %).

The mean follow-up duration was 30.2 ± 10.4 months. Disease evolution was marked by relapse in 2 patients with CDEIS = 0 (6.7 %) versus 16 patients with CDEIS 1–3 (53.3 %) ($p < 0.001$).Therapeutic adjustment was required in 16 patients with CDEIS = 0 (53.3 %) and in 25 patients with CDEIS 1–3 (83.3 %) ($p = 0.012$).

A reassessment colonoscopy was performed in 13 patients (21.7 %): 6 with complete healing and 7 with partial healing. All patients with initial complete healing maintained a CDEIS = 0, whereas among those with partial healing, 4 patients (57.1 %) had a follow-up CDEIS of 4, 2 patients (28.6 %) had a score of 3, and 1 patient (14.3 %) had a score of 1 ($p = 0.005$).

Therapeutic strategy differed significantly between the two groups. De-escalation therapy was undertaken in 13 patients with initial complete healing (81.3 %), whereas a step-up approach was applied in 15 patients with partial healing (60 %) and treatment optimization in 4 patients (16 %) ($p < 0.001$).

Hospitalization was required for none of the patients with complete healing (0 %), compared with 8 patients with partial healing (26.7 %) ($p = 0.002$).

Similarly, no surgical intervention was required for patients with complete healing (0 %), while 6 patients (20 %) with partial healing underwent surgery ($p = 0.010$).

Conclusions Complete endoscopic healing was associated with more favorable outcomes compared with partial healing. It correlated with a significantly reduced risk of relapse, hospitalization, and surgical complications, while also allowing for therapeutic de-escalation. These findings highlight the relevance of adopting a stricter definition of endoscopic healing, paving the way for a re-evaluation of current therapeutic targets.

eP469 Sessile serrated lesion with dysplasia – we see, we predict, we remove!

Authors Tatiana N[1], Ageykina N[1], Fedorov E[1]

Institute **1** Pirogov Russian National Research Medical University, Moskva, Russia

DOI 10.1055/s-0046-1821796

Aim. identify and study endoscopic signs of dysplasia in sessile serrated lesions with dysplasia (SSLd).

Materials and methods. A total of 199 patients were examined, in whom 260 SSL were detected, polyps were removed, examined histologically, in 45 cases dysplasia was detected in 41 patients – 11/41 (26.8 %) men and 30/41 (72.2 %) women aged 25 to 75 years (mean age 54.2 ± 3.4). We used acetochromoscopy with a 1.5 % acetic acid solution in all cases to enhance visualization and the presence of a positive and mixed acetowhite reaction in SSLd. Endoscopic and histological signs of SSLd were compared and summarized.

Results: SSLd were located in the right part of the colon – 42/45 (93.3 %). The size of SSLd was 2-25 mm, of which the majority, 24/45 (53.4 %) – 10-19 mm; by color pale 12/45 (26.7 %), pale pink 15/45 (33.3 %), with a red tint 18/45 (40.0 %). The surface is heterogeneous 22/45 (47.8 %), with the presence of a

nodular component or double elevation 12/45 (26.7 %), with serrated margin 42/45 (93.9 %), in 5/45 (9.8 %) the edges are raised with a central depression. According to the Paris classification, all formations corresponded to type 0-IIa – 36/45 (80.0 %), less common were 0-Is 9/45 (20.0 %); According to the JNET classification: type 1 was 23/45 (51.1 %), with 2A and 2B equally distributed at 12/45 (26.7 %). The pit pattern according to the Kudo type 2, was shown by 18/45 (40.0 %), with a specific sign for SSLd according to Kimura 2-O – 13/45 (28.9 %), III 13/45 (28.9 %), IV 1/45 (2.2 %); capillary pattern type 1 according to Y.Sano 23/45 (51.1 %), 2 – 21/45 (46.7 %), 3 – 1/45 (2.2 %). The formations were removed by cold snare resection 34/45 (75.6 %) and EMR 11/45 (24.4 %); 34/45 (75.6 %) were removed en – bloc, 11/45 (24.4 %) in fragments, with the radicality of removal R0 32/45 (71.1 %), R1 1/45 (2.2 %) – with cold snare removal, Rx 12/45 (26.7 %) – fragmentation of material during extraction.

Conclusions: Verification of dysplasia in SSL during colonoscopy helps to determine the optimal tactics for removing the lesion, thereby reducing the risk of developing CRC, and also to determine the timing of subsequent observation.

DOI 10.1055/s-0046-1821797

Aims A potential negative effect of glucagon-like peptide 1 (GPL-1) receptor agonists on bowel cleanliness in colonoscopy has been reported in literature. However, most of the evidence comes from retrospective studies.

The main aim of this study is to prospectively compare bowel preparation quality and overall tolerability of bowel preparation among diabetic patients treated with GLP-1 receptor agonists and not. Secondary outcomes included comparison of the number of polyps detected, cecal intubation rate, procedure duration and procedure-related complications among the two groups.

Methods This prospective observational study has been conducted across 6 Italian Gastroenterology and Digestive Endoscopy units, which consecutively enrolled diabetic patients undergoing colonoscopy for any indication, both those treated with GLP-1 receptor agonists and those not. All patients received a low-volume, split-dose bowel preparation regimen. The Boston Bowel Preparation Scale (BBPS) was used to assess bowel cleansing quality, and the validated Lawrence score was employed to evaluate preparation tolerability in the two groups. Preliminary results are presented.

Results A total of 111 diabetic patients were enrolled, 36 (32.4 %) in the GLP-1 group and 75 (67.6 %) in the non–GLP-1 group. Two groups were comparable for age (70.6 ± 8.5 vs 70.4 ± 6.7 years, p = 0.90), sex distribution (p = 0.94), smoking status (p = 0.12), and diabetes-related complications (p = 0.75), body mass index (BMI, 25.9 ± 3.7 kg/m² vs 27.0 ± 4.6 kg/m², p = 0.16), diabetes duration (12.6 ± 7.9 vs 11.1 ± 6.9 years, p = 0.34).

No significant difference in bowel cleansing was found among the two groups (BBPS ≥ 6 in 83.3 % of the GLP-1 group and 76.0 % of the non–GLP-1 group, p = 0.53). Tolerability was also comparable between groups: 20 (26.7 %) patients in the non–GLP-1 group and 12 (33.3 %) in the GLP-1 group reported no difficulty; 34 (45.3 %) and 11 (30.5 %) reported mild difficulty; 19 (25.3 %) and 13 (36.1 %) reported moderate difficulty; 2 (2.7 %) and 0 reported severe difficulty, respectively (p = 0.30). Cecal intubation rates were likewise similar (GLP-1: 88.9 % vs non–GLP-1: 86.7 %, p = 0.98). No significant difference in polyp per colonoscopy and colonoscopy duration were found. No colonoscopy-related complications occurred in either group.

Conclusions This preliminary results did not reveal any significant difference in bowel cleansing quality and tolerability of preparation among diabetic patients taking GLP-1 receptors agonists or not as well as other key colonoscopy quality indicators.

Initial data in our cohort suggest a lower impact of GPL-1 receptor agonist on bowel preparation compared with what is currently reported in the literature and that diabetes itself is the main cause of inadeguate bowel preparation

eP471 Technical Feasibility Of Transoral Incisionless Fundoplication With Laparoscopic Hiatal Hernia Repair (C-Tif) And Concomitant Sleeve Gastrectomy For The Treatment Of Gerd And Obesity: A Preliminary Experience

Authors Palma R[1], Angrisani L[2], Angrisani F[3], Ormando VM[4], Iovino P[1], Maselli R[5]

Institutes **1** Gastrointestinal Unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Salerno, Italy; **2** Department of Public Health, "Federico II" University of Naples, Napoli, Italy; **3** Digestive Endoscopy Unit, University of Naples Federico II, Napoli, Italy; **4** Gastroenterology and Endoscopy Unit, AORN San Giuseppe Moscati, Avellino, Italy; **5** Humanitas San Pio X, Milano, Italy

DOI 10.1055/s-0046-1821798

Aims Gastroesophageal reflux disease (GERD) is frequently associated with obesity. The onset or worsening of GERD after sleeve gastrectomy (SG) remains a matter of debate in metabolic and bariatric surgery (MBS). Concomitant hiatal hernia repair (HHR) is increasingly performed, and SG combined with fundoplication has emerged as a potential bariatric option, although current evidence is conflicting and the learning curve can lead to a considerable rate of reinterventions. Transoral Incisionless Fundoplication (TIF) is a minimally invasive endoscopic approach that reconstructs the gastroesophageal valve and provides a 270° fundoplication. To date, only one case report has described TIF performed simultaneously with SG without HHR, demonstrating the basic feasibility of this combined strategy [1–7].

AIMS. To evaluate the feasibility of concomitant TIF with laparoscopic HHR and SG (C-TIF + SG) and to assess the postoperative evolution of GERD symptoms in obese patients with confirmed preoperative GERD.

Methods Four obese patients with typical GERD symptoms were prospectively enrolled. Symptom severity and frequency were assessed using the GERD-HRQL questionnaire. All patients underwent preoperative endoscopy, 24-hour pH-impedance monitoring, and high-resolution manometry (HRM). GERD was diagnosed following the Lyon Classification 2.0 criteria. Under general anesthesia, five laparoscopic trocars were placed, followed by posterior cruroplasty after dissection of the diaphragmatic crura and abdominalization of the distal esophagus. The EsophyX device was then inserted transorally, retroflexed, and used to create a 270° gastroesophageal valve under laparoscopic control. The procedure was performed jointly by two experienced endoscopists. A standard laparoscopic sleeve gastrectomy followed. Clinical follow-up was scheduled at 1, 3, 6, and 12 months.

Results The mean preoperative BMI was 35.4 kg/m² (SD ± 3.99). All patients were taking daily standard-dose PPIs. The mean preoperative GERD-HRQL score was 40.5 (SD ± 11). Hiatal hernia was present in all patients (mean size 2.1 ± 0.6 cm), along with Grade A esophagitis (Los Angeles Classification). pH-monitoring confirmed pathological reflux, while HRM demonstrated hiatal hernia with an IRP < 15 mmHg.Mean follow-up was 10.5 months (range 8–13). Total body

Endoscopy 2026; 58: S1–S1041

weight loss at 6 months was 25.3 %. GERD symptoms significantly improved at last follow-up ($p < 0.01$), with a mean postoperative GERD-HRQL score of 2.25. All patients discontinued PPI therapy within one month. Follow-up endoscopy at 6 months showed no recurrence of hiatal hernia or esophagitis. No complications were observed.

Conclusions In this preliminary experience, C-TIF with concomitant SG appears safe, technically feasible, and associated with favorable mid-term outcomes in terms of both weight loss and GERD symptom resolution. Larger studies with longer follow-up are needed to validate the combined approach for the simultaneous management of obesity and GERD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP472 Is it possible to predict hemorrhage after endoscopic papillectomy?

Authors Kiremitçi S[1], Koçhan K[2], Hakkı Koker I[3], Degirmencioglu Tosun S[4], Tuzun Ince A[5], Senturk H[5]

Institutes **1** Bezmiâlem Foundation University, İstanbul, Türkiye; **2** Biruni University Hospital, Istanbul, Türkiye; **3** Başkent University Hospital, İstanbul, Türkiye; **4** Bağcılar eğ, ıst, Türkiye; **5** Bezmialem Foundation University, İstanbul, Türkiye

DOI 10.1055/s-0046-1821799

Aims Endoscopic papillectomy (EP) is an efficacious intervention for the management of papillary adenomas. It may also be considered for carcinoma without S2 invasion and neuroendocrine tumors. However post-papillectomy bleeding (PPB) requiring reintervention is not rare. We aimed to study several parameters to predict post-papillectomy bleeding.

Methods Over a fifteen year period, we performed EP for 132 patients. There were 68 males and 64 females. Median age was 46 (range: 32-76). For resection Endocut Q current (ERBE, VIO 300 S electrosurgical unit with APC; Germany) was used.

Results Bleeding requiring re-intervention or blood transfusion happened in 14 patients (10 %). In another 7, bleeding manifested with melena and drop in hemoglobin, expectant management was suffice (Total 15.9 %). Bleeding manifested with a median time of 12 hours (1-42). Management by re-intervention included; clips, argon plasma coagulation (APC), ancaferd spray, and metallic stent inserion into common bile duct. None required surgery, death did not happen. We compared these 21 against 111 who did not bleed in reference to age, gender, coagulation parameters, use of anti-platelet or anti-coagulant agents (that were stopped before a certain time of the procedure), size and histology of the resected papilla, administration of APC after papillectomy and no significant difference was found. In five of 21 patients (23 %), bleeding happened after 24 hours and all had been discharged before bleeding manifested.

Conclusions Bleeding after EP seems to be an unpredictable event. However keeping the patients in-hospital and withholding antiplatelet and anticoagulant agents for 48 hours after procedure, if possible, may be a safer.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP473 EUS-guided treatment in patients with gallstone disease who are unsuitable for ERCP, have failed ERCP, or cannot undergo cholecystectomy: A retrospective cohort with long-term follow-up

Authors Senturk H[1], Kiremitçi S[2], ÇAğlar E[3], Hakkı Koker I[4], Degirmencioglu Tosun S[5], Tuzun Ince A[1]

Institutes **1** Bezmialem Foundation University, İstanbul, Türkiye; **2** Bezmiâlem Foundation University, İstanbul, Türkiye; **3** Sarıkız gas, balık, Türkiye; **4** Başkent University Hospital, İstanbul, Türkiye; **5** Bağcılar eğ, ıst, Türkiye

DOI 10.1055/s-0046-1821800

Aims Treatment of gallstone disease involves cholecystectomy for cholelithiasis and ERCP for choledocholithiasis.However,cholecystectomy may be risky elderly patients and those with significant comorbidities.In surgically altered patients, ERCP can not be possible for choledocholithiasis,and in patients with preserved gastrointestinal anatomy,ERCP may also fail.The long-term outcomes of EUS-guided treatment performed between 2011 and 2022 in a group of such patients were evaluated.

Methods The study included 23 patients.In the bile duct group, 16 patients consisted of 13 males and 3 females.In the gallbladder group,6 were female and 1 was male.The mean age was 62 ± 18.6 (range: 28–86) in the bile duct group and 73 ± 11.7(51–83) in the gallbladder group.In the bile duct group,one patient had a hepaticojejunostomy without tract surgery,12 had gastroenterostomy (including one with Billroth II and nine with Roux-en-Y anastomosis), and one had a total gastrectomy with esophagojejunostomy.In two patients, the anatomy was physiological,but ERCP had failed.All patients in the gallbladder group had recurrent cholecystitis and had high surgical risk. Under EUS guidance,13 patients underwent hepaticogastrostomy,one underwent hepatoesophagostomy,two underwent choledochoduodenostomy,five underwent cholecystogastrostomy, and two underwent cholecystoduodenostomy.In the bile duct patients with normal anatomy,choledochoduodenostomy was preferred. After fistula formation,the stones were mostly treated with antegrade laser lithotripsy under cholangioscopic guidance.

Results Technical success was achieved in all patients.However,seven of those with bile duct stones continued to experience episodes of cholangitis.In all of these patients,the diameter of the common bile duct or main hepatic duct was greater than 20 mm.In the other six patients, the duct diameter was 15 mm or less,and no further episodes of cholangitis occurred.In patients who underwent the procedure for gallbladder stones,clinical success was 100 %.

Conclusions EUS-guided treatment is a safe and highly effective option for managing bile duct stones in which ERCP is not feasible and gallbladder stones in patients at high risk for cholecystectomy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP474 ERCP treatment of recurrent gallstones in patients who have undergone cholecystectomy: What are the profiles?

Authors Farhi S[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2]
Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821801

Aims Cholecystectomy is recommended in patients with gallstones after endoscopic extraction of bile duct stones to prevent cholecystitis or recurrent gallstones.

However, recurrence of common bile duct (CBD) stones is still observed in a considerable number of patients after cholecystectomy.

The standard treatment is endoscopic retrograde cholangiopancreatography (ERCP).

The aim of this study is to determine the profiles of these patients.

Methods The endoscopic retrograde cholangiopancreatography (ERCP) database of our hepatology-gastroenterology department was retrospectively reviewed between January 2020 and October 2025. All patients with a history of cholecystectomy and presenting with stones in the common bile duct were included in the study.

Results Twenty-eight patients were included in the study. The mean age of our patients was 66 ± 14.1 years, with a female predominance of 78 % (n = 21) and a female-to-male ratio of 3.5.

The median interval between cholecystectomy and the occurrence of common bile duct stones was 10 years.

The medical histories of our patients were as follows: diabetes in 7 cases (25 %), oral contraceptive use in 9 cases (33 %), dyslipidemia in 9 cases (33 %), obesity in 8 cases (29 %), LPAC syndrome in 1 case (3 %), sickle cell disease in 1 case (3 %), and 3 patients (10 %) had no medical history.

The clinical presentation was dominated by biliary colic in 13 cases (48 %), acute cholangitis in 10 cases (37 %), acute pancreatitis in 3 cases (11 %), cholecystitis in 2 cases (7 %), and a sickle cell crisis in 1 case (3 %).

All patients underwent imaging, which showed dilation of the biliary ducts upstream of lithiasic obstruction.

The mean CBD diameter was 15 mm, ranging from 9 mm to 22 mm.

The number and size of stones within the CBD varied:

- Macro-stone in 10 cases (36 %) with a mean diameter of 14.4 mm.
- Two stones in 4 cases (14 %) with a mean diameter of 17 mm.
- Multiple stones (choledocholithiasis impaction) in 14 cases (50 %)

Conclusions The recurrence of common bile duct stones is considered an unresolved problem after cholecystectomy. These patients present multiple risk factors, particularly metabolic syndrome, and a more frequent follow-up evaluation is suggested for the early detection of recurrent CBD stones.

eP475 Predictive Factors of Colorectal Degeneration in Familial Adenomatous Polyposis

Authors Khsiba A[1], Mahmoudi M[2], Gharbi G[2], Ben Mohamed A[2], Yakoubi M[2], Medhioub M[3], Hamzaoui L[2]
Institutes 1 Hôpital régional Mohamed Taher El Maamouri, Mrezga, Tunisia, Mrezga, Tunisia; 2 Regional Hospital Mohamed Taher Al Maamouri, Mrezga, Tunisia; 3 Regional Hospital Mohamed Taher Al Maamouri, Mrezga, Tunisia, Mrezga, Tunisia
DOI 10.1055/s-0046-1821802

Aims Familial adenomatous polyposis (FAP) is a hereditary disorder that, in the absence of appropriate therapeutic management, invariably progresses to colorectal adenocarcinoma. It represents the most common form of colorectal polyposis and the second leading cause of hereditary colorectal cancer. after lynch syndrom The aim of this study was to identify prognostic factors associated with malignant degeneration.

Methods We conducted a retrospective, descriptive study in the Departments of Gastroenterology and General Surgery at Mohamed Tahar Maamouri University Hospital. A total of 33 patients managed for FAP over a 16-year period (January 2005 to December 2024) were included.

Results During the study period, 33 patients were included: 16 women and 17 men, with a sex ratio of 1.06. The mean age was 48.2 years [18–78]. FAP was diagnosed after the age of 40 in 21 patients. Fifteen patients were smokers and four were chronic alcohol consumers. A family history of FAP or colorectal cancer in first-degree relatives was documented in 15 patients (45.5 %).At diagnosis, the number of polyps exceeded 100 in 4 patients (12 %).Colorectal cancer occurred in 15 patients. The mean age at cancer diagnosis was 59 years. Thirteen patients (86 %) underwent elective surgery, while two required emergency surgery for bowel obstruction.Seven patients underwent total proctocolectomy with ileal pouch–anal anastomosis. Two underwent subtotal colectomy with ileocolic anastomosis, and six had total colectomy with ileorectal anastomosis.

In univariate analysis, the risk of degeneration was associated with age > 40 years at the time of FAP diagnosis (p = 0.02). A polyp count > 100 at diagnosis—observed in 12 % of patients—was correlated with the subsequent development of colorectal adenocarcinoma (p = 0.042).Polyps measuring > 5 mm, with or without high-grade dysplasia on histology and present in 26 patients (78 %), also constituted a poor prognostic factor predictive of malignant transformation (p = 0.036).Among the 33 included patients, 23 were diagnosed through colonoscopy performed for gastrointestinal symptoms; this group showed a higher risk of developing colorectal cancer (p = 0.015).Finally, the presence of at least one extracolonic manifestation—documented in 16 patients—was associated with an increased risk of colorectal cancer (p = 0.025).

Conclusions Our study demonstrated a positive correlation between age at FAP diagnosis, polyp size and number, and the risk of colorectal cancer. It also highlighted the increased risk of colorectal cancer in the presence of extracolonic manifestations and emphasized the importance of diagnosing FAP at the presymptomatic stage to reduce the likelihood of malignant degeneration.

eP476 EUS-guided tissue acquisition with and without on-site evaluation: a single-center experience from the Hungarian Institute of Pancreatic Diseases

Authors Turquier C[1], Mariyappan D[1], Várkonyi T[2], Hegyi JP[3]
Institutes 1 Institute of Pancreatic Diseases, Semmelweis University, Budapest, Hungary; 2 Department of Pathology, Forensic and Insurance Medicine, Semmelweis University, Buda, Hungary; 3 Semmelweis University, INSTITUTE OF PANCREATIC DISEASES/CENTRE FOR TRANSLATIONAL MEDICINE, Budapest, Hungary
DOI 10.1055/s-0046-1821803

Aims Pancreatic cancer is the third leading cause of cancer related mortality, and early diagnosis remains essential to enable potentially curative resection. Although histopathology is the diagnostic standard, endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) has emerged as the preferred method for tissue acquisition. Our aim was to evaluate whether on-site assessment techniques, specifically rapid on-site evaluation (ROSE) and macroscopic on-site evaluation (MOSE), can enhance sample adequacy and reduce the need for repeat biopsy during EUS-guided tissue acquisition.

Methods We performed a retrospective analysis of 95 consecutive patients undergoing EUS-guided tissue acquisition at the institute of Pancreatic Diseases, Semmelweis University, between September and December 2024. Outcomes assessed included technical success, the impact on ROSE and MOSE on tissue adequacy, re-biopsy rates, and procedure-related adverse events.

Results Among 95 patients (55 % male, 45 % female), the technical success rate was 97.25 %. ROSE was performed in 69 cases, yielding 100 % diagnostic positivity with a mean of 2.15 needle passes. MOSE was used in 73 cases. Re-bi-

opsy rates were 13.4 % for ROSE and 17.7 % when both techniques were applied. MOSE alone demonstrated a re-biopsy rate of 14.3 %. The overall adverse event was 2.78 %.

Conclusions In our single-center experience, MOSE demonstrated performance comparable to ROSE and appears to be a reliable option in settings where ROSE availability is limited.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP477 Is gastric ptosis a predictor of response to endoscopic treatments for gastroparesis?

Authors Semenou C[1], Gonzalez JM[1], Barthet M[2], Vitton V[2]
Institutes **1** Hôpital nord, Marseille, France; **2** Hospital Nord, Marseille, France
DOI 10.1055/s-0046-1821804

Aims When conservative treatments fail, the treatment of gastroparesis relies on endoscopic strategies, but the predictors of success for these treatments remain poorly identified. Gastric ptosis is an anatomo-clinical entity whose links with gastroparesis remain poorly understood. The main objective of our study was to investigate the influence of gastric ptosis on the response to pyloric endoscopic treatments in patients with clinical gastroparesis.

Methods In this retrospective, single-centre study, all patients who underwent endoscopic treatment and TOGD between September 2012 and January 2025 were eligible. The primary objective was to evaluate the relationship between ptosis and treatment success (improvement in GCSI ≥ 1 after 3 months). Secondary objectives included identifying other factors predictive of treatment efficacy.

Results Forty-four patients with a median age of 52 years (36.9-61.4) were included. Gastric ptosis was significantly associated with a lower success rate of endoscopic treatment (5.56 % vs. 48 %, p = 0.003). Among the other criteria analysed, longer symptom duration and the presence of oesophageal motor disorder were significant predictors of failure (p = 0.025 and p = 0.001, respectively), while diabetic aetiology was associated with a higher success rate (p = 0.019).

Conclusions Our study is the first to identify gastric ptosis as a predictive factor for failure of pyloric treatments for gastroparesis. The inclusion of an upper gastrointestinal endoscopy in the pre-treatment assessment could be particularly relevant before proposing endoscopic pyloric treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP478 Endoscopic Ultrasound-guided Fine Needle Biopsy of an extremely rare mesenchymal pancreatic tumor: a case report

Authors Petrucci G[1], Borrelli De Andreis F[1], Bulajic M[2], Vadalà Di Prampero SF[3], Costamagna G[4], Aparo S[1], Ricci F[1]

DOI 10.1055/s-0046-1821805

Abstract Text

A 51-year-old male presented to the emergency department with acute back pain, suspicious for renal colic. An abdominal CT scan incidentally revealed a 30 mm hypodense lesion in the pancreatic uncinate process with central calcifications. An endoscopic ultrasound (EUS) demonstrated a hypoechoic, heterogeneous mass in the uncinate process, with irregular margins and a huge posterior acoustic shadowing. No signs of vascular or ductal involvement were noted. Therefore, EUS-guided fine needle biopsy (FNB) with a 22-G Franseen-tip needle was performed via transduodenal and transgastric approaches, obtaining an adequate histological sample after macroscopic on-site examination (MOSE).Histological analysis revealed spindle cells positive for CD34, BCL2, STAT6, and CD99, and negative for CKIT, DOG1, desmin, actin, S100, and cytokeratins, with Ki-67 index > 5 %, suggesting for solitary fibrous tumor (SFT) of the pancreas. Immunohistochemical confirmation was obtained at a tertiary referral pathology laboratory. A multidisciplinary tumor board advised conservative follow-up based on the benign histology and absence of local invasion. Conclusion: Pancreatic SFTs are extremely rare, with only 34 cases reported to date [2]. They are more frequently located in the pancreatic head and are slightly more common in females [2]. Most are discovered incidentally [2]. This case highlights the critical diagnostic value of EUS-FNB, which enabled accurate tissue acquisition for advanced immunohistochemical analysis, informing a nonsurgical, surveillance-based approach. Because of the non-specific clinical presentation and radiological features of pancreatic SFTs, diagnosis is particularly challenging using preoperative imaging and laboratory tests alone [1, 2]. Therefore, histopathological and immunohistochemical evaluation is essential for definitive diagnosis [1].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP479 Development of standards for an endohepatology fellowship training program: Survey of international experts using a modified RAND/UCLA approach

Authors Benmassaoud A[1], Farah A[1], Chen YI[1], Martel M[2], Magahis P[3], Bazarbashi AN[4], Cosgrove N[5], Adler D[6], Ryou M[7]
Institutes **1** MUHC – McGill University Health Centre (Glen Site), Montréal, Canada; **2** RI MUHC, Montréal, Canada; **3** Brigham and Women's Hospital, boston, United States of America; **4** King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia; **5** AdventHealth Orland, orland, United States of America; **6** Center for Advanced Therapeutic Endoscopy, Porter Adventist Hospital, Denver, CO, United States of America; **7** Brigham and Women's Hospital, Boston, United States of America
DOI 10.1055/s-0046-1821806

Aims Over the past decade, advances in therapeutic EUS have expanded the interface between hepatology and endoscopy, giving rise to the emerging field of endohepatology. Despite increasing clinical adoption and evidence supporting these procedures, no standardized training framework currently exists. This project seeks to inform the development of consensus-driven standards for an Endohepatology Fellowship by identifying the essential hepatology and endoscopic competencies required for safe and effective practice.

Methods We conducted a cross-sectional electronic survey of international experts in hepatology, advanced endoscopy, and endohepatology to assess essential standards for endohepatology fellowship development. A steering committee of recognized leaders designed the survey, drawing on published literature, existing training curricula, and expert experience to generate statements across key training domains. Participants were asked to rate a total of 74 statements on the following topics: 1) basic framework for a proposed endohepatology fellowship program; 2) candidate selection; 3) training environment; 4) supervisor qualification; 5) clinical exposure; 6) endoscopic exposure; 7) interventional radiology exposure; 8) evaluation of training; 9) support from learned societies; and 10) maintenance of competence after training. Statements were rated on a 9-point Likert scale (1 = strongly disagree, 9 = strongly agree) with the possibility to add free-text comments. Consensus was defined using a modified RAND/UCLA approach. Agreement or disagreement was determined based on median panel scores (7-9 = agreement; 1-3 = disagreement), and statistical disagreement was assessed using the IPRAS method (▶ **Fig. 1–3**).

Results Forty-four (83 %) out of 53 invited experts completed the survey (21 (48 %) advanced endoscopists; 18 (41 %) hepatologists; 5 (11 %) endohepatologists). Duration of independent practice was < 5 years in 9 (20 %), 5-10 years

in 13 (30), and > 15 years in 22 (50 %). Location of practice was USA in 22 (50 %), Canada in 11 (25 %), Europe in 7 (16 %; Belgium, Italy, Spain, UK), KSA in 1 (2 %), and 3 did not say. In total, all panelists reached a consensus on 55 (74 %) statements. An additional 8 (11 %) statements reached consensus in only a subgroup of participants. All statements reaching consensus are highlighted in Figure 1 and 2. These statements belong to all topics covered. More than half of survey responders thought that the minimum number of cases needed to evaluate competency were at least 25 cases for EUS-liver palpation, 50 cases for EUS-guided non-liver biopsy, 25 cases for EUS-guided liver biopsy, 25 cases for EUS-portal pressure gradient measurement, 25 cases for EUS-shear wave elastography, 25 cases for variceal gluing, and 10 cases for variceal gluing and coiling.

Conclusions Our survey identifies multiple statements and establishes key standards that should be used to develop an endohepatology fellowship training program. Further work is needed to refine these standards.

eP480 Various types of familiar sessile serrated lesions without dysplasia

Authors Tatiana N[1], Fedorov E[1], Ageykina N[1]
Institute 1 Pirogov Russian National Research Medical University, Moskva, Russia
DOI 10.1055/s-0046-1821807

Aim. to identify and study endoscopic various diagnostic criterias of sessile serrated lesions (SSLs) without displasia.

Materials. We included 158 patients 44 (27.8 %) men and 114 (72.2 %) women aged 17 to 81 (mean age 52.1 ± 3.4), in whom 215 SSLs were detected. All lesions were endoscopically removed and pathological examination.

Results. The SSLs were located in the right colon – 177/215 (82.3 %), in the left colon – 38/215 (17.7 %). The size was 2-25 mm, the majority (165/215 (76.7 %)) were 6-15 mm; the color of the SSLs was white – 107/215 (49.7 %) or similar to the surrounding mucosa – 104/215 (48.4 %), rarely red – 4/215 (1.9 %). The surface was most often smooth – 103/215 (47.8 %), less often cloud-like 58/215 (27.0 %); the borders of the SSLs were distributed equally – serrated 202/215 (93.9 %); more often there were irregular shaped SSLs – 139/215 (64.8 %), to a lesser extent oval (61/215 (28.3 %) and round shape 15/215 (6.9 %); a «mucinous cap» on the surface was in 190/215 (88.4 %), which was washed off well in 134/215 (62.3 %), and in 25/215 (11.6 %) cases it was absent. According to the Paris classification SSLs were the type 0-IIa – 192/215 (89.3 %), less common were type 0-Is 20/215 (9.5 %), type 0-Is + IIc 3/215 (1.2 %), type 0-IIb 1/215 (0.4 %), type 0-IIa + IIc 3/215 (1.2 %); according to the NICE and JNET classifications in all cases SSLs were type 1 – 215/215 (100 %). According to the Kudo classification was type II – 158/215 (73.6 %), with specific sign according to Kimura type II-O – 48/215 (22.0 %), in rare cases according to Kimura type IIL 9/215 (4.4 %) were presented; capillary pattern in all 215/215 (100 %) cases is not dilated, regular, type 1 according to Y. Sano.

Conclusion. Sessile serrated lesions (SSLs) without displasia can be varied, not only with the usual and well-known features. The use of an extended set of endoscopic criterias contribute accurate verification of SSL during colonoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP481 Correlation between the Rutgeerts score and clinical recurrence in Crohn's disease

Authors Farhi S[1], Cherkaoui Malki M[2], Temdaoui M[2], Mechhor S[2], Mghyly F[2], Cherkaoui Malki O[2], Nadia B[3], Errabih I[3], El Bacha H[3]

DOI 10.1055/s-0046-1821808

Aims Surgery is frequently performed in patients with Crohn's disease (CD), with a risk of short bowel syndrome. The aim of our study is to evaluate the correlation between the Rutgeerts score and clinical and endoscopic recurrence during the first year following intestinal resection surgery in patients with CD.

Methods We conducted a retrospective analytical and descriptive study within the Hepatology, Gastroenterology, and Proctology Department of Medicine B, which collected data on all patients with Crohn's disease who underwent ileocecal or right ileocolonic resection between January 2019 and November 2025. Patients who did not undergo postoperative colonoscopy were excluded. Postoperative endoscopic recurrence was defined as a Rutgeerts score ≥ i2.

Results A total of 92 patients were included. The mean age was 41.3 years (20–70 years). There was a female predominance, with a female-to-male ratio of 1.19 (50 women and 42 men). The mean interval between the diagnosis of Crohn's disease and surgery was 2.6 years.Crohn's disease was ileocecal in 50 % of cases (n = 59), ileocolic in 44.5 % (n = 41), isolated ileal in 4.3 % (n = 4), and extensive in 1 % of patients. The disease phenotype was stenosing in 64.1 % (n = 59), fistulizing in 18.4 % (n = 17), combined stenosing and fistulizing in 14.1 % (n = 13), and inflammatory in 2 patients.

Thirty-three patients (35.8 %) had ano-perineal manifestations, including complex fistulas in 29 patients (31.5 %), anal ulcerations in 2 patients (2.1 %), anal stenosis in 1 patient (1 %), and an anal fissure in 1 patient (1 %).The surgical indications were ileal or ileocecal stenosis in 73.9 % of cases (n = 59), internal or external fistulas in 20.6 % (n = 19), and deep abscesses in 2 patients.

Postoperative colonoscopy was performed after a mean interval of 9.2 months (6–11 months) following surgery. Endoscopic recurrence (Rutgeerts score ≥ i2) was observed in 59.7 % of patients (n = 55), including Rutgeerts i2 in 20 patients (21.7 %), i3 in 9 patients (9.7 %), and i4 in 26 patients (28.2 %). Clinical recurrence occurred in 53.2 % of patients (n = 49).

On univariate logistic regression analysis, statistically significant predictors of clinical recurrence were a Rutgeerts score ≥ i2 ($p < 0.001$) and the presence of LAP ($p = 0.042$). On multivariate analysis, only a Rutgeerts score ≥ i2 remained statistically significant ($p < 0.001$)

Conclusions Endoscopic recurrence (ER) of Crohn's disease, assessed using the Rutgeerts score, is strongly correlated with the risk of clinical recurrence.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP482 Texture and Color Enhancement Imaging (TXI) versus White Light Imaging (WLI) in Detecting Colorectal Adenomas: A Meta-Analysis of Randomized Controlled Trials

Authors Mendoza R[1], Aguila E[1], Sy-Janairo ML[1]
Institute 1 St. Luke's Medical Center – Global City, Taguig, Philippines
DOI 10.1055/s-0046-1821809

Aims Colonoscopy is the gold standard for colorectal cancer screening, but its effectiveness depends on factors like bowel preparation, technique, and strategies to improve detection. Enhancing visualization is key to reducing missed lesions. Texture and Color Enhancement Imaging (TXI) augments texture, brightness, and color which could potentially help identify adenomatous lesions. This meta-analysis evaluates the effectiveness of TXI on adenoma detection rate (ADR) and adenomas per colonoscopy (APC) compared to white light imaging (WLI).

Methods A comprehensive literature search for randomized controlled trials (RCTs) comparing TXI to WLI in patients undergoing colonoscopy was done in PubMed, EMBASE, and Cochrane CENTRAL. Statistical analysis was conducted with RevMan using a random-effects model to compute the risk ratio and mean difference [1–3].

Results This meta-analysis included 3 RCTs. The TXI group comprised 989 patients while the WLI group had 978 patients. Analysis of the outcomes of interest showed a trend favoring TXI vs. WLI, with increased ADR (Risk Ratio: 1.22, 95 % CI: 0.98-1.52) and increased APC (Mean Difference: 0.34, 95 % CI: -0.13-0.81) with no statistical significance. However, there was significant heterogeneity for both outcomes.

Conclusions This meta-analysis of RCTs suggests that TXI, compared to WLI, can improve ADR and APC. The heterogeneity may possibly be explained in the use of older generations of colonoscopes in the WLI arm in the RCTs of Antonelli and Young. In the RCT of Toyoshima, the same latest generation scope was used in both arms. Thus, we recommend that subsequent studies use the same latest generation scope for both arms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP483 MELD 3.0 is a more accurate predictor of mortality in decompensated liver cirrhosis than MELD and MELD-Na

Authors Khsiba A[1], Chtioui S[2], Gharbi G[3], Mahmoudi M[3], Ben Mohamed A[3], Yakoubi M[3], Medhioub M[4], Hamzaoui L[3]

Institutes **1** Hôpital régional Mohamed Taher El Maamouri, Mrezga, Tunisia, Mrezga, Tunisia; **2** Tahar maamouri, Nabeul, Tunisia; **3** Regional Hospital Mohamed Taher Al Maamouri, Mrezga, Tunisia; **4** Regional Hospital Mohamed Taher Al Maamouri, Mrezga, Tunisia, Mrezga, Tunisia

DOI 10.1055/s-0046-1821810

Aims In cirrhosis, several prognostic scores have been developed to predict overall survival. The MELD (Model for End-Stage Liver Disease), MELD-Na and MELD3.0 scores have been proposed as a criteria for allocating organs.
The aim of our study was to explore MELD 3.0 score for predicting survival in decompensated Tunisian cirrhotic patients.

Methods We conducted an observational, retrospective study involving all patients with decompensated cirrhosis managed in Gastroenterology department of Taher Maamouri hospital during the period from January 2010 to December 2021. Mortality was assessed using the Kaplan Meier model. The performance of the scores was assessed using the AUROC (Area under the Receiver Operating Characteristic curve).

Results One hundred and fifty-two patients were included with an average age of 62 years. The main causes of chronic liver disease were hepatitis C virus (HCV) infection (30.9 %) and hepatitis B virus (HBV) infection (32.2 %). The mean value of the MELD, MELD-Na and MELD3.0 scores was 17.78, 17.74 and 19.4, respectively. The mean follow-up time was 17.1 months. The overall mortality at 3-month, 6-month and 1-year was 18.4 %, 24.3 % and 35.5 % respectively.
In the prediction of 3-month mortality, the AUROCs of the MELD, MELD-Na and MELD3.0 scores were 0.786; 0.841 and 0.850 respectively. The cut-off value of the MELD3.0 score was 24 (sensitivity 68 %, specificity 88 %). A statistically significant correlation was noted between the MELD3.0 score ≥ 24 and 3-month mortality (p = 0.04).

Conclusions Overall, MELD3.0 shows promising value with the highest AUROC in all assessed scoring systems. MELD 3.0 has the best performance for predicting mortality at various time points. Multicenter and long-term studies with larger samples would be helpful for the scoring systems to predict the mortality more precisely in decompensated liver cirrhosis patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP484 Why Are Small Rectal NETs Yellow? A Colorimetric Analysis Linked to Mucosal Invasion Depth

Authors Uragami N[1], Tanabe M[1], Toshimori A[1], Daijiro S[1], Fukuda M[1], Yumi K[1], Noboru Y[1], Haruhiro I[1]

Institute **1** Showa Medical University Koto Toyosu Hospital, Tokyo, Japan

DOI 10.1055/s-0046-1821811

Aims Aims:Rectal Neuroendocrine Tumors (R-NETs) carry a risk of lymph node metastasis even when smaller than 10 mm, and detecting small R-NETs endoscopically is clinically important. R-NETs are generally recognized as yellowish submucosal tumors; however, the reason why they appear yellow has not been elucidated. In this study, we analyzed R-NETs at our institution to evaluate the diagnostic utility of color characteristics.

Methods Methods:From April 2021 to September 2025, we identified lesions ≤ 5 mm that had not undergone pre-treatment biopsy and were observed using the Olympus X-1 system (CF-XZ1200). From stored endoscopic images, we extracted tumor and surrounding mucosal areas and measured color values (RGB) at nine points each to obtain mean color values.**Analysis 1:** We evaluated diagnostic capability based on color differences between tumor and surrounding mucosa. RGB values were converted to the CIE-Lab color space, and color differences (ΔE) were calculated.**Analysis 2:** We assessed diagnostic utility incorporating pathological findings, specifically the depth of tumor extension from the submucosa into the mucosa.

Results Results:A total of 32 patients with 35 lesions were included (16 males, 19 females; mean age 56.3 ± 13.1 years). The mean tumor size was 3.5 ± 0.9 mm.**Analysis 1:** Five endoscopists evaluated whether the color of each tumor could be visually distinguished from the surrounding mucosa. In 16 lesions (46 %), differentiation was not possible (non-CD group), whereas in 19 lesions (54 %), it was possible (CD group). Although tumor size did not differ between groups, ΔE values showed a significant difference($P < 0.01$).**Analysis 2:** Pathological invasion depth was classified as follows: no invasion into mucosa (MI-1): 8 lesions (23 %), < 1/3 mucosal invasion (MI-2): 9 lesions (26 %), ≥ 1/3 mucosal invasion (MI-3): 18 lesions (51 %). While tumor size did not differ among MI categories, ΔE was significantly higher in MI-1 vs MI-3($P < 0.01$).A nominal logistic regression analysis using color difference as the dependent variable revealed that MI classification was significantly associated with endoscopic color recognition ($p < 0.01$).

Conclusions Conclusions:In small R-NETs, the yellowish appearance is not attributable to tumor size but instead to the reverse invasion of tumor cells from the submucosa into the mucosa.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP485 EUS-Guided Fiducial Placement For GI Malignancies: A Tertiary Hospital's 9-Year Experience

Authors Thanos C[1], Piskopou D[1], Tsitsigiannis K[1], Georgakopoulou N[1], Ntailianas D[1], Triantafyllou M[1], Kalakos N[1], Georgiou E[1], Argyropoulos T[1], Varmpompitis I[1], Striki A[1], Michalopoulos G[1], Karoumpalis I[1]

Institute **1** General Hospital of Athens "G. Gennimatas", Athina, Greece

DOI 10.1055/s-0046-1821812

Aims Fiducial markers are radiopaque implants, typically composed of gold, that aid in the precise and reproducible targeting of tumors. These markers serve as reference points during CT-based planning, including four-dimensional assessment, enabling real-time correction for tumor motion. Initially, fiducial markers were placed intraoperatively or percutaneously under ultrasound (US) or CT guidance. However, endoscopic ultrasound (EUS) offers superior visualization of deep structures in the mediastinum and abdomen while providing a less invasive alternative to surgical placement. EUS-guided fiducial placement has been successfully used for tumors in nearly all gastrointestinal malignancies such as pancreatic, hepatic, esophageal, gastric, and colorectal cancers. Modern fiducials can fit into 22-gauge fine-needle aspiration (FNA) needles and come preloaded in needle carrier devices for easier deployment. Despite in-

creasing evidence supporting the efficacy of EUS-guided fiducial marker placement in gastrointestinal malignancies, there remains a lack of systematic evaluation in large, prospective, randomized trials. Data regarding its feasibility and safety in patients with gastrointestinal cancers undergoing radiation therapy are particularly scarce. Therefore, this study aimed to assess the success rate of EUS-guided fiducial marker placement in these indications within a tertiary hospital setting.

Methods This retrospective, single-center study was conducted at our tertiary hospital and included patients diagnosed with esophageal, rectal, or pancreatic tumors who required fiducial marker placement for image-guided radiation therapy. The study period extended from January 2016 to October 2025. Patients underwent EUS-guided fiducial marker placement using a preloaded 22-gauge EchoTip Ultra Fiducial Needle (Cook Medical, Limerick, Ireland). The primary outcome was the technical success of the procedure, defined as the accurate deployment of fiducial markers at both the proximal and distal margins of the tumor under EUS guidance. Additionally, the occurrence of procedure-related adverse events was assessed. All procedures were performed by experienced endosonographers using standard EUS techniques. Patients were closely monitored post-procedure for potential complications and CT scan and chest xray were used to confirm marker positioning both immediately after placement and at the completion of radiotherapy [1–5].

Results During the study period, a total of 19 patients underwent EUS-guided fiducial marker placement in our endoscopic unit. The mean age was 65.2 ± 9.8 years, and 52 % of the patients were male. Of the participants, two had rectal adenocarcinoma, two had esophageal malignancies, and 15 were diagnosed with pancreatic adenocarcinoma. The overall technical success rate of fiducial marker placement was 94.7 %, with successful deployment achieved in 18 patients. In one case, the presence of an extensive collateral venous network (cavernoma) prevented the safe placement of fiducial markers. On average, 2.6 ± 1.2 fiducial markers were placed per patient. The mean tumor size was 23 ± 7 mm. No procedure-related complications were observed. At the completion of radiation therapy, imaging confirmed the presence of markers in all patients.

Conclusions Our nine-year experience with EUS-guided fiducial marker placement for esophageal, pancreatic, and rectal tumors demonstrates that the procedure is both safe and highly effective, with no reported complications. Fiducial markers remained intact and visible throughout the course of radiation therapy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP486 Self-Assembling Peptide Hydrogel Does Not Reduce Adverse Outcomes After Endoscopic Submucosal Dissection: systematic review Meta-analysis

Author Hasanin E[1]

Institute 1 Faculty of Medicine, University of Tripoli, Tripoli, Libya

DOI 10.1055/s-0046-1821813

Aims To evaluate the efficacy and safety of self-assembling peptide **hydrogel (**SAP) in endoscopic submucosal dissection (ESD), specifically assessing their impact on delayed bleeding, perforation risk, resection quality, procedure time, and wound healing, through a comprehensive meta-analysis and trial sequential analysis.

Methods I conducted a comprehensive search of **PubMed, Scopus, Web of Science, Embase, and Cochrane** from their inception to **November 2025**, focusing on **randomized controlled trials (RCTs)** evaluating **the** efficacy and safety of self-assembling peptide **hydrogel (**SAP) in endoscopic submucosal dissection **(ESD).** Meta-analyses were performed using a **random-effects model**. Odds **ratios (ORs), hazard ratios (HRs), and mean differences (MDs)** were calculated with **95 % confidence intervals (CIs)**.

Results Across six studies, SAP showed **no significant reduction in delayed bleeding** compared with no SAP (RR 0.87; p = 0.47). However, a **significant effect modification by study design (p = 0.017)** was detected: retrospective studies demonstrated a **lower bleeding risk with SAP** (RR 0.61; p = 0.04), while RCTs showed **no benefit** (RR 1.53; p = 0.15). Subgroup analyses by prophylactic use, lesion location, and sensitivity testing revealed **no change to the overall non-significant result**, and TSA confirmed **insufficient evidence**.

Similarly, **perforation risk did not differ** between SAP and controls (RR 0.74; p = 0.16), with subgroup analyses and TSA indicating **inconclusive evidence**. SAP had **no impact on resection outcomes** (En bloc: RR 1.00; R0: RR 1.01; both p > 0.70) or **procedure time** (p > 0.30). Wound healing rates were also **comparable** (p > 0.25), though limited data prevented definitive conclusions.

Conclusions SAP does not significantly reduce delayed bleeding or perforation following ESD and has no impact on resection quality, procedure time, or wound healing. Although retrospective data suggests a possible reduction in bleeding, RCTs do not support this effect, and TSA confirms that current evidence remains insufficient. Larger high-quality randomized trials are needed to clarify the clinical value of SAP in ESD.

eP487 Case series on the use of X-TACK as a closure technique of EMR defects of colorrectal lesions

Authors Saez Fuster J[1], Brotons A[1], Gurbillon A[1], Saorin L[1], Pardo R[1], Roger Ibañez M[2], Sola-Vera Sánchez J[1], García Sepulcre MF[1]

Institutes 1 Hospital General Universitario de Elche, Elche, Spain;
2 Hospital General Universitario de Elda Virgen de la Salud, Elda, Spain

DOI 10.1055/s-0046-1821814

Aims X-TACK is a through-the-scope system for tissue approximation in endoscopic procedures. The aim of this study is to describe the efficacy and safety of this device for EMR defects of colorectal lesions.

Methods Retrospective study involving all the patients who underwent EMR for colorectal lesions and the use of x-tack as a suturing device in our center. The primary outcome was technical success. The secondary outcomes were adverse events rates and the rate of using double closure technique.

Results 13 patients were included, 77 % male and 23 % female, with a mean age of 62 years. The main location where the x-tack was used was the ascending colon, and the mean size of the defect was 40 mm. Regarding to the time spent applying the x-tack, it was 26 minutes. Technical success rate was 100 % and there were no adverse events. In 77 % of the patients, a double closure technique was needed.

Conclusions X-tack system is an effective and safe option for tissue approximation of resection defects. However, it has a steep learning curve and in most cases a double closure technique is needed.

eP488 Extracolonic Manifestations in Familial Adenomatous Polyposis

Author Khsiba A[1]
Institute 1 Hôpital régional Mohamed Taher El Maamouri, Mrezga, Tunisia, Mrezga, Tunisia
DOI 10.1055/s-0046-1821815

Aims Familial adenomatous polyposis (FAP) may be associated to several other pathologies involving multiple organs and can significantly influence the disease prognosis. The objective of this study was to determine the frequency of extracolonic manifestations in patients with FAP.

Methods This retrospective, descriptive study was conducted in the Departments of Gastroenterology and General Surgery at Mohamed Tahar Maamouri University Hospital, including 33 patients managed for FAP over a 16-year period (January 2005 to December 2024).

Results During the study period, 33 patients were included. The mean age was 48.2 years [18–78].A first-degree family history of FAP was present in 45.5 % of patients. Regarding the circumstances of diagnosis, screening colonoscopy led to the diagnosis in 9 patients (28 %).Fifty-five percent of patients presented with colorectal symptoms, including rectal bleeding (13 patients), abdominal pain (11 patients), diarrhea (5 patients), and alternating diarrhea and constipation (3 patients). In three cases, colonoscopy was performed to investigate anemia. One case was diagnosed after examination of the operative specimen from an emergency surgery for a perforated right-colon cancer presenting with peritonitis.

Regarding the assessment of extracolonic manifestations:Upper gastrointestinal endoscopy was performed in 93.3 % of patients and revealed, in 9 % of them, the presence of fundic gland polyps and subcentimetric tubular adenomas of the antrum.

Duodenoscopy was performed in 32 patients and revealed duodenal polyps in 5 cases. In three cases, two polyps smaller than 5 mm were observed, corresponding to low-grade tubular adenomas on histology, with a Spigelman score ≤ 4.A sessile 8-mm polyp without dysplasia was found in one patient.The fifth case involved a 20-mm pedunculated polyp with low-grade dysplasia and a Spigelman score of 7 (stage III). Resection was performed surgically via transverse duodenotomy during the same operative session as the total proctocolectomy. Histological examination revealed a tubular adenoma with low-grade intraepithelial neoplasia.

Concerning abdominal imaging, abdominal ultrasound was performed in 18 patients and CT scan in 23 patients. A single case of intra-abdominal desmoid tumor was identified. Abdominal imaging was unremarkable in 96.96 % of cases. No pancreatic, gallbladder, or biliary tract tumors were noted.

Ophthalmologic examination including fundoscopy was performed in 31 patients and revealed congenital hypertrophy of the retinal pigment epithelium (CHRPE) in 4 patients, bilateral in two cases and unilateral in the remaining two.

Thyroid ultrasound, performed in 91 % of patients, revealed abnormalities in 7 patients (24 %):– A right-lobe nodule suggestive of papillary thyroid carcinoma, confirmed histologically.– Three nodules in another patient, classified as EU-TI-RADS 4, with indeterminate cytologic atypia (Bethesda class III), managed with total thyroidectomy.– Other abnormalities consisted of nodules classified as TIRADS 2 and 3, requiring follow-up.

Long-bone radiography was performed in 76 % of patients and showed an osteoma of the left ischiopubic ramus in one case. Skull radiography, performed in 15 patients, revealed osteomas in six cases (40 %): cranial osteomas in three patients, two frontal sinus osteomas in one patient, and one orbital rim osteoma in another.

Dermatologic examination was performed in 30 patients and demonstrated sebaceous cysts on the back in two patients (6 %).

In the absence of neurologic symptoms suggestive of brain tumors, no cerebral CT scan was performed.

Conclusions FAP is a rare and complex disorder. Diagnosis relies on family history assessment, colonoscopy, and confirmation by molecular testing. Several extracolonic manifestations may be associated with FAP. Gastroduodenal lesions and desmoid tumors should be investigated as a priority, as they significantly impact prognosis.

eP489 Comparative Evaluation of Swin Transformer V2 for MES Classification, Segment Localization, and Inflamed Area-annotation in Ulcerative Colitis

Authors Zhao X[1], Feng W[1], Sun J[1, 2]
Institutes 1 Wuxi People's Hospital, Wu Xi Shi, China; 2 Corresponding author, Wuxi, China
DOI 10.1055/s-0046-1821816

Aims Multimodal large language models (MLLMs) demonstrate potential in assessing the mayo endoscopic score (MES) for ulcerative colitis (UC). However, they primarily focus on single tasks and lack the capability for integrated analysis. To address these limitations, we developed a multitask system based on the Swin Transformer V2 architecture, which offers improved accuracy in MRS grading, segment-located capabilities, and inflamed intestinal mucosa area annotation features.

Methods MES classification and colonic segment localization models were trained using the LIMUC datasets (11276 images) and Real-Colon datasets (622 images) respectively, with ten-fold cross-validation based on patient ID. An external validation set (402 images) from wuxi people's hospital was independently annotated by three experienced experts. The MES scores with a unanimous consensus were included as the reference standard (283 images). Trained with AdamW, cosine annealing learning rate, and standard data augmentation, the image net-pretrained Swin Transformer V2 used weighted cross-entropy for MES, and cross-entropy for segment localization. In addition, four contemporary MLLMs (GPT-4o, Gemini-2.5 Pro, Grok-4, Qwen-VL-Max), which demonstrated potential, were incorporated for comparative analysis. Inflamed intestinal mucosa area-annotated ability was shown as a real-time Open CV-based prototype enabled frame-by-frame colonoscopy video prediction, and was evaluated via occlusion-based annotation diagram by the result of three experienced experts on external dataset.

Results The Swin Transformer V2 model achieved better performance on public datasets (accuracy = 0.767; F1 = 0.692), and the best accuracy in four contemporary MLLMs was 0.443 for GPT-4o. The Swin Transformer V2 model also retained good performance on external dataset (accuracy = 0.654; F1 = 0.604), and the best accuracy in four contemporary MLLMs was 0.594 for GPT-4o. For segment localization on external dataset, the Swin Transformer V2 model obtained an accuracy of 0.526 and an F1 score of 0.508, which was better than the best contemporary MLLMs GPT-4o (accuracy = 0.220; F1 = 0.264). It shown obvious consistency between model annotated inflamed intestinal mucosa area and experts-annotated area.

Conclusions The Swin Transformer V2-based multitask system outperformed general-purpose MLMMs in MES classification, segment localization, and inflamed intestinal mucosa area-annotation. This transparent model demonstrates strong potential to enhance UC endoscopic assessment and support clinicians across experience levels.

eP490 Endoscopic Papillectomy of a Traditional Serrated Adenoma of the Ampulla of Vater: A Case Report

Authors Tudor C[1], Busuioc B[1], Mocanu C[2], Brezean I[1], Florea A[3], Paun C[1]
Institutes 1 Clinical Hospital Dr. Ion Cantacuzino, București, Romania; 2 Clinical Hospital Dr. Ion Cantacuzino, buchares, Romania; 3 Institutul Național "Victor Babeș", București, Romania
DOI 10.1055/s-0046-1821817

Background & Aims Traditional serrated adenomas (TSAs) are a distinct subtype of gastrointestinal polyps with serrated glandular architecture and com-

plex histologic features, predominantly reported in the distal colorectum. TSAs of the duodenum, and particularly the ampulla of Vater, are extremely rare, with fewer than ~40 cases documented. While colorectal TSAs are common, upper gastrointestinal TSAs account for < 1 % of small bowel polyps. Despite their scarcity, ampullary TSAs carry significant malignant potential, with up to 28.6 % associated with invasive carcinoma. Histologically, they show serrated architecture and ectopic crypt foci, sometimes with elongated nuclei and eosinophilic cytoplasm. Due to limited cases, evidence on optimal management and outcomes is scarce. We report a periampullary TSA with high-grade dysplasia successfully treated with endoscopic papillectomy.

Methods A 64-year-old woman with obesity and gastroesophageal reflux disease underwent upper endoscopy in an external center, revealing a 2-cm ampullary lesion; biopsies showed adenoma with low-grade dysplasia (LGD). Contrast-enhanced CT confirmed a 2-cm periampullary lesion with mild billiary dilatation, without biliary duct involvement or deep invasion. We repeated endoscopy, revealing an enlarged papilla of Vater, polypoid with a villous surface, suggestive of papillary adenoma. Given the lesion was well-circumscribed,without invasive signs, and showed no alarming characteristics, en bloc endoscopic papillectomy was performed with prophylactic biliary and pancreatic stenting. Histopathology and immunohistochemistry were performed on the resected specimen. Follow-up endoscopies were scheduled at 1, 3, and 12 months.

Results The procedure was completed without complications, and the patient was discharged after 48 hours. Histopathology confirmed a traditional serrated adenoma with high-grade dysplasia and clear margins. Follow-up endoscopies demonstrated complete mucosal healing and no recurrence at 1 year.

Conclusion Ampullary TSAs are exceptionally rare lesions with significant malignant potential. This case demonstrates that endoscopic papillectomy is a safe and effective organ-preserving treatment for well-circumscribed lesions without ductal or deep invasion. High-grade dysplasia underscores the importance of structured long-term endoscopic surveillance. Reporting such cases enhances understanding of periampullary TSAs and supports evidence-based endoscopic management in carefully selected patients.

eP491 Real-World Endoscopic Outcomes of Risankizumab in Crohn's Disease: A Systematic Review and Meta-analysis

Authors Bota AD[1], Saftoiu A[2], Arstiom K[3], Tieranu CG[4]
Institutes **1** Elias Emergency University Hospital, București, Romania; **2** Elias Emergency University Hospital, Bucharest, Romania; **3** Uniklinik Balgrist, Zürich, Switzerland; **4** Spitalul Universitar de Urgență Elias, București, Romania
DOI 10.1055/s-0046-1821818

Aims Crohn's disease is characterized by deep, transmural inflammation, making structural healing an essential therapeutic objective. According to STRIDE-II treatment targets for Crohn's disease, achieving objective measures of improvement—including endoscopic response as a key indicator of transmural healing—is essential for long-term disease control. Risankizumab (RISA), an interleukin-23 p19 inhibitor, demonstrated significant endoscopic benefits in clinical trials; however, its real-world performance regarding endoscopic improvement requires further evaluation. The aim of this study is to systematically assess real-world endoscopic outcomes associated with RISA therapy in patients with moderately to severely active Crohn's disease.

Methods A systematic review and meta-analysis of real-world studies reporting endoscopic outcomes following RISA treatment was performed. Pooled rates of endoscopic response and endoscopic remission were calculated using a random-effects model with 95 % confidence intervals.

Results Across included real-world studies, the pooled endoscopic response rate was 69 % at 24 weeks and 58 % at 52 weeks. Endoscopic remission at 52 weeks was achieved in 52 % of patients.

Conclusions Real-world evidence demonstrates that RISA produces substantial and durable endoscopic improvement, supporting its role as a long-term therapeutic option that contributes meaningfully to the pursuit of transmural healing in Crohn's disease.

eP492 Results of screening aimed at detecting Helicobacter pylori infection and precancerous stomach diseases

Authors Riabtseva V[1], Pirogov S[1], Sergeeva N[1], Alentov I[1]
Institute **1** Moskovskiy Nauchno-Issledovatel'skiy Onkologicheskiy Institut Imeni P. A. Gertsena, Moskva, Russia
DOI 10.1055/s-0046-1821819

Aims To evaluate, using the "GastroPanel", the frequency of detection of H. pylori infection and associated gastricdiseases among doctors and medical staff of the National Medical Research Radiological Centre of the Ministryof Health of the Russian Federation, Moscow.

Methods Employees of three branches of the National Medical Research Radiological Centre (n = 434, average age – 48.5 ± 0.6 years) were examined using laboratory tests "GastroPanel" (Biohit Oyj, Finland). The test results make it possible to identify infection of the stomach with H. pylori, hypo- and hyperacid conditions, as well as atrophic gastritis of the antrum and body of the stomach, as its precancerous conditions. Upper endoscopy for suspected atrophic gastritis was performed with an Olympus GIF-HQ190 video endoscope (Japan) in a narrow-band imaging with close focus (NBI Dual Focus).
an) in a narrow-spectrum mode with close focus (NBI Dual Focus)

Results The absence of pathological signs detected by "GastroPanel" was established in 23.3 % of cases; hyperacid state – in 18.4 %, and hypoacid state – in 5.2 %. These disorders are classified as functional. Consequently, the conditional norm as a whole was identified in 46.9 % of observations. An increased level of antibodies to H. pylori was found in 43.3 % of those examined. Atrophic gastritis in the body of the stomach according to the results of the GastroPanel was detected in 4.8 % of cases (median age – 59 years), and in the antrum (or increased secretion of hydrochloric acid) – also in 4.8 % of cases (median age – 52 years). Within two months after laboratory diagnostics, upper endoscopy was performed by 10 out of 15 patients examined at the P.A. Hertsen Moscow Oncology Research Institute – branch of the National Medical Research Radiological Centre of the Ministryof Health of the Russian Federation, in whom, based on the results of the "GastroPanel", the presence of atrophic gastritis in the antrum (or increased secretion of hydrochloric acid) is suspected. In 6 out of 10 cases, atrophic gastritis of the antrum was confirmed (in 2 of them, the atrophy extended to the body of the stomach and was assessed as severe). Of the 11 people with the GastroPanel conclusion "Atrophic gastritis of the body of the stomach", an endoscopic examination was carried out in 7 people, and in all these cases the diagnosis was confirmed, and in 2 of them the conclusion was made of severe atrophic pangastritis.

Conclusions "GastroPanel" confirmed its high significance in identifying H. pylori infection and precancerous atrophic changes in the gastric mucosa. Considering the occupational risks of infection among medical workers, we consider it advisable to conduct such screening without selecting an asymptomatic population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP493 Age is just a number... but is it in ERCP?

Authors Moutzoukis M[1], Theopistos V[1], Tzampouras N[1], Soukovelos A[1], Christodoulou D[1]
Institute **1** Greece, Ioannina, Greece, Neochoropoulo, University Hospital of Ioannina, Ioannina, Greece
DOI 10.1055/s-0046-1821820

Endoscopy 2026; 58: S1–S1041

Aims Choledocholithiasis is the most common indication for endoscopic retrograde cholangiopancreatography (ERCP), particularly in older adults, who often present with multiple comorbidities and may carry a higher risk for procedural complications. As the aging population grows, clinicians frequently face the question of whether ERCP remains equally effective and safe in elderly patients compared with younger individuals. The purpose of the present study was to evaluate outcomes of ERCP in these age groups, focusing on therapeutic success, technical difficulty, and the incidence of intra- and postoperative events. By comparing patients aged < 75 years with those ≥ 75 years, the study sought to provide updated real-world data from a high-volume Greek university hospital.

Methods This case–control study was conducted at the University General Hospital of Ioannina and included ERCP procedures performed between September 2023 and September 2025. A total of 804 patients were analyzed. Based on international age-stratification definitions from the World Health Organization (WHO), participants were divided into two predefined groups: patients < 75 years (n = 431) and patients ≥ 75 years (n = 373). For each patient, demographic information, clinical presentation, endoscopic interventions performed during ERCP, and recorded complications were obtained retrospectively from institutional records. Particular attention was given to stone removal success, cannulation difficulty, duration of the procedure, and the frequency of adverse events. A predefined subgroup analysis was used to examine outcomes specifically in elderly individuals with significant comorbidities, allowing a more detailed assessment of risk and therapeutic benefit in frail patients.

Results When comparing patients ≥ 75 years with those < 75 years, a statistically significant difference was found regarding the rate of complete and partial stone extraction ($x2 = 9.503$, $p = 0.002$). This suggests that although ERCP remains effective in both cohorts, stone removal success patterns differ slightly across age groups.The degree of cannulation difficulty, however, did not differ significantly between the two groups ($x2 = 1.777$, $p = 0.411$). Older patients did not require more attempts or advanced techniques for ductal access. Similarly, procedure duration for ERCP was comparable between younger and older individuals ($b = -0.045$, $p = 0.912$), indicating that advanced age alone did not prolong endoscopic manipulation or therapeutic steps. Regarding safety, elderly patients were not more likely to experience intraoperative or postoperative complications compared with younger patients ($x2 = 0.080$, $p = 0.777$). The verall rate of adverse events—including pancreatitis, bleeding, cholangitis, or cardiopulmonary issues—remained consistent across age categories.In the predefined subgroup of older adults with multiple comorbidities, ERCP ontinued to demonstrate high therapeutic efficacy. The procedure was also shown to have an acceptable safety profile even in this more fragile subpopulation, supporting its use as a frontline intervention when indicated.

Conclusions The findings of this study indicate that ERCP can be performed with a high degree of effectiveness in elderly patients aged ≥ 75 years, including those with complex medical histories. Although clinicians often hesitate to refer older adults for invasive procedures, the present data show that both technical success and complication rates are comparable to those observed in younger patients.ERCP should be considered a viable and generally safe option for elderly patients with choledocholithiasis, provided that potential intraoperative and postoperative risks are considered during clinical decision-making.

eP494 Characteristics, complications, and methods of foreign bodies removal

Authors Rai F[1], Cherkaoui M[1], Mechhor S[1], Mghyly F[1], Charkaoui Malki O[1], Benzzoubeir N[1], Errabih I[2], El Bacha H[2]

Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821821

Aims The ingestion or inhalation of foreign bodies is a common emergency in gastroenterology. They represent a major clinical challenge. Although often benign, they can lead to serious complications if not removed quickly and appropriately. Endoscopy, as a non-invasive and relatively safe method, has become the preferred tool for removing these foreign bodies. However, managing these situations requires a good understanding of the characteristics of the objects, the associated risks, and the extraction techniques available.

The purpose of this article is to outline the various types of foreign bodies encountered in endoscopy, the potential complications, and the current methods used for their extraction.

Methods This is a retrospective descriptive study conducted at the Hepatology-Gastroenterology Department "Medicine B" over a period of 36 months (January 2022 to January 2025). All patients who were hospitalized for voluntary or involuntary ingestion of foreign bodies are included. The data collected included age, gender, medical history, type of foreign body, its location, and the method used to extract it.

Results During the study period, 25 patients presented to our emergency department with foreign bodies. The median age was 47 years (range 20-74). The sex ratio was 1.27 (11 women to 14 men). The medical histories noted were hypertension in 3 patients (12 %), chronic smoking in 4 patients (16 %), diabetes in 2 patients (8 %), and a history of caustic ingestion in only 1 patient (4 %). The average time taken to treat patients was 6 hours.

Endoscopy revealed 15 food impactions (60 %) (pieces of meat/chicken with or without bones or cartilage/fish bones), 3 metal keys (12 %), four sharp objects (16 %) (pieces of glass, needles), one nail clipper (4 %), one lighter (4 %), and one plastic denture (4 %). As for the location of these various foreign bodies, 10 (40 %) were between 18 and 25 cm AD, 2 (8 %) were more than 30 cm AD, 7 (28 %) were in the stomach (at the cardia, greater curvature, or fundus), and 6 (24 %) were not found during FOGD.

The different extraction methods used were: 6 (24 %) pushback to the stomach, 4 (16 %) extraction with a polyp snare, 5 (20 %) extraction with foreign body forceps, 2 (8 %) extraction with a basket snare, and 2 (8 %) extraction with rat tooth forceps.

Among the population studied, two cases of failure were reported: the first was treated at a later stage after injection of 60 mg of IV corticosteroids; the second required surgical intervention.

Conclusions Endoscopic removal of foreign bodies is a common but delicate procedure. Successful removal depends on the location, nature, and size of the object, as well as the speed of treatment. Possible complications highlight the importance of rapid and appropriate management to minimize risks.

Endoscopy remains an essential tool in the management of foreign bodies, allowing for rapid and effective intervention while minimizing the risks inherent in complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP495 Quantifying the Bias of Visual Polyp Size Estimation in Colonoscopy: A Prospective Comparison Against Objective Measurement Standards

Authors Raymond J[1, 2], Oleksiw M[1, 2], Michal V[1], Djinbachian R[2, 1], Battat R[1, 2], Daoud DC[2], Bouchard S[2], Bouin M[2], Liu Chen Kiow J[2], Panzini B[2], Cristea E[2, 1], Aleksieva P[1, 2], Zineddine Mahdadi M[2, 1], von Renteln D[2, 1]

Institutes **1** Division of Gastroenterology, Montreal University Hospital Research Center (CRCHUM), Montréal, Canada; **2** Division of Gastroenterology, Montreal University Hospital Center (CHUM), Montréal, Canada

DOI 10.1055/s-0046-1821822

Aims Visual estimation of polyp size is imprecise yet still predominantly determines surveillance intervals, resection techniques, and risk stratification. We therefore aimed to quantify its systematic bias against objective measurement standards.

Methods This prospective cohort study (NCT06822816) at the *Montreal University Hospital Center* included 574 polyps from 289 consecutive patients (mean age 66.3 years, 47.1 % female). Thirteen endoscopists performed visual size

estimations of polyps. Each polyp was also measured using one or more objective methods, and a single objective size was retained as the reference standard according to the order: (1) on-site microscopy (DinoLite models AF4515ZTL and AM8917MZTL) of fresh polypectomy specimens before formalin fixation (169 polyps, 29.4 %), (2) virtual scale endoscopy (VSE, *Scale-Eye*, Fujifilm, Tokyo, Japan) (351 polyps, 61.1 %), or virtual tape measurement (*AccuMeasure*, VTM Technologies, Haifa, Israel) (54 polyps, 9.4 %). The primary outcome was measurement bias, defined as the mean difference between visual and objective measurements. Secondary outcomes included the impact of morphology, lesion size, and histology.

Results Visual estimation demonstrated a significant systematic overestimation with a mean bias of 0.36 mm (95 % CI: 0.20–0.52, P < 0.001). Bias varied by reference method: 0.82 mm versus on-site microscopy (95 % CI: 0.33–1.31, P = 0.003), 0.10 mm versus virtual scale endoscopy (95 % CI: 0.01–0.19, P = 0.115), and 0.60 mm versus virtual tape measurement (95 % CI: 0.08–1.12, P = 0.074). Overestimation was most pronounced for diminutive polyps (0.37 mm, P < 0.001), for polypoid morphology (0.41 mm, P < 0.001), and for neoplastic histology (0.47 mm, P = 0.002).

Conclusions Visual estimation systematically overestimates colorectal polyp size. Although overestimation appears modest when all objective methods are pooled, it may be attenuated by combining methods of varying accuracy. Indeed, when compared specifically with the most accurate method—on-site microscopy—the systematic visual overestimation is larger. This bias also varied by morphology, among other lesion characteristics, and was more pronounced for polypoid lesions. This consistent bias may influence clinical decisions, including risk stratification, surveillance intervals, and appropriate resection techniques, particularly for polyps near critical size thresholds. Routine implementation of objective measurement tools should be considered.

Conflicts of Interest Daniel von Renteln received speaker honoraria or consultant fees from ERBE Elektromedizin GmbH, Boston Scientific Inc., and Pendopharm. eP496 ERCP outcomes from a Greek University Hospital

Authors Moutzoukis M[1], Theopistos V[1], Baltagiannis G[1], Tzampouras N[1], Christodoulou D[1]

Institute 1 Greece, Ioannina, Greece, Neochoropoulo, University Hospital of Ioannina, Ioannina, Greece

DOI 10.1055/s-0046-1821823

Aims The purpose of this study was to review the indications, technical success, complications, and overall outcomes of ERCP procedures performed at our center.

Methods A total of 864 patients were initially considered for inclusion, of whom 58 were excluded because ERCP could not be completed (technical inability, patient instability, or early termination). Ultimately, 806 patients who underwent ERCP between January 2024 and September 2025 were included in the analysis.

Results The age range of the 806 patients was 18–100 years, with a mean age of 71.26 years. Among women, the mean age was 71.42 years (range 18–97), while among men it was 71.99 years (range 20–100). The cohort consisted of 390 women (48.4 %) and 416 men (51.6 %).

ERCP indications included: confirmed or suspected common bile duct stones (CBDS), biliary strictures, sepsis/cholangitis, pancreatic mass with jaundice, scheduled follow-up after previous ERCP, cholangiocarcinoma, acute pancreatitis, suspected postoperative bile leak, stent dysfunction, liver mass with jaundice, ampullary mass with jaundice, sclerosing cholangitis, and papillary narrowing suggestive of sphincteritis. Cannulation of the common bile duct (CBD) was successful in 799 patients (99.13 %), while pancreatic duct cannulation was achieved in 127 patients (15.75 %). Both ducts were cannulated in 122 patients (15.13 %); two patients could not be cannulated. Among the 127 pancreatic duct cannulations, 88 (69.29 %) were successful on the first attempt, 27 (21.26 %) on the second attempt, and 12 (9.45 %) required more than three attempts. Regarding cannulation techniques, 714 patients (88.8 %) underwent wire-guided cannulation, 26 (3.2 %) underwent pre-cut access, and 64 (8 %) underwent transpancreatic sphincterotomy. Prior sphincterotomy was present in 246 patients (30.6 %), while conventional sphincterotomy was performed in 468 (58.2 %), transpancreatic sphincterotomy in 64 (8 %), and pre-cut in 26 (3.2 %).Among the 799 patients with successful biliary cannulation, 508 (63.18 %) had CBD stones, 52 (6.46 %) had biliary sludge, 232 (28.85 %) had ductal dilation, 210 (26.11 %) had strictures, 11 (1.37 %) showed bile leakage, and 7 (8.70 %) had purulent bile. In 36 cases (4.47 %), no CBD pathology was detected. Additional findings included one patient with sphincter of Oddi dysfunction (ODS), one with stent migration, one with a cholecystoenteric fistula. Benign strictures were identified as follows: 15 (7.14 %) in the common hepatic duct, 37 (17.61 %) in the CBD, 12 (5.71 %) at the ampulla, 4 (1.9 %) at the hepatic hilum, and one in the left hepatic duct. Malignant strictures included: 19 (9.04 %) in the common hepatic duct, 39 (18.57 %) in the CBD, 7 (3.33 %) at the ampulla, 11 (5.2 %) at the hilum, two in the left hepatic duct, and one in the right hepatic duct. Ductal dilation was documented in 80 patients (34.48 %) in the common hepatic duct, 186 (80.17 %) in the CBD, 54 (23.27 %) at the hilum, 52 (22.4 %) in the left hepatic duct, 49 (21.12 %) in the right duct, and 2 at the ampulla. Patients with CBD stones underwent stone extraction and/or placement of a plastic biliary stent. Stents were also placed in patients with pancreatic head tumors, CBD tumors, bile leaks, and CBD strictures. Endoscopic biopsy was performed in all patients with suspected ampullary tumors. Procedure duration ranged from 15 to 48 minutes. The overall complication rate was 7.9 %. After ERCP, 14 patients (1.7 %) developed severe cholangitis and 19 (2.4 %) developed severe acute pancreatitis. Bleeding requiring endoscopic therapy occurred in 6 patients (0.7 %), while 7 patients (0.8 %) had minor bleeding (hemoglobin drop < 3 g/dL without transfusion). Moderate bleeding requiring transfusion (≤ 4 units) occurred in 3 patients (0.3 %). Perforation occurred in 2 patients (0.9 %).

Conclusions ERCP is a complex endoscopic intervention requiring specialized expertise and equipment. Optimizing patient selection and identifying risk factors are essential for minimizing complications. Unnecessary diagnostic ERCP should be avoided, especially in patients with low likelihood of biliary stones or strictures, normal bilirubin, or absence of clinical signs of biliary disease. The use of non-invasive imaging modalities whenever possible can significantly reduce ERCP-related adverse events.

eP497 Contribution of echoendoscopy to the diagnosis of acute pancreatitis

Authors Rai F[1], Cherkaoui M[1], Mechhor S[1], Mghyly F[1], Charkaoui Malki O[1], Benzzoubeir N[1], El Bacha H[2], Errabih I[2]

Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821824

Aims Acute pancreatitis is an inflammatory condition with multiple causes, which can be classified as biliary, metabolic, toxic, infectious, or traumatic. Its diagnosis is based on a combination of clinical, biological, and imaging data, aimed at determining its etiology and guiding treatment. In this context, endoscopic ultrasound offers superior resolution compared to other imaging techniques and allows for detailed exploration of pancreatic and biliary structures.

The aim of this study is to highlight the role and contributions of endoscopic ultrasound in the diagnosis of acute pancreatitis.

Methods This is a retrospective descriptive study conducted in the endoscopy unit of the Hepatology and Gastroenterology Department over a period of 43

months (January 2022 to August 2025). It includes all patients who were hospitalized for AP and underwent EUS.
The data collected include age, gender, medical history, stage of pancreatitis on CT scan, and etiologies revealed by EUS
The data collected included age, sex, medical history, stage of pancreatitis on CT scan, and etiologies revealed by EUS.
Results During the study period, 124 patients were hospitalized in our department for
acute pancreatitis. In 24 patients (19 %), the initial etiological assessment did not reveal any obvious cause.
The average age of this population was 49.4 years (19-73). The sex ratio was 1.3 (13 women to 10 men). The medical history noted was diabetes in 5 patients (4 %), cholecystectomy in 2 patients (1.7 %), and Caroli's disease in one patient (0.8 %).
Four patients (3.2 %) had recurrent pancreatitis. The stage of AP was stage A in 3 cases (13.04 %), stage B in 7 cases (30.43 %), stage C in 5 cases (21.7 %), and stage E in 8 cases (34.8 %).
Echoendoscopy revealed a lithiasic origin in 16 cases (12.9 %), autoimmune pancreatitis in 3 cases (2.4 %), and a mass in the head of the pancreas in 3 patients (2.4 %), with histology confirming pancreatic adenocarcinoma in one patient and autoimmune pancreatitis in its pseudotumoral form in the other patient, pancreas divisum in one patient (0.8 %), and TIPMP in one patient (0.8 %). In 4
patients (3.22 %), echoendoscopy revealed no abnormalities.
Among the four patients who presented with recurrent pancreatitis, endoscopic ultrasound revealed a heterogeneous appearance with diffuse calcifications in two of them, thus revealing
chronic calcifying pancreatitis.
Conclusions In light of our study, echoendoscopy has established itself as an essential diagnostic modality in the evaluation of acute pancreatitis, particularly for identifying underlying causes such as microlithiasis or unrecognized biliary abnormalities, diagnosing chronic pancreatitis and autoimmune AP, determining the benign or malignant nature of pancreatic masses through histology, and detecting pancreatic malformations.
benign or malignant nature of pancreatic masses, and to detect pancreatic malformations.
Its high resolution and ability to combine morphological exploration and interventional procedures make it a tool of choice in an integrated diagnostic and therapeutic approach. However, its use must be carefully considered and reserved for appropriate indications, as part of an optimized multidisciplinary management approach.

DOI 10.1055/s-0046-1821825

Aims Lymphocytic esophagitis (LyE) is the finding of a dense lymphocytic infiltrate in the esophageal epithelium, along with spongiosis, in the absence of granulocytes or other causes of esophageal inflammation such as eosinophilic esophagitis or gastroesophageal reflux disease (GERD). It is a novel disease, first described in 2006, that can cause dysphagia and other esophageal dysfunction symptoms. However, its clinical manifestations, endoscopic appearance and risk factors are still in debate, with some authors considering it as a phenotype of esophageal inflammation rather than an independent disease. While Crohn's Disease is a known risk factor in children, risk factors in adults, as well as the disease, are yet to be determined [1–3].
Methods We collectively analysed esophageal biopsy reports and endoscopy reports from two referral centers in Spain from 2000 to 2025. Reports compatible with lymphocytic esophagitis or esophageal intraepithelial lymphocytosis were carefully analyzed with the patient's clinical history to determine a proper diagnosis of lymphocytic esophagitis. Patients with more than 20 lymphocytes per high power field (LxHPF) in esophageal biopsies were considered as potential patients with LyE. Afterwards, if more than 15 eosinophils per high power field (EoxHPF) or other entities such as candidiasic esophagitis were found, such patients were excluded. As such, only patients with more than 20 LxHPF, less than 15 EoxHPF and no evidence of other esophageal disease were considered as patients with LyE and their clinical records were studied. Regarding endoscopic appearance, we considered an EREFS-like system, describing findings similar to eosinophilic esophagitis, although there was no score calculated on these patients.
Treatment response was considered when, after an onset of treatment, less than 20 LxHPF were found. If no LxHPF were found, it was considered as a complete response.
Results A total of 7 patients were included from both centers. Women were more frequent than men on a 2.5 ratio with a mean age of 62.43 years. 85 % of patients had dysphagia as a symptom, with 28.5 % of them presenting with food bolus impaction. Chest pain was also reported on 28.5 % of patients. Regarding comorbidities, none of them were recurring in our patients. Only one of them presented autoimmune comorbidities with a case of sclerosing lupus erythematosus (SLE).
Regarding endoscopic appearance, edema (57.14 %) and rings (57.14 %) were the most common findings. We have to point out the appearance of panesophagic rings throughout the whole esophagus in these patients, which leads to a macroscopic appearance of trachealization (Figure 1). In our patients, panesophagic affection was more common, reported in 71.43 % of cases.
Regarding treatment and response, proton pump inhibitors (PPIs) were the first treatment on all patients, although dosage and PPI of choice differ. Oral budesonide was used in 1 patient but candidiasic esophagitis developed as an adverse effect. While response was found in 2 patients, in 3 patients it was not studied with further endoscopic studies, pointing out a need for standardised protocols in such patients. All these results are summarized in Table 1.
Conclusions Lymphocytic esophagitis appears to be more frequent in women older than 60 years old. While no comorbidities are associated with this disease, the presence of dysphagia and the endoscopic findings of panesophagic rings should make us consider this disease. While PPIs are an effective treatment, dosage and treatment of choice are still not standardized, as well as follow-up via biopsy.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP499 Assessment of the Accuracy of Colonic Polyp Classification Scores by Endoscopy (PARIS, NICE, CONNECT) and Their Correlations With Histopathological Findings

Authors Oubella H[1], Mechhor S[1], Cherkaoui Malki M[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], El Bacha H[2], Errabih I[2]
Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821826

Aims Colonic polyps are common lesions of the lower digestive tract and often represent precursors of colorectal adenocarcinomas. Their accurate detection and characterization are essential for appropriate management and for optimizing screening and prevention strategies.

Endoscopic classification systems such as the Paris, NICE (Narrow-band Imaging International Colorectal Endoscopic), and CONNECT (Classification for Optical Diagnosis of Colorectal Neoplasia) classifications were developed to standardize the description of polyps and predict their histological nature.

This study aims to assess the accuracy of these classifications in characterizing colonic polyps and to evaluate their correlations with histopathological results in order to determine their reliability and clinical relevance.

Methods This is a retrospective descriptive study conducted between 2018 and 2025 within our department. All adult patients (aged over 18 years) who underwent complete ileocolonoscopy with polypectomy and for whom the Paris, NICE, and CONNECT classifications were used to describe the polyps were included. Histopathological data corresponding to each resected polyp were collected.

Results A total of 134 polypectomies were recorded, including 129 polyps classified according to the Paris classification, 4 according to the CONNECT classification, and 1 according to the NICE classification. The mean age of patients was 61.7 years [26–85], with a clear male predominance (sex ratio 1.9). Polyps were discovered during endoscopy performed because of rectal bleeding (40 %) or a history of polypectomy (19 %). The remaining polyps were incidentally found during colonoscopy performed for chronic abdominal pain (9.5 %), chronic constipation (8 %), follow-up of inflammatory bowel disease (7.5 %), chronic diarrhea (6.5 %), investigation of anemia (4.5 %), personal history of surgically treated familial adenomatous polyposis (2 %), family history of FAP (1 %), family history of colorectal cancer (1 %), and radiation proctitis (1 %). Most resected polyps were located in the colon (83 %), predominantly in the left colon (68 %), and 17 % were found in the ileocecal region.

Regarding the Paris classification, 95 % of polyps were classified as 0-Is and 5 % as 0-Ip. This classification is based solely on macroscopic features and does not directly predict the histological nature of the lesions. Histopathological analysis revealed that 56 % were tubular adenomas with low-grade dysplasia, 17 % sessile serrated adenomas with low-grade dysplasia, 10 % tubulovillous adenomas with low-grade dysplasia, 9 % inflammatory pseudopolyps, 5 % hyperplastic polyps, 1 % glandulocystic polyps, 1 % intramucosal adenocarcinoma arising in a tubular adenoma with high-grade dysplasia, and 1 % fibroblastic polyps (Vanek's tumor). For the CONNECT classification, four polyps were identified: Two CONNECT IIA polyps corresponded to Paris 0-Is polyps: one was a tubular adenoma with low-grade dysplasia and the other an inflammatory pseudopolyp on histology. One CONNECT IIA polyp corresponded to a Paris 0-Ip polyp, histologically confirmed as a tubular adenoma with low-grade dysplasia. One CONNECT IH polyp corresponded to a Paris 0-Ip polyp, confirmed as an inflammatory pseudopolyp. For the NICE classification, a single polyp was identified: A NICE 1 polyp corresponded to a Paris 0-Is polyp, confirmed histologically as a hyperplastic polyp.

Conclusions This study shows that the Paris classification, being solely macroscopic, is the most frequently used system in our setting for describing colonic polyps. However, it does not allow prediction of the histological nature of lesions, unlike the NICE and CONNECT classifications, which show generally good correlation with histology. Nevertheless, the limited use of the NICE and CONNECT classifications in our study restricts the interpretation of these findings. More systematic use of these scoring systems could improve diagnostic accuracy and the effectiveness of screening strategies.

eP500 Endoscopic Management Of Gastric Variceal Bleeding With Cyanoacrylate Glue: Single-Center Outcomes

Authors Thanos C[1], Georgakopoulou N[1], Ntailianas D[1], Piskopou D[1], Georgiou E[1], Triantafyllou M[1], Tsitsigiannis K[1], Kalakos N[1], Argyropoulos T[1], Varmpompitis I[1], Michalopoulos G[1], Mpraimakis A[1], Kotzagiannidou E[1], Striki A[1], Karoumpalis I[1]
Institute 1 General Hospital of Athens "G. Gennimatas", Athina, Greece
DOI 10.1055/s-0046-1821827

Aims Bleeding from gastric varices is a life-threatening complication of portal hypertension, carrying high morbidity and mortality. Endoscopic injection of cyanoacrylate glue is a first-line therapy for isolated gastric varices (IGV1) and gastroesophageal varices (GOV), achieving immediate hemostasis in over 90 % of cases in prior studies. We report our 8-year experience from a tertiary hospital in Athens, evaluating the efficacy, safety, and survival outcomes of this treatment.

Methods We retrospectively analyzed all patients treated with N-butyl cyanoacrylate (Glubran) injection for acute IGV1 or GOV bleeding from 2014 to 2022 in our endoscopy unit. Twenty-six patients (n = 26) were identified (77 % male; median age 57 years, range 14–86). Underlying etiologies of portal hypertension included cirrhosis (alcoholic or viral), portal vein thrombosis, myeloproliferative disorders, and others. Data on hemostasis success, complications, and survival to hospital discharge were collected. Hemostasis success was defined as control of bleeding without need for additional rescue therapy. Safety assessment focused on procedure-related adverse events. Survival was evaluated as survival to discharge and early outcomes [1–5].

Results A total of 26 endoscopic glue injection sessions were performed for active gastric variceal hemorrhage (85 % IGV1, 15 % GOV). Acute bleeding control was achieved in 24 patients (92.3 %). Two patients (7.7 %) had refractory hemorrhage despite glue injection, requiring emergency intubation and intensive care. No patient required a second endoscopic session, and no procedure-related complications (such as glue embolization or distant thrombosis) were observed. Twenty-one patients (80.8 % of the cohort) survived the acute episode and were discharged alive, yielding an in-hospital mortality of 0 % among cases with known outcomes. Three patients (11.5 %) had indeterminate immediate outcomes due to transfer or loss to follow-up, but none of these had documented failure of hemostasis at the time of endoscopy. No early rebleeding was noted in the successfully treated patients during their hospital stay. Over the 8-year period, the annual case load ranged from 1 to 6 cases, with a noticeable dip in 2020–2021 (COVID19 pandemic years). There was no clear temporal trend in treatment success or complication rates – outcomes remained consistently high across the study period regardless of year. Notably, the efficacy of glue injection was comparable in both isolated gastric varices and gastroesophageal varices. Overall, our series demonstrated a high hemostasis success rate and favorable short-term survival in this high-risk patient population

Conclusions Endoscopic cyanoacrylate injection proved to be a highly effective and safe intervention for bleeding IGV1 and GOV varices in our single-center experience. The therapy achieved prompt hemostasis in the vast majority of cases and resulted in excellent survival to discharge, with minimal procedure-related adverse events. These findings support cyanoacrylate glue injection as an indispensable first-line treatment for gastric variceal hemorrhage, offering life-saving hemorrhage control and encouraging outcomes even in a Western tertiary care setting. Our real-world results align with previously reported success rates and underscore the critical role of endoscopic intervention in improving survival for gastric variceal bleeding

eP501 VC-6: A Superior, AI-Friendly CODEC For Next-Generation Medical Imaging And Analysis

Authors Coelho-Prabhu N[1], Fetzer J[1], Leggett C[2], League J[1]

Institutes **1** Mayo Clinic, Rochester, United States of America; **2** Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States of America

DOI 10.1055/s-0046-1821828

Problem to solve The growing volume of high-resolution medical images demands efficient compression for storage and transmission. While JPEG is widely used, its lossy nature can introduce artifacts that compromise diagnostic integrity and hinder the performance of AI-driven analysis. This study evaluates VC-6, a novel,AI-friendly codec, as a superior alternative to JPEG for modern medical imaging workflows.

Innovation We performed a quantitative comparison of VC-6 and JPEG image compression. Our source material was an endoscopy video encoded as a ProRes file. For VC-6, TIFF frames were extracted and then encoded into the VC-6 format. For JPEG, the ProRes file was converted to MPEG4, and JPEG frames were extracted at a quality level consistent with our standard workflow. We then conducted a full-reference quality assessment using the decoded VC-6 image as the reference and the JPEG image as the distorted input. The key metrics evaluated were Video Multimethod Assessment Fusion (VMAF), Contrast Aware Multiscale Banding Index (CAMBI), Peak Signal-to-Noise Ratio (PSNR), and Structural Similarity Index Measure (SSIM).

Results The results demonstrated a significant quality degradation in the JPEG images when compared to the VC-6 reference. The mean VMAF score of 82.63 for the JPEG images indicates a noticeable loss of perceptual quality compared to the VC-6 source. The mean CAMBI score of 0.009 for the JPEGs suggests minimal banding artifacts, but still measurable differences from the VC-6 reference. The mean PSNR of 33.97 dB and mean SSIM of 0.9068 for the JPEGs further quantify the distortion introduced by JPEG compression. In terms of file size, VC-6 files were found to be ~315 % larger than JPEGs. However, both offer substantial compression compared to uncompressed TIFFs, with VC-6 being 82.2 % smaller and JPEG being 95.7 % smaller.

Conclusions While VC-6 files are slightly larger than their JPEG counterparts, this increased file size is directly correlated with superior image quality and fidelity. More importantly, its inherent AI-friendly design, with its multi-resolution representation, makes it an ideal format for next-generation endoscopy AI video and image applications. By enabling more efficient and accurate data access for machine learning models, VC-6 has the potential to accelerate the development and adoption of AI-powered tools, where image fidelity and AI utility outweigh the increased storage footprint.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP502 Evaluating Platelet-to-Lymphocyte and Neutrophil-to-Lymphocyte Ratios in endoscopic disease activity in Inflammatory Bowel Disease

Authors Rellou S[1], Kordalis L[2], Panagaris S[1], Efstathiou S[1], Lamprou S[1], Masina V[1], Manou D[1], Sdonas T[1], Tasovasili A[1]

Institutes **1** Department of Gastroenterology, General Oncology Hospital of Kifisia Oi Agioi Anargyroi, Athens, Greece; **2** Department of Mathematics, National and Kapodistrian University of Athens, Athens, Greece

DOI 10.1055/s-0046-1821829

Aims Inflammatory bowel disease (IBD) frequently requires repeated endoscopic assessments to evaluate mucosal inflammation and guide treatment decisions. However, endoscopy is invasive, expensive, and not always readily available. The neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) have emerged as potential blood-derived inflammatory markers, but their relationship with objective measures of disease activity remains uncertain. We aimed to evaluate the association of NLR and PLR with endoscopic activity in patients with IBD [1].

Methods This retrospective study reviewed medical records of patients followed in our department from January 2020 to October 2025. Demographic data, endoscopic findings, and histology results were collected. Patients with confirmed IBD were included if they underwent endoscopy in our unit and blood count parameters (neutrophils, lymphocytes, platelets) available within two weeks of the procedure. Endoscopic activity was classified using the Mayo endoscopic score for ulcerative colitis (UC) and the Simple Endoscopic Score for Crohn's Disease (CD) and histological activity as present or absent. Comparisons between activity groups, correlation analyses, logistic regression, and ROC curve evaluation were performed to assess the association and predictive value of NLR and PLR for endoscopic and histologic disease activity. All analyses were conducted in RStudio.

Results A total of 104 patients met the inclusion criteria (mean age 47.6 years; 66 males; 38 females), including 42 with CD and 62 with UC. PLR demonstrated a statistically significant association with endoscopic disease activity ($\beta_0 = -1.2774$, $\beta_1 = 0.0063$). ROC analysis showed an AUC of 0.608, with an optimal threshold of 145.09 corresponding to a sensitivity of 64.44 % and a specificity of 59.32 %. PLR did not correlate with histological inflammation ($p = 0.18$).

NLR was significantly associated with histologic inflammation in a probit regression model ($\beta_0 = -0.02707$, $\beta_1 = 0.23253$, $p = 0.041$), with an AUC of 0.629 and an optimal cut-off of 2.7 (sensitivity 52 %, specificity 80 %). However, NLR did not correlate significantly with endoscopic disease activity ($p = 0.10$).

Deep remission (combined endoscopic and histologic remission) was not significantly associated with PLR ($p = 0.467$) or NLR ($p = 0.149$). No significant associations were found between PLR ($p = 0.892$) or NLR ($p = 0.947$) and residual histologic inflammation among patients in endoscopic remission.

Conclusions PLR demonstrated a significant association with endoscopic disease activity, suggesting potential utility as a simple, accessible biomarker to support non-invasive assessment in IBD. In contrast, NLR was associated only with histologic inflammation and did not correlate with endoscopic findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Association between the immune-inflammation index and the severity and clinical outcomes of patients with inflammatory bowel disease: a systematic review and meta-analysis. BMC Gastroenterol. 2025; 25 (1): 414. doi:10.1186/s12876-025-04033-4 PMID: PMID: 40442599 PMID: PMC12121125

eP503 The Current State of Endoscopic Submucosal Dissection in the UK: A Nationwide Cross-Sectional Survey

Authors Alyacoubi S[1], Hong SP[1], Patel N[1], Haji A[2], Runciman M[1], Darzi A[1], Mylonas G[1], Peters CJ[1]
Institutes 1 Imperial College London, London, United Kingdom; 2 King's College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1821830

Aims The study aimed to characterise the current landscape of independent practice of Endoscopic Submucosal Dissection (ESD) in the UK. It assessed workforce characteristics, training experience, case volumes, service provision, technical approaches, and perceived barriers to training and service delivery. It also examined endoscopists' views on the potential role of robotics in ESD.

Methods A nationwide, cross-sectional, anonymised online survey was conducted between 1 May and 30 June 2025 among UK endoscopists independently performing upper and/or lower gastrointestinal (GI) ESD. The 43-item questionnaire was piloted by two expert ESD endoscopists. It was hosted on Qualtrics and disseminated through major professional societies, a curated database, and social media. Responses were analysed descriptively using Qualtrics and SPSS.

Results Twenty-eight responses were analysed. Most respondents were gastroenterologists (79 %), with the remainder being upper or lower GI surgeons; 82 % were male. Responses were received from across the UK, with the largest proportions from Greater London (39 %) and the South East (18 %). Most units were perceived as low-volume for Upper GI ESD, whereas the majority reported high-volume lower GI activity. Across all ESD sites, only a minority achieved the ESGE-recommended threshold of ≥ 25 procedures annually, with high-volume practice largely confined to rectal ESD. Overall, 68 % had completed an advanced fellowship (commonly in the UK or Japan), and 82 % had attended accredited ESD courses, often on multiple occasions. Respondents reported varied experiences across different ESD modalities during their training, including ex vivo, in vivo and human cases. Narrow Band Imaging (93 %) and white light endoscopy (86 %) were the most common delineation methods; colloid-based solutions (75 %), epinephrine (82 %), and blue dye (100 %) were widely used for submucosal injection. Most respondents routinely used tunnelling (93 %) and traction-assisted techniques (82 %). General anaesthesia was preferred for upper GI ESD (82 %), and conscious sedation for lower GI ESD (46 %). Most procedures were scheduled within 1–3 months, with longer delays uncommon; 85 % of respondents maintained a prospective ESD database. Reported barriers to training included heavy workload (37 %), low caseload (26 %), and limited institutional support (19 %). Nearly all respondents (93 %) believed robotics has a future role in ESD. Nearly as many expressed interest in adopting them (89 %)

Conclusions Independent ESD practice in the UK is delivered by a small workforce, with heterogeneous training backgrounds and case volumes often below recommended thresholds. National strategies for structured training, centralisation, and evaluation of new technologies are needed to support safe and sustainable expansion of ESD.

eP504V Same-session aspiration of unexpected significant ascites and EUS-guided gastroenterostomy in gastrojejunal anastomotic stenosis

Authors Marcozzi G[1, 2], Poletti V[2, 1], Andreozzi M[1], Franchellucci G[1], Colombo M[1], Spadaccini M[2, 1], Hassan C[1, 2], Repici A[1, 2], Fugazza A[1]
Institutes 1 Humanitas Research Hospital, Rozzano, Italy; 2 Humanitas University, Pieve Emanuele, Italy
DOI 10.1055/s-0046-1821831

Abstract Text

Endoscopic ultrasound-guided gastroenterostomy (EUS-GE) represents an effective minimally invasive alternative for gastric outlet obstruction (GOO). Ascites has traditionally been considered a contraindication due to the risk of LAMS misdeployment. We report a 79-year-old man with recurrent GOO after pancreaticoduodenectomy for pancreatic adenocarcinoma. CT revealed gastrojejunal anastomotic stenosis with mild ascites. During EUS-GE, a large, unexpected, perigastric ascites impaired visualization of the target loop. To avoid aborting the procedure, ascites were aspirated transgastrically using a 19-gauge needle in the same session. This restored a clear acoustic window and allowed safe LAMS deployment. This case supports the feasibility and safety of same-session EUS-guided ascites aspiration to enable EUS-GE and avoid procedural delays or repeat sedation.

eP505 Rectal suturing in the lower gastrointestinal tract

Authors Cavanagh Pérez-Nievas P[1], Vidal Pelayo M[1], Sánchez Bravo JD[1], Zaballos Gandarias C[2], Comas Redondo C[1], Honrubia López R[1]
Institutes 1 Infanta Sofia University Hospital, San Sebastián de los Reyes, Spain; 2 Infanta Sofia University Hospital, San Sebastian de los Reyes, Spain
DOI 10.1055/s-0046-1821832

Aims This study aimed to assess the clinical success rate of endoscopic hand suturing (EHS), defined as complete closure of the mucosal defect. While current literature supports the feasibility of closing post-ESD defects in the upper gastrointestinal tract, data regarding its application in the colorectum remain scarce. This case series assessed the outcomes of EHS for rectal mucosal defects following ESD and for the closure of fistulous tracts. Secondary objectives included documenting intraprocedural and delayed adverse events and total procedure time [1–3].

Methods This prospective, single-centre case series was conducted between November 2023 and October 2025 and included 12 patients meeting the following criteria: presence of a mucosal defect after rectal ESD requiring EHS, or an indication for endoscopic closure of a fistulous orifice. Data were reported descriptively using continuous quantitative variables without inferential statistical analysis.

Results The cohort comprised 66.6 % male and 33.3 % female patients, with a median age of 65.3 years (range 44–86). One patient was classified as ASA I, eight as ASA II, and three as ASA III. One patient on acetylsalicylic acid continued therapy without interruption, while another receiving a direct oral anticoagulant discontinued treatment three days prior to the procedure.

A total of 10 rectal lesions were treated, and two fistulous tracts were closed. According to the Paris classification, lesions included three 0-IIa, two 0-Is, four 0-IIa + IIc, and one 0-IIa + Is. Histology revealed eight lesions with low-grade dysplasia and one neuroendocrine tumour. Absorbable 3-0 barbed sutures mounted on 17-mm needles were used in all procedures without overtube assistance.

The overall complete closure rate was 83 % (10/12). En bloc resection was achieved in 90 % of ESDs, and both unsuccessful closures occurred after ESD. Fistula closure demonstrated a 100 % immediate success rate; however, one case subsequently reopened, resulting in a final 50 % success rate. A combined EHS-clip strategy was required in 66.6 % of procedures. Intraprocedural adverse events included one perforation and one episode of bleeding not controlled with haemostatic forceps. Only one delayed bleed occurred, corresponding to the case in which suturing could not be successfully completed.

The median procedural time was 120 minutes (range 48–189), with a mean of 130 minutes.

Endoscopy 2026; 58: S1–S1041

Conclusions This study suggests that EHS is both effective and safe for colorectal defect closure, achieving an 83 % success rate. Published evidence supports its potential to reduce post-ESD bleeding in high-risk patients. In this series, the only perforation occurred in the sole fragmented ESD. Fistula closure achieved a 100 % initial response, suggesting its potential application for other indications. Nevertheless, procedure duration remains a limiting factor, influenced by operator expertise, defect size, anatomical location, and technical complexity. The single-centre design and small sample size constitute the main limitations, underscoring the need for further research and larger multicentre studies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP506 Risk of neoplasms in patients with inflammatory bowel disease: a study of 11 cases

Authors Khsiba A[1], Ghamougui A[1], Ben Mohamed A[1], Nechi S[1], Mahmoudi M[1], Gharbi G[1], Yakoubi M[1], Medhioub M[1], Chelbi E[1], Hamzaoui L[1]

Institute **1** Regional Hospital Mohamed Taher Al Maamouri, Mrezga, Tunisia

DOI 10.1055/s-0046-1821833

Aims Chronic inflammatory bowel diseases (IBD) are associated with an increased risk of gastrointestinal cancers, influenced by various individual factors and the duration of disease progression. The aim of this study was to assess neoplastic transformation in patients with IBD based on the experience of our center.

Methods We conducted a retrospective single-center study spanning 2017 to 2024. Data were collected from patient medical records

Results We report a series of 11 patients who developed tumors in the context of IBD: 10 with Crohn's disease and 1 with ulcerative colitis (sex ratio 1.2). Neoplasia was the presenting feature in five cases. In the remaining cases, the mean duration of IBD prior to diagnosis was 9.16 years (range 1–16). Five patients had been treated with corticosteroids. Only one was on salicylates, while the others had not received any maintenance therapy. The tumors were diagnosed under various circumstances: screening colonoscopy (1 patient), symptomatic presentation (e.g., weight loss, bowel habit disturbances) in 6 patients, or tumor-related complications such as superinfection or acute intestinal obstruction (4 patients). The mean age at tumor diagnosis was 60 years (range 36–88). Among the identified tumors, two patients had MALT lymphoma—one located in the colon and the other in the cecum. One of these cases showed isolated colonic involvement, while the other revealed additional lesions in the tonsils, nasopharynx, duodenum, and ileum. Treatment involved a combination of surgical resection and chemotherapy (Chlorambucil-Rituximab). Nine patients were diagnosed with infiltrating adenocarcinoma: 4 in the small intestine, 1 in the cecum, 1 in the colon, and 3 in the rectum. One case presented with metastases. Additionally, one patient with rectal adenocarcinoma was found to have a neuroendocrine tumor (NET) in the colon, diagnosed through stepwise colonic biopsies. All patients underwent surgical resection and chemotherapy: 5 ileocolic resections, 1 subtotal colectomy, 1 anterior resection, and 2 abdominoperineal amputations with total proctocolectomy and permanent ileostomy. Two patients also received radiotherapy. After a mean follow-up of 205 months (range 2–1496), 4 patients were in remission without recurrence—one of whom developed nodular regenerative hyperplasia as a chemotherapy complication. Two patients were still receiving adjuvant treatment, and 5 were lost to follow-up.

Conclusions Neoplasms linked to chronic inflammation in IBD are not uncommon and may be the initial presentation, as seen in nearly half of our cases—highlighting frequent underdiagnosis. This series also includes two rare cases of colonic MALT lymphoma, an association rarely reported. In patients with chronic ileal involvement, treatment strategies should consider early surgical options before initiating immunosuppressants. Additionally, the detection of a neuroendocrine tumor in a non-affected segment underlines the importance of systematic stepwise biopsies. These findings call for heightened clinical vigilance and further investigation into emerging and underrecognized tumor types in IBD.

Conflicts of Interest I have nothing to declare

eP507 Endobrachyoesophagus epidemiological profile and risk factors: which population in Morocco?

Authors Oubella H[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[2], El Bacha H[2]

Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821834

Aims Barrett's esophagus (BE), or endobrachyesophagus, is a precancerous condition characterized by intestinal metaplasia of the esophageal epithelium. This pathology results primarily from chronic gastroesophageal reflux disease (GERD) and is associated with an increased risk of esophageal adenocarcinoma. The objective of this study is to describe the epidemiological profile of BE and to identify the main risk factors in the Moroccan population. It aims to determine the prevalence of BE among Moroccan patients who underwent esophagogastroduodenoscopy (EGD), to identify the risk factors associated with this condition, and to analyze the clinical and endoscopic characteristics of patients diagnosed with BE.

Methods This is a retrospective descriptive study conducted on a population of patients who underwent EGD in Morocco between 2020 and 2025. Inclusion criteria involved patients with an endoscopic and/or histological diagnosis of BE, while exclusion criteria comprised patients with incomplete records or confirmed malignant pathology. The parameters studied included age, sex, medical history, clinical symptoms, endoscopic findings, and management.

Results 153 patients were included. The results show that the mean age of patients with BE is 55 years, with a male predominance. Sixty percent of patients with BE are over 50 years old. Among the identified risk factors, hiatal hernia was present in the majority of BE patients (65 %), heartburn in 38 % of cases, and regurgitation in 42 %. Several comorbidities were also reported, including hypertension (23 %), diabetes (17 %), and chronic kidney disease (15 %). Dietary habits—particularly the consumption of tea, coffee, and spices—are common in the Moroccan population and also appear to play a role in the development of BE. The diagnosis of BE was established according to the Prague classification, with a predominance of short-segment forms: C1M1 (20 %), C2M1 (15 %), and C1M2 (8 %). Biopsies were performed following the Seattle protocol to confirm the histological diagnosis.

Conclusions This study highlights the importance of screening for BE in at-risk patients, particularly those with a hiatal hernia and chronic gastroesophageal reflux. Implementing a national surveillance strategy could improve the management of this condition and prevent complications related to esophageal adenocarcinoma.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP508 Endoscopy-Driven Diagnosis and Management of Digestive Strictures in Crohn's Disease: Insights From a 10-Year Cohort

Authors Dhib A[1], Hassine H[1], Debbabi H[1], Yacoub H[1], Cherif D[1], Kchir H[1], Maamouri N[1]
Institute 1 Gastroenterology B, University hospital of La Rabta, Tunis, Tunisia
DOI 10.1055/s-0046-1821835

Aims Digestive strictures are a major cause of morbidity in Crohn's disease (CD), yet their endoscopic assessment and contribution to treatment allocation remain underreported.
Our aim was to characterize the endoscopic features of CD-related strictures and evaluate how endoscopy influences subsequent medical or surgical management.

Methods We performed a 10-year retrospective study of adult CD patients with clinically and radiologically confirmed digestive strictures. Endoscopic parameters included location, traversability, ulceration, and histology. Post-endoscopic therapeutic decisions and outcomes after medical therapy were analysed.

Results Eighty-eight patients were included, with an average age of 39 years ± 12 and a sex ratio M/F = 1.3. The stricture was the initial presentation of CD in 36 % of cases and was symptomatic in 88 %. Endoscopy was performed in 90 % and confirmed the diagnosis in 78 %. The ileocecal valve was the most frequent location (38 %), followed by anastomotic (20 %), colonic (10 %), ileal (6 %), and duodenal (4 %) locations. Upper gastrointestinal strictures (3 %) were identified exclusively by gastroscopy. Strictures were non-traversable in 92 % and ulcerated in 68 %. Biopsies were performed in all cases, with malignancy excluded in all. Among patients responding to medical therapy (39 %), follow-up endoscopy demonstrated complete resolution of the stricture in all evaluated responders. In contrast, persistent stenosis was observed in 32 % of non-responders (n = 34), leading to surgical referral in more than half (n = 18).

Conclusions Endoscopy plays a decisive role in the diagnostic confirmation and morphological characterization of CD-related strictures. It directly influences therapeutic pathways by identifying inflammatory strictures responsive to medical therapy and persistent stenoses requiring surgery. These findings highlight the central role of endoscopic evaluation in the multidisciplinary management of stricturing CD.

eP509 The yield of ERCP in Hydatid biliary Disease in a Tertiary Care Center

Authors Benazzouz H[1], Kadiri M[1], Lagdali N[1], Ajana FZ[1], Borahma M[1]
Institute 1 MEDECINE C HEPATOGASTROENTEROLOGY DEPARTEMENT, IBN SINA UNIVERSITY HOSPITAL, Rabat, Morocco
DOI 10.1055/s-0046-1821836

Aims Hydatid hepatic cysts may fistulize into the biliary tree, leading to obstructive jaundice, cholangitis, and septic complications. ERCP plays a major therapeutic role in endemic regions, yet high-quality real-life data remain limited. This study aimed to evaluate endoscopic findings, therapeutic maneuvers, and outcomes in patients with hydatid cysts fistulized into the bile ducts.

Methods This retrospective, descriptive and analytical study included all patients with hydatid hepatic cysts complicated by biliary fistula who underwent ERCP in a tertiary center. Clinical, radiological, endoscopic and biological data were extracted from standardized records. Technical success was defined as complete ductal clearance, and clinical success as full symptomatic and inflammatory resolution. Exploratory analytical comparisons were performed between preoperative vs postoperative ERCP and between patients with vs without acute cholangitis. Categorical variables were compared using Chi-square or Fisher's exact test.

Results Eighteen patients were included, the mean age was 51.1 ± 15.4 years. All patients were presented with hydatid cysts fistulized into the biliary tree. Acute cholangitis was the presenting circumstance in 4 patients (22.2 %), including one case of septic shock (5.6 %), whereas the remaining patients presented with obstructive jaundice, biliary colic, abdominal pain or postoperative bile leaks. Intraductal hydatid membranes or daughter vesicles were found in 8 patients (44.4 %), and purulent bile in 9 (50.0 %). ERCP was performed in a preoperative setting in 8 cases (44.4 %) and in a postoperative context in 5 cases (27.8 %). Endoscopic sphincterotomy was carried out in 9 patients (50.0 %), while balloon extraction was required in 17 cases (94.4 %), and Dormia basket extraction in 1 case (5.6 %). Plastic biliary stents were placed in 3 patients (16.7 %), typically in the presence of large fistulas or incomplete clearance of biliary duct. Technical success was achieved in all patients (100 %), and clinical success in 17 patients (94.4 %), with only one documented recurrence of hydatidobiliary obstruction after an initial favorable response.
In comparative analyses, intraductal hydatid membranes were significantly more frequent during preoperative ERCPs than during postoperative procedures (87.5 % vs 20.0 %, p = 0.032). The presence of pus showed a non-significant tendency to be higher in postoperative ERCPs (100 % vs 50.0 %, p = 0.105). Biliary stenting rates did not differ significantly between preoperative and postoperative groups (37.5 % vs 0 %, p = 0.231). Moreover, acute cholangitis was neither associated with the timing of ERCP nor with the need for stent placement (0 % vs 18.8 %, p > 0.05).

Conclusions In this real-life cohort, all hydatid cysts were complicated by biliary fistulization, confirming the major burden of hydatid biliary disease in our setting. ERCP proved highly effective, with universal technical success and near-complete clinical resolution, and the hydatid materials extraction (mainly with ballon) was the cornerstone of therapy. The strong association between intraductal hydatid material, cholangitis and preoperative presentations highlights the need for early endoscopic management in hydatid biliary complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP510 Endoscopic Profile of Cirrhotic Patients According to Helicobacter pylori Status: A 7-Year Cohort Analysis

Authors Dhib A[1], Shema A[1], Bel Hadj Mabrouk E[1], Mensi A[1], Yosra S[1], Leila M[1], Debbech R[1]
Institute 1 Hospital Charles Nicolle, Tunis, Tunisia
DOI 10.1055/s-0046-1821837

Aims Helicobacter pylori (HP) infection is common worldwide, but its influence on portal hypertension–related gastroduodenal lesions in cirrhotic patients remains uncertain. Upper gastrointestinal endoscopy (EGD) is essential for assessing mucosal injury and bleeding risk in this population.
Our aim was to determine the prevalence of HP infection in cirrhotic patients and evaluate its impact on the type and severity of endoscopic gastroduodenal lesions.

Methods We conducted a retrospective study including all cirrhotic patients who underwent EGD with systematic gastric biopsies between January 2017 and August 2023. Patients were classified into two groups: HP-negative (GA) and HP-positive (GB). Endoscopic findings—including esophageal varices, gastric varices, portal hypertensive gastropathy (PHG), and congestive, erosive, or ulcerative gastroduodenal lesions—were compared between groups.

Results A total of 127 patients were included (mean age 61 years, sex ratio 1.49). HP infection was detected in 54 % of patients. The most frequent endoscopic findings were esophageal varices (100 %), gastric varices (14 %), PHG (32 %), congestive gastropathy (51 %), ulcerated lesions (39 %), nodular lesions (13 %), and gastroduodenal ulcer (25 %).Comparison between the two groups

showed no significant difference in the prevalence or severity of endoscopic lesions, including PHG (31 % vs 33.3 %; p = 0.783), ulcerated lesions (34.5 % vs 42 %; p = 0.384), and gastroduodenal ulcer (29.3 % vs 21.7 %; p = 0.328). HP status was not associated with the grade or type of portal hypertension–related lesions.

Conclusions HP infection is frequent among cirrhotic patients but does not appear to influence the type or severity of gastroduodenal or portal hypertension–related endoscopic lesions. However, given its high prevalence and potential role in mucosal fragility, systematic HP screening and eradication may still offer clinical benefit and should be considered as part of comprehensive cirrhosis management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP511 Endoscopic Glue Injection for Gastric Varices: Experience of a Tertiary Care Center

Authors Hassoun C[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[2], El Bacha H[2]
Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821838

Aims Endoscopic obturation using cyanoacrylate glue injection is currently the reference treatment for active gastrointestinal bleeding due to ruptured gastric varices, as well as for secondary prophylaxis.

The aim of this study was to describe the epidemiological profile and clinical outcomes of patients who underwent biological glue injection for gastric varices.

Methods This was a single-center, retrospective, descriptive study conducted over 4 years and 10 months, from March 2020 to January 2025, within the endoscopy unit of our department.

All patients who underwent esophagogastroduodenoscopy (EGD) with biological glue injection were included.

Results During the study period, 27 patients underwent endoscopic glue therapy. The mean age was 48 years (range 23–68). The sex ratio was 1.25 (15 women and 12 men).

All patients had clinically significant portal hypertension and presented with hemorrhagic decompensation: melena in 12 patients (44.4 %), isolated hematemesis in 5 patients (18.5 %), and hematemesis associated with melena in 10 patients (37 %).

Portal hypertension was of cirrhotic origin in 14 patients (51.8 %), secondary to Budd–Chiari syndrome in 2 women (7.4 %), to portal vein thrombosis in 5 patients (18.5 %), and remained under investigation in 6 patients (22.2 %).

Gastric varices were classified as GOV2 in 14 patients (51.8 %), GOV1 in 7 patients (25.92 %), and IGV1 in 6 patients (22.2 %). Gastric varices were associated with esophageal varices in 21 patients (77.7 %).

The mean number of glue injection sessions was 1.9 per patient (range 1–3). Minor immediate bleeding occurred in 3 patients and was rapidly controlled with additional glue injection. Immediate therapeutic efficacy was achieved in 100 % of cases.

During follow-up, rebleeding occurred in only 3 patients (11.11 %), all successfully managed with a second glue injection session. Subcardial ulcerations at the previous injection site were observed in 2 patients (7.4 %) during follow-up.

Conclusions Biological glue injection is an effective technique for the treatment of gastrointestinal bleeding due to ruptured gastric varices, as well as for secondary prophylaxis. The recurrence rate remains low, confirming the value of this approach in the management of gastric variceal bleeding.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP512 Factors Associated with Recurrence of Hemorrhage from Esophageal Varices

Authors Bourehouat H[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[2], El Bacha H[2]
Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821839

Aims Hemorrhage from esophageal varices represents a major complication of portal hypertension and is commonly observed in patients with cirrhosis. This condition is associated with significant mortality, mainly due to the risk of recurrent bleeding, which may lead to severe complications and a poor prognosis if left untreated. The objective of this study is to analyze the factors contributing to recurrence of hemorrhage from esophageal varices, with the aim of identifying clinical and therapeutic elements that can improve prevention strategies and optimize patient management.

Methods This is a retrospective, descriptive, single-center study conducted over a period of 5 years (2020–2025), consecutively including patients hospitalized for recurrent upper gastrointestinal bleeding due to rupture of esophageal varices (EV), confirmed by esophagogastroduodenoscopy performed in the HepatoGastroenterology and Proctology Department "Medicine B" of Ibn Sina Hospital, Rabat. Demographic, clinical, endoscopic, and therapeutic data, as well as risk factors associated with recurrence of bleeding, were collected from patients' medical records.

Results A total of 24 patients were included. The mean age was 49 ± 13 years, ranging from 26 to 80 years. A male predominance was observed, with 14 men (58.33 %) versus 10 women (41.66 %), resulting in a male-to-female ratio of 1.4. The majority of patients (45 %) had hepatic cirrhosis (n = 11), with an indeterminate etiology (64 %), followed by hepatitis C (18 %), alcohol-related cirrhosis (9 %), and portal hypertension-related (9 %). Patients classified as Child A and Child B each represented 44.4 % of cases, while Child C accounted for 11.1 %. The mode of gastrointestinal bleeding presentation was hematemesis in 41 %, melena in 41 %, and both in 16 % of patients. Esophageal varices were graded as grade III in 62.5 %, grade II in 29.16 %, and grade I in 8.33 %, with red signs observed in the majority of cases (79 %). 13 patients (54 %) received beta-blocker therapy after the initial hemorrhagic episode, and 12 patients (50 %) underwent endoscopic variceal ligation to prevent recurrence. The time to recurrence of bleeding was measured in months, with a median of 4 months [range: 1–6.5].

Conclusions Recurrence of hemorrhage from esophageal varices is multifactorial, involving hemodynamic, clinical, and therapeutic factors. Optimal management requires strict control of portal hypertension, effective secondary prophylaxis (endoscopic ligation and beta-blockers), and close endoscopic follow-up to reduce recurrence risk and improve patient survival.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP513 Cyanoacrylate injection for gastric varices: real-world outcomes and quality indicators from a prospective audit in a Sri Lankan tertiary endoscopy centre

Authors Dasanayaka P[1], Subasinghe J[2], Dinamithra N[2]
Institutes **1** National Hospital Sri Lanka, Colombo, Sri Lanka; **2** National Hospital Kandy, Sri Lanka, Kandy, Sri Lanka
DOI 10.1055/s-0046-1821840

Aims To evaluate real-world outcomes and key quality indicators of cyanoacrylate injection for gastric varices in a tertiary hepatology–endoscopy unit, and to benchmark performance against international standards for portal hypertensive bleeding

Methods We conducted a prospective single-centre audit of consecutive patients undergoing cyanoacrylate glue injection for gastric varices between April 2025 and August 2025. Data collected using a standardised proforma included demographics, Child–Pugh class, indication, varix type, operator level, glue

volume, adjunctive pharmacotherapy (antibiotics, vasoactive drugs, carvedilol), technical success, intraprocedural complications, early (≤ 5 days) and 6-week rebleeding, 6-week mortality, and follow-up endoscopy findings. Results are descriptive

Results Seventeen patients (median age 61 years; IQR 57–67; 13/17 male) were included. Most had decompensated cirrhosis: Child–Pugh A/B/C in 29 %, 53 % and 18 % respectively. Indications were prophylactic treatment in 13/17 (76 %) and active bleeding in 4/17 (24 %). Varix types included GOV2 (47 %), IGV1 (29 %), GOV1 (18 %) and IGV2 (6 %). Management reflected real-world practice patterns in our unit, including selected use of cyanoacrylate for high-risk GOV1 lesions when band ligation was not feasible.

Median glue volume was 2 mL (IQR 1–3). Procedures were performed by consultants in 82 % and by Senior registrars in 18 %. Carvedilol was used in 65 % and antibiotics in 69 % of cases. Vasoactive drugs were appropriately administered only in patients with active bleeding. Immediate technical success was achieved in 15/17 (88 %). Intraprocedural complications occurred in 4/17 (24 %): bleeding in 3 patients, controlled endoscopically, and mild pain in 1; no embolic events were observed.

Early (≤ 5 days) rebleeding occurred in 19 % (3/16) with available data, and 6-week rebleeding in 17 % (2/12). Six-week mortality was 19 % (3/16), all in Child–Pugh C patients. Follow-up endoscopy was planned in 71 % and completed in 3 to date, all showing residual varices requiring further therapy. Key quality indicators (technical success, safety, rebleeding) align with expected ranges for a predominantly Child–Pugh B/C population.

Conclusions Cyanoacrylate injection for gastric varices demonstrated high technical success and an acceptable safety profile in this real-world cohort, with no embolic complications. Rebleeding and mortality reflected underlying disease severity. These findings highlight opportunities to strengthen adjunctive therapy consistency and structured follow-up endoscopy. Ongoing audit cycles will support benchmarking against ESGE and Baveno VII quality standards.

eP514 Jejunal adenocarcinoma as the index presentation of lynch syndrome: the pivotal role of endoscopy

Authors Bógalo Romero C[1], Sánchez Roncero FJ[2], Madrigal Bayonas L[2], Gómez Gómez A[1], Romero Martínez M[1], Calatayud Vidal G[2], Alajarín Cervera M[1], Egea Valenzuela J[1], Alberca De Las Parras F[1]

DOI 10.1055/s-0046-1821841

Introduction: Primary small bowel adenocarcinoma (SBA) is a rare entity, representing a diagnostic challenge due to its vague clinical presentation. While Lynch syndrome (hereditary nonpolyposis colorectal cancer) is a known risk factor, SBA is infrequently the first manifestation of the syndrome. We present a case where endoscopic investigation of anemia led to the diagnosis of both SBA and Lynch syndrome [1–3].

Case Description: A 50-year-old woman with no significant personal or family history was evaluated for chronic abdominal pain and anemia. Standard bidirectional endoscopy (gastroscopy and colonoscopy) was normal, and a thoracoabdominal computed tomography (CT) scan showed no relevant findings.

Suspecting small bowel pathology, a Video Capsule Endoscopy (VCE) was performed. It revealed a mid-jejunal exophytic lesion occupying two-thirds of the lumen circumference, with a neoplastic, partially obstructive, and ulcerated appearance. To obtain histological confirmation, a device-assisted enteroscopy was performed. The procedure identified the lesion extending approximately 4–5 cm; it was friable to the touch with indurated areas. Biopsies were taken. Histopathological analysis confirmed a primary small bowel adenocarcinoma. Crucially, immunohistochemistry demonstrated a loss of expression of DNA mismatch repair (MMR) proteins, specifically MLH1, MSH2, and MSH6. This distinct immunophenotype is highly consistent with microsatellite instability and Lynch syndrome, prompting genetic counseling and family screening.

Conclusion: This case underscores the essential role of VCE and enteroscopy in patients with explained symptoms and negative standard workup. Furthermore, it highlights the importance of testing for MMR protein deficiency in all small bowel adenocarcinomas, as this rare malignancy can serve as the sentinel event for hereditary syndromes, even in patients without a suggestive family history.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP515 Peptic Esophagitis: Epidemiological Profile and Risk Factors

Authors Bourehouat H[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[2], El Bacha H[2]

Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821842

Aims Peptic esophagitis, the most common complication of gastroesophageal reflux disease (GERD), involves inflammatory lesions of the esophageal layers. It can cause debilitating symptoms and, in the long term, severe complications such as strictures or increased risk of esophageal cancer. The aim of this study was to evaluate the current epidemiology and risk factors of peptic esophagitis.

Methods This is a retrospective, descriptive, single-center study conducted over 5 years (2020–2025), including all cases of peptic esophagitis confirmed by upper gastrointestinal endoscopy at the HepatoGastroenterology and Proctology Department "Medicine B" of Ibn Sina Hospital, Rabat. Demographic, clinical, endoscopic data, and risk factors were collected from medical records.

Results Among 1,654 patients undergoing upper gastrointestinal endoscopy, 23 cases of peptic esophagitis were identified, yielding a prevalence of 1.39 %. The mean age was 46 years, ranging from 23 to 71 years. A male predominance was observed, with 15 men (65 %) and 8 women (35 %), resulting in a male-to-female ratio of 1.86. Most patients resided in urban areas (86.95 %), compared to 13.04 % in rural areas. Identified risk factors included hiatal hernia in 4 patients (17.3 %), chronic smoking in 2 patients (8.6 %), and a history of alcohol consumption in 2 patients (8.6 %). The mean BMI was 19.2 kg/m². H. pylori infection was present in 39.13 % of cases. High-risk medications included NSAIDs in 48.82 % of patients, bisphosphonates in 4.38 %, and certain sedatives in 4.38 %. Clinically, gastroesophageal reflux was the main symptom in 82.6 % of cases, dysphagia in 56.56 %, and digestive bleeding in 30.43 %. Endoscopically, according to the Los Angeles classification, 5 cases (21.73 %) were grade A, 5 cases (21.73 %) grade B, 4 cases (17.39 %) grade C, and 9 cases (39.13 %) presented with severe peptic stricture (grade B).

Conclusions Peptic esophagitis in this urban cohort predominantly affects middle-aged men. Key risk factors include smoking, H. pylori infection, and certain medications. Early detection and appropriate treatment are essential to prevent severe complications such as strictures. These findings highlight the need for increased awareness and careful monitoring of at-risk patients.

eP516 Endoscopic Diagnosis of Segmental Portal Hypertension Caused by a Giant Pancreatic Serous Cystadenoma

Authors Dhib A[1], Yacoub H[1], Cherif D[1], Hassine H[1], Debbabi H[1], Kchir H[1], Maamouri N[1]
Institute 1 Gastroenterology B, University hospital of La Rabta, Tunis, Tunisia
DOI 10.1055/s-0046-1821843

Abstract Text

Serous cystadenomas of the pancreas (SCP) are rare benign tumors, usually asymptomatic and diagnosed incidentally. Segmental portal hypertension (SPH) caused by vascular compression from an SCP is exceptional. We report a case in which endoscopy played a pivotal role in confirming SPH and guiding management.

An 85-year-old woman with a history of hypertension and type 2 diabetes presented with a gradually enlarging abdominal mass in the left flank and epigastrium. Laboratory tests were unremarkable. Abdominal CT revealed a 24 × 13 cm multiloculated mass originating from the pancreas, compressing the splenic vein, inferior mesenteric vein, and partially the portal vein, suggesting SPH. Upper GI endoscopy was performed to assess for portal hypertension and showed grade I esophageal varices and isolated gastric varices (IGV1), confirming SPH. Percutaneous biopsy of the mass demonstrated a multiloculated cystic lesion consistent with a benign serous cystadenoma without malignant features. The case was discussed in a multidisciplinary tumor board. Owing to the giant size of the lesion, vascular involvement, and the patient's operative risk, surgical resection was not recommended. A conservative management strategy was adopted. Primary prophylaxis for gastroesophageal varices was initiated with non-selective beta-blockers. Clinical, endoscopic, and radiologic surveillance was planned.

This case highlights a rare complication of serous pancreatic cystadenomas: segmental portal hypertension secondary to major vascular compression. Endoscopy played a key role in diagnosing SPH, stratifying bleeding risk, and guiding therapeutic decisions. Awareness of this unusual presentation is essential to ensure appropriate multidisciplinary management of large benign pancreatic tumors.

eP517 The "single stripe sign" beyond the left colon: a diagnostic red flag for crohn's disease

Authors Bógalo Romero C[1], Madrigal Bayonas L[2], Romero Martínez M[1], Gómez Gómez A[1], Sánchez Roncero FJ[2], Calatayud Vidal G[2], Alberca De Las Parras F[1], Egea Valenzuela J[1]
Institutes 1 Virgen of Arrixaca University Clinical Hospital, El Palmar, Spain; 2 Rafael Méndez University General Hospital, Lorca, Spain
DOI 10.1055/s-0046-1821844

Introduction: The "single stripe sign" (a continuous longitudinal ulceration) is widely recognized as a highly specific marker for mild ischemic colitis, particularly when observed in the left colon (descending and sigmoid segments). However, when this morphology appears outside this typical topographic distribution, alternative diagnoses must be considered. We present a case of severe Crohn's disease (CD) masquerading as ischemia through a right-sided "stripe sign."

Case Description: A 35-year-old male was admitted with fever, polyarthralgia, oral aphthae, and erythema nodosum. Laboratory workup showed anemia, elevated acute phase reactants, and high fecal calprotectin. The patient reported a history of recurrent bloody diarrhea [1, 2].

Colonoscopy revealed a dual morphological pattern. The sigmoid colon showed a large, deep, excavated ulcer occupying 75 % of the circumference with a fibrin-covered base, causing stenosis. Surprisingly, the right colon displayed long, linear ulcerations (> 3 cm) surrounded by normal mucosa. While this longitudinal appearance strongly resembled the "single stripe sign" of ischemia, its location in the ascending colon and the patient's young age made vascular etiology highly unlikely.

Biopsies from both the right-sided "stripes" and the sigmoid ulcer confirmed chronic active inflammation compatible with Crohn's disease, ruling out ischemia, CMV, or tuberculosis.

Conclusion: This case highlights a critical diagnostic caveat: while the "single stripe sign" in the left colon is a reliable indicator of ischemia, its specificity drops precipitously when found in the right colon. In such atypical locations, especially in young patients with extraintestinal symptoms, this longitudinal ulceration represents the "railroad track" pattern of Crohn's disease. Endoscopists must integrate lesion morphology with anatomical location to avoid misdiagnosing CD as ischemia.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP518 Prevalence of Colorectal Polyps in Lower Gastrointestinal Bleeding

Authors El Anouni I[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[2], El Bacha H[2]
Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821845

Aims Lower gastrointestinal bleeding (LGIB), defined as bleeding originating distal to the ligament of Treitz, is a common reason for consultation in gastroenterology, often related to colorectal lesions. Colorectal polyps, implicated in 6–12 % of LGIB cases, include adenomatous polyps with malignant potential and non-adenomatous polyps. According to the literature, 25–40 % of adenomatous polyps progress to colorectal adenocarcinoma within approximately ten years, highlighting the importance of screening and early management. The aim of our study was to determine the prevalence of colorectal polyps in the context of LGIB, to describe the epidemiological and clinical characteristics of affected patients, and to analyze the endoscopic and histological features of these lesions along with their therapeutic management.

Methods This was a retrospective, descriptive study conducted over a 3-year period, from January 1, 2022 to October 31, 2025, within our department. The study included all patients who underwent colonoscopy for evaluation of LGIB with endoscopic confirmation of colorectal polyps. Data were collected from colonoscopy report registries. Descriptive analysis was performed using a standardized data collection sheet ensuring patient anonymity.

Results During the study period, 160 colonoscopies were performed for LGIB, identifying 54 cases of colorectal polyps, yielding a prevalence of 33.7 %.The male-to-female ratio was 1.6 (33 men, 21 women). The mean age was 51.7 years (range: 23–78), with 72 % of patients aged ≥ 45 years (39 patients). One patient (2 %) had a family history of familial adenomatous polyposis (FAP), and 20 patients (37 %) were chronic smokers.

Clinically, 34 patients (63 %) presented with isolated rectorrhagia, while 20 (37 %) had associated symptoms, including anemia (9 cases), constipation (4), proctalgia (3), weight loss (2), diarrhea (1), and abdominal pain (1).

Endoscopically, polyps were mainly located in the left and right colon (n = 20; 37 %), followed by the rectum (n = 6; 11.1 %). Extensive colonic involvement was observed in 2 patients (3.7 %).Thirty patients (55.6 %) had sessile polyps and 14 (25.9 %) had pedunculated polyps. Eight patients (14.8 %) had both sessile and pedunculated polyps, 2 (3.7 %) had pedunculated and flat polyps, and 1 patient (1.9 %) had sessile and flat polyps.A single polyp was found in 28 patients (51.9 %), and 2 cases (3.7 %) of colorectal polyposis were reported.

Regarding size, 33 patients (61.1 %) had polyps measuring 3–10 mm, 9 (16.7 %) had polyps 1–2 mm, and variable sizes were observed in 8 patients (14.8 %).

Most patients underwent polypectomy (n = 53; 98 %), including cold-snare resection in 12 patients (22.2 %) and mucosectomy in 2 patients (3.7 %).Seventeen patients (31.5 %) had associated endoscopic findings, such as a tumoral process (6 cases), internal hemorrhoids (4), uncomplicated diverticulosis (3), angiodysplasia (2), mild proctitis (1), and colonic melanosis (1).
Histopathological analysis identified 45 adenomatous polyps (83.3 %), including 28 (51.9 %) tubular, 11 (20.4 %) serrated, and 6 (11.1 %) tubulovillous. One hyperplastic polyp (1.9 %) and 3 cases (5.6 %) of in situ adenocarcinoma were also noted.

Conclusions Colorectal polyps are a frequent cause of lower gastrointestinal bleeding, accounting for 37.8 % of cases in our study, and carry a significant risk of malignant transformation. Our findings underscore the importance of systematic screening and early management to prevent progression to adenocarcinoma.

eP519 Quality Criteria in Endoscopy: A Retrospective Study

Authors Hassoun C[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[2], El Bacha H[2]
Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821846

Aims Endoscopy is a visual exploration technique that allows for the diagnosis, treatment, and monitoring of a wide range of gastrointestinal conditions. The quality of endoscopic procedures is essential to ensure patient safety, comfort, and diagnostic accuracy. However, despite strict protocols, variations in examination quality may still occur.
The aim of our study was to analyze quality criteria in digestive endoscopy based on retrospective data and to identify areas for improvement in clinical practice.

Methods This is a retrospective, descriptive study conducted over one year, from January 2024 to January 2025, within the endoscopy unit of our department. All patients who underwent an esophagogastroduodenoscopy (EGD) or a total ileocolonoscopy during this period were included. We collected epidemiological data, indications for endoscopy, as well as information on tolerance, quality of visualization, completeness of the procedure, and complications. For EGD, procedural completeness was defined as visualization of the second portion of the duodenum (D2). For colonoscopy, completeness was defined as intubation of the cecal pole. Quality of preparation was assessed through the visualization of the gastric mucosa for EGD and using the Boston Bowel Preparation Scale for total ileocolonoscopy.

Results A total of 330 endoscopic procedures were performed during the study period, including 199 esophagogastroduodenoscopies (EGD) and 131 total ileocolonoscopies. Among the patients undergoing EGD, women were slightly predominant (56.3 %), with a mean age of 47.9 years. The most common indication was anemia (10.05 %), followed by upper and lower gastrointestinal bleeding, epigastric pain, vomiting, and dysphagia. Nearly all patients (95 %) benefited from a pre-anesthesia consultation, while 5 % underwent the examination without sedation. Overall tolerance was good in 96 % of cases, with only 3.5 % showing intolerance related mainly to desaturation or difficulties with the unsedated procedure. Visualization of the gastric mucosa was satisfactory in 93.5 % of EGD examinations, while limitations were mostly due to non-aspirable food debris, esophageal strictures, or significant gastric stasis. The procedure was complete—with successful progression to the second portion of the duodenum—in 91.5 % of patients. Incomplete examinations (8.5 %) were mainly due to solid food residue, non-passable esophageal stenosis, gastric stasis, or early termination caused by intolerance. No major complications occurred, aside from a few cases of desaturation and intolerance to unsedated endoscopy. Among the 131 ileocolonoscopies, there was a female predominance with 73 women (55.7 %) and 58 men (44.3 %) (sex ratio 1.25). The mean age was 47.6 years (16–86). The main indications were rectal bleeding in 26 cases (19.84 %), IBD-related evaluation colonoscopies in 25 cases (19.08 %), bowel habit disorders in 22 cases (16.79 %), and chronic abdominal pain in 16 cases (12.21 %). Most procedures were performed under anesthesia (126 patients, 96.2 %), while 5 (3.8 %) were unsedated. Tolerance was good in 129 patients (98.5 %), whereas 2 unsedated patients (1.5 %) did not tolerate the procedure. Bowel preparation quality (Boston Scale) showed: 9 patients (6.9 %) with a score of 0 requiring rescheduling; 9 (6.9 %) with a score of 4; 35 (26.7 %) with 5; 32 (24.4 %) with 6; 21 (16 %) with 7; 21 (16 %) with 8; and 4 (3.1 %) with a score of 9. Cecal intubation was achieved in 87 cases (66.41 %), including 74 with terminal ileum (TI) intubation and 13 without. Completion was not possible in 44 cases (33.58 %): 29 due to poor preparation, 14 due to stenosis, and 1 due to high perforation risk. No complications were reported.

Conclusions Endoscopy is an essential technique for the diagnosis and management of many gastrointestinal diseases, but ensuring high-quality examinations remains a major challenge to guarantee patient safety and continuously improve medical practice. Our study showed that the majority of endoscopic procedures achieved good quality in terms of diagnostic precision and safety. However, improvements are still needed, particularly regarding unsedated procedures and patient education on optimal preparation, to ensure the best possible outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP520 Eradication protocol of esophageal varices in cirrhotic patients: what timeframe and which influencing factors?

Authors El Anouni I[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[2], El Bacha H[2]
Institutes 1 CHU Ibn Sina, Rabat, Morocco; 2 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821847

Aims Esophageal variceal rupture is a major complication of portal hypertension in cirrhotic patients, leading to a high risk of upper gastrointestinal bleeding. Although endoscopic variceal ligation (EVL) is a cornerstone of both primary and secondary prophylaxis, rebleeding remains frequent. This study aims to determine the average time required for variceal eradication and to identify predictors of hemorrhagic recurrence to improve the management of cirrhotic patients treated with EVL.

Methods This was a retrospective, descriptive, and analytical study conducted over a five-year period, from January 1st, 2019 to 31 October, 2025, within our department. The study included all patients followed for cirrhosis who underwent an upper GI endoscopy (EGD) with esophageal variceal ligation. Patients were divided into two groups: **Group I:** 40 cirrhotic patients in whom variceal eradication was achieved within ≤ 3 months and **Group II:** 28 cirrhotic patients in whom eradication was achieved after > 3 months. Data were collected from patient medical records and endoscopy reports. Descriptive data analysis was performed using a standardized data collection form, while statistical analysis was carried out using JAMOVI software.

Results During the study period, 172 patients underwent EGD with EVL. Among them, 68 (39.5 %) were cirrhotic. Cirrhosis was of indeterminate etiology in 21 patients (30.9 %). Post-viral hepatitis B cirrhosis was found in 9 patients (13.2 %) and post-viral hepatitis C cirrhosis in 8 patients (11.8 %).

Group I The male-to-female ratio was 1.2 (22 men, 18 women). The mean age was 50.4 years (range 19–74).EVL was performed as primary prophylaxis in 23 patients (57.5 %) and as secondary prophylaxis in 17 patients (42.5 %). Beta-blockers were used for primary prophylaxis in 21 patients (52.5 %) and for secondary prophylaxis in 19 patients (47.5 %). According to the Child-Pugh classification, 17 (42.5 %) were Child A, 14 (35 %) Child B, and 9 (22.5 %) Child C. Endoscopically, 26 patients (65 %) had grade III varices and 14 (35 %) had grade II varices. Most patients presented red signs (72.5 %; n = 29) and more than three variceal columns (80 %; n = 32).The mean number of bands applied per session was 4 (1–7). The mean number of sessions required for variceal

eradication was 6 (2–7). The mean interval between the first and last ligation sessions was 56 days (14–84).Hemorrhagic recurrence occurred in 5 patients (12.5 %). Eradication within ≤ 3 months was associated with EVL performed as primary prophylaxis (p = 0.003) and with the use of beta-blockers in primary prophylaxis (p = 0.0004).

Group II The male-to-female ratio was 1.5 (17 men, 11 women). The mean age was 50.7 years (range 25–74).EVL was performed as primary prophylaxis in 6 patients (21.4 %) and as secondary prophylaxis in 22 patients (55 %). Beta-blockers were used for primary prophylaxis in 5 patients (17.9 %) and for secondary prophylaxis in 23 patients (82.1 %). According to the Child-Pugh score, 10 (35.5 %) patients were Child A, 11 (39.3 %) Child B, and 7 (25 %) Child C. Endoscopically, 22 patients (55 %) had grade III varices and 6 (21.4 %) grade II varices. Red signs were present in 75 % (n = 21), and more than three variceal columns in 96.4 % (n = 27).The mean number of bands applied per session was 5 (2–7). The mean number of sessions required for eradication was 8 (3–9). The mean time between the first and last sessions was 154 days (112–336). Hemorrhagic recurrence occurred in 9 patients (32.1 %). Eradication beyond 3 months was associated with secondary prophylaxis (p = 0.003), the use of beta-blockers in secondary prophylaxis (p = 0.0004), and hemorrhagic recurrence (p = 0.049).

Conclusions Endoscopic variceal ligation (EVL) is a key treatment for cirrhotic patients at risk of variceal bleeding. Our study shows that anticoagulant use is a significant predictor of hemorrhagic recurrence and that early EVL combined with beta-blockers may improve effectiveness and shorten variceal eradication time.

eP521 The "ulcerated yellowish nodule": a distinctive endoscopic phenotype of ileal neuroendocrine tumors

Authors Bógalo Romero C[1], Romero Martínez M[1], Gómez Gómez A[1], Madrigal Bayonas L[2], Calatayud Vidal G[2], Sánchez Roncero FJ[2], Egea Valenzuela J[1], Alberca De Las Parras F[1]

Institutes **1** Virgen of Arrixaca University Clinical Hospital, El Palmar, Spain; **2** Rafael Méndez University General Hospital, Lorca, Spain

DOI 10.1055/s-0046-1821848

Introduction: Small bowel neuroendocrine tumors (NETs) are the most common malignancy of the small intestine but often face diagnostic delays due to their subtle presentation. While they originate from the submucosa, advanced lesions can develop specific mucosal alterations. We present a case that illustrates the classic "yellowish and ulcerated" morphology, a key endoscopic sign that should trigger immediate suspicion of a NET during ileoscopy [1–3].

Case Description: A 72-year-old male was referred for evaluation of chronic intermittent diarrhea, right lower quadrant pain, and significant weight loss (10 kg). Biochemical workup revealed elevated serum chromogranin A and urinary catecholamines, raising suspicion for a neuroendocrine etiology.

High-definition ileocolonoscopy was performed. The colon was endoscopically normal. However, deep intubation of the terminal ileum (5 cm proximal to the valve) revealed a solitary, 3-cm exophytic lesion. Morphologically, the mass was striking: it presented a distinct yellowish submucosal hue that differentiated it from typical adenomas. Furthermore, the lesion exhibited a central surface ulceration with irregular edges and friability upon contact.

Biopsies taken from the ulcerated margin confirmed a well-differentiated, low-grade neuroendocrine tumor. The patient underwent oncological resection, confirming the diagnosis.

Conclusion: This case underscores the importance of recognizing specific visual patterns during ileoscopy. The combination of a yellowish coloration (reflecting the lipid-rich neuroendocrine tissue) and spontaneous surface ulceration constitutes a highly suggestive phenotype for ileal NETs. Endoscopists observing a "yellowish ulcerated nodule" in the distal ileum should prioritize this diagnosis over Crohn's disease or simple inflammatory polyps to expedite appropriate surgical management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP522 Familial Adenomatous Polyposis: Clinical and Therapeutic Insights from a Tunisian Cohort of 30 Patients

Authors Yakoubi M[1], Gharbi G[2], Ben Mohamed A[2], Mahmoudi M[2], Medhioub M[2], Hamzaoui L[2]

Institutes **1** Hôpital régional Mohamed Taher El Maamouri, Mrezga, Tunisia, Mrezga, Tunisia; **2** Regional Hospital Mohamed Taher Al Maamouri, Mrezga, Tunisia

DOI 10.1055/s-0046-1821849

Aims Familial adenomatous polyposis (FAP) is a rare hereditary condition marked by thedevelopment of numerous adenomatous polyps in the colon and rectum, significantly elevating therisk of colorectal cancer.

This retrospective study aimed to delineate the epidemiological, clinical, and therapeuticcharacteristics of a cohort of patients followed-up at our institution.

Methods We reviewed the medical records of the patients diagnosed with FAPbetween 2012 and 2025. Data on family history, presenting symptoms, findings from colonoscopy,and therapeutic interventions were analyzed.

Results Thirty patients were enrolled. The mean age at diagnosis was 49.5 years (range: 17–78), witha male-to-female ratio of 1.14. A family history of FAP was present in 40 % of cases. Diagnosis wasmade via family screening in 26.7 %, incidentally in 16.7 %, and in 56.6 % due to digestive symptoms.The attenuated FAP phenotype was predominant, affecting 76.6 % of patients. Polyps were mainlyfound in the rectum and descending colon (66.7 %). Nine patients (30 %) had prophylactic colectomy.Surgery was performed in 70 % of the cases after diagnosis of cancerous polyposis. Adenocarcinomawas located in the rectum in 20 % of patients and treated by coloproctectomy and ileoanalanastomosis. In 80 % of the cases it was located in the colon: 13 patients (61.9 %) underwent a totalcolectomy with ileorectal anastomosis, while 2 (9.5 %) underwent a coloproctectomy with ileoanalanastomosis. The 5-year recurrence rate was 19 %, predominantly involving the rectum. Extra-colonicmanifestations were frequent, with 33.3 % of patients presenting with gastric polyps (mostlyhyperplastic), 26.7 % with duodenal polyps, 43.3 % with thyroid nodules, 10 % with retinitispigmentosa, and one patient with desmoid tumors.

Conclusions This study highlights the critical need for early diagnosis and regular surveillance in FAPpatients. The attenuated phenotype was prevalent, and extra-colonic manifestations were common.Prophylactic colectomy remains the gold standard for colorectal cancer prevention in these patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP523 Inflammatory pseudopolyp secondary to chronic diverticulitis: an unusual finding

DOI 10.1055/s-0046-1821850

Abstract Text

Inflammatory pseudopolyps are benign, reactive lesions usually arising in chronic inflammatory bowel disease, formed by regenerating mucosa surrounded by ulcerated areas. Their occurrence following acute diverticulitis is exceedingly rare, as diverticular inflammation typically resolves without producing localized polypoid regenerative changes [1].

We present the case of a 46-year-old male evaluated in the endoscopy unit for follow-up after an episode of acute diverticulitis occurring four months before colonoscopy.

Colonoscopy revealed colonic diverticulosis from the sigmoid colon to the hepatic flexure. A 5-cm sigmoid segment showed luminal narrowing and edematous mucosa, with difficulty advancing the endoscope. Immediately proximal to this segment, an arboriform polypoid lesion measuring approximately 8 mm was identified. The surface showed no features of dysplasia but demonstrated increased vascular pattern. Close inspection of the polyp base revealed glandular elongation. Given the unusual appearance, biopsies were obtained for further evaluation.

Histopathology reported vascular dilation and stroma with abundant collagenous tissue, without adenomatous changes, consistent with an inflammatory lesion. At follow-up, the patient reported persistent but gradually improving abdominal pain since the diverticulitis episode. A second-look colonoscopy was therefore scheduled.

On repeat colonoscopy performed three months later, the previously described sigmoid segment persisted, but the polyp had completely disappeared, leaving a diverticulum containing granulation tissue.

This case represents an uncommon inflammatory pseudopolyp arising after acute diverticulitis, with complete endoscopic resolution on short-term follow-up, highlighting the rarity and transient nature of such reactive postdiverticulitis lesions.

eP524 The "coalescing" esophageal ulcer in acute severe colitis: biopsy strategy and endoscopic patterns of herpes simplex infection

Authors Bógalo Romero C[1], Sánchez Roncero FJ[2], Madrigal Bayonas L[2], Gómez Gómez A[1], Romero Martínez M[1], Calatayud Vidal G[2], Egea Valenzuela J[1], Alberca De Las Parras F[1]

Introduction: In patients with acute severe ulcerative colitis (ASUC) undergoing rescue therapy with cyclosporine and steroids, new-onset odynophagia is an ominous sign. Differentiating between drug-induced injury, Candida, CMV, and Herpes Simplex Virus (HSV) is critical but endoscopically challenging. We present a case illustrating the distinct "coalescing geographic" pattern of severe HSV esophagitis and the importance of targeted biopsy sampling [1–3].

Case Description: A 43-year-old female with extensive ulcerative colitis was admitted for a severe corticosteroid-refractory flare. Rescue therapy with intravenous cyclosporine was initiated. During hospitalization, she developed acute, intense odynophagia.

Urgent gastroscopy revealed a striking pathology in the mid-esophagus (31–37 cm from incisors). Unlike the discrete plaques of Candida or the deep, punched-out ulcers typically seen in CMV, the mucosa exhibited multiple flat, geographic ulcerations. These lesions were non-fibrinous with an erythematous base and showed a clear tendency to coalesce, resulting in circumferential involvement of the esophageal lumen. The distinct lack of raised plaques or pill fragments shifted the suspicion toward a viral etiology.

Crucially, biopsies were targeted at the raised margins of the ulcers rather than the necrotic center. Histopathology revealed multinucleated giant cells with nuclear molding and "ground-glass" chromatin (Cowdry type A bodies). Immunohistochemistry confirmed Herpes Simplex Virus Type 1 (HSV-1). Treatment with acyclovir resulted in rapid symptom resolution.

Conclusion: This case highlights two essential learning points for the endoscopist managing immunosuppressed IBD patients. First, the endoscopic phenotype of HSV esophagitis evolves from vesicles to diffuse, coalescing geographic ulcers with friable borders, mimicking caustic or pill-induced injury. Second, diagnostic yield depends on technique: unlike CMV (which resides in the ulcer base), HSV infects the squamous epithelium at the ulcer margins. Recognizing this pattern ensures correct biopsy targeting and avoids diagnostic delay in the critical setting of ASUC.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821852

Aims Surgery remains frequent in patients with Crohn's disease (CD), with a potential cumulative risk of short bowel syndrome. The aim of our study was to evaluate the correlation between the Rutgeerts endoscopic score and clinico-endoscopic recurrence during the first year following intestinal resection in patients with CD.

Methods We conducted a retrospective analytical and descriptive study within the Department of Hepato-Gastroenterology and Proctology, including all patients with CD who underwent ileocecal or right ileocolic resection between 2019 and 2024. Patients without postoperative colonoscopy were excluded. Postoperative endoscopic recurrence was defined as a Rutgeerts score ≥ i2.

Results A total of 92 patients were included. The mean age was 41.3 years (20–72 years), with a slight female predominance (F/M sex ratio = 1.19; 50 women and 42 men). The mean interval between CD diagnosis and surgery was 2.6 years. Six patients (6.5 %) were smokers.

Disease location was ileocecal in 50 % of patients (n = 59), ileocolic in 44.5 % (n = 41), ileal in 4.3 % (n = 4), and extensive in 1 %. The phenotype was stricturing in 64.1 % (n = 59), penetrating in 18.4 % (n = 17), mixed stricturing/penetrating in 14.1 % (n = 13), and inflammatory in 2 cases.

Thirty-three patients (35.8 %) had perianal Crohn's disease, including: complex fistulas: 29 patients (31.5 %) anal ulcerations: 2 patients (2.1 %) anal stenosis: 1 patient (1 %) anal fissure: 1 patient (1 %)

Indications for surgery were ileal or ileocecal stricture in 73.9 % of patients (n = 59), internal or external fistulas in 20.6 % (n = 19), and deep abscess in 2 patients.

Postoperative colonoscopy was performed after a mean of 9.2 months (6–11 months). Endoscopic recurrence (Rutgeerts ≥ i2) was observed in 59.7 % of patients (n = 55), distributed as follows: Rutgeerts i2: 20 patients (21.7 %) Rutgeerts i3: 9 patients (9.7 %) • Rutgeerts i4: 26 patients (28.2 %)

Clinical recurrence occurred in 53.2 % of patients (n = 49).

In univariate logistic regression analysis, statistically significant predictors of clinical recurrence were:Rutgeerts score ≥ i2 ($p < 0.001$) presence of perianal disease ($p = 0.042$)

In multivariate analysis, only a Rutgeerts score ≥ i2 remained significantly associated with clinical recurrence ($p < 0.001$).

Conclusions Endoscopic recurrence of Crohn's disease assessed by the Rutgeerts score is strongly correlated with the risk of clinical recurrence. These findings highlight the predictive value of the Rutgeerts score in postoperative monitoring and support early therapeutic optimization in high-risk patients.

eP526 Hemostatic powder for the management of massive "geographic" gastric ulcers: a safer approach to cmv-induced bleeding

Authors Bógalo Romero C[1], Madrigal Bayonas L[2], Sánchez Roncero FJ[2], Calatayud Vidal G[2], Romero Martínez M[1], Gómez Gómez A[1], Alberca De Las Parras F[1], Egea Valenzuela J[1]

DOI 10.1055/s-0046-1821853

Introduction: Cytomegalovirus (CMV) gastropathy is a serious complication in solid organ transplant recipients. Endoscopically, these ulcers often present as large, deep, and friable lesions with diffuse oozing bleeding. Standard hemostatic techniques (clips, thermal coagulation) carry a high risk of tissue tearing or perforation in this setting. We present a case demonstrating the utility of hemostatic powder as a safe and effective primary therapy for high-risk CMV ulcers.

Case Description: A heart transplant recipient (1 year post-transplant) with a history of prior rectal CMV infection presented with melena and hemodynamic instability. Emergent gastroscopy revealed multiple ulcerations in the gastric body posterior wall.

The dominant lesion was a giant (> 3 cm) ulcer with a characteristic "geographic" morphology, deep fibrin base, and irregular borders. An adherent clot was present, and upon washing, active diffuse oozing ("sheet-like") bleeding was observed from the ulcer edges. Given the extreme friability of the tissue and the extensive surface area of the bleeding, mechanical clipping was deemed technically unsafe, and thermal therapy posed a perforation risk. Consequently, hemostatic powder was applied as the primary modality, achieving immediate hemostasis without tissue contact [1–3].

Biopsies taken from the ulcer margins were positive for CMV on immunohistochemistry. The patient was treated with intravenous ganciclovir. A follow-up gastroscopy showed complete re-epithelialization of the ulcer, replaced by a flat, hyperplastic nodular scar, confirming therapeutic success.

Conclusion: This case highlights two critical points for the endoscopist. First, the "geographic" ulcer pattern in an immunocompromised patient is pathognomonic for CMV and mandates biopsy for immunohistochemistry, even in the setting of acute bleeding. Second, hemostatic powder represents an ideal therapeutic tool for these specific lesions, offering effective control of diffuse bleeding in friable, high-risk tissue where conventional mechanical or thermal methods may be hazardous.

eP527 Endoscopic balloon dilation of Roux-en-Y anastomotic stricture after gastric bypass: a systematic review and meta-analysis

Authors Rancatore G[1], Rizzo GEM[1], Ligresti D[1], Quintini D[1], Pizzicannella M[1], Tarantino I[1]

Institute **1** IRCCS ISMETT – UPMC, Palermo, Italy

DOI 10.1055/s-0046-1821854

Aims Bariatric surgery is the most effective treatment to achieve weight loss and to improve metabolic outcomes. In this context, Roux-en-Y gastric bypass (RYGB), is one of the main surgical procedures for obesity. Although it is effective, it is burdened by early and late complications such as gastro-jejunal (GJ) anastomotic stricture. In this context, endoscopic balloon dilation is an effective non-operative approach. Aim of our meta-analysis is to evaluate clinical success and safety of endoscopic balloon dilation.

Methods This MA was conducted in accordance with the Cochrane Handbook for Systematic Reviews of Interventions and in accordance with the Preferred Reporting Items for Systematic Review and Meta-Analyses (PRISMA) statement. A systematic literature search of MEDLINE, SCOPUS and EMBASE databases was performed. For clinical success, the DerSimonian and Laird random-effects model estimated the untransformed proportions. This approach provides a point estimate from the analysis along with 95 % Confidence Interval (95 % C.I.) from the rate proportion of the estimate. For all other analyses, a p value less than .05 was considered statistically significant.We included 26 studies.

Results In 26 studies, the overall clinical success rate was 98.3 % (95 % CI: 97.08-99.61 %) with no significant difference between patients undergoing open and laparoscopic surgery. The presence of anastomotic ulcers was significantly associated with reduced clinical success, with a negative correlation (estimate = 0.0021, $p < 0.0001$), suggesting that the presence of anastomotic ulcers negatively impacts the clinical success. Among the 24 studies, the improvement rate after a single session was 54.13 % (95 % CI: 44.09–64.17 %). A significant inverse correlation between the presence of anastomotic ulcers and symptom improvement after one dilation session, confirming that ulcer on anastomotic stricture may require more than one dilation session ($p = 0.007$). Overall the pooled rate of adverse (EAs) was 0.72 % (95 %. CI: 0.12-1.33 % $I^2 = 0$ %). Most of EAs are bleeding, perforation or mucosal tears managed conservatively with no needed of surgery. No significant difference on safety was observed between patients undergone laparotomy ($p = 0.53$) compared to those undergone laparoscopic surgery ($p = 0.40$). Furthermore, no association with stapler type ($p = 0.34$), time to diagnosis/treatment ($p = 0.71$) and presence of anastomotic ulcer ($p = 0.49$)was observed.

Conclusions Endoscopic balloon dilation is a highly effective and safe treatment for GJ anastomotic strictures following Roux-en-Y gastric bypass. Altough patients with ulcer-associated strictures may need multiple dilation sessions, the overall clinical success remain excellent.

eP528 Assessment of the Value of Colonoscopy in Patients With Rectal Bleeding: Comparative Study According to Age

Authors Mechhor S[1], El Bacha H[2], Cherkaoui Malki M[1], Nadia B[2], Errabih I[2]

Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821855

Aims Rectal bleeding is a common reason for consultation, with etiologies ranging from benign anorectal and colorectal conditions to more severe diseases, including neoplastic processes, whose prevalence varies with age.The aim of this study was to assess the diagnostic value of colonoscopy in cases of rectal bleeding according to patient age.

Methods A retrospective descriptive and analytical study was conducted from January 2022 to December 2024, including 225 patients who underwent colonoscopy for rectal bleeding. Patients were divided into two groups: Group 1

(patients under 50 years) and Group 2 (patients over 50 years). Epidemiological, clinical, and endoscopic data were compared between the two groups. Patients diagnosed with inflammatory bowel disease (IBD) were excluded. Statistical analysis was performed using Jamovi software version 2.3.28.

Results Results: The mean age of patients was 54 ± 13 years, with a female predominance: 120 women (53.3 %) and 105 men (46.6 %), corresponding to a male-to-female ratio of 0.9.Among the 225 patients presenting with rectal bleeding, 35.6 % were under 50 years of age and 64.4 % were over 50. Rectal bleeding was isolated in 50.5 % of cases, associated with constipation in 20.3 % (G1: 15 % vs G2: 13 %; p = 0.213), with diarrhea in 17.3 % (G1: 13 % vs G2: 9.9 %; p = 0.184), and with iron-deficiency anemia in 8 % (G1: 6.8 % vs G2: 6.7 %; p = 0.645).Colonoscopy findings were normal in 57 % of cases and pathological in 43 % (G1: 30.6 % vs G2: 69.3 %; p = 0.001).The most frequently observed pathologies were: colorectal polyps in 46.6 % of cases (G1: 30.7 % vs G2: 52.1 %; p = 0.041) , rectitis/colitis in 23.2 % (G1: 46.6 % vs G2: 10.9 %; p < 0.002) , colorectal tumors or suspicious processes in 14 % (G1: 6.7 % vs G2: 19.7 %; p = 0.02) colonic diverticulosis in 11 % (G1: 6.3 % vs G2: 12.8 %; p = 0.122) , colonic angiodysplasia in 8 % (G1: 5.2 % vs G2: 13.5 %; p = 0.409) , solitary rectal ulcer in 1.3 % (G1: 0.8 % vs G2: 0.4 %; p = 0.816). Univariate and multivariate analyses revealed that factors associated with pathological colonoscopy findings in rectal bleeding were age over 50 years (p = 0.03) and the presence of associated constipation (p = 0.011).

Conclusions Colonoscopy remains a key diagnostic tool in the evaluation of rectal bleeding. In our study, age over 50 years was associated with pathological findings, most commonly polyps and colorectal lesions, whereas rectitis or rectocolitis was the most frequent diagnosis in patients under 50 years.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP529 Associated factors with advanced colorectal polyps in patients under 50 years: A retrospective study

Authors Ncir M[1], Ayari M[1], Ben Azouz S[1], Chehaider A[1], Douggui H[1], Jomni T[1]

Institute 1 Internal Security Forces Hospital, Marsa, Tunisia

DOI 10.1055/s-0046-1821856

Aims Advanced colorectal polyps (ACPs) are the immediate precursors of colorectal cancer. Although less common in individuals under 50, the occurrence of ACPs in this age group is an emerging concern due to the risk of malignant progression to colorectal cancer, highlighting the need to investigate associated risk factors in younger adults.

This study aims to investigate the frequency and associated factors for the development of ACPs in patients under 50 years.

Methods We conducted a descriptive, retrospective study of 302 consecutive patients aged under 50 who underwent total colonoscopy between April 2023 and October 2024. Data were extracted from electronic medical records, including demographics, lifestyle factors (BMI, smoking, alcohol), family history, and comorbidities. Endoscopic characterization of polyps were classified according to the NICE and CONNECT criteria. ACPs were defined as adenomas ≥ 10 mm, those with villous histology, or high-grade dysplasia.

Results The study included 302 patients, with a male-to-female ratio of 1.51. The mean age was 41.13 years (range: 16–50 years). A family history of colorectal cancer was present in 10.9 %. Overall, colonic polyps were found in 32.4 % of the cohort, while ACPs based on polyp size and histopathological examination were detected in 4.6 % (n = 14). Statistical analysis identified age (p = 0.002), family history of polyps (p = 0.026) and macroangiopathic diabetes complications (p = 0.05) as significant associated factors. Polyp-related characteristics were also strongly associated with ACPs, including polyp multiplicity (p < 0.001), polyp location (p < 0.001), and both the NICE (p < 0.001) and CONNECT classifications (p = 0.04). In addition, ACPs were significantly associated with resection-related complications (p < 0.001) and with polyp recurrence (p < 0.001).

Conclusions These findings suggest that although ACPs are relatively uncommon in young adults, several demographic, clinical, and polyp-specific characteristics can help identify individuals at higher risk. Identification of these factors may allow early detection and better prevention strategies in younger individuals.

eP530 EUS-guided biliary drainage versus percutaneous transhepatic biliary drainage after failed ERCP in oncological patients: a 10-year retrospective comparison

Authors Alves P[1], Lenz L[2], Clemente C[2], Kristal I[1], Beltrami M[1], Gustavo ADP[2], Costa Martins B[2], Safatle-Ribeiro A[2], Maluf-Filho F[2]

Institutes 1 Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil; 2 Cancer Institute of the State of São Paulo, São Paulo, Brazil

DOI 10.1055/s-0046-1821857

Aims To compare technical success, clinical success, bilirubin response, safety, and survival between EUS-BD and PTBD after failed ERCP in patients with malignant biliary obstruction treated at a Brazilian tertiary referral center.

Methods Retrospective cohort study including 67 consecutive oncology patients (34 EUS-BD, 33 PTBD) managed between 2013 and 2023 after unsuccessful ERCP. All EUS-BD procedures were performed with lumen-apposing metal stents (LAMS) or self-expandable metal stents via hepaticogastrostomy or choledochoduodenostomy routes. Demographic, laboratory, procedural and follow-up data were collected. Categorical variables were compared using χ^2 or Fisher's exact test; continuous variables using Student's t-test or Mann–Whitney U test. Survival was evaluated by Kaplan–Meier curves and log-rank test. A p-value < 0.05 was considered significant [1–3].

Results Baseline characteristics were comparable except for oncological stage: stage IV disease was significantly more frequent in the EUS-BD group (p = 0.004). Technical success was 100 % in both arms. Clinical success (resolution of jaundice or > 50 % bilirubin reduction within 30 days) was similar (EUS-BD 70.6 % vs PTBD 78.8 %; p = 0.576). Pre-procedure total and direct bilirubin levels were higher in the PTBD group (p = 0.019 and p = 0.011, respectively), yet both techniques achieved significant bilirubin decline.

Peri-interventional adverse events occurred in 8.8 % (EUS-BD) versus 3.0 % (PTBD) (p = 0.614); most were mild and managed conservatively. In-hospital late adverse events (AE) were 29.4 % versus 33.3 % (p = 0.796) and post-discharge AE 29.4 % versus 18.2 % (p = 0.147), with no significant differences. Severity of AE according to ASGE lexicon was also comparable. Notably, despite more advanced oncological stage at baseline, the EUS-BD cohort exhibited significantly better in-hospital survival (log-rank p < 0.05); overall survival did not differ between groups.

Conclusions In this 10-year Latin-American oncology cohort with failed ERCP, EUS-BD provided technical and clinical success rates equivalent to PTBD, with comparable safety profiles despite treating patients with more advanced disease. EUS-BD was associated with improved in-hospital survival and avoided external catheters, enhancing patient comfort and quality of remaining life. Selection bias (physician preference) cannot be excluded. Nevertheless, our findings support EUS-BD as the preferred rescue strategy after failed ERCP in malignant biliary obstruction and underline the need for institutional protocols favouring endoscopic ultrasound-guided approaches over percutaneous routes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP531 Endoscopic Resection of a Gastric Metastasis From Malignant Melanoma: A Case Report

Authors Espinel P[1], Pérez Urra C[1], Bulnes Labrador CB[1], Martín IC[1], Robles de la Osa D[1], Rizzo Rodríguez MA[1], González de Castro E[1], Montero Moretón ÁM[1], Pérez Citores L[1], Santos Fernández J[1], Maestro Antolín S[1], Santos Santamarta F[1], Cimavilla Román M[1], Moreira Da Silva BA[1], Rancel Medina FJ[1], Barcenilla Laguna J[1], Pérez Millán AG[1]
Institute 1 General Hospital Río Carrión, Palencia, Spain
DOI 10.1055/s-0046-1821858

Introduction Malignant melanoma is one of the most aggressive cancers. It primarily affects the skin and has a strong metastatic potential, involving multiple organs and systems such as the gastrointestinal tract. Within the digestive system, the small intestine is the most common metastatic site, followed by the stomach, although overall incidence remains low [1–4].

Case Report A 68-year-old male, active smoker, with a history of nodular melanoma on the back (Breslow index 3.7 mm and Clark level III), resected with clear margins and no evidence of malignancy in three right axillary sentinel lymph nodes. He later developed pulmonary metastases that were treated with anti-PD1 therapy, achieving complete radiological response. A follow-up abdominal CT scan revealed an apparent polypoid mural thickening with lobulated contours in the gastric antrum, measuring approximately 5 cm in its longest axis. Upper endoscopy with biopsy was performed, and histology confirmed metastatic melanoma. A subsequent endoscopic reassessment demonstrated a pedunculated lesion, which was completely resected and removed endoscopically (in fragments).

Discussion The gastrointestinal tract is among the most frequent sites of melanoma metastasis. The most affected organs are the small intestine (51–71 %), followed by the stomach (27 %), colon (22 %), and esophagus (5 %). Clinical symptoms of gastric melanoma are nonspecific and, in many cases—like our patient—may be absent. Most common presenting features include abdominal pain, gastrointestinal bleeding, nausea, vomiting, anemia, and weight loss. In this case, routine imaging surveillance allowed early detection and treatment of the lesion. It is estimated that up to 60 % of patients who die from melanoma have gastrointestinal metastases; however, only about 4.4 % are diagnosed before death due to the frequent absence of symptoms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP532 Locally Advanced Rectal Cancer and Total Neoadjuvant Therapy: The Endoscopist's Perspective

Authors Axiaris G[1], Georgiadou G[1], Athanasiadou E[1], Mamalis S[1], Baxevanis P[1], Stafylidou M[1], Soufleris K[1], Lazaraki G[1], Tzilves D[1]
Institute 1 Theageneio Anticancer Hospital of Thessaloniki, Thessaloniki, Greece
DOI 10.1055/s-0046-1821859

Aims Total neoadjuvant therapy (TNT) has emerged as the standard approach for locally advanced rectal cancer (LARC), aiming to improve tumor downstaging and organ preservation. Post-TNT evaluation is crucial to identify patients eligible for a non-operative "watch and wait" strategy. This study aimed to analyze the clinical, endoscopic, and radiologic response assessment of patients with LARC who underwent TNT.

Methods This retrospective observational study included patients who received TNT between July 2023 and June 2025 at the Gastroenterology Department of Theageneio Anticancer Hospital. Demographic, clinical, endoscopic, and imaging data were collected. Endoscopic response was categorized as complete, near complete or incomplete based on mucosal appearance (flat white scar, telangiectasia, mucosal nodularity, persistent erythema or residual ulceration). MRI response was assessed in parallel, and management outcomes (surgical vs. non-surgical) were recorded. Follow-up included endoscopic and imaging surveillance every 3-6 months. Statistically comparisons were performed using Fisher's exact, Student's t-, or Mann–Whitney U tests, as appropriate.

Results Twenty patients were included, mean age of 68.65 ± 8.05 years, and 11 (55 %) were male. Presenting symptoms were rectal bleeding (55 %), pseudo-diarrhea (15 %), perianal pain (10 %), constipation (10 %), anemia (10 %) and tenesmus (5 %). Baseline MRI staging: stage IIIB in 60 %, stage IIA in 15 %, and stage IIIC in 25 %. After TNT, complete endoscopic response was observed in 5/20 patients (25 %), characterized by a flat white scar (4/5) or telangiectasia (1/5). Near complete response was noted in 1/20(5 %) with mild erythema and small mucosal nodules, while 14/20 (70 %) showed no endoscopic response. MRI assessment demonstrated complete response in complete endoscopic responders, yielding a 100 % concordance rate between MRI and endoscopy, these five patients were managed non-operatively under a watch-and-wait protocol, with a median follow-up of 21 months (range 10–27). Rectal bleeding was significantly more frequent in the conservative group (5/5,100 %, p = 0.038) than in the surgical group (6/15, 40 %). All other variables did not differ between groups. During follow-up, one patient developed local recurrence and underwent surgical resection. Fourteen patients (75 %) proceeded to surgery, with one specimen showing no residual dysplasia. whereas one patient refused surgery for personal reasons. At last follow-up, all patients were alive.

Conclusions Endoscopy is a valuable tool for assessing treatment response in patients with LARC undergoing TNT. Integrating systematic endoscopic evaluation into TNT response protocols may improve patient selection for organ preservation and reduce unnecessary surgery, as a substantial proportion of patients (25 % in our cohort) achieve complete clinical response and can safely avoid operative management through structured endoscopic and radiologic surveillance. Familiarity of endoscopists with post-TNT findings is essential for accurate evaluation, multidisciplinary decision-making, and implementation of "watch and wait" strategies.

eP533 Predicting Post-Clearance Stone Events After ERCP: A Simple Real-Life Risk Model

Authors Dendane Y[1], Azarkan A[1], Elmqaddem O[2], Koulali H[3], Kharrasse G[4], Zazour A[5], Ismaili Z[6]

Institutes **1** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Morocco, Oujda, Morocco; **2** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Oujda, Morocco; **3** Mohammed VI University Hospital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **4** Mohammed VI University Hôpital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **5** Mohammed VI University Hospital Center, Digestive Disease Research Laboratory, Oujda, Morocco; **6** Oujda, Morocco

DOI 10.1055/s-0046-1821860

Aims Despite technically successful ERCP, a subset of patients re-presents with stone-related events requiring repeat interventions. Current ESGE guidance acknowledges recurrence but offers no practical strategy to identify high-risk individuals. This study aimed to determine real-life predictors of post-clearance events and develop a simple, immediately applicable risk model.

Methods Consecutive patients with confirmed choledocholithiasis undergoing therapeutic ERCP were retrospectively analyzed. Only procedures with strict verification of complete clearance (stone extraction and clean cholangiogram) were included. Stone-related reintervention was defined as any repeat ERCP for residual or recurrent stones. Clinical, radiologic, and endoscopic variables were assessed. A concise 3-item risk score was constructed based on the strongest predictors.

Results Among 494 patients with complete duct clearance, 33 (6.7 %) required stone-related reintervention. Stone burden was the dominant determinant: empierrement (≥ 3 stones) increased risk nearly fourfold (12.4 % vs 3.7 %; OR 3.7). Papillary anatomical difficulty (bombante, deformed, or peri-diverticular papilla) showed a synergistic impact. In contrast, stone size ≥ 15 mm, CBD dilation ≥ 12 mm, and prior cholecystectomy were not independent predictors. The resulting 3-item Stone-Risk Score (empierrement + papillary difficulty + pre-ERCP drainage) stratified risk from 2.1 % (score 0) to 14.8 % (score ≥ 2), with meaningful discrimination (AUC ≈ 0.72).

Conclusions Post-clearance stone events are predictable rather than random. Stone burden and papillary complexity—rather than stone size or duct dilation—drive recurrence risk. This pragmatic model provides immediate clinical value and can refine post-ERCP follow-up strategies. These findings highlight a gap in current ESGE recommendations and justify targeted surveillance for high-risk profiles.

eP534 Prevalence of post-traumatic stress symptoms and risk factors among advanced endoscopists: the second victim phenomenon

Authors Salazar Parada N[1], Bautista C[1], Vazquez Gomez D[1], Arberas B[1], Ibañez-Pinto A[1], Esteban Fernández-Zarza C[1], Salces I[1], Herranz R[1], Rojo E[1], Poveda JJ[1], Casals Seoane F[2], Olivares R[1], Rodriguez-Muñoz S[1]

Institutes **1** Hospital Ruber Juan Bravo, Madrid, Spain; **2** Ruber, Madrid Spain

DOI 10.1055/s-0046-1821861

Aims Therapeutic endoscopy has evolved significantly, with increasingly complex procedures carrying higher complication risks. While severe adverse events profoundly impact patients (first victims), their psychological effect on endoscopists (second victims) remains understudied in our setting. This research assessed the prevalence of post-traumatic stress symptoms (PTSS) and associated risk factors among advanced endoscopists in Spain.

Methods A nationwide cross-sectional study was conducted among Spanish Society of Digestive Endoscopy (SEED) members. Using the validated PCL-5 questionnaire (DSM-5 criteria), we evaluated PTSS prevalence and severity. Data from 85 complete responses (out of 100 collected; 15 excluded for incompleteness) were analyzed using SPSS 31.

Results Participants' mean age was 46.34 years (SD 9.96), with 55.29 % male representation. PTSD prevalence was 12.94 % (n = 11), while 31.76 % (n = 27) reported significant symptoms without meeting full diagnostic criteria. Among symptomatic participants, symptom severity distribution was: mild (18.17 %; n = 21), moderate (12.94 %; n = 11), and severe (8.23 %; n = 7). Univariate analysis identified performing ≥ 12 procedures per endoscopy list as a potential risk factor (p = 0.04), though this association did not persist in multivariate analysis. No significant associations were found with age, sex, or years of experience.

Conclusions A non-negligible prevalence of PTSD was identified among advanced endoscopists in our setting. These findings highlight the need to recognise the endoscopist as a potential second victim and to promote institutional strategies for psychological support and prevention. In a field where technical precision is essential, our results emphasise that the emotional well-being of the endoscopist is also a critical component of patient safety.

eP535 Predictors of Technical Failure During ERCP for Malignant Biliary Strictures

Authors Dendane Y[1], Azarkan A[1], Elmqaddem O[2], Koulali H[3], Kharrasse G[4], Zazour A[5], Ismaili Z[6]

Institutes **1** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Morocco, Oujda, Morocco; **2** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Oujda, Morocco; **3** Mohammed VI University Hospital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **4** Mohammed VI University Hôpital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **5** Mohammed VI University Hospital Center, Digestive Disease Research Laboratory, Oujda, Morocco; **6** Oujda, Morocco

DOI 10.1055/s-0046-1821862

Aims Technical failure in ERCP for malignant biliary strictures remains a major determinant of patient outcome and procedural quality. This study aimed to identify robust, real-life predictors of technical failure using universally available anatomical and procedural variables, with the goal of guiding strategy in high-risk malignant obstruction.

Methods All index ERCPs performed for malignant biliary obstruction (2017–2023) were retrospectively reviewed. Technical failure was defined as the inability to achieve selective biliary cannulation or complete intended drainage. Candidate predictors included stricture level, intrahepatic duct dilation, completeness of cholangiogram, baseline bilirubin, and papillary anatomy. Independent predictors were identified using multivariable logistic regression.

Results Among 510 patients (mean age 66 ± 13 years; 51 % male), technical success was achieved in 94.8 %. Failures occurred predominantly in proximal or extensive hilar strictures. Incomplete cholangiogram was the strongest predictor of technical failure (adjusted OR ≈ 7.5), followed by absence of intrahepatic duct dilation (adjusted OR ≈ 5.8). Markedly elevated baseline bilirubin (> 300 µmol/L) was also associated with higher failure rates. Papillary distortion showed a weaker but consistent association.

Conclusions Technical failure during malignant ERCP follows a reproducible anatomical pattern rather than procedural variability. Three high-risk features—incomplete cholangiogram, non-dilated ducts, and severe cholestasis—characterize nearly all failures and should prompt upfront adaptation of drainage strategy. Anticipating rather than managing failure aligns directly with ESGE quality principles and enhances the safety and effectiveness of malignant biliary drainage in routine practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP536 Comparative Efficacy and Safety of Remimazolam Versus Propofol for Sedation in Gastrointestinal Endoscopy: A Systematic Review and Meta-Analysis of 37 Randomized Controlled Trials

Authors Hammad N[1], Ahmed LY[2], Ziad WE[3], Aya MR[4], Ahmed FY[5], Amr RS[6], Karim AK[7], Basma MEK[8], Mohamed NH[9], Belal H[10], Awad AA[10]
Institutes **1** Faculty of Medicine, University of Port Said, Port Said, Egypt; **2** Faculty of Medicine, Al-Azhar University Damietta, Damietta, Egypt; **3** Faculty of Medicine, Kafr El-Shaikh, Egypt; **4** Faculty of Medicine – Menofia University, Menoufia, Egypt; **5** Faculty of medicine, Damietta, Egypt; **6** Faculty of Medicine, Kafr Elsheikh Egypt; **7** Faculty Of Medicine – Tanta University, Tanta, Egypt; **8** Faculty of Medicine – Mansoura University, MANS, Egypt; **9** Misr University for Science & Technology, Giza, Egypt; **10** Faculty of Medicine Al-Azhar University, CAIRO, Egypt
DOI 10.1055/s-0046-1821863

Aims The aim of this study was to systematically compare the efficacy and safety of remimazolam versus propofol for sedation in gastrointestinal endoscopic procedures by synthesizing evidence from randomized controlled trials. Specifically, the study sought to evaluate differences in induction and recovery profiles, procedural performance, patient and endoscopist satisfaction, and the incidence of adverse cardiopulmonary events.

Methods A comprehensive search of PubMed, Web of Science, Scopus, Cochrane, and Embase was conducted from inception to January 2025. Randomized controlled trials comparing remimazolam and propofol in adult patients undergoing endoscopy were included. Primary outcomes included induction time, total sedation time, sedation success, procedure time, recovery parameters, and satisfaction. Safety outcomes included hypotension, bradycardia, hypoxemia, respiratory depression, postoperative nausea/vomiting, injection pain, and body movement. Random-effects models, subgroup analyses, sensitivity analyses, and meta-regression were performed.

Results From 2,304 records, 37 randomized controlled trials involving 8,533 patients met inclusion criteria. All studies were conducted in China or South Korea between 2020–2024. Risk of bias assessment showed 35 studies at low risk, one with some concerns, and one at high risk.

Induction time showed no overall difference between remimazolam and propofol (MD 0.13 s; 95 % CI − 0.05 to 0.31), though subgroup analysis showed significantly longer induction with remimazolam when MOAA/S = 1. Remimazolam was associated with shorter total sedation time (MD − 1.84 min; 95 % CI − 3.07 to − 0.61). Sedation success, procedure time, time to discharge, time to recovery, awake time, and endoscopist satisfaction showed no significant differences between drugs. Patient satisfaction slightly favored remimazolam (RR 1.06; 95 % CI 1.00–1.11).

Safety outcomes consistently favored remimazolam, with significantly lower risks of hypotension (RR 0.42), bradycardia (RR 0.42), respiratory depression (RR 0.37), hypoxemia (RR 0.42), and injection pain (RR 0.11). No significant differences were found for postoperative nausea/vomiting or body movement. Subgroup analyses across gastroscopy, colonoscopy, and ERCP highlighted procedure-specific differences, with remimazolam demonstrating longer induction time in gastroscopy and colonoscopy, but comparable performance in ERCP. Meta-regression showed age significantly modified induction time (P = 0.0239) but did not influence other outcomes.

Conclusions Remimazolam provides a markedly safer sedation profile than propofol for GI endoscopy, with significantly reduced cardiopulmonary adverse events and comparable efficacy across most clinical endpoints. Although induction may be slower, especially in certain procedures, remimazolam's overall performance supports its integration into routine endoscopic sedation practice. Larger multicenter trials with standardized MOAA/S criteria and more diverse populations are needed to refine clinical recommendations.

Noha Hammad, MD, earned her medical degree from Port Said University, Egypt. She is an active clinical researcher with growing expertise in gastrointestinal endoscopy and procedural sedation, with a particular focus on the comparative safety and efficacy of emerging sedative agents. Dr. Hammad is a trainee member of the American Society for Preventive Cardiology and a member of both the Medical Research Group of Egypt and Negida Academy (USA). She has authored multiple peer-reviewed publications and has presented her work at national and international conferences. Her current research interests include endoscopic sedation strategies, optimization of patient safety during GI procedures, and evidence-based evaluation of novel anesthetic and analgesic agents.

eP537 Predictors and Clinical Impact of Post-ERCP Complications in Malignant Biliary Strictures

Authors Dendane Y[1], Azarkan A[1], Elmqaddem O[2], Koulali H[3], Kharrasse G[4], Zazour A[5], Ismaili Z[6]
Institutes **1** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Morocco, Oujda, Morocco; **2** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Oujda, Morocco; **3** Mohammed VI University Hospital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **4** Mohammed VI University Hôpital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **5** Mohammed VI University Hospital Center, Digestive Disease Research Laboratory, Oujda, Morocco; **6** Oujda, Morocco
DOI 10.1055/s-0046-1821864

Aims Complications after ERCP for malignant biliary obstruction remain an important determinant of safety and procedural quality. This study assessed the incidence, spectrum, and predictors of post-ERCP adverse events using universally available clinical and procedural variables.

Methods All ERCPs for malignant biliary strictures (2017–2023) were retrospectively reviewed. Adverse events were defined according to ESGE criteria (pancreatitis, bleeding, perforation, cholangitis). Candidate predictors included sphincterotomy, papillary morphology, intrahepatic duct dilatation, completeness of cholangiogram, and procedural success. Associations were evaluated using univariate and multivariable logistic regression.

Results Among 510 patients (mean age 66 ± 13 years; 51 % male), overall complication rate was 9.8 %. Pancreatitis was most frequent (5.6 %), followed by bleeding (2.5 %), cholangitis (1.3 %), and perforation (0.4 %). Minimal functional sphincterotomy showed a higher pancreatitis rate numerically (7.4 % vs 4.1 %) but without statistical significance. Abnormal papillary anatomy doubled overall complication risk (10.8 % vs 4.2 %, p = 0.02). Absence of intrahepatic duct dilatation and incomplete cholangiogram were also associated with increased complications (14.3 % vs 7.5 %, p = 0.03). On multivariable analysis, non-dilated ducts (adjusted OR 2.9, 95 % CI 1.1–7.6) remained the only independent predictor. No procedure-related mortality occurred.

Conclusions Post-ERCP complications in malignant strictures follow reproducible patterns rather than patient fragility. Papillary anatomy, ductal architecture, and opacification strategy—not the underlying malignancy—drive risk. Identifying non-dilated ducts and avoiding excessive contrast injection are key to improving safety. Tailored technique and anticipatory strategy align directly with ESGE quality principles and enhance the safety of malignant biliary drainage in routine practice.

eP538 Stenosing Esophageal Involvement in Acquired Epidermolysis Bullosa

Authors mahiou S[1], Mitiche A[2], Mahiou I[3], Mahiou H[4], Saoula H[5]
Institutes **1** CHU Lamine Debaghine, Bab El Oued, Algeria; **2** Chu lamine debaghine, bab el oued, algeria, algiers, Algeria; **3** Chu mustapha bacha, algiers, Algeria; **4** Chu lamine debaghine, bab el oued, algiers, Algeria; **5** Chu lamine debaghine bab el oued, Algiers, Algeria
DOI 10.1055/s-0046-1821865

Introduction Acquired epidermolysis bullosa (AEB) is a rare autoimmune subepidermal blistering disorder mediated by autoantibodies against type VII collagen. Mucosal lesions are frequent, but esophageal involvement remains exceptional. When present, it may cause progressive dysphagia linked to cicatricial strictures, with major nutritional impact and impaired quality of life.

Case Report A 50-year-old man presented with bullous and post-bullous lesions on friction areas, associated with atrophic scarring and milia. Oral and nasal mucosal erosions were noted, with an 8-kg weight loss. Histopathology showed a subepidermal blister; direct immunofluorescence revealed linear IgG/C3 at the dermo-epidermal junction. ELISA demonstrated markedly elevated anti–type VII collagen antibodies and marginal anti-envoplakin positivity.Corticosteroids (0.5 mg/kg/day) were ineffective. Dapsone (100 mg/day) produced partial cutaneous improvement only. Endoscopy revealed a 7-cm circumferential mid-esophageal ulceration. Cyclosporine (3 mg/kg/day) induced transient improvement followed by progressive dysphagia.Repeat endoscopy showed an ulcerated cervical stricture with extensive mucosal detachment. Balloon dilation combined with high-dose corticosteroids and IVIG restored swallowing, improved weight, and prevented recurrence despite persistent mucosal fragility. Rituximab was subsequently initiated [1–3].

Discussion Esophageal involvement in AEB, although rare, represents a severe mucosal manifestation. Blistering, ulceration, and fibrotic strictures may occur, and endoscopy—while essential—is technically hazardous due to high mucosal fragility. Conventional therapies frequently fail to control severe mucosal disease. Endoscopic dilation is often required but carries procedural risks.Recent literature supports IVIG and rituximab as effective options in severe, refractory AEB, including stenosing esophageal forms, with favorable tolerance profiles.

Conclusion Esophageal AEB necessitates individualized, multidisciplinary management. Biologic therapies offer promising perspectives for refractory and stenosing mucosal disease.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP539 Recurrent Lower Gastrointestinal Hemorrhage Due to Post-Embolization Ischemic Injury

Authors Espinel P[1], Pérez Urra C[1], Bulnes Labrador CB[1], Martín IC[1], Robles de la Osa D[1], Moreira Da Silva BA[1], Santos Fernández J[1], Maestro Antolín S[1], González de Castro E[1], Barcenilla Laguna J[1], Santos Santamarta F[1], Cimavilla Román M[1], Rizzo Rodríguez MA[1], Pérez Citores L[1], Montero Moretón ÁM[1], Rancel Medina FJ[1], Pérez Millán AG[1]

Institute 1 General Hospital Río Carrión, Palencia, Spain

DOI 10.1055/s-0046-1821866

Introduction Endovascular angiography (EA) and transcatheter arterial embolization (TAE) are diagnostic and therapeutic procedures indicated in the management of selected gastrointestinal bleedings, particularly in hemodynamically unstable patients or when endoscopy is ineffective or unable to localize the bleeding source. Although it is a minimally invasive and generally safe technique, it is not exempt from complications, including intestinal ischemia.

Case Report A 78-year-old man with a history of ischemic heart disease was admitted to the hospital due to episodes of hematochezia without initial analytical impact. An abdominal CT scan revealed only diverticulosis. During hospitalization, rectal bleeding recurred with hemodynamic instability and anemia, requiring transfusion of up to eight red blood cell units. Upper endoscopy showed no abnormalities, and colonoscopy revealed abundant fresh blood without an identifiable source. CT angiography demonstrated an arterial bleeding focus in the hepatic flexure. Arteriography with embolization of three arterial branches from the ascending branch of the right colic artery was performed, achieving a significant reduction in blood flow. After 48 hours, new bleeding and anemia occurred. Repeat colonoscopy identified a pale mucosa with a fibrin-covered ulcer located at the hepatic flexure, likely secondary to post-embolization ischemia. The patient improved with conservative management, achieving clinical and analytical stability, with no further bleeding episodes [1–3].

Discussion Transcatheter arterial embolization is an effective and minimally invasive therapy for lower gastrointestinal bleeding, especially when endoscopic management fails. Although modern super-selective techniques have reduced complications, intestinal ischemia remains the main risk. A decrease in local blood flow may lead to mucosal damage, manifesting as ulcers or, rarely, necrosis or perforation. The hepatic flexure is particularly vulnerable due to its watershed vascular supply, which explains the ischemic ulcer observed in this patient. Early endoscopic reassessment is essential when rebleeding occurs, allowing prompt diagnosis and conservative management in most cases. This case highlights the importance of clinical vigilance after embolization to ensure timely recognition of ischemic injury and prevent severe outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP540 Plastic Stents for Malignant Biliary Obstruction: High Technical Success and Reliable Clinical Outcomes in a Resource-Limited Center

Authors Dendane Y[1], Azarkan A[1], Elmqaddem O[2], Koulali H[3], Kharrasse G[4], Zazour A[5], Ismaili Z[6]

Institutes 1 Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Morocco, Oujda, Morocco; 2 Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Oujda, Morocco; 3 Mohammed VI University Hospital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; 4 Mohammed VI University Hôpital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; 5 Mohammed VI University Hospital Center, Digestive Disease Research Laboratory, Oujda, Morocco; 6 Oujda, Morocco

DOI 10.1055/s-0046-1821867

Aims In settings where metallic stents are rarely available, plastic stents remain widely used for malignant biliary obstruction. This study evaluated real-life technical and clinical outcomes of plastic stent drainage in a Moroccan tertiary center and assessed predictors of early reintervention.

Methods All index ERCPs with plastic stent placement for malignant biliary strictures (2017–2023) were retrospectively reviewed. Technical success was defined as successful cannulation and stent deployment across the stricture with adequate drainage. Clinical success at one month required symptomatic improvement and ≥ 50 % bilirubin reduction when available. Data included demographics, stricture level, papillary anatomy, and prior drainage. Outcomes were technical/clinical success, early ERCP-related adverse events, and need for repeat ERCP due to stent dysfunction. Logistic regression explored predictors of reintervention.

Results A total of 510 patients were analyzed (mean age 66 ± 13 years; 51 % male). Technical success reached 99 %, with effective drainage in nearly all cases. Clinical success at one month was 80 %, consistent with ESGE benchmarks. Early adverse events occurred in 8 %, mainly mild pancreatitis (5 %) and limited post-sphincterotomy bleeding (2 %); perforations were rare (< 1 %). Repeat ERCP was required in 11 %, predominantly due to stent occlusion or migration. No independent predictors of early reintervention were identified

Conclusions In the absence of metallic stents, plastic stents achieve excellent technical success, reliable early clinical improvement, and an acceptable safety profile in malignant biliary obstruction. These real-life results highlight that high-quality biliary drainage can be delivered in resource-limited centers while aligning with ESGE quality indicators. Plastic stents remain a pragmatic, cost-effective solution when SEMS availability is restricted.

eP541 "Whipple's Disease: Capsule Endoscopy as a Non-Invasive Diagnostic Tool"

Authors Hernández Hernández N[1], Díez Martín J[1], Broco Fernández C[1], Patiño Delgadillo V[1], Boada Ortega D[1], Fernández Moreno M[1], Buela Fungueiriño L[1], Xavier Oliveira F[1], Jorquera Plaza F[1], Domínguez CAB[1]

Institute 1 University Hospital of León, León, Spain

DOI 10.1055/s-0046-1821868

Introduction: Whipple's disease is a rare, chronic multisystemic infection caused by *Tropheryma whipplei*, a Gram-positive bacillus. Its low prevalence and non-specific presentation lead to diagnostic delay, although early treatment is essential as the disease can be fatal.

Case Report: A 40-year-old man with no relevant medical history was admitted to the rheumatology department for axial and peripheral arthralgias of 3-year duration. He developed acute-onset diarrhea lasting less than one week, without pathological products. He reported constitutional symptoms, including 5-kg weight loss over the previous year, asthenia, fever, and cervical lymphadenopathy. Laboratory tests indicated malabsorption with iron-deficiency anemia, hypoproteinemia, and low vitamin D, along with elevated acute-phase reactants. Upper and lower endoscopy revealed only mild, non-specific erythema in the duodenum and distal ileum. Capsule endoscopy (CE) demonstrated marked villous atrophy, multiple ulcerations, and whitish infiltrates—more prominent in the proximal small bowel—suggestive of lymphangiectasia. Terminal ileum biopsies showed periodic acid–Schiff (PAS)-positive foamy macrophages. Based on CE findings and histology, treatment with intravenous ceftriaxone 2 g daily for 14 days was initiated. Extraintestinal involvement was excluded by transthoracic echocardiography and cerebrospinal fluid polymerase chain reaction (PCR). Stool PCR for *T. whipplei* was positive. The patient then received oral trimethoprim–sulfamethoxazole 800/160 mg every 12 hours for one year, with significant clinical improvement.

Discussion: Whipple's disease is caused by *T. whipplei*, a ubiquitous actinomycete with an incidence of 1–3 cases per 1,000,000, occurring mainly in predisposed individuals. Its clinical course is typically long-standing and non-specific, mimicking several rheumatologic conditions. The onset of gastrointestinal symptoms increases diagnostic specificity. Neurological involvement is associated with poorer prognosis. Diagnosis relies on identifying PAS-positive foamy macrophages in affected tissue or detecting the microorganism by PCR in stool, urine, or cerebrospinal fluid. The intestinal mucosa may appear normal on endoscopy in up to 30 % of cases, and PCR can yield false positives. Immunohistochemistry is not universally available. In this case, CE was decisive in guiding the diagnosis by identifying characteristic patterns—villous atrophy, edema, lymphangiectasia, and denuded mucosa with petechiae—previously reported in other cases. CE also avoided the need for deep enteroscopy. Antibiotic therapy leads to clinical improvement within weeks, but long-term follow-up is required to prevent relapse. CE may represent a valuable non-invasive tool for disease monitoring. Given the limited literature, additional CE-based case reports may improve recognition of this rare entity.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP542 ERCPs in Malignant Hilar Biliary Obstruction – 10 years' experience from a tertiary centre

Authors Turner E[1], Nkaze Yanno S[1], Edwards A[1], On W[1]

Institute 1 St James's University Hospital, Leeds, United Kingdom

DOI 10.1055/s-0046-1821869

Aims Malignant Hilar Biliary Obstruction (MHBO) is caused by a variety of malignancies and patients often present with jaundice, necessitating biliary drainage. Endoscopic retrograde cholangiopancreatography (ERCP) is typically performed however this can be technically challenging in MHBO. We aim to present the characteristics and outcomes of patients who underwent ERCP for MHBO at Leeds Teaching Hospital Trust, a tertiary institution.

Methods Patients were identified from a prospectively maintained database of patients who underwent ERCP between November 2014 and December 2023. All those diagnosed with MHBO during this period were included. Retrospective analysis of electronic patient records was performed.

Results 228 patients underwent ERCP for MHBO. 51.8 % (n = 118) were male and 48.2 % (n = 110) were female. The mean age was 68 years old (SD ± 13.2), and the median follow-up period was 89.5 days (IQR 38.5-248.75). The commonest aetiology was cholangiocarcinoma in 58.0 % of patients (n = 130), followed by colorectal metastasis in 12.1 % (n = 27), gallbladder cancer in 8.0 % (n = 18) and hepatocellular carcinoma in 4.9 % (n = 11).

Technical success of ERCP, defined as successful placement of stents into the intended ducts, was achieved in 82.1 % of patients (n = 184); 68.5 % (n = 126) of which had metal stents and 28.8 % (n = 53) had plastic stents inserted. 5 patients had both plastic and metal stents inserted. Of the 40 patients who did not achieve technical success, 23 underwent further biliary intervention within 30 days (17 percutaneous transhepatic cholangiograms (PTC) and 6 repeat ERCP).

Clinical success, defined as reduction of pre-procedural bilirubin to ≤ 50 % within 30 days, was achieved in 57.5 % of patients (n = 107); 68.2 % (n = 73) of which had metal stents and 28.0 % (n = 30) had plastic stents inserted. 4 patients had both plastic and metal stents inserted. Of the 79 who did not achieve clinical success, 30 patients underwent further biliary re-intervention within 30 days (16 repeat ERCP and 14 PTC).

The post-procedural adverse event rate was 35.6 % (n = 79). Cholangitis occurred in 23.2 % (n = 51), pancreatitis in 10.5 % (n = 23), perforation in 0.9 % (n = 2) and liver abscess in 0.45 % (n = 1). 31 patients had multiple adverse events. The 30-day mortality rate was 16.1 % (n = 36); 21 patients died due to disease progression and 10 due to post-operative complications, of which cholangitis (n = 6) was most frequent.

Of the 94 patients who were deemed technically surgically operable at time of index ERCP, 29.8 % (n = 28) went on to have surgical intervention, with 19.2 % (n = 18) having successful curative resection. Surgical resection did not occur in 80.8 % of patients due to inoperable disease identified during work up (n = 34), poor surgical fitness (n = 19), disease progression (n = 10), perioperative finding of metastatic disease (n = 9), patient declined (n = 1) and failed portal vein embolization (n = 1). The median time from index ERCP to surgical resection was 76 days (IQR 42-137).

Conclusions Cholangiocarcinoma represented the majority of patients with MHBO requiring ERCP. Post ERCP adverse events occurred in just over a third of patients, although 30-day mortality was largely due to disease progression, indicating a need for better patient selection for a high-risk intervention. Only a small proportion of patients progressed to surgical resection.

eP543 Beyond Sedation: Can Virtual Reality Make Colonoscopy More Comfortable?

Authors Bouhdoud N[1], Sadik A[1], Machayi FZ[1], Aouroud H[1], Lairani FZ[1], Nacir O[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 Mohammed VI University hospital marrakech, Marrakesh, Morocco
DOI 10.1055/s-0046-1821870

Aims In many low- and middle-resource settings, unsedated colonoscopy remains widely practiced due to limited access to anesthetic support, cost constraints, and overloaded endoscopy units. Although safe and feasible, the procedure is often perceived as uncomfortable and anxiety-provoking, which may reduce patient adherence to surveillance programs. Virtual reality (VR) has emerged as a simple, low-cost, and scalable non-pharmacological tool that may enhance patient experience during endoscopic procedures. The aim of our study is to assess whether VR distraction can improve comfort, reduce pain and anxiety, and increase patient satisfaction during unsedated colonoscopy.

Methods Adult patients undergoing elective unsedated colonoscopy at our department , were invited to participate. Participants were randomized either to receive VR immersion during the procedure or to standard care. A low-cost VR headset displaying 20-minute immersive tropical landscape sequences with low-volume audio was used. Exclusion criteria included cognitive impairment, visual/hearing deficits, balance disorders, epilepsy, or limited language abilities.Outcomes were evaluated at four time points using validated tools: Anxiety: State-Trait Anxiety Inventory (STAI), pre/post – Pain: Numeric Rating Scale (NRS) – Comfort: Gloucester 5-point scale- Satisfaction: Net Promoter Score (NPS) and willingness-to-return Procedural metrics included cecal intubation rate, cecal intubation time, and total procedure duration.

Results Of 40 invited patients, 32 consented; 24 were analyzed (VR: n = 12; control: n = 12). Baseline characteristics were similar between groups.
Technical success: 100 % cecal intubation in both groups.
Cecal intubation time: shorter in the VR group (median 12 min vs 15 min), although not statistically significant.
Pain: lower expression in VR patients, without significant difference.
Comfort: higher in the VR group, with 64 % reporting good comfort vs 42 % in controls.
Anxiety: significantly reduced after the procedure in VR patients compared with controls.
Satisfaction: higher with VR (NPS 85.7 % vs 50 %).No VR-related adverse events occurred, and all VR participants completed the procedure wearing the headset and rated the experience as positive.

Conclusions In a real-world setting where unsedated colonoscopy remains common due to resource limitations, VR proves to be a safe, inexpensive, and highly acceptable tool to improve patient comfort and reduce anxiety. While this pilot experience does not compromise procedural performance, it offers an innovative, scalable strategy to enhance patient experience and could support broader adoption of unsedated colonoscopy in similar healthcare systems. Larger studies are warranted to confirm these findings.

DOI 10.1055/s-0046-1821871

Aims Minimally invasive endoscopic techniques have been proposed in recent years for non-medical symptom control in patients with gastroesophageal reflux disease (GERD). Anti-reflux mucosal resection (ARMS) and ablation (ARMA) involve resection or ablation of the mucosa at the cardia to induce scar retraction at the esophagogastric junction (EGJ), with the aim of tightening the flap valve. Various technical variations have been described to optimize the technique. To date, their efficacy has been demonstrated in numerous reports and a few meta-analyses.

Methods Between March 2023 and November 2025, patients on long-term proton pump inhibitor (PPI) therapy for diagnosed GERD were enrolled at our institution. The technique consists in ablation of the cardiac mucosa for 3 cm on the gastric side and along the Z-line, sparing 25 % of the mucosa at the greater curvature. We chose to include the Z-line in the ablation area (ARMA-Z), hypothesizing that this approach may reduce acid sensitivity by improving mucosal integrity and restoring the impaired esophageal barrier function in GERD. Ablation was performed in the retroflex position using an Argon Plasma Coagulation probe (Forced APC, effect 2, 40W). A submucosal bleb was first created by injecting saline mixed with methylene blue along the EGJ. Clinical and endoscopic data were collected at baseline and at follow-up (3, 6, and 12 months). The primary outcome was subjective symptom improvement; secondary outcomes included changes in flap valve grade and and rates of PPI discontinuation.

Results A total of 15 patients underwent ARMA-Z (8 women, mean age 57 ± 4.4 years). All had a long history of typical symptoms and 7 also reported pharyngo-laringeal symptoms. All showed positive 24-hour pH-impedance monitoring with significant symptom correlation. High-resolution manometry ruled out major motility disorders. All patients had experienced satisfactory symptom control on standard-dose PPIs but relapsed rapidly after withdrawal (PPI-dependent). One patient experienced medication-related side effects. Technical success was achieved in 100 % of cases, with no immediate adverse events. Follow-up data are available for 12 patients. All patients reported symptomatic improvement at 3 months and all subsequent follow-ups, with 58 % achieving complete remission. At 6 months, 8 patients (67 %) discontinued PPI therapy and 1 (8 %) reduced the dose; the remaining 25 % continued on standard dose. Among patients who discontinued PPI, 75 % remained off medication at 12 months follow-up, while 25 % required short courses of therapy for occasional symptoms. Upper endoscopy confirmed improvement in flap valve morphology, with all patients achieving Hill grade 1. No transient stenosis or significant dysphagia was observed.

Conclusions Our preliminary findings demonstrate promising results in GERD symptom control through mechanical strengthening of the flap valve and desensitization of the Z-line. Compared with similar techniques, ARMA-Z appears to have a safer profile, is easier to perform, and is cost-effective. If longer follow-up and objective testing in larger cohort studies confirm these results, ARMA-Z could become a game changer for GERD patients with persistent troublesome symptoms requirinbg long-term medical therapy or those experiencing adverse drug reactions.

Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; 6 Department of Pathophysiology and Organ Transplantation, Università degli Studi di Milano, Milan, Italy; 7 Liver Transplant Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy
DOI 10.1055/s-0046-1821872

Aims Biliary anastomotic strictures (BAS) are the most common biliary complication following orthotopic liver transplantation (OLT) with duct-to-duct anastomosis, occurring in up to 25 % of cases [1]. Endoscopic plastic multistenting (EPM), with [2] or without [3] previous stent exchange, is the first-line treatment for post-OLT BAS [4].While most patients respond favorably, a significant proportion fail EPM and require percutaneous transhepatic biliary drainage (PTBD) or surgical revision [5]. This study aims to determine the incidence of BAS in a high-volume transplant center, the effectiveness and safety of EPM without stent exchange and of PTBD in ERCP-failure patients.

Methods This retrospective single-center cohort study included all adult patients who developed BAS after OLT and completed a 6-months biochemical and radiological follow-up after completion of the EPM or PTBD treatment protocol.Clinical, biochemical, radiological, and procedural data were systematically collected.The EPM group included patients who completed ERCP treatment protocol as previously described by Tarantino et al., i.e. ERCP scheduled every 3 months, up to 1 year, with endoscopic dilation plus sequential plastic stents across the narrowing without removing the previous stents. The PTBD group included any ERCP failure patients receiving a 2-step PTBD with metal stenting to be removed 4-6 later via ERCP.The primary endpoint was the clinical success defined by biochemical and radiological resolution at six months follow-up. EPM or PTBD with a clear radiological success in patients with biochemical alterations secondary to chronic rejection or hepatocarcinoma recurrence were classified clinically successful on a case-by-case basis with a multidisciplinary judgment.

Results Between January 2017 and April 2024, 43 BAS were identified among 348 OLT, corresponding to an overall incidence of 12.4 %.

Among these, 33 entered the EPM group and 10 the PTBD group.Baseline characteristics were comparable in the EPM and the PTBD group: median age at first ERCP 58.9 years (52.6–63.6) vs 59.1 years (57.2–62.8), male sex 79 % vs 60 %, Kehr T-tube placement 48 % vs 30 %, respectively.

Pre-procedural imaging identified a clear BAS in 73 % of cases within the EPM group and in all PTBD cases (p = 0.089); consistently, upstream biliary dilatation was slightly more frequent in the PTBD cohort (100 % vs 67 %, p = 0.043). Biliary stones or sludge were found in 15 % vs 10 % (p = 1.00). Median follow-up following EPM and PTBD was 21.6 and 34.6 months (p = 0.24).

In the EPM group, the biochemical, radiological and clinical success at 6-months follow-up was achieved in 93.5 %, 96.0 %, and 90.9 % respectively. Only one late BAS recurrence (3.0 %) occurred 4.2 months after a successful EPM and was conservatively treated with additional ERCP plus balloon dilation. Adverse events included stent migration in 8 patients (24 %), cholangitis in 9 (27 %), fever in 10 (30 %), and transient abdominal pain in 7 (21 %).

In the PTBD group, biochemical, radiological and clinical success at 6-month follow-up were achieved in 20.0 %, 30.0 % and 30.0 % of patients, respectively, all markedly inferior to the ERCP group (p < 0.01). BAS recurrence occurred in 2/10 PTBD patients (20.0 %) compared with 1/33 in the ERCP cohort (3.0 %). In the PTBD group, 3 patients (30 %) ultimately required re-transplant and 2 (20 %) underwent hepaticojejunostomy because of persistent or recurrent biliary complications.

Conclusions In this eight-year experience, the incidence of BAS after OLT was 12.4 %, consistent with international benchmarks. EPM has excellent effectiveness and long-term outcomes, with > 90 % clinical success and sporadic late recurrence. PTBD was a rescue treatment to prevent surgical anastomotic revision or re-transplant successful only in a proportion of patients with failed EPM, reflecting the higher intrinsic complexity of ERCP-refractory post-OLT BAS. These findings confirm the strategy of sequential EPM without stent exchange as a robust first-line therapy and highlight the importance of early identification of ERCP-failure to optimize therapeutic sequencing in post-OLT biliary complications.

eP546 Successful management of portal cavernoma cholangiopathy induced CBD stricture with haemobilia using Fully Covered Self Expanding Metal Stent and somatostatin infusion

Author Kothari H[1]

Institute 1 Yashoda Super Speciality Hospital, Ghaziabad, India
DOI 10.1055/s-0046-1821873

Background:A 40-year-old woman with a 15-year history of extrahepatic portal vein obstruction (EHPVO) presented with jaundice and pancreatic-type of pain. Magnetic Resonance Cholangiopancreatography(MRCP) revealed portal cavernoma, lienorenal collaterals, and multiple small choledocholithiasis. Mild acute pancreatitis was also noted [1–3].

Objectives:

- To highlight the challenges and caution needed while attempting ERCP in patients with portal cavernoma cholangiopathy (PCC)
- To evaluate the utility of peri-procedural somatostatin infusion in preventing haemobilia
- To assess the role of fully covered self-expanding metal stents (FCSEMS) in managing biliary stricture with concurrent choledocholithiasis

Methods and Treatment: Endoscopic Ultrasound revealed multiple vascular channels obscuring the lower CBD. Endoscopic Retrograde Cholangiopancreatography(ERCP) done which showed filling defects and distal CBD narrowing. After small sphincterotomy no obvious bleed seen. Hence, decision taken to do balloon dilatation of papilla, however massive haemobilia occurred, necessitating urgent plastic stent placement. This stent became clogged within three days due to haemobilia. A repeat ERCP was planned with prophylactic somatostatin infusion. The stent was removed, and a 10 × 60 mm FCSEMS was placed under somatostatin cover and no repeat episode of haemobilia happened.

Outcome: Six weeks later, the FCSEMS was removed uneventfully under cover of somatostatin infusion. No residual stones or bleeding were observed. The patient remained asymptomatic at four weeks follow-up.

Discussion: PCC poses unique therapeutic challenges due to vascular alterations around the bile duct. ERCP can be hazardous, with haemobilia being a major complication. Peri-procedural somatostatin may reduce bleeding risk. FCSEMS offers stricture dilatation, salvage bleeding, and facilitates spontaneous passage of stones.

Conclusion: In patients with PCC, ERCP should be approached with caution and planning. Somatostatin infusion and FCSEMS can enhance safety and efficacy in complex biliary interventions.

eP547 Technological advances in endoscopic imaging and their implication in improving colonic adenoma detection

Authors Hoffman A[1], Yanakieva I[1]
Institute 1 Klinikum Aschaffenburg-Alzenau, Aschaffenburg, Germany
DOI 10.1055/s-0046-1821874

Aims Detection and removal of colonic adenomas is a cornerstone in the prevention of colorectal carcinoma. However, a significant portion of adenomas remain undetected during index colonoscopy, that could lead to interval carcinoma. Many factors play a role, including patient characteristics, bowel preparation, investigator experience, and the technical features of the colonoscopy device. This study aimed to evaluate whether a new introduced advanced endoscopic system featuring ultra–high-resolution imaging fulfils the required adenoma detection rate in a real-world setting at a tertiary care hospital in Germany.

Methods Fifty consecutive patients undergoing screening colonoscopy between May 2025 and October 2025 were examined using the new AOHUA AQ-300 4K UHD Endoscopy System. All examinations were performed with high-definition white-light endoscopy followed by virtual chromoendoscopy. The system was launched in 2022 as one of the first 4K ultra-high-definition imaging system with a 4K display and 4K processor. There are four virtual chromoendoscopy modes, enabled by a 5-LED light source, which significantly improves image brightness. In our study we used only one of the integrated CBI modes.

The patient population was highly heterogeneous, aiming to reproduce a real-world scenario of colorectal carcinoma screening. The reasons for hospital-based screening included incomplete colonoscopy in an ambulatory setting or comorbidities with a high risk of periprocedural complications. The study population included 20 female and 30 male patients, with a mean age of 65 years. Bowel preparation was performed using a standard polyethylene glycol (PEG) formula, and the quality of bowel preparation was documented using standardised scale. Terminal ileum could not be reached in only one of the fifty patients. All colonoscopies were performed by the same experienced investigator.

Results Out of the 50 patients we screened, adenomas were detected in 20, corresponding to an adenoma detection rate (ADR) of 40 % in our study population. In all patients with detected lesions, we used CBI to predict if a lesion is dysplastic or not. We detected altogether 56 lesions. Each lesion was endoscopically removed and histologically examined. Of the 44 lesions predicted as dysplastic, dysplasia was confirmed in 28. Of the 12 lesions predicted as non-dysplastic, 8 lesions were histologically confirmed as non-dysplastic. The virtual chromoendoscopy mode CBI demonstrated a sensitivity of 87 % and the negative predictive value (NPV) in our cohort was 66 %.

Conclusions With these results, the ADR in our study was higher than the average reported in Germany, suggesting a potential improvement in patient outcomes. The diagnostic performance of the evaluated CBI mode in predicting dysplasia was moderate.

The primary focus of this first study using the new AOHUA AQ-300 4K UHD Endoscopy System was the adenoma detection rate (ADR), as current European guidelines recommend only the routine use of high-definition white-light endoscopy systems in this population. Whether the additional application of chromoendoscopy, and moreover the use of all four available chromoendoscopy modes, could further enhance diagnostic accuracy warrants investigation in future studies with a larger cohort.

eP548 Effectiveness of once-daily orodispersible budesonide 1 mg as maintenance therapy in eosinophilic oesophagitis: a pragmatic real-world cohort study

Authors Kumar R[1], Mcdonald H[1], Shaw K[1], Santa E[1], Cole F[1], Baker P[1], Morris D[1]
Institute 1 East & North Hertfordshire NHS Trust, Stevenage, United Kingdom
DOI 10.1055/s-0046-1821875

Aims Eosinophilic oesophagitis (EoE) is a chronic immune-mediated oesophageal disease requiring long-term anti-inflammatory therapy [1]. Budesonide orodispersible tablets (BOT) are licensed for induction and maintenance treatment [2], although real-world induction outcomes are more variable. The population-based DanEoE cohort reported 48 % histological, 57 % clinical and 39 % combined remission after induction [3], illustrating the challenge of achieving stable disease control outside trial conditions. In the UK, maintenance prescribing policies vary geographically, leading many patients to choose a once-daily 1 mg regimen after induction to avoid treatment breaks. However, evidence for the effectiveness of this regimen is limited.

This study aims to evaluate the real-world effectiveness of once-daily orodispersible budesonide 1 mg as maintenance therapy in adult EoE patients.

Methods We conducted a single-centre prospective observational cohort study, over 25 months (Oct 2023–Nov 2025), of adults with confirmed EoE who achieved histological remission < 15 eosinophils / high powered field (phpf) following induction BOT, and chose to take 1 mg once-daily maintenance. Disease activity was assessed using endoscopy and/or capsule sponge test (Endosign) with EREFS scoring, histology (peak eosinophil count phpf). Symptoms were documented using the Dysphagia Symptom Questionnaire (DSQ) and direct symptom enquiry. Primary endpoints were histological and clinico-histological remission. Secondary endpoints included DSQ outcomes and phenotype-based comparisons.

Results 30 patients commenced once-daily 1 mg maintenance therapy (median age 46 years, IQR 32–58; 57 % male). The median duration of maintenance treatment before reassessment was 17.9 weeks (IQR 12.3–35.6).

Of these, 29/30 (96.7 %) patients underwent gastroscopy, and 20/30 (66.7 %) had same-day capsule sponge sampling; 1/30 (3.3 %) had capsule sponge only. Using the highest peak eosinophil count across gastroscopy and capsule sponge, 25/30 (83.3 %) were in histological remission and 5/30 (16.7 %) had active inflammation. Clinical remission occurred in 26/30 (86.7 %) patients. Clinical remission occurred in 26/30 (86.7 %). DSQ scores were available for 23/30 (76.7 %), of whom 14/23 (60.9 %) had a DSQ score of 0. Clinico-histological remission occurred in 23/30 (76.7 %).

Among the 29 gastroscopy patients, 16/29 (55.2 %) had fibrostenotic disease and 12/29 (41.4 %) had inflammatory-only disease. Histological remission occurred in 13/16 (81.3 %) fibrostenotic patients vs 11/12 (91.7 %) inflammatory patients (Fisher p = 0.61). Clinical remission occurred in 13/16 (81.3 %) vs 11/12 (91.7 %) (p = 0.61). Clinico-histological remission occurred in 11/16 (68.8 %) vs 10/12 (83.3 %) (p = 0.66). Median treatment duration did not differ significantly between phenotypes (p = 0.35).

Conclusions In this real-world cohort once-daily 1mg BOT maintained remission with similar or better efficacy to reported series using twice daily dosing. These findings support dose de-escalation after induction therapy to a once

daily 1mg regime which may be easier to implement. They also demonstrate the previously reported use of capsule sponge sampling in monitoring EoE. Larger studies with extended follow-up are needed to confirm these findings but this study supports current pragmatic clinical practice. Additionally, once daily treatment may also improve compliance and be more financially acceptable.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP549 Diagnostic and therapeutic cholangioscopy for biliary strictures and choledocholithiasis: A single-center experience from 24 patients with various indications

Authors Papatheodoridi M[1], Lekakis V[2], Papadakos S[2], Markakis G[2], Alexopoulos T[2], Neonaki A[2], Bouga G[2], Papatheodoridis G[2], Koutsoumpas A[2]

Institutes **1** Department of Gastroenterology, General Hospital "Laiko", Athen, Greece; **2** 1st Academic Department of Gastroenterology, General Hospital of Athens "Laiko", Athens, Greece

DOI 10.1055/s-0046-1821876

Aims Cholangioscopy is an important tool, adjunctive to endoscopic retrograde cholangiopancreatography (ERCP),for cases that cannot otherwise be adequately evaluated or treated. Both single-operator peroral cholangioscopy (SOC) and percutaneous transhepatic cholangioscopy are available in our center. Our aim is to describe our experience with cholangioscopy, including safety and efficacy across various indications

Methods We retrospectively collected data from patients who underwent cholangioscopy from 2023 to 2025 and recorded demographics, medical history, ERCP–cholangioscopy procedure details (description–video–images), and complications such as cholangitis, pancreatitis, perforation, or bleeding that prolonged hospitalization for > 2 days.

Results A total of 24 patients were included. Their mean age was 66.2 ± 11.6 years, and 10/24 (42 %) were women. Fifteen patients (62.5 %) had undergone a prior ERCP. Difficult choledocholithiasis was the indication in 6 procedures (20.8 %); in 5/6, ERCP had previously failed to clear the common bile duct (CBD), which had a diameter > 20 mm. In cholangioscopy procedures for choledocholithiasis, electrohydraulic lithotripsy was performed, and in 3 of these cases multiple balloon trawls and basket stone retrievals were also carried out. In the remaining 18/24 cases, the indication was indeterminate biliary strictures. Three cases were approached percutaneously via a transhepatic route due to altered anatomy, and three involved anastomotic strictures in liver-transplant recipients. Sphincteroplasty was required in 7/24 patients (29 %), and biliary stents were placed in 20/24 (83 %). Complications occurred in 9/24 (37.5 %) patients, while the median length of hospitalization after cholangioscopy was 2 (IQR 3) days. Age, sex, sphincteroplasty, stent placement, prior ERCP, or the indication for cholangioscopy were not significantly associated with the development of complications (P > 0.620).

Conclusions Cholangioscopy is an effective procedure with acceptable safety, which can assist in the diagnostic evaluation and management of challenging biliary cases in clinical practice.

eP550 Endoscopic Management of Fistulized Hepatic Echinococcus Cysts

Authors Cherkaoui Malki M[1], Errabih I[2], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], El Bacha H[2]

Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821877

Aims The aim of this study was to describe the clinical and evolutionary features of patients presenting with biliary involvement of hydatid cysts.

Methods We conducted a retrospective descriptive study in the Hepato-Gastroenterology and endoscopy department , from January 2019 to July 2025. Were incuded all patients admitted for biliary dilatation secondary to hepatic cystic echinococcosis and managed by endoscopic drainage.

Results Eleven patients were hospitalized for hydatid cysts complicated by biliary fistulization. The mean age was 44.6 years (range: 22–79), with a marked female predominance (female-to-male ratio: 4.5).Clinically, 7 patients (64 %) presented with acute cholangitis, 2 cases were incidentally discovered, and 2 patients reported right upper quadrant pain.

Hydatid serology was positive in 7 patients (64 %). Leukocytosis was observed in 9 patients (82 %), associated with elevated CRP levels in 10 patients (90 %). Cyst localization was as follows: the left hepatic lobe in 6 patients (54 %), the right lobe in 2 patients (18 %), and bilobar involvement in 3 patients (28 %).Two patients (19 %) had cysts larger than 10 cm, six (54 %) had cysts between 5 and 10 cm, and three (27 %) had cysts smaller than 5 cm.WHO-IWGE staging was: CE2 in 5 patients (45 %), CE1 in 1 patient (9 %), CE4 in 1 patient (9 %), and CE5 in 1 patient (9 %). All patients (100 %) presented with biliary dilatation and underwent endoscopic sphincterotomy with successful extraction of hydatid material. No post-procedural complications were noted, and no morbi-mortality was noted.

Conclusions Biliary fistulization represents the most common complication of hepatic hydatid disease. Endoscopic treatment is effective and safe. In our series, left-lobe localization and cyst diameter greater than 5 cm were the most frequent characteristics of those patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP551 Optimizing Colorectal Screening: The Added Value of Endocuff Vision for Polyp Detection

Authors Bouhdoud N[1], Machayi FZ[1], Sadik A[1], Aouroud H[1], Lairani FZ[1], Nacir O[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute **1** Mohammed VI University hospital marrakech, Marrakesh, Morocco

DOI 10.1055/s-0046-1821878

Aims Colonoscopy is the gold standard for colorectal cancer screening, yet up to one-third of adenomas may remain undetected due to limited mucosal visibility, particularly in hidden areas such as the sigmoid colon and caecum. Endocuff Vision (EC), an add-on device with flexible projections designed to flatten colonic folds, has emerged as a promising tool to improve mucosal exposure and optimize detection rates. The aim of this study is to evaluate whether the use of Endocuff Vision enhances polyp and adenoma detection compared with standard colonoscopy.

Methods A prospective randomized study was conducted in the our Department of CHU Mohammed. Twenty-five patients undergoing colorectal adenoma screening were enrolled. All underwent standard colonoscopy with or without EC assistance. Outcomes included polyp detection rate (PDR), adenoma detection rate (ADR), number of polyps per patient, segmental lesion distribution, and safety. Statistical analysis was performed to compare both groups.

Results The EC group demonstrated a 63 % higher number of polyps detected per patient compared with standard colonoscopy [2.00 (IQR 1.00–4.00) vs 1.00 (IQR 1.00–2.25), $p < 0.0001$]. PDR improved by 14 % with EC assistance (56 % vs 42 %, $p = 0.001$).Significant superiority was observed for polyps < 1 cm in the

sigmoid colon ($p = 0.001$) and caecum ($p = 0.002$).ADR increased by 86 % in the EC group ($p = 0.002$).No major complications occurred in either group.

Conclusions Endocuff Vision significantly improves both polyp and adenoma detection, particularly in anatomically challenging segments. The device is safe, feasible, and easy to integrate into routine practice. Its adoption may enhance the effectiveness of colorectal cancer screening programs by reducing missed lesions.

eP552 Incidence and Determinants of Post ERCP Pancreatitis Following Metallic Biliary Stent Placement: A Two Year Retrospective Cohort from a UK Tertiary Hepatopancreatobiliary Centre

Authors Asim H[1], saeed S[2], Bilal S[3], Saeed S[4], Nick S[1], Rizwan S[1]
Institutes 1 Aintree University Hospital, liverpool, United Kingdom; 2 Aintree University Hospital, Manchester, United Kingdom; 3 Aintree University Hospital, liver, United Kingdom; 4 Aintree university Hospital, Lower Lane, Fazakerley, Liverpool, UK, liverpool, United Kingdom
DOI 10.1055/s-0046-1821879

Aims To determine the incidence and characterise contributory risk factors for post-ERCP pancreatitis (PEP) in patients undergoing metallic biliary stent placement at a UK tertiary hepatopancreatobiliary centre [1, 2].

Methods A retrospective review was undertaken of 217 adult patients undergoing ERCP with biliary stent placement between January 2023 and April 2025. Stents comprised fully covered self-expandable metallic stents (FcSEMS) and uncovered SEMS (UnSEMS). Patients were observed for 20 days following ERCP. Post-ERCP pancreatitis (PEP) was defined in accordance with the revised Atlanta criteria and ESGE guidelines.

Results Post-ERCP pancreatitis (PEP) occurred in 7.83 % (17/217) of patients. The cohort demonstrated a male predominance, with mean age 78.7 years. Prophylaxis with NSAIDs or GTN was administered in all cases. Distribution was comparable between fully covered SEMS (8/17) and uncovered SEMS (9/17). Indications were dominated by complex proximal malignant strictures 76.5 % (13/17), with distal strictures 17.6 % (3/17) and Mirizzi syndrome 5.9 %. Procedural complexity was notable: prolonged duration > 15 minutes in 76.5 %, difficult cannulation in 35.3 % , pancreatic duct cannulation with contrast injection in 41.2 % , and trainee involvement in 52.9 % of the cases.
Mortality within three months of PEP was 0.51 % (1/197).

Conclusions Post-ERCP pancreatitis (PEP) was observed in 7.83 % of patients undergoing metallic biliary stent placement. A distinct male predominance was noted. Risk was heightened by metallic stents, pancreatic duct manipulation, and procedural complexity. Prophylaxis was near-universal, yet procedural factors remained decisive. Prolonged duration, PD cannulation, and trainee involvement were prominent contributors. These findings underscore the need for gender-aware risk stratification, meticulous procedural planning, and for complex ERCP procedures to be performed by expert endoscopists. Such measures may reduce PEP incidence and optimise patient outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821880

Abstract Text

A 69-year-old man, six years post–orthotopic liver transplantation for alcoholic cirrhosis, presented with abnormal liver-function tests. 3D-MRCP showed a 14-mm dilation of the common hepatic duct and marked caliber mismatch at the biliary anastomosis. ERCP failed to achieve guidewire passage despite standard techniques and cholangioscopy revealed minimal bile flow without a visible orifice. Bite-on-bite attempts were unsuccessful. A 0.3-mm polypectomy snare was modified by removing its protective sheath to create a cutting tool compatible with the cholangioscope. During a second ERCP, a small endocut incision enabled proximal duct cannulation, balloon dilation (6 mm), and placement of a fully covered metal stent. Four-month follow-up ERCP showed normal intrahepatic ducts and a significantly improved anastomotic caliber.

DOI 10.1055/s-0046-1821881

Abstract Text

Capsule endoscopy (CE) is a highly effective and safe technique for small-bowel evaluation, though capsule retention occurs in fewer than 2 % of cases and may uncover significant pathology. We report a 56-year-old woman with iron-deficiency anemia and positive fecal occult blood whose CE revealed a friable, stenosing proximal jejunal lesion that blocked capsule progression. Retention was confirmed radiographically, and the capsule was successfully retrieved endoscopically. Biopsies identified a moderately differentiated jejunal adenocarcinoma, subsequently treated with curative surgery and adjuvant chemotherapy. This case illustrates how capsule retention, despite being rare, can represent the first diagnostic clue to small-bowel malignancy and highlights the need for pre-procedure assessment for potential strictures to ensure safe CE use [1, 2].

eP555 The role of endoscopic ultrasound before ERCP in pancreatico-biliary emergencies with inconclusive imaging: a real-world analysis from an emergency hospital

Authors Alexe MC[1], Tieranu CG[1], Calu V[1], Enciu O[1], Saftoiu A[1]
Institute **1** Elias Emergency University Hospital, Bucharest, Romania
DOI 10.1055/s-0046-1821882

Aims Current ESGE guidelines recommend endoscopic ultrasound (EUS) or MRCP before ERCP to confirm choledocholithiasis, minimizing unnecessary therapeutic procedures[1]. Additionally, the ASGE recommends evaluating patients by assessing the risk of choledocholithiasis before any therapeutic intervention[2,3]. Patients with intermediate and high risk were evaluated. We evaluated the diagnostic impact of EUS performed before ERCP in such cases, focusing on small-stone and sludge detection and on avoidance of negative ERCPs [1–3].

Methods We retrospectively analyzed 524 patients with EUS examination in which 24 patients with pancreatico-biliary emergencies (acute biliary pancreatitis, acute cholangitis, or cholestatic jaundice) and inconclusive imaging (only normal / dilated common bile duct or intrahepatic bile ducts described on US, CT, or MR/MRCP) admitted over 36 months. All underwent EUS before ERCP according to local emergency-unit protocol. EUS findings, ERCP results, therapeutic yield, and complications were compared with historical controls managed by ERCP-first strategy.

Results Among 24 patients (mean age 65 ± 15 years; 29.2 % female), EUS identified bile-duct stones or sludge in 66.70 % of cases despite inconclusive cross-sectional imaging. ERCP confirmed stones in 93.75 % of EUS-positive cases. In 45.80 % of patients with negative EUS, ERCP was avoided, thus reducing overall ERCP rate.

Conclusions EUS before ERCP significantly improves diagnostic accuracy and prevents unnecessary invasive procedures in pancreatico-biliary emergencies with inconclusive imaging. Adoption of an "EUS-first" strategy, even in resource-limited emergency hospitals, aligns with ESGE guidelines and enhances patient safety, procedural efficiency, and cost-effectiveness.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text
Anastomotic dehiscences after colorectal resections are serious complications following oncologic surgery and may require an individualized management. Colorectal Tube-in-tube Endoscopic Vacuum Therapy (CR TT-EVT) has emerged as a promising minimally invasive alternative for the treatment of these complications [1, 2].
We report the case of a 72-year-old man who underwent a rectosigmoidectomy with extended left colectomy and primary mechanical colorectal anastomosis, without derivative stoma, for colon cancer treatment (pT4a pN2b M0, stage III). Because of a slow post-operative recovery, a rectoscopy was performed on the 21th day, revealing an anastomotic dehiscence, with cavity formation which allowed finding the lower mesenteric artery clip visualization. Intracavitary, transanal, CR TT-EVT was initiated. By the 13th day of treatment, a marked reduction in the dehiscence was observed, with only a small residual fistulous tract opening remaining. Given the confirmed closure of the cavity on CT imaging and the patient's clinical improvement, therapy was interrupted and patient discharged. Adjuvant chemotherapy was initiated. Following his first chemotherapy cycle, 37-days after discharge, the patient was readmitted with fistula recurrence and fever. A new course of CR TT-EVT was then initiated and, once again, a remaining small fistulous opening was found on the 19th day, when a full thickness clip (Padlock) was deployed to achieve complete closure and complete recovery.EVT is an effective minimally invasive strategy for managing anastomotic fistulas, even in cases of recurrence. Debate remains on when to interrupt it. However, pursuing complete closure should be the goal, mainly in the scenario of no diverting stoma. Whether achieved by continued vacuum therapy or with complementary techniques such as clipping.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP557V Expanding the Horizons of EUS for Cervical Vertebral and Prevertebral Pathologies: A Case Series

Authors Gopi S[1], Sri Sai Bhavya J[1], Eshwar Chandra N[1], Nikhil H[1], Y BRC[1], Nagarjuna MV[1], Ashish A[2], Naveen P[1], Somashekhar K[1], Santosh E[1]
Institutes **1** Yashoda Hospitals Hitech City, Hyderabad, India; **2** AIIMS Jodhpur, Jodhpur, India
DOI 10.1055/s-0046-1821884

Problem to solve Cervical vertebral and prevertebral pathologies – including retropharyngeal/prevertebral abscesses, spondylodiscitis and vertebral body lesions – are difficult to sample due to their deep location and proximity to vital neurovascular structures. Blood cultures are frequently negative, with a sensitivity ≤ 50 % in deep neck or vertebral infections, making microbiological diagnosis uncertain and leading to frequent use of empirical antibiotics. CT-guided biopsy in the cervical region is technically challenging, offers limited real-time feedback, and carries procedural risks due to tight anatomical confines. Surgical biopsy is invasive and associated with higher morbidity. A safe, minimally invasive, real-time method for sampling cervical vertebral and prevertebral lesions—especially at high cervical levels (C2)—represents a major unmet clinical need.

Innovation We applied an innovative trans-pharyngeal and transesophageal EUS-guided sampling technique for cervical vertebral and prevertebral pathologies. Using a linear echoendoscope (FUJIFILM EG-580UT with ARIETTA system) introduced into the oropharynx and then the proximal esophagus under general anesthesia, the cervical vertebral column (C2–C7) was visualized in real

time. Between March 2024 and July 2025, patients with suspected cervical vertebral or prevertebral pathologies difficult for interventional radiology sampling underwent EUS-guided sampling under general anesthesia with endotracheal intubation. In the left lateral position, a linear echoendoscope (FUJIFILM EG-580UT with ARIETTA 750) was introduced into the oropharynx and proximal esophagus, and lesions were aspirated or biopsied using 19G or 22G needles. Fluoroscopy was used in selected cases to confirm the location of the vertebral body. Samples were sent for bacterial culture (in aerobic blood culture bottles to maximize yield), cytology, histopathology, and GeneXpert MTB/RIF when tuberculosis was suspected. This technique extends the application of EUS—traditionally limited to thoracic and mediastinal structures—into the cervical spine, offering a minimally invasive diagnostic pathway for lesions previously inaccessible or unsafe to sample using radiology or surgery.

Results Nine patients underwent EUS-guided sampling (median age 60 years; range 37–77; 6 males, 3 females). All presented with neck pain; one had dysphagia and another stridor. Sampling was successfully achieved from C2 through C7, including the first documented EUS-guided sampling of a C2 vertebral body lesion. The following were the diagnostic yield. A) Tuberculosis (n = 4): Caseating granulomas or MTB positivity on GeneXpert for TB or AFB staining. All patients responded to ATT alone with full clinical recovery. B) Pyogenic infections (n = 3): Organisms included *Acinetobacter baumannii*, *Enterobacter cloacae*, and *Klebsiella pneumoniae* with *Granulicatella adiacens*. Two patients required surgical drainage; one was managed medically. C) Others (n = 2): One culture-negative lesion with acute suppurative inflammation improved with prolonged antibiotics and drainage. Another non-diagnostic sample (only squamous cells) resolved with short oral antibiotics – likely self-resolving pathology. EUS confirmed TB in four and ruled it out in others. EUS-guided cultures enabled tailored antibiotic therapy. At least one patient avoided unnecessary surgery due to microbiological diagnosis via EUS. All patients improved clinically (follow-up range: 1.5–18 months). No procedural complications or adverse events occurred.

Conclusions Transesophageal EUS-guided sampling is a safe, feasible, and clinically transformative technique for diagnosing cervical vertebral and prevertebral lesions. It significantly expands the diagnostic reach of EUS into the cervical spine—previously accessible only via invasive CT-guided or surgical methods—while providing high diagnostic yield with excellent safety. By enabling accurate pathogen identification, EUS supports evidence-based treatment decisions and can help avoid unnecessary surgery. This is the largest reported series of EUS-guided cervical vertebral sampling to date and includes the first documented C2 vertebral body case. Further multicenter studies are needed to validate and standardize this novel approach.

eP558 The Contribution of Endoscopic Ultrasound in Tumor Pathology: A Retrospective Study

Authors Bouayad L[1], Cherkaoui Malki M[2], Mechhor S[2], Mghyly F[2], Cherkaoui Malki O[2], Benzzoubeir N[2], Errabih I[3], El Bacha H[3]
Institutes 1 CHU Souissi, Rabat, Morocco; 2 CHU Ibn Sina, Rabat, Morocco; 3 Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1821885

Aims Endoscopic ultrasound (EUS) is an imaging technique that combines endoscopy and high-frequency ultrasound, allowing precise evaluation of the digestive wall and adjacent structures.Digestive tumors pose a major diagnostic challenge due to their location and histological variability. EUS has become an essential tool for assessing parietal and submucosal tumors of the gastrointestinal tract, as well as for guiding biopsies for diagnostic purposes.

Methods This is a descriptive retrospective study conducted in our department over a 4-year period, from October 2021 to August 2025.It included all patients with a clinically or radiologically suspected digestive tumor who underwent endoscopic ultrasound in our institution.Clinical, radiological, EUS, and histological data were collected and analyzed [1–6].

Results In this study, 57 patients with a clinically or radiologically suspected digestive tumor were included, all of whom underwent endoscopic ultrasound in our department. The mean age was 63.78 years (range: 31–87 years), with a male predominance: 30 men (52.63 %) and 27 women (47.36 %), M/F ratio 1,1.

Regarding the indication for EUS, 50 patients (87.71 %) underwent the procedure for histological confirmation via fine-needle aspiration, while 7 patients (12.25 %) underwent EUS for tumor staging.

The most frequent tumor locations were the pancreas, with 50 cases (87.71 %), distributed as follows: 70 % in the pancreatic head, 14 % in the head and isthmus, 4 % in the pancreatic tail, and 12 % in the uncinate process. Other locations included the rectum (2 cases, 3.5 %), the stomach (4 cases, 7 %), and the ampulla of Vater (1 case, 1.75 %).

The average tumor size was 30.5 mm × 30.1 mm. concerning echogenicity, tumors were heterogeneous in 36 cases (63.15 %), hypoechoic in 16 cases (28.07 %), and hyperechoic in 2 cases (3.5 %).

EUS demonstrated locoregional invasion in 29 cases (50.87 %) and identified lymph node metastases in three patients that had not been detected on CT. Fine-needle aspiration was carried out in 50 patients (87.71 %).

Adenocarcinoma was the most common histological type, found in 44 patients (88 %). A gastrointestinal stromal tumor (GIST) was identified in 1 patient (2 %). Two cytological samples (4 %) revealed no tumor cells within the sample limits, while three cytological samples (6 %) were inconclusive.

Conclusions Endoscopic ultrasound is an essential tool for diagnosing and monitoring tumor pathology. It allows precise exploration of internal organs, particularly for digestive cancers, by locating tumors and assessing their extent. It also facilitates targeted biopsies and helps determine appropriate treatment. Thus, EUS plays a key role in tumor management, providing accuracy and therapeutic guidance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP559V Dual-Access Endoscopic Closure of a Long, Oblique Jejuno-Bronchial Fistula Using a Self-Expanding Nitinol Occlusion Device and Cyanoacrylate Glue: An Innovation in Complex Fistula Management

Authors Michelon M[1], Alioua SA[1], Leduc D[2], Tannouri F[3], Lemmers A[1]
Institutes 1 Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Erasme Hospital, Brussels, Belgium; 2 Department of Pneumology, Hôpital Erasme, Université libre de Bruxelles (ULB), Brussels, Belgium; 3 Department of Interventional Radiology, Erasme Hospital, Hôpital Universitaire de Bruxelles, Brussels, Belgium
DOI 10.1055/s-0046-1821886

Problem to Solve Broncho-digestive fistulas are rare but serious post-surgical complications, and their management is particularly challenging in long or oblique tracts where the fistulous channel does not align parallel to luminal surfaces. Conventional endoscopic options—including clipping, stenting, or sealant injection—often fail because of fibrosis, poor tissue apposition, and high mechanical tension.We report the case of an 80-year-old woman with a complex surgical history, presenting with chronic cough and weight loss. After a Nissen fundoplication complicated by pleural empyema, vagotomy, and severe gastroparesis, she underwent multiple pyloric dilations for gastric outlet obstruction. 10 years later, a first gastro-bronchial fistula developed, likely secondary to chronic stasis, and several endoscopic treatments (fibrin glue, coagulation, bulking agents, and a bronchial plug) achieved only transient benefit. A subtotal gastrectomy with gastrojejunal reconstruction eventually progressed to total gastrectomy with left lung resection and Roux-en-Y esophagojejunal reconstruction 12 years after that. 4 years later, she developed a new jejuno-bronchial fistula between the alimentary limb and the left bronchial tree. Multiple endoscopic approaches the years afterwards—including TTS clips, APC, OTSC for candy-cane syndrome, ESD-flap with OTSC, vacuum-assisted stenting, and endoscopic suturing—resulted only in temporary improvement. Given the chronicity, fibrosis, and oblique trajectory of the tract, conventional endoscopic repair was considered unlikely to succeed, and no standardized strategy for definitive closure currently exists. Recently, systematic cough and inability to tolerate oral food recurred with exacerbation compromising quality of life and prognosis, letting to propose a novel modality of fistula closure to the patient.

Innovation A combined digestive–bronchial endoscopic approach was developed for definitive closure of this complex jejuno-bronchial fistula.

The procedure was performed under general anesthesia and fluoroscopic control. Simultaneous access through the jejunal and bronchial routes enabled full visualization using contrast opacification, of the fistulous path. Because the rigid bronchoscope could not reach the fistulous origin, a guidewire was advanced from the jejunal side into the left main bronchus and retrieved bronchoscopically.

Using a rendez-vous technique (bronchoscopic-jejunoscopic), after gentle abrasion of the fistula tract, an 8 Fr bronchial introducer was advanced through the fistula, and a self-expanding nitinol occlusion device (12 × 9 mm) was deployed, with the distal disc expanded into the jejunal lumen and the proximal portion anchored along the long, oblique tract.

A 50:50 mixture of cyanoacrylate glue (Glubran) and Lipiodol was then injected under fluoroscopic control into the expanded device, achieving homogeneous opacification and complete occlusion without extravasation.

Results The procedure was completed safely without complications. Immediate fluoroscopic and endoscopic assessment confirmed stable device positioning and complete tract sealing. A nasojejunal feeding tube was placed, and the patient resumed oral intake after 24 hours.At follow-up, she reported marked improvement of cough, with no symptoms during solid intake and only mild, qualitatively different cough with liquids. Early satiety persisted, but her nutritional status improved, and the nasojejunal tube was maintained per nutritional recommendations.

Conclusions This dual-access endoscopic strategy demonstrates that self-expanding nitinol occlusion devices can be adapted to long, fibrotic, non-parallel fistulous tracts traditionally considered unsuitable for endoscopic repair.Although desscribed for tracheo-esophageal short fistula closure with parallel expanded discs, the use of self-expandable nitinol occlusion devices in long fistula tracts has not been reported.The combination of mechanical occlusion and cyanoacrylate sealing provides a reliable, minimally invasive solution for refractory broncho-digestive fistulas.This approach underscores the importance of multidisciplinary collaboration among interventional endoscopy, interventional radiology, and pulmonology in managing complex post-surgical fistulas.

eP560 Ampullary masses: cases series

Authors Fennich FA[1], Kadiri M[1], Lagdali N[2], Ajana FZ[3], Borahma M[3]
Institutes **1** Rabat, Morocco; **2** Mohammed V University, Rabat, Morocco; **3** MEDECINE C HEPATOGASTROENTEROLOGY DEPARTEMENT, IBN SINA UNIVERSITY HOSPITAL, Rabat, Morocco
DOI 10.1055/s-0046-1821887

Aims Ampullary masses constitute a rare but important pathology of the biliopancreatic junction. They include benign or malignant lesions that may manifest as cholestatic jaundice, sometimes associated with pancreatic pain. This work aimed to describe the epidemiological, clinical, radiological, and histological characteristics of ampullary masses.

Methods Patients and Methods

This was a retrospective descriptive study including all patient hospitalized for suspicion or confirmation of an ampullary mass in the Medicine C Department of CHU Avicenne between 2020 and 2025. Data were collected from medical records, imaging examinations (ultrasound, CT scan, MRCP, endoscopic ultrasound), and histological results.

Results We recorded 40 cases of ampullary masses. The mean age of the patients was 64 years, with extremes ranging from 38 to 91 years. A female predominance was noted (55 %, n = 22) with a male-to-female sex ratio of 0.81. The main clinical presentation was cholestatic jaundice observed in 87.5 % of cases (n = 35), followed by pancreatic pain in 12.5 % of cases (n = 5). Imaging showed double-duct sign in 82.5 % of cases (n = 33), with a tissue process at the biliopancreatic junction measuring on average 17 mm (10–30 mm), responsible for an average dilation of the common bile duct to 15 mm (6–30 mm) and of the Wirsung duct to 6 mm (3–11 mm).

Histologically, 65 % of the lesions corresponded to ampullary adenocarcinoma (n = 26), 10 % to high-grade dysplasia (n = 4), 5 % to a neuroendocrine tumor (n = 2), 5 % to benign lesions (n = 2), and 15 % of biopsies (n = 6) were negative or non-contributive.

EUSstaging showed a predominance of stage T2 (45 %, n = 18) followed by T3 (30 %, n = 12), T1 (20 %, n = 8), and T4 (5 %, n = 2). Lymph node involvement was observed in 30 % of cases (n = 12) and metastases in 5 % (n = 2).

Regarding treatment, endoscopic ampullectomy was performed in 20 % of patients (n = 8) and cephalic duodenopancreatectomy in 25 % (n = 10). The remaining 55 % (n = 22), who did not undergo any curative procedure, were managed palliatively, mainly with biliary drainage and stent placement.

The evolution was favorable in 60 % of cases (n = 24), with 20 % deaths (n = 8) and 20 % lost to follow-up (n = 8).

Conclusions ampullary masses represent a significant cause of cholestatic jaundice in elderly patients, with a female predominance and a clear predominance of malignant forms dominated by adenocarcinoma. Modern imaging techniques, particularly endoscopic ultrasound and MRCP, help refine the diagnosis and guide management. Treatment is based on surgery or endoscopic ampullectomy depending on the stage and histological nature. Despite diagnostic advances, the prognosis remains poor in infiltrative forms, highlighting the importance of early diagnosis and close follow-up.

eP561 An unexpected choledochoduodenal fistula identified during ERCP: a rare enterobiliary communication

Authors Neokleous A[1], Penesis G[1], Pagoni A[1], Bellou G[1], Tsokanta K[1], Christoulakis M[1], Internos I[1], Zacharopoulou E[1], Tzouvala M[1]

DOI 10.1055/s-0046-1821888

Abstract Text

Choledochoduodenal fistulas (CDFs) – between the common bile duct and the duodenum – represent the rarest type of abnormal enterobiliary communications. The most common type is the cholecystoduodenal fistula (70 % of all EFs) followed by cholecystogastric fistula (0-13.3 %), cholecystocolic fistula (0-10.9 %) and cholecystoileal (0-2.5 %) [1]. Possible etiologies may include cholelithiasis, peptic ulcer disease and trauma. Diagnosis is typically made on endoscopic retrograde cholangiopancreatography (ERCP) [2]. We present a case of a 73-year-old female with choledocholithiasis.

Case Presentation A 73-year-old female with a medical history of arterial hypertension and smoking, presented to our department with mild abdominal pain and jaundice. Clinical examination revealed mild epigastric tenderness and scleral jaundice; otherwise, the examination was unremarkable. Her labs on presentation were notable for a high level of C-reactive protein (CRP). Her liver function panel was abnormal with a total bilirubin of 2.6 mg/dl, direct bilirubin 1.4 mg/dl, AST 138 U/L and ALT 144 U/L, alkaline phosphatase 446 U/L and γ-GT 640 U/L. INR and albumin were normal. A magnetic retrograde cholangiopancreatography (MRCP) had been conducted a few months prior to the visit, had demonstrated multiple gallstones within the intra- and extrahepatic biliary tree, accompanied by common bile duct dilatation. No biliary strictures were identified. The patient subsequently underwent endoscopic intervention. ERCP revealed the presence of a choledochoduodenal fistula containing a huge impacted stone (diameter greater than 45mm) within the fistula tract. A wide sphincterotomy and sphincteroplasty were performed and biliary double pigtail stent was placed, uneventfully, achieving satisfactory drainage. The patient was discharged the next day, while on antibiotic therapy, after demonstrable improvement in laboratory values and remained asymptomatic with spyglass cholangioscopy lithotripsy pending.

Discussion Choledochoduodenal fistulas are extremely rear, pose a diagnostic challenge and are found mainly incidentally during endoscopy, which remains fundamental for their identification and direct visualization. Therapeutic decision making is contingent upon the underlying etiology, the presence of concomitant complications and overall symptom burden [3]. Our patient supposedly developed the fistula as a result of longstanding choledocholithiasis. In this case, it appears that cannulation of the common bile duct with subsequent stent placement contributed to effective biliary decompression, improvement of patients' symptoms and lowering the risk of recurrent biliary events. Management strategies of CDFs are not standardized, depend on etiology and symptom severity, with endoscopic intervention being effective in many cases. Larger fistulas may require surgical management, especially when other treatment strategies fail. Each case should be individualized based on the underlying etiology and the patients' clinical profile.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP562 Fecal microbiota transplantation in recurrent and refractory Clostridioides difficile infection: long-term insights from a tertiary health care center in a South European country

Authors Vidal Lima F[1], Ribeiro H[1], Gravito-Soares M[1, 2], Gravito-Soares E[1, 2], Narra Figueirdo P[1, 2]

Institutes **1** Gastroenterology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; **2** Faculty of Medicine, University of Coimbra, Coimbra, Portugal

DOI 10.1055/s-0046-1821889

Aims*Clostridioides difficile* infection (CDI) is associated with substantial morbidity and mortality. Patients at greatest risk are typically older, hospitalized and/or with multiple comorbidities. Fecal microbiota transplantation (FMT), a method aimed to restore the composition and diversity of gut's microbiota, has been recently approved for treating refractory CDI or recurrent CDI (rCDI), after a second recurrence that did not respond to conventional antibiotics. Current evidence suggests that FMT is a safe therapeutic method with few adverse effects, although, protocol optimization and long-term outcomes have not been completely elucidated [1, 2].

Methods We conducted a retrospective longitudinal analysis of all patients who underwent FMT in our department between 2017 and 2025. A rigorous selection of potential unrelated/cohabiting donors was carried out. All procedures were performed under aseptic conditions, ensuring that no more than 6 hours elapsed between the collection of fresh donor stools and the FMT execution. Demographic data, comorbidities, prior treatments, clinical outcomes (efficacy and safety), and follow-up data were collected.

Results Ten patients underwent FMT during the study period. The indication was rCDI for all cases. All procedures were performed via colonoscopy, with instillation of donor fecal solution into the ileum and cecum. The median age was 72.8 ± 12.1 years-old ; 70 % (n = 7) of patients were men . The mean Charlson Comorbidity Index was 6.4 ± 2.8. Type 2 diabetes was the most common comorbidity, followed by ulcerative colitis. Patients had experienced an average of 3.6 ± 1.0 prior CDI episodes before FMT. The mean interval between the first CDI episode and FMT was 15.6 ± 19.1 months with a range from 3 to 50 months. Three patients were receiving immunosuppressive therapy. All patients had been previously treated with antibiotics, the most frequent being vancomycin, followed by fidaxomicin and metronidazole. All patients responded to one-single FMT with an overall success rate of 100 % and no CDI recurrence. Median follow-up was 6(1-24) months. Five patients died during follow-up, three of them within 6 months of the procedure (due to pulmonary infection, suspected disseminated metastatic disease and non-Hodgkin B-cell lymphoma). No adverse events were registered. No deaths were attributed to CDI or the FMT.

Conclusions FMT proved to be effective and safe even in high-risk patients, including those who were chronically immunosuppressed, had inflammatory bowel disease and multiple and significant comorbidities. In case of refractory/recurrent CDI, repeat FMT via another route and/or another fecal donor may be considered. Mortality during follow-up was related to underlying comorbid conditions rather than FMT. Larger studies are need to further assess the outcomes and consider the use of frozen stool capsules from universal stool donor banks.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP563 Diagnostic Value of EUS in Patients With Weight Loss

Authors Addajou T[1], ait iken F[2], Benhamdane A[2], Amine M[2], Mrabti S[2], Elkoti I[2], Fedoua R[1], Seddik H[2]

Institutes **1** Mohamed V Military training hospital, Rabat, Morocco; **2** Mohammed V Military Training Hospital, Rabat, Morocco

DOI 10.1055/s-0046-1821890

Aims This study evaluated EUS diagnostic yield in patients presenting with weight loss.

Methods Among 74 EUS procedures performed between 2023–2024, patients with weight loss were identified (n = 28). Clinical presentation, EUS morphology, and final diagnoses were analyzed.

Results Of 28 patients with weight loss, 10 (35.7 %) were diagnosed with a significant underlying lesion. Diagnoses included:

- 7 pancreatic adenocarcinomas
- 1 neuroendocrine tumor
- 1 pancreatic tuberculosis
- 1 TIPMP

The remaining 18 patients (64.3 %) had no structural lesion on EUS.

Weight loss combined with jaundice showed the strongest association with malignancy.

Weight loss with fever predicted benign/infectious disease (TB case).

Cystic lesions (TIPMP and serous cystadenomas) did not present with isolated weight loss.

Conclusions In patients referred for EUS due to weight loss, approximately one-third had a clinically relevant diagnosis, predominantly pancreatic malignancy. Weight loss alone was not sufficiently specific, but its association with jaundice greatly increased the likelihood of malignancy. EUS remains an essential tool in the evaluation of unexplained weight loss.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP564 Optimal number of needle passes without ROSE during EUS-FNA and EUS-FNB: a marginal yield analysis

Authors Elommal H[1], Elmqaddem O[2, 3], Koulali H[4, 5], Zazour A[6], Kharrasse G[7], Ismaili Z[7]

Institutes **1** Hospital Center University Mohammed Vi, Oujda, Morocco; **2** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Oujda, Morocco; **3** Faculty of Medicine and Pharmacy of Oujda, Oujda, Morocco; **4** Mohammed VI University Hospital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **5** Laboratoire de recherche de maladie de l'appareil digestif(LARMAD) Oujda,Maroc, Oujda, Morocco; **6** Mohammed VI University Hospital Center, Digestive Disease Research Laboratory, Oujda, Morocco; **7** Mohammed VI University Hôpital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco

DOI 10.1055/s-0046-1821891

Aims To determine the minimal number of EUS-guided needle passes that maintains high diagnostic adequacy in solid pancreatic masses when rapid on-site evaluation (ROSE) is not available, and to compare the marginal diagnostic yield and safety of FNA versus FNB.

Methods In a single-centre retrospective cohort of pancreatic EUS-FNA/FNB procedures, cases were grouped according to the number of needle passes. For each stratum, diagnostic adequacy (conclusive vs non-conclusive) was calculated separately for FNA and FNB. For FNA, complication rates were compared between procedures with ≤ 2 versus ≥ 3 passes (Fisher's exact test). ROSE was not used in any procedure.

Results For FNA, adequacy rates were 69.0 % (20/29) with 1 pass, 73.4 % (80/109) with 2 passes, 73.9 % (34/46) with 3 passes and 100 % (2/2, small n) with 4 passes, showing only a limited marginal gain beyond 2–3 passes. For FNB, adequacy was 81.8 % (18/22) with 1 pass and 83.3 % (10/12) with 2 passes, with an early plateau from 1–2 passes. Only one complication (a pseudoaneurysm) was observed in the FNA group, with no clear association with the number of passes; no complications occurred in the FNB group.

Conclusions In the absence of ROSE, FNB achieves a high diagnostic yield with only 1–2 passes. For FNA, 2–3 passes appear sufficient, and the benefit of additional passes beyond this threshold seems minimal, with no signal of increased complications in this cohort.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP565 EUS-FNA versus EUS-FNB for solid pancreatic masses: diagnostic performance, needle passes and predictors of failure

Authors Elommal H[1], Elmqaddem O[2, 3], Koulali H[4, 5], Zazour A[6], Kharrasse G[7], Ismaili Z[7]

Institutes **1** Hospital Center University Mohammed Vi, Oujda, Morocco; **2** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Oujda, Morocco; **3** Faculty of Medicine and Pharmacy of Oujda, Oujda, Morocco; **4** Mohammed VI University Hospital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **5** Laboratoire de recherche de maladie de l'appareil digestif(LARMAD) Oujda,Maroc, Oujda, Morocco; **6** Mohammed VI University Hospital Center, Digestive Disease Research Laboratory, Oujda, Morocco; **7** Mohammed VI University Hôpital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco

DOI 10.1055/s-0046-1821892

Aims To compare the diagnostic performance (adequacy), number of needle passes and safety of endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) versus fine-needle biopsy (EUS-FNB) for solid pancreatic masses, and to identify predictors of non-diagnostic sampling.

Methods Single-centre retrospective study including all pancreatic EUS-FNA/FNB procedures from a local database (FNA n = 187, FNB n = 34).The primary endpoint was diagnostic adequacy (conclusive vs non-conclusive). Secondary endpoints were number of passes and adverse events within 7 days. Proportions were compared using χ^2/Fisher's exact tests and non-parametric variables using the Mann–Whitney test. A multivariable logistic regression model (outcome: non-conclusive result) included sampling technique (FNB vs FNA), lesion size (> 3 cm), location (head vs body/tail), puncture route (trans-duodenal vs trans-gastric) and number of passes. Because a reference standard (surgery/biopsy/follow-up) was not available, diagnostic performance was assessed through adequacy rather than sensitivity/specificity.

Results Adequacy was 73.3 % (137/187) for FNA vs 82.4 % (28/34) for FNB (p = 0.365; OR 1.70, 95 % CI 0.66–4.36).Median passes (IQR) were 2 (2–3) for FNA vs 1 (1–2) for FNB ($p < 10^{-8}$).Adverse events were rare: one pseudoaneurysm in the FNA group (0.5 %, 1/187) and none in the FNB group (0/34; p = 1.00). Adequacy did not differ by size (> 3 cm 75.3 % vs < 3 cm 73.6 %; p = 0.95) or access route. In FNA, adequacy was 69.9 % for head vs 78.4 % for body/tail lesions; a similar, non-significant trend was seen with FNB. In multivariable analysis, no factor was significantly associated with failure, although head location showed a trend towards higher non-conclusive rates (OR 2.61, 95 % CI 0.96–7.07). FNB achieved high adequacy with 1–2 passes, whereas FNA plateaued around 2–3 passes.

Conclusions In this cohort, EUS-FNB required significantly fewer needle passes than EUS-FNA without an excess of complications and showed a numerically higher, though not statistically significant, adequacy. Lesion size and puncture route did not impact adequacy, while head lesions tended to be more frequently non-diagnostic. Robust sensitivity/specificity estimates will require linkage to a reference standard.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP566 Validation of a Fully Synthetic 3D-Printed Simulator for Paediatric Therapeutic EUS: Overcoming Ethical and Educational Barriers

Authors brusco M[1], Cristina F[2], Simona F[2], Paola DA[2], Valerio B[2]

Institutes **1** Azienda Ospedaliero Universitaria delle Marche, Torrette, Italy; **2** Bambino Gesù Children's Hospital, Roma, Italy

DOI 10.1055/s-0046-1821893

▶ Table 1

Characteristic	Novice group (n = 7)	Expert group (n = 4)	Total sample (n = 11)
	Professional role

Prior EUS experience	none	Only observational	-

Problem to solve Low procedural volumes and a shortage of expert trainers limit clinical access to paediatric interventional Endoscopic Ultrasound (EUS), creating a paradox where minimally invasive alternatives are precluded to the population with the greatest need. Given the significant ethical and hygienic limitations of animal-based "hybrid" simulators, there is an unmet need for a fully synthetic, realistic, and sustainable training tool to democratize access to advanced EUS skills without biohazard constraints.

Innovation We developed PROMETEUS (Polymeric, Realistic, Open, Modular, and Enhanced Trainer for EUS), a high-fidelity simulator designed to overcome the constraints of existing synthetic models regarding biomimetic accuracy. Unlike hybrid models requiring animal organs, PROMETEUS is fully synthetic, featuring:

"**Glass-Box" Design:** A transparent housing allowing direct visualization of needle trajectory, enhancing procedural awareness compared to blind in-vivo training.

Modular & Electrifiable: Compatible with electrosurgical units for realistic procedures with standard devices and equipment.

AI-Ready Architecture: Designed to facilitate future asynchronous learning through computer vision integration.

Results 1. To validate its educational efficacy, we conducted a prospective non-inferiority study comparing PROMETEUS with established benchmarks published for the "Magic Box" hybrid simulator. Procedural proficiency was quantified using a validated 4-point Global Rating Scale (GRS) focusing on endoscope manipulation, electrocautery, and stent placement (▶ **Table 1**).

Our validation study enrolled 11 participant: 7 Novices (young pediatricians) and 4 Experts (senior pediatric endoscopists) both groups naïve to therapeutic EUS.

Consistently with the "magic box" study, all participants successfully completed EUS-guided lumen – apposing metal stent (LAMS) placement. The simulator demonstrated an excellent construct validity, effectively discriminating between expertise levels. Experts achieved scores consistent with proficiency benchmarks (Mean: 3.50), whereas novices scored significantly lower (Mean: 2.17), confirming the realism of the task difficulty (Mann–Whitney U test). Statistical analysis (Mann–Whitney U test) revealed significant differences specifically for **scope positioning** ($p = 0.019$) and **stent deployment** ($p = 0.019$), confirming the non-inferiority of PROMETEUS to the hybrid model in terms of realism and skill differentiation.

Conclusions PROMETEUS is a valid, sustainable, and ethical educational resource. By eliminating the hygienic and ethical barriers of animal tissue while maintaining high construct validity, it bridges the gap between limited pediatric procedural exposure and the demand for competency-based training. It offers an accessible platform for novices to achieve baseline proficiency and experts to refine techniques before patient contact. Future developments will focus on deploying the AI-driven feedback system to further facilitate an asynchronous learning modality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP567 Atraumatic Over-the-Scope Clip (aOTSC): A Primary Hemostatic Tool or a Rescue Option in GI Bleeding?

Authors Vidal Lima F[1], Ribeiro H[1], Gravito-Soares M[1, 2], Gravito-Soares E[1, 2], Amaro P[1], Narra Figueirdo P[1, 2]

Institutes **1** Gastroenterology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; **2** Faculty of Medicine, University of Coimbra, Coimbra, Portugal

DOI 10.1055/s-0046-1821894

Aims Non-variceal gastrointestinal hemorrhage (NVGIH) remains a common and potentially life-threatening emergency associated with substantial morbidity and mortality. Endoscopic intervention is the cornerstone of management, with conventional modalities—including pharmacological, thermal and/or mechanical approaches such as through-the-scope (TTS) clips or band ligation—achieving high rates of initial hemostasis. However, rebleeding can occurs in up to 26 % of patients with high-risk stigmata. The atraumatic over-the-scope clip (aOTSC) system represents a newer endoscopic device capable of full-thickness tissue approximation and durable mechanical compression. Growing evidence suggests that aOTSC provides superior hemostatic efficacy as both rescue or primary therapy in selected high-risk patients, with lower rebleeding and mortality rates [1, 2].

Methods Prospective study of total of patients treated with 11/6 aOTSC (Ovesco Endoscopy AG, Germany) as a primary or rescue therapy for gastrointestinal bleeding at a tertiary health care center in Portugal, since device acquisition (2023). Efficacy and safety rates were evaluated.

Results Seven cases of gastrointestinal bleeding were managed with aOTSC (57.1 % (n = 4) male sex and mean age of 82.0 ± 7.7 years-old). Mean Charlson Comorbidity Index was 5.6 ± 2.2. About eighty-eight percent (n = 6) of patients presented with upper gastrointestinal bleeding. Only two patients (28.6 %) were on antithrombotic medication. On admission, the mean hemoglobin was 5.9 ± 1.3g/dL, systolic blood pressure 106.7 ± 40.5mmHg, and heart rate 86.2 ± 11.5bpm. Endoscopy revealed two Dieulafoy lesions (one gastric, one duodenal), four gastric ulcers (Forrest Ib and IIa), and one sigmoid diverticular bleeding. Five (71.4 %) patients initially received conventional hemostatic therapy—on average 2.0 ± 0.8 attempts—including argon plasma coagulation, epinephrine injection, and TTS clips. The mean Rockall score after the first endoscopy was 7.1 ± 2.2, indicating high rebleeding risk. Mean calibre of bleeding vessel was 3.0 ± 0.7mm in diameter. Two (28.6 %) patients were readmitted for rebleeding before aOTSC placement. First-line use of aOTSC reduced the number of hospitalization days (9.00 ± 1.00 vs 11.00 ± 3.74days; $p = 0.558$), as well as the number of procedures required (0 vs 2.0 ± 0.84procedures; $p = 0.047$). Immediate hemostasis was achieved in all cases. No rebleeding for a medium follow-up of 6.6 ± 6.5months. No complications or mortality were observed.

Endoscopy 2026; 58: S1–S1041

Conclusions aOTSC proved to be effective and safe as hemostatic endoscopic therapy for both primary and rescue gastrointestinal bleeding due to the high transmural grip force without tissue trauma, particularly to the blood vessel walls. All patients presented with high-risk features, such as high post-endoscopic Rockall score and bleeding vessel > 2mm in diameter. This highlights the further need to establish standardized criteria and clinical scoring systems for the early or first-line aOTSC use.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP568 "Crossing the Wrong Lumen" Rare complication of EUS-Gastroenterostomy

Authors Shahzad MA[1], Godfrey E[1], Varghese S[1]

Institute 1 Cambridge University Hospitals, Cambridge, United Kingdom

DOI 10.1055/s-0046-1821895

Aims 68 year old female who presented to our hospital with nausea ,vomiting and weight loss.Her medical history included high BMI and stage 3 ovarian cancer with peritoneal metastases.

Methods CT scan of abdmen and pelvis revealed gastric outlet obstruction secondary to metatstatic cancer . Patient was referred to our endoscopy unit for EUS-guided gastro-enterostomy after discussion in multidiciplinary team [1–3].

Results Procedure was performed under consitious sedation. A loop of small bowel was identified on EUS close to the distal body of stomach. Direct EUS-GJ technique without fluroscopy was used where a 19-G needle was used to puncture the target lumen . After distension of lumen with 600 ml of saline, 20x10mm LAMS stent was placed. Greenish colour discharge was noticed into the stomach.CT scan after the procedure confirmed entry into wrong lumen -inadvertent gastrocolostomy. Complication was discussed in MDT and international expert opinion was taken as this was likely first case of type-4 complication. LAMS was removed 3 weeks after the procedure to ensure fistula was epithelised , tattoo was placed for marking the fistula and NG tube was placed .While patient remained on parenteral nutrition, one week later , fistula was closed with OVESCO Clip. NJ tube was placed to distend the small bowel with saline and indigocarmine . Fluroscopy confirmed NJ guided distension. 20X10 mm Axios stent was placed to connect the right lumen with the stomach , cofirmed with blue dye flow into the stomach and small bowel mucosal images on endoscopic view. Patient was started on oral feed and PN was gradually tapered off.

Conclusions EUS-GE is a high risk procedure and accidental placement of LAMS into colon is uncommon complication. Our case highlights the importance of sharing knowledge,complication and involvement of multidiciplinary team to manage rare complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP569 Predictors of failure in endoscopic ultrasound-guided choledochoduodenostomy in malignant biliary obstruction

Authors Amaral N[1], Taveira F[1], Côrte-Real F[1], Silva AR[1], Rego AC[1], Paz N[1]

Institute 1 Hospital do Divino Espírito Santo, Ponta Delgada, Portugal

DOI 10.1055/s-0046-1821896

Aims Endoscopic ultrasound–guided choledochoduodenostomy (EUS-CDS) using a lumen-apposing metal stent (LAMS) has emerged as an alternative method for biliary drainage when endoscopic retrograde cholangiopancreatography (ERCP) fails, particularly in the management of malignant obstructive jaundice. Given the growing applicability of this procedure, especially in palliative settings, recognizing factors that influence procedural success is crucial. The aim of our study is to identify predictors of failure in EUS-CDS with LAMS in malignant biliary obstruction.

Methods We conducted a retrospective single-center cohort study including patients with malignant obstructive jaundice who underwent EUS-CDS with LAMS, between 2018 and 2025. The following data were collected: patient and procedure details, adverse events, technical (correct placement of the LAMS) and clinical success (≥ 50 % reduction in baseline bilirubin levels within four weeks). Univariable analysis was performed to identify predictors associated with technical failure. Statistical analysis included both parametric and non-parametric tests, chi-square and binomial logistic regression. A p-value < 0.05 was considered statistically significant.

Results A total of 31 patients were included (median age 71 [36–91] years, 48.5 % female). Pancreatic cancer was the most common etiology of malignant biliary obstruction (MBO) (n = 24, 77.4 %). Technical success was 87.1 %, with a clinical success rate of 96.3 % among these patients. In our analysis, extrahepatic bile duct diameter of ≤ 15mm was not associated with increase odds of technical failure, although lower diameters were more common in this group (16 [9–24] vs 14 [12–17] mm, p = 0.49). Non-pancreatic MBO (cholangiocarcinoma, ampullary cancer and metastasis) exhibited higher rates of technical failure (p = 0.03). Technical failure was significantly associated with elevated C-reactive protein (CRP) levels (3.9 [1.1–10.3] vs 12.2 [1.1–15.0] mg/dL; p = 0.02; OR = 1.49 [1.10–2.09]) and with severe hypoalbuminemia (< 2.5 mg/dL) (7 (25.9 %) vs 4 (100 %); p = 0.01; OR = 1.57 [1.11–2.46]). Median survival was 118 [7–1432] days.

Conclusions The etiology of MBO and the interaction between pro-inflammatory evolving tumor microenvironment and nutritional deterioration, reflected by elevated CRP and severe hypoalbuminemia, may contribute to technical failure of EUS-CDS. These findings highlight the need for careful pre-procedural assessment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP570 Determinants of Therapeutic Response and Recurrence in Digestive Angiodysplasias Treated with Argon Plasma Coagulation : A Monocentric Analytical Study

Authors Lamraoui H[1], Belabbes F[2], Bahlaoui O[3], Delsa H[4], Anass N[5], Bennani Y[6], Benjelloun N[7], Khannoussi W[8], Ben El Barhdadi I[4]

University of sciences and health., Casablanca, Morocco; 7 Sheikh Khalifa Bin Zayed Hospital, Casablanca, Casablanca, Morocco; 8 Cheikh khalifa international university hospital, casablanca, Morocco

DOI 10.1055/s-0046-1821897

Aims Digestive angiodysplasias are acquired vascular malformations responsible for chronic or acute gastrointestinal bleeding, mainly affecting elderly and polymorbid patients. Diagnosis relies primarily on endoscopy, and argon plasma coagulation (APC) is the standard therapeutic approach. However, the recurrence risk remains high and depends on several clinical and lesion-related factors. The aim of this study was to identify the therapeutic and clinical outcome determinants of digestive angiodysplasias, to assess the efficacy of endoscopic APC, and to analyze factors associated with recurrence.

Methods We conducted a retrospective, descriptive, and analytical study at a university hospital, including 79 patients treated with APC for endoscopically confirmed digestive angiodysplasias between January 2022 and June 2025. Clinical and endoscopic data were reviewed, and treatment details, immediate efficacy, clinical improvement, and recurrence were recorded. Statistical analyses were performed to identify factors associated with therapeutic response and recurrence.

Results The median age was 75 years, with a male predominance (59.5 %). The most common comorbidities were hypertension (68.4 %), diabetes (34.2 %), coronary artery disease (27.8 %), and renal insufficiency (20.3 %). Anemia was the most frequent presenting symptom (67.1 %), followed by rectal bleeding (46.8 %). Lesions were predominantly located in the cecum. All patients underwent APC treatment, mostly in a single session. Immediate efficacy was achieved in most cases, and a significant clinical improvement was observed in 59.5 % of patients. However, bleeding recurrence occurred in nearly half of cases, with a mean delay of 5.5 months. A better prognosis was observed in patients with localized involvement and a limited number of lesions, whereas multi-segmental disease, multiple lesions, and duodenal or jejunal localizations were significantly linked to higher recurrence rates.

Conclusions In our series, argon plasma coagulation was effective as a first-line treatment for digestive angiodysplasias, providing significant clinical improvement in most patients. Despite this, recurrence of bleeding remained relatively common, particularly in patients with multiple lesions or duodenojejunal involvement. Patients with localized and limited lesions experienced a better prognosis, highlighting the importance of careful endoscopic evaluation and close follow-up, especially for those at higher risk of recurrence.

eP571 Endoscopic Dilatations: Indications and Outcomes

Authors Amrharhe EM[1], Cherkaoui Malki M[1], El Hiouy H[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[1], El Bacha H[1]
Institute 1 CHU Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821898

Aims Endoscopic dilatation is a reference, first-line, simple, and effective technique used in the management of symptomatic digestive strictures. The objective of our study was to identify the indications for these dilatations and to evaluate their outcomes.

Methods This was a retrospective, descriptive, monocentric study conducted over a 6-year period (January 2019 to November 2025) in the endoscopy unit of the Department of Hepato-Gastroenterology and Proctology. It included patients who underwent endoscopic dilatation for digestive strictures. Dilatations performed using metallic or plastic stents were excluded. The collected variables included demographic data, the location and type of stricture, the type of dilatation, the mean number of dilatation sessions, and the success and failure rates.

Results A total of 72–74 patients underwent 132–139 endoscopic dilatations. The mean age was 43.8 years, ranging from 17 to 84. A male predominance was observed with 41 men (55.4 %) and 33 women (44.6 %), corresponding to a male-to-female ratio of 1.24.Stricture locations were esophageal in 35 cases (50 %), gastric in 1 case (1.35 %), pyloro-bulbar in 17 cases (22.9 %), small bowel in 4 cases (5.4 %), colonic in 6 cases (8.1 %), rectal in 2 cases (2.7 %), and anal in 2 cases (2.7 %). In addition, 5 patients (6.8 %) presented with an ileocolic anastomotic stricture, and 2 patients (2.7 %) had an ileorectal anastomotic stricture.

Indications for dilatation included peptic strictures in 25 cases (35.1 %), strictures related to inflammatory bowel disease in 17 cases (22.9 %), achalasia in 10 cases (13.5 %), tumoral strictures in 5 cases (6.8 %), Plummer–Vinson syndrome in 4 cases (5.4 %), and post-radiation strictures in 3 cases (4.1 %).Four postoperative strictures (5.4 %) were also dilated, including three esophageal strictures (4.1 %) and one gastric stricture (1.35 %) after sleeve gastrectomy. Additional indications included caustic esophageal strictures in two patients (2.7 %), a post-band-ligation esophageal stricture in one patient (1.3 %), an infectious colonic stricture due to intestinal tuberculosis in one patient (1.3 %), and a stricture over an esophageal stent.

The types of dilatation performed were hydrostatic balloon dilatation (TTS) in 56 patients (75.7 %), pneumatic dilatation in 9 patients (12.1 %), and Savary bougie dilatation in 9 patients (12.1 %). The mean number of dilatation sessions was 2.3 (range: 1–8).Clinical evolution showed a success rate of 95.9 % (71 patients). Three cases (4.1 %) of failure were reported due to refractory strictures after multiple sessions. Four strictures (5.4 %) were recurrent. Three endoscopic dilatations (4.1 %) were complicated by perforation, which was treated with clipping.

Conclusions Endoscopic management of digestive strictures remains the reference therapeutic approach. The choice of technique depends on the etiology and location of the stricture. Nevertheless, some strictures may recur or become refractory, which may require surgical intervention.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP572 Quality of colonoscopy reports in IBD patients: preliminary audit according to ESGE 2022 standards

Authors Karam I[1], Amine M[1], Benhamdane A[1], Addajou T[1], Mrabti S[2], Fedoua R[3], Seddik H[1], Elkoti I[1]
Institutes 1 Mohammed V Military Training Hospital, Rabat, Morocco; 2 Mohammed V Military Teaching Hospital Rabat, Morocco, Rabat, Morocco; 3 Mohamed V Military training hospital, Rabat, Morocco
DOI 10.1055/s-0046-1821899

Aims The quality of colonoscopy reports is essential for the follow-up and management of patients with inflammatory bowel disease (IBD), influencing diagnosis, disease activity assessment, dysplasia surveillance, and overall patient care. This study aimed to evaluate the compliance of colonoscopy reports from our center with ESGE 2022 standards and to identify areas for improvement, with the perspective of extending the audit over a two-year period.

Methods A preliminary prospective analysis was conducted on 50 colonoscopy reports from patients followed for IBD, including 13 ulcerative colitis and 37 Crohn's disease patients, of whom 7 had undergone previous surgery. ESGE indicators assessed included the precise indication for colonoscopy, quality of bowel preparation, Boston bowel preparation score, endoscopic activity score, performance of biopsies, terminal ileum intubation (TI), photodocumentation, and use of chromoendoscopy. Patients who had undergone surgery were excluded from items that were not applicable. Photodocumentation was not available in our center, and chromoendoscopy, although available, was not routinely used; these indicators were therefore considered non-assessable. For each ESGE indicator, the observed proportion was compared to the recommended threshold using a proportion z-test. This preliminary analysis will be extended over a two-year period to allow a more representative assessment of reporting practices and identify potential areas for quality improvement.

Results Among the 50 reports analyzed, the precise indication for colonoscopy was clearly documented in 72 % of cases (vs 95 % ESGE, $p = 0.0003$). The quality of bowel preparation was reported in 100 % of evaluable reports; however, the Boston score was reported in only 49 % (vs 90 %, $p < 0.0001$) and the endoscopic activity score in 16 % (vs 90 %, $p < 0.0001$).

Biopsies were performed in 84 % of reports (vs 80 %, $p = 0.44$), and terminal ileum intubation was documented in 66 % of cases after excluding non-applica-

ble items (vs 80 %, p = 0.12). In post-surgical Crohn's patients, the Rutgeerts score was documented in only 43 % of cases.

Conclusions This preliminary analysis shows that documentation in colonoscopy reports varies according to ESGE indicators. The precise indication for colonoscopy, Boston score, and endoscopic activity score were underreported, whereas biopsy performance and terminal ileum intubation were closer to ESGE standards. Extending the audit over a two-year period will provide a more comprehensive evaluation of compliance, help identify areas for improvement, and contribute to harmonizing colonoscopy reporting practices in our center.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP573 Concordance Between Pancreatic MRI and Endoscopic Ultrasound in the Evaluation of Intra-Ductal Papillary Mucinous Neoplasms (IPMN)

Authors Benhamdane A[1], Hdiye S[2], Mrabti S[3], Addajou T[3], Amine M[3], ait iken F[3], Elkoti I[3], Fedoua R[1], Seddik H[3]

Institutes **1** Mohamed V Military training hospital, Rabat, Morocco; **2** Mohamed V Military Hospital , Rabat, Morocco; **3** Mohammed V Military Training hospital, Rabat, Morocco

DOI 10.1055/s-0046-1821900

Aims Assessing the risk of malignant transformation of intraductal papillary mucinous neoplasms (IPMN) is crucial for determining the optimal therapeutic approach, whether conservative or surgical. Early diagnosis and surveillance of features suggestive of malignancy rely mainly on imaging, particularly endoscopic ultrasound (EUS) and pancreatic magnetic resonance imaging (MRI).

The aim of this study was to evaluate the concordance between pancreatic MRI and EUS in detecting *Worrisome Features* and *High-Risk Stigmata* in patients with IPMN.

Methods This study reports results from a prospective, single-center, descriptive and analytical cohort conducted over a 36-month period starting in May 2024.Adult patients (≥ 18 years) who underwent both pancreatic MRI and EUS and who presented imaging features consistent with IPMN were included.

Exclusion criteria were: contraindications to either EUS or MRI, or pancreatic lesions not compatible with IPMN.

Radiological Worrisome Features were defined as the presence of at least one of the following: main pancreatic duct (MPD) diameter between 5–9 mm, MPD caliber change with parenchymal atrophy, lymphadenopathy, non-enhancing mural nodule, focal wall thickening.

High-Risk Stigmata were defined as: MPD diameter > 10 mm, presence of an enhancing solid component.

Statistical analysis was performed using JAMOVI software.

Results A total of 17 patients were included: 58.8 % male and 41.2 % female, with a mean age of 70.8 ± 7.96 years.Among them, 52.9 % were diabetic and 23.5 % had undergone cholecystectomy. None had a history of acute pancreatitis.

Indications for performing MRI and EUS were: cholestatic jaundice (58.8 %), abdominal pain (23.5 %), and incidental discovery (17.6 %).

Lesion location: 35.3 % in the pancreatic head on MRI versus 29.4 % on EUS, 23.5 % in the tail on MRI versus 11.8 % on EUS, 11.8 % in the body on MRI versus 5.9 % on EUS.Multifocal lesions were found in 2 patients on MRI and in 7 patients on EUS.

When Worrisome Features were absent on MRI, they were also absent on EUS in only 77.8 % of cases, with no statistically significant difference (p = 0.057).

When High-Risk Stigmata were absent on MRI, they were present on EUS in 27.3 % of cases, with a statistically significant difference (p = 0.009).

Conclusions Based on these results, EUS appears to be more sensitive than pancreatic MRI for detecting High-Risk Stigmata in IPMN.However, diagnostic performance depends greatly on operator expertise, which supports the complementary use of both modalities—at least during the initial evaluation of IPMN and during follow-up, especially when Worrisome Features are present on either imaging technique.

eP574 Optimizing Polypectomy Training: Findings From a Prospective Multi-Center Survey

Authors El Amrani K[1], Delsa H[1], Bahlaoui O[1], Belabbes F[1], Nadi A[1], Bennani Y[1], Benjelloun N[1], Harouchi A[1], Alaoui Mdaghri R[1], Khannoussi W[1], Ben El Barhdadi I[1]

Institute **1** Cheikh Khalifa International University Hospital, Mohammed VI University of Sciences and Health, Casablanca, Morocco

DOI 10.1055/s-0046-1821901

Aims Colorectal polyps are frequent lesions detected during colonoscopy, and their identification and management can be challenging. Training in polypectomy should be an integral part of the gastroenterology residency curriculum to ensure optimal patient care.

This study aimed to assess, through an anonymous survey, the training needs of endoscopists regarding polypectomy to identify the obstacles encountered and to propose adapted educational programs

Methods This was a cross-sectional, prospective, descriptive, and analytical study conducted using an online questionnaire distributed to several gastroenterologists. Training needs were assessed using the FGP (Frequency, Gravity, Problems) grid for seven items. Each item was evaluated according to its frequency (0, 1, 2), its severity (0, 1, 2), and the difficulties related to knowledge, technical skills, and professional attitudes (0, 2, 4). Statistical analysis was performed using Jamovi software (Version 2.4).

Results Fifty-three responses from 12 countries were analyzed. A total of 60.4 % of participants were women, with a female-to-male ratio of 1.5. Participants aged 30–40 years accounted for 39.6 % of the sample, while those aged 20–30 years comprised 28.3 %. Residents represented 34 % of respondents, and 19 % were physicians.

More than 60 % of participants had been practicing hepatogastroenterology for over 5 years, yet only 37.7 % had received polypectomy training during residency. Six out of ten participants had been trained in polyp characterization and the use of polypectomy devices. Several teaching modalities were reported for these two items, with a predominant role of workshops held during national and international congresses (45.3 % and 41.5 %, respectively) and self-learning (69.8 % and 45.3 %).

More than half of the participants considered the training they received to be insufficient (64.2 %), expressing a preference for hands-on training on models (62.3 %) and on patients (71.7 %).

According to the FGP grid, the main difficulties concerned technical skills (mean score of 13.9 per participant for the seven items), followed by theoretical knowledge (12.6).

87 % of participants reported theoretical difficulties in polyp characterization, 81 % in managing post-resection complications, and 75 % in performing polypectomy.

Regarding technical skills, 94 % of participants reported difficulties in polyp characterization and 91 % in resection and complication management.

Among the variables studied — including status, initial training, training modalities (hands-on, webinar, certification), and years of endoscopic practice — none were significantly associated with the reported difficulties. In contrast, the frequency of performing polypectomies was the only factor associated with a reduction in difficulties (OR = 0.79; 95 % CI: 0.52–0.96; p = 0.0249).

Conclusions Endoscopic polypectomy is a common procedure in digestive endoscopy, but it requires specific expertise. This multicentre survey identified several training needs, particularly in the areas of polyp characterisation, resection techniques, and managing complications.

More than half of the participants considered their training to be insufficient, highlighting the need for strengthened continuing education and structured hands-on training programs to optimize polyp management and enhance endoscopists' skills.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP575 VACStent therapy for upper gastrointestinal leaks and perforations: real-world outcomes from a single tertiary gastroenterology center

Authors Ribeiro R[1], Bezerra J[1], Andrade A[1], Tarrio I[1], Guimarães D[1], Gomes L[1], Moreira M[1], Araújo T[1], Lopes L[2, 3, 1]

Institutes **1** Hospital de Santa Luzia (Unidade Local de Saúde (ULS) do Alto Minho), Viana do Castelo, Portugal; **2** ICVS – Life and Health Sciences Research Institute, Braga, Portugal; **3** 3B's Research Group, Guimarães, Portugal

DOI 10.1055/s-0046-1821902

Aims Anastomotic leaks and iatrogenic perforations of the upper gastrointestinal tract remain challenging complications associated with significant morbidity and mortality. Current endoscopic management relies mainly on fully covered self-expanding metal stents (SEMS) or endoscopic vacuum therapy (EVT). Although effective, SEMS are limited by high migration rate and lack of active drainage, whereas EVT with a polyurethane sponge may delay oral nutrition. The VACStent, a recent device that combines a fully covered SMES with a polyurethane sponge-cylinder connected to a vacuum pump, was developed to overcome these limitations. This system enables continuous drainage of purulent material and granulation tissue formation, while reducing the risk of migration and preserving lumen patency. Real-world data regarding its performance remains limited. This study aimed to assess the clinical efficacy and safety of VACStent therapy in the management of upper gastrointestinal defects.

Methods We conducted a retrospective study including all consecutive patients with upper gastrointestinal defects treated with the VACStent between July 2024 and October 2025 at the Digestive Endoscopy Unit of Hospital de Santa Luzia, Viana do Castelo, Portugal. Demographic characteristics, type of defect, procedural details, treatment duration, need for adjunctive therapies and adverse effects were collected using a database based on electronic medical records. The primary outcome was complete closure of the defect. A descriptive statistical analysis was performed, reporting categorical variables as percentages, and continuous variables as means or medians, as appropriate.

Results VACStent was used in 7 patients (mean age 71.7 ± 10.0 years; 71.4 % female) for the management of anastomotic leaks (57.1 %, all after total gastrectomy) and iatrogenic perforations (42.9 %, all occurring during balloon dilation for achalasia treatment). The median time between the index procedure and diagnosis of the defect was 4 days, and the time from diagnosis to VACStent placement was 0 days. The mean defect size was 14.4 ± 6.9mm. VACStent was used as first-line therapy in 71.4 % (n = 5) of cases. Technical success was achieved in 100 %. The mean duration of VACStent therapy was 8.9 ± 4.0 days, with a median of 2 exchanges per patient. Oral diet was resumed after a median of 4 days of VACStent placement. Complete closure of the defect was achieved in 71.4 % of patients; 2 patients required adjunctive therapy (SEMS and EVT, respectively). Among patients in whom closure was not achieved, one presented with severe sepsis and had the largest defect (two with more than 20mm), while in the other case VACStent was removed due to bleeding from an ulcer at the site of the distal flange of the device; both cases occurred in context of anastomotic leaks in which VACStent was used as first-line therapy. Device-related adverse events occurred in 42.9 % patients – bleeding (n = 1), retrosternal pain (n = 1) and stenosis (n = 1) – all managed endoscopically.

Conclusions VACStent therapy proved to be a safe and effective minimally invasive option for managing upper gastrointestinal anastomotic leaks and perforations, achieving defect closure in most patients and enabling early oral nutritional resumption, with a favorable safety profile. It also demonstrated effectiveness in cases where it was not used as first-line therapy. Therefore, VACStent emerges as an alternative to surgery and other endoscopic methods in these settings, although larger studies are required to validate these findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP576 Early Predictive Performance of Pre-Endoscopic Risk Scores for Identifying Patients Requiring Endoscopic Therapy in Suspected Non-Variceal Upper Gastrointestinal Bleeding

Authors Juarez-Leon O[1], Torres-Ruíz MI[1], Muñoz-Fuentes D[1], Zavala CJC[1], Silis CJC[1], López Pérez RY[1]

Institute **1** General Hospital of Mexico Dr. Eduardo Liceaga, Ciudad de México, Mexico

DOI 10.1055/s-0046-1821903

Aims Non-variceal upper gastrointestinal bleeding (NVUGIB) is a frequent emergency requiring early risk stratification to identify patients needing urgent endoscopy and hospitalization. This study evaluated the predictive performance of the AS, modified Glasgow-Blatchford (GBm), AIMS65, and H3B2 scores in suspected NVUGIB [1, 2].

Methods A retrospective observational study included adults undergoing upper endoscopy for suspected NVUGIB between May and December 2024 at Hospital General de México. Clinical, laboratory, and endoscopic data were collected. Pre-endoscopic scores (AS, AIMS65, GBm, H3B2) were calculated. Diagnostic accuracy for predicting endoscopic treatment and hospitalization was assessed using ROC curves and AUC analysis (▶ **Table 1**).

Results A total of 122 patients were analyzed (63.1 % male; mean age 57.7 ± 16.3 years). Melena (54.1 %), coffee-ground emesis (25.4 %), and hematemesis (16.4 %) were the main presenting symptoms. Endoscopic therapy was required in 16.4 % of cases, mostly with epinephrine or hemoclips. Gastropathy (40.2 %) and peptic ulcer disease (35.3 %) were the predominant findings. Hospitalization was required in 38.5 % of patients.

For predicting endoscopic therapy, the AS score had the highest AUC (0.636; $p = 0.055$), followed by H3B2 (0.629) and AIMS65 (0.615). For hospitalization prediction, GBm (AUC 0.745; $p < 0.001$) and H3B2 (AUC 0.738; $p < 0.001$) performed best, while AS also showed significant discrimination (AUC 0.664; $p = 0.002$). Optimal cutoffs were AS > 2, AIMS65 > 1, H3B2 > 2, and GBm > 6.

Conclusions The AS score, based on clinical variables available at first contact, showed comparable performance to laboratory-dependent scores—particularly for predicting hospitalization. Its simplicity supports its potential use as a practical triage tool in emergency settings. Further validation could consolidate its role in early NVUGIB management.

Endoscopy 2026; 58: S1–S1041

▶ **Table 1**

Outcomes	Scores	AUC (95 % CI)	P value	Cutoff point	Sensitivity	Specificity
Need for endoscopic treatment	**AS**	0.636 (0.502–0.770)	0.055	>2	0.700	0.578
	AIMS65	0.615 (0.462–0.768)	0.104	>1	0.700	0.657
	H3B2	0.629 (0.509–0.750)	0.068	>2	0.850	0.588
	GBm	0.600 (0.483–0.716)	0.159	>7	0.850	0.608
Need for hospitalization	**AS**	0.664 (0.564–0.764)	0.002	>2	0.723	0.520
	AIMS65	0.595 (0.492–0.697)	0.079	>1	0.766	0.600
	H3B2	0.738 (0.649–0.827)	<0.001	>2	0.830	0.507
	GBm	0.745 (0.655–0.836)	<0.001	>6	0.894	0.613

eP577 Endoscopic Management of Intrabiliary Rupture of Liver Hydatid Cysts: High Success Rate and Real-World Outcomes

Authors Benhamdane A[1], Mrabti S[2], Addajou T[2], Amine M[2], ait iken F[2], Hdiye S[3], Elkoti I[2], Fedoua R[1], Seddik H[2]

Institutes **1** Mohamed V Military training hospital, Rabat, Morocco; **2** Mohammed V Military Training hospital, Rabat, Morocco; **3** Mohamed V Military Hospital , Rabat, Morocco

DOI 10.1055/s-0046-1821904

Aims To assess the diagnostic and therapeutic performance of ERCP in the management of intrabiliary rupture of hepatic hydatid cysts.

Methods We retrospectively included 60 patients with liver hydatid cysts fistulized into the bile ducts, treated between January 2016 and September 2025. Overall success was defined as complete clearance of the common bile duct. Statistical analysis was performed using JAMOVI 2.0.

Results Among all ERCP procedures performed during the study period, 4.6 % (n = 60) were indicated for a hydatid cyst communicating with the bile ducts. The median age was 46.1 ± 14.8 years, with a sex ratio of 2. ERCP was performed for acute cholangitis in 44.9 % of cases and for persistent external biliary fistula in 34 %.The median bile duct diameter was 10 [7–14] mm, and the median cyst diameter was 35 [27–47] mm.

Sphincterotomy was performed in 96 % of patients, allowing hydatid material extraction (balloon or Dormia) in 87.8 %.Naso-biliary drainage was required in 24 % of cases, and biliary stent placement in 8 %.

The overall success rate was 93.3 % (n = 56), while 4 patients (6.7 %) developed complications.Clinical improvement was reflected by resolution of jaundice within 5–10 days in most cases.

Conclusions Our findings confirm that ERCP is a highly effective therapeutic option for intrabiliary rupture of liver hydatid cysts, with a high success rate, low complication rate, and excellent short-term and long-term outcomes. This minimally invasive approach represents a valuable alternative to surgery in appropriately selected patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP578 Exploring the Expanded Use of RADA16 in the Management of Non-Ulcer, Non-Variceal Bleeding

Authors Mannering E[1], Haboubi H[2]

Institutes **1** Cardiff University, Cardiff, United Kingdom; **2** Cardiff and Vale University Health Board, Heath Park, Cardiff, United Kingdom

DOI 10.1055/s-0046-1821905

Aims Non-variceal gastrointestinal bleeding is a common condition worldwide with an annual incidence of between 50 to 150 per 100,000. Despite improvements in diagnosis and treatment, it remains a clinical challenge, with a 30-day mortality of up to 11 %. RADA16 is a novel haemostat, with no risk of thermal injury or perforation. It is applied endoscopically as a transparent hydrogel, physically preventing further bleeding. This case series aims to explore the expanded use of RADA16 in the management of non-ulcer, non-variceal bleeding.

Methods A retrospective evaluation was undertaken at a busy, tertiary university hospital, that has a high rate of refractory bleeding. Data were collected from Welsh Clinical Portal and Synapse Clinical Workflow Manager (CWM) in patients who underwent RADA16 treatment for non-ulcer, non-variceal bleeding between 2014 – June 2025. Aetiology of bleeding, haemoglobin level, other haemostatic treatments, number of endoscopies and outcome (haemostasis achieved or rebleeding) were recorded. Endoscopic images were also taken for analysis.

Results RESULTS: A total of eight patients were treated (▶ **Table 1**), mean age 69 (SD = 9), male to female ratio 6:2. Initial haemostasis was achieved in eight (100 %) patients, five (62.5 %) of whom had experienced failure of other haemostatic therapies. Rebleeding occurred in three (37.5 %) cases. The average increase in haemoglobin on hospital admission and one month after initial treatment with RADA16 was 25.4g/L. A dependent-samples t-test indicates there was a significant difference between haemoglobin on admission ($M = 80.3$, $SD = 22.8$) and after RADA16 treatment ($M = 105.7$, $SD = 20.2$), $t(6) = 3.6$, $p = .012$. The eta squared statistic (.68) indicated a large effect size. The average decrease in number of endoscopies and treatments was 3.0 and 1.28 respectively.

▶ **Table 1** Summary of Cases Treated with RADA16

Cases	Age	Sex	Aetiology of bleeding	Procedure type	Co-morbidities
1	51	M	GAVE	Endoscopy	T2DM, Cirrhosis
2	65	F	GAVE	Endoscopy	Liver Steatosis, Liver Fibrosis, Acquired Hypothyroidism, Bilateral Internal Jugular Vein Thrombosis, Portal Vein thrombosis
3	65	F	GAVE	Endoscopy	T2DM, Hypertension, NAFLD
4	66	M	RAVE	Sigmoidoscopy	Malignant Neoplasm of the Prostate
5	68	M	Post-Radiotherapy Angiodysplasia	Endoscopy	T2DM, Hodgkins Lymphoma, Atrial fibrillation, Acute Renal Failure, Gout
6	73	M	GAVE	Endoscopy	Congestive Hepatopathy, Cirrhosis, Epilepsy, Hypertension, Atrial Fibrillation
7	78	M	Post-Endoscopic Therapy Bleed	Endoscopy	Cirrhosis, Oesophageal Varices, Subarachnoid Haemorrhage
8	83	M	GAVE	Endoscopy	NAFLD, Advanced fibrosis, T2DM

GAVE: Gastric Antral Vessel Ectasia, T2DM: Type 2 Diabetes Mellitus, NAFLD: Non-Alcoholic Fatty Liver Disease, RAVE: Radiation-Associated Vascular Ectasia

Conclusions RADA16 is effective in achieving haemostasis in various bleeding aetiologies. Its transparency, low risk and ease of use are advantages, though further prospective studies are required to confirm its efficacy in comparison to other treatments.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP579 Achalasia and Esophageal Diverticula: Comparative Performance of ChatGPT-5 and Gemini in Therapeutic Decision-Making

Authors Amine M[1], Mrabti S[2], Benhamdane A[1], Karam I[1], Azammam S[1], Hiji C[1], Addajou T[1], Elkoti I[1], Fedoua R[3], Seddik H[1]

Institutes **1** Mohammed V Military Training Hospital, Rabat, Morocco; **2** Mohammed V Military Teaching Hospital Rabat, Morocco, Rabat, Morocco; **3** Mohamed V Military training hospital, Rabat, Morocco

DOI 10.1055/s-0046-1821906

Aims Conversational artificial intelligence (AI) models are increasingly used as clinical decision-support tools. This study aimed to compare ChatGPT (GPT-5) and Gemini (Google) in their ability to provide safe, justified, and guideline-compliant therapeutic strategies for esophageal achalasia and diverticula, with particular emphasis on the indication for Per Oral Endoscopic Myotomy (POEM)

Methods Twenty-two simulated clinical cases were developed: 18 achalasia cases (types I, II, III, atypical, post-radiotherapy, post-dilation, or post-POEM) and 4 esophageal diverticula cases (epiphrenic and Zenker, symptomatic and asymptomatic). Cases included complex clinical scenarios such as cardiac or neurological comorbidities, megaesophagus, pre-existing reflux, or post-treatment recurrence.

Each case was independently submitted to both AI models using identical phrasing. The primary question was:

"Is POEM indicated for this patient? Justify your answer."

Responses were evaluated by a clinical expert using five criteria: therapeutic relevance, clinical justification, safety, clarity, and adherence to guidelines. Each criterion was scored 0–2, except for clarity and guideline references (0–1), for a maximum score of 8 points. Qualitative analyses were conducted to assess overall trends, response structure, and adherence to international recommendations and patient safety.

Results ChatGPT achieved a higher global score (96 %) than Gemini (89.8 %). Both models reached identical performance for therapeutic relevance (90.9 %) and clarity (100 %). ChatGPT outperformed Gemini in safety (100 % vs. 95.5 %) and explicit guideline citation (86 % vs. 27 %).

Integrated examples revealed consistent differences in approach:

- In an elderly patient with megaesophagus and cardiac comorbidity, ChatGPT recommended Botox or pneumatic dilation prior to POEM, demonstrating a risk-adapted, guideline-aligned strategy. In contrast, Gemini suggested POEM directly, acknowledging its efficacy but without referencing guideline-based precautions for fragile patients.
- In a post-fundoplication achalasia recurrence, ChatGPT advised caution due to altered anatomy and emphasized alternative treatments, whereas Gemini proposed POEM as a technically feasible option, illustrating its more procedural and pragmatic orientation.Qualitative trends emerged clearly across cases.

ChatGPT consistently adhered to ACG/ASGE/WGO guidelines, provided structured bullet-point responses, and privileged less invasive or staged approaches in high-risk scenarios. Gemini delivered more detailed, educational explanations of pathophysiology and procedural mechanics but was less concise and occasionally favored aggressive interventions even in complex situations. ChatGPT justified decisions through explicit links between physiology, expected outcomes, and risks, while Gemini relied more on practical reasoning and technical consideration

Conclusions Both AI models produced clinically relevant and safe recommendations. However, ChatGPT demonstrated superior guideline adherence, structured clarity, and risk-sensitive therapeutic reasoning. Gemini offered richer pedagogical explanations and a pragmatic technical viewpoint. Their complementary strengths suggest potential value in combined use for clinical decision-support and medical training in disorders such as achalasia and esophageal diverticula.

eP580 Life Between Endoscopies and Family: Pregnancy and Parenthood Challenges in Gastroenterology Trainees

Authors Bouhdoud N[1], Aouroud M[1], Machayi FZ[1], Aouroud H[1], Lairani FZ[1], Nacir O[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 Mohammed VI University hospital marrakech, Marrakesh, Morocco
DOI 10.1055/s-0046-1821907

Aims Pregnancy and parenthood during gastroenterology training present unique challenges. Long hours, exposure to endoscopic procedures, and workplace expectations can affect wellbeing, career progression, and professional performance. The aim of this study is to evaluate the experiences, challenges, and support systems for gastroenterology trainees during pregnancy or parenthood.

Methods A cross-sectional survey targeted trainees who were pregnant or whose partners were pregnant over the last three years. Data collected included demographics, working hours, perceived support from colleagues and supervisors, exposure to occupational hazards (anesthetic gases, radiation, bloodborne pathogens), pregnancy complications, and postnatal adaptation to work

Results Thirty-four female and three male trainees (mean age 28 ± 3.5 years) participated. Among women, 60 % experienced pregnancy during training. Prior to pregnancy, 80 % worked > 40 hours/week; during pregnancy, 70 %, 55 %, and 35 % continued similar workloads in the first, second, and third trimesters, respectively. Over half (53 %) experienced at least one pregnancy complication. Major occupational risks were inadequately addressed: anesthetic gases (45 %), bloodborne pathogens (35 %), radiation (18 %), and prolonged endoscopy sessions (30 %). Postpartum, male trainees were more likely to resume full-time work than females (93 % vs 62 %, $p = 0.03$). Both sexes reported challenges balancing childcare with training and reduced productivity. Women more frequently perceived parenthood as affecting ambition and career progression ($p = 0.02$).

Conclusions Pregnancy and parenthood during gastroenterology training pose significant physical and professional challenges. Training programs should proactively assess occupational risks, implement supportive policies, and promote a culture that normalizes parental responsibilities to ensure trainee wellbeing, professional growth, and gender equity.

eP581 Endoscopic sedation and monitoring practices in Portugal: a nationwide web-based survey

Authors Bargas A[1], Abrantes D[1], Gututui M[1], Bravo AC[1], Abreu B[1], Palmela C[1], Frias-Gomes C[1], Barjas E[1], Glória L[1], Ferreira A[1]
Institute 1 Hospital Beatriz Ângelo, Loures, Portugal
DOI 10.1055/s-0046-1821908

Aims National surveys have been used to obtain information on sedation and monitoring practices in endoscopy in several countries. To provide data from Portugal and query the Portuguese endoscopists on nonanesthesiologist administration of propofol.

Methods A 31-item web survey was sent to all 490 members of the Portuguese Society of Gastroenterology.

Results A total of 127 members (26 %) responded the questionnaire; 20 % were residents. 52 % worked in both public and private practice. Most endoscopists performed esophagogastroduodenoscopy (EGD) without propofol in the public sector (68 %), compared to 37 % in the private sector, a trend also observed for colonoscopy without propofol (62 % vs. 30 %, respectively). Propofol provided the best satisfaction against midazolam + /-opioid, both in EGD and Colonoscopies (mean 9.5 and 9.7/10 vs 4.9 and 5.4/10 respectively). Nonanesthesiologist administration of propofol was performed only by seven respondents; however, 52 % reported that they would consider its use, given adequate training. Pulse oximetry is monitored routinely (99 %); oxygen supplementation is administered by 87 % with propofol and 51 % with traditional sedation. 75 % would consider useful the existence of certified courses in Sedation Training in Gastrointestinal Endoscopy in the Gastroenterology Residency curriculum.

Conclusions Propofol is the preferred sedation agent among Portuguese endoscopists, with a possible interest in expanding its use through targeted training.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP582 Predisposing Factors for Gastrointestinal Hemorrhage in Cirrhotic Patients

Authors Amrharhe EM[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Benzzoubeir N[1], Errabih I[1], El Bacha H[1]
Institute 1 CHU Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821909

Aims Gastrointestinal bleeding is a common and potentially life-threatening complication of liver cirrhosis, mainly resulting from portal hypertension. It represents a major cause of morbidity and mortality in this patient population. Early identification of risk factors is essential to prevent this complication and to guide an appropriate management strategy. Through this study, we aimed to describe the clinical, biological, and etiological characteristics of cirrhotic patients presenting with gastrointestinal bleeding, and to analyze the predictive factors associated with its occurrence.

Methods This was a retrospective, descriptive, and analytical monocentric study conducted in the Hepato-Gastroenterology and Proctology Department "Medicine B" of Ibn Sina University Hospital in Rabat.The study included 122 patients with liver cirrhosis over a 6-year period, from July 2018 to November 2025. Predictive factors for gastrointestinal bleeding were assessed using binary logistic regression, performed with JAMOVI software. A p-value < 0.05 was considered statistically significant.

Results Among the 122 included patients, gastrointestinal bleeding occurred in 46 patients (37.7 %).Regarding demographic characteristics, there were 24 men (52.1 %) and 22 women (47.9 %), with a mean age of 52.3 ± 14.9 years. Smoking was reported in 9 patients (19.5 %), type 2 diabetes in 7 patients (15.2 %), and alcohol consumption in 2 patients (4.3 %).The ECOG performance status was 0 in 22 patients (47.8 %), 1 in 13 patients (28.2 %), 2 in 9 patients (19.5 %), and 3 in 2 patients (4.3 %).

According to the Child-Pugh classification, 12 patients (26 %) were Child A, 13 (28.2 %) Child B, and 21 (45 %) Child C.

Platelet count was < 50,000/mm³ in 12 patients (26.1 %), prothrombin time < 50 % in 18 patients (39.1 %), and the mean serum albumin level was 29.7 ± 8.6 g/L.

Cirrhosis etiologies included HBV in 14 patients, HCV in 12 patients, NASH in 4 patients, alcohol in 3 patients, PBC in 4 patients, AIH in 1 patient, Wilson's disease in 1 patient, and cryptogenic cirrhosis in 4 patients. Three patients were still undergoing etiological assessment.

Upper endoscopy revealed grade III esophageal varices in 18 patients, grade II in 16 patients, and grade I in 11 patients.

Multivariate analysis identified the following as the main predictive factors for gastrointestinal bleeding:

Child-Pugh C score (OR = 2.73, CI = 1.04–7.13, p = 0.04)

Neurological decompensation (OR = 4.55, CI = 1.49–13.89, p = 0.008)

Portal vein thrombosis (OR = 0.2, CI = 0.06–0.65, p = 0.008)

Conclusions This study highlights the principal predictive factors of gastrointestinal bleeding in cirrhotic patients, particularly a high Child-Pugh score, neurological decompensation, and portal vein thrombosis. These findings emphasize the need for close monitoring and optimised management of patients presenting with these risk factors to reduce morbidity and mortality. A preventive strategy combining control of portal hypertension and management of complications may improve outcomes in cirrhotic patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP583 Are guidelines actually improving quality of examinations? A multicenter study shining the light on endosonographic examinations

Authors Braadt L[1], Ruwisch L[2], Tischendorf M[3], Meister T[4], Floer WM[4], Heinzow H[5], Ellrichmann M[6], Trebicka J[7], Domagk D[8]
Institutes **1** Josephs-Hospital Warendorf, Warendorf, Germany; **2** Josephs Hospital Warendorf, Warendorf, Germany; **3** Münster University Hospital, Münster, Germany; **4** Klinikum Ibbenbüren, Ibbenbüren, Germany; **5** Krankenhaus Bamherzigen Brüder, Trier, Germany; **6** University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany; **7** Department of Medicine B, Münster University Hospital, Münster, Germany; **8** Clemenshospital Münster, Düesbergweg, Münster, Germany, Münster, Germany
DOI 10.1055/s-0046-1821910

Aims In order to keep the quality of diagnostic EUS improving, as it is a dynamic process, the European Society for Gastrointestinal Endoscopy wants to set high standards and review their Impact. The aim of this multicenter study is to observe the impact that the publication and implementation of the ESGE guideline on quality improvement in 2017 had on the performance of endoscopists. We can furthermore establish a direct link to the new guidelines from November 2025 to find out whether the key performance measurements can be met [1].

Methods This study is designed as a multicenter study involving three academic teaching hospitals (Warendorf (W), Ibbenbueren (I), and Trier (T)) and three university hospitals (Muenster (M), Kiel (K), and Oldenburg (O)) in Germany. The primary endpoint focuses on the frequency of obtaining a diagnostic tissue sample from EUS-FNA/FNB of solid lesions. The secondary endpoint is adequate endosonographic description of landmarks. As a further secondary endpoint in accordance with the ESGE updated Guidelines from 11/2025 we also included the signed informed consent before the examination. Until now we included 812 patients.

Three patient groups were formed:

- Before implementation of the guideline, before 2018 (retrospective, group I)
- After implementation of the guideline, from 10/2018 to 12/2023 (retrospective, group II)
- After implementation of the guideline, from 2024 on (prospective, group III)

For the calculation of the case number planning, it is assumed that the rate in group A is 78 % and in groups B and C 88 %.

The study was approved by the local Ethics Committee of University in Muenster and registered at ClinicalTrials.gov (NCT06727851).

Results Preliminary data has been collected in 4/6 hospitals (W, M, I, O) to date. Frequency rates of obtaining a diagnostic tissue sample:

- 77.6 %, 91.7 %, and 85 % for W
- 92.5 %, 84 %, and 82 % for M
- 84 %, 80 %, and 92.9 % for I
- 83 %, 85 % and 85 % for O

Adequate description of EUS landmarks

- 87.8 %, 86.9 %, and 90 % for W
- 71.7 %, 56 %, and 68 % for M
- 58 %, 98 %, and 100 % for I

With regard to the corresponding explanations provided prior to EUS procedures, the mean values were 98.8 %, 97.6 %, and 94 %. The data of the hospitals in Oldenburg and Kiel are under review and are expected to present for ESGE Days 2026.

ConclusionsIn light of the most recent update to the guidelines, we can conclude that the aim of tissue sampling during EUS-FNA/FNB is met in three of four centers with a key performance measurement of more than 85 %. The frequency of adequate description of landmarks in EUS improved in two of three centers following publication of the quality-improving ESGE guideline, reaching a KPM of 90 %. A high degree of standardization using text building blocks may have been helpful in this regard. The slightly lower values for Center M could be explained by previous endosonographic examinations in other centers or the performance of CT scans. The rate of obtaining a diagnostic tissue sample improved in three of four centers. The informed consent was generally available. We assume that the slightly lower rates might be due to missed scanning of the documents.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP584 Endoscopic surveillance and risk factors for colorectal dysplasia in patients with primary sclerosing cholangitis

Authors Hlavaty M[1], Macinga P[2], Pavel W[1], Tetiana O[1], Hucl T[1], Pavel D[2]
Institutes **1** Institute of Clinical and Experimental Medicine, Prague, Czech Republic; **2** Institute for Clinical and Experimental Medicine, Prague, Czech Republic
DOI 10.1055/s-0046-1821911

Aims The aim of this study was to evaluate the incidence of colorectal neoplasia over time in patients with primary sclerosing cholangitis and inflammatory bowel disease (PSC-IBD) and to identify the risk factors associated with the development of colorectal dysplasia.

Methods This retrospective study included 365 patients with PSC-IBD who were followed between 2007 and 2025, and underwent a total of 2,352 colonoscopies with high-definition white light endoscopy. Demographic and clinical data, endoscopic findings, and histological results were analyzed. Risk factors for dysplasia and carcinoma were assessed using a time-dependent Cox regression model.

Results Dysplasia was detected in 76 patients (20.8 %), with a neoplasia detection rate of 9.18 %. A total of 216 dysplastic lesions were identified (50.9 % from polypectomies and 49.1 % from biopsies). Adenocarcinoma was diagnosed in 13 patients (3.6 %). Statistically significant risk factors included higher age (HR = 1.03; P = 0.008), biologic therapy (HR = 2.48; P = 0.029), and disease duration (P < 0.001). The Mayo endoscopic subscore showed a positive trend toward significance (HR = 1.27; P = 0.051).

Conclusions Our study confirms the high risk of colorectal neoplasia in patients with PSC-IBD, particularly in older individuals, those with longer disease duration, and those receiving biologic therapy. It highlights the importance of annual surveillance colonoscopies with both targeted and random biopsies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP585 Early Complications and Risk Factors After Percutaneous Endoscopic Gastrostomy: A Retrospective Cohort Study

Authors Souilem E[1], Houssem H[2], Jemai R[3], Wafa D[2], Elleuch N[2], Jaziri H[2], Braham A[2], Ben Slama A[2], Ksiaa M[2]
Institutes **1** UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia; **2** Sahloul Hospital, Sousse, Tunisia; **3** Mohamed Taher Maamouri Hospital, Nabeul, Tunisia
DOI 10.1055/s-0046-1821912

Aims Percutaneous endoscopic gastrostomy (PEG) is the standard method for long-term enteral nutrition, yet procedure-related complications may occur. This study aimed to determine the incidence of early complications and identify associated risk factors.

Methods We conducted a 10-year retrospective monocentric study (January 2015–March 2024) including 178 consecutive patients who underwent PEG placement using the “pull” technique. Demographic characteristics, indica-

tions, procedural parameters, and early complications (≤ 30 days) were recorded. Univariate and multivariate logistic regression analyses were performed to identify independent predictors of complications.

Results The study included 178 patients (mean age 46.5 years; range 5–88) with a male-to-female ratio of 1.7. Most patients (≈ 80 %, n = 142) were referred from intensive care units. The main indication was severe neurological impairment (≈ 86 %, n = 153), predominantly traumatic brain injury (≈ 53 %, n = 94) and stroke (≈ 16 %, n = 28). Procedural success was achieved in 99.4 % of cases (177/178). Difficult endoscopic transillumination occurred in ≈ 13 % (n = 23). The overall early complication rate was ≈ 8 % (n = 15). Complications included abdominal wall infections (n = 6; 3.4 %), bleeding events (n = 5; 2.8 %—2 hemoperitoneums and 3 minor gastrointestinal bleeds), and one perforation-related peritonitis (0.6 %).In univariate analysis, prior abdominal surgery (p = 0.004), abnormal abdominal wall thickness (p = 0.001), pre-procedural sepsis (p = 0.008), and difficult transillumination (p < 0.001) were significantly associated with early complications.On multivariate regression, pre-procedural sepsis remained the only independent predictor (p = 0.001).

Conclusions PEG is a safe and effective procedure with a low rate of early complications. Pre-procedural sepsis represents the principal independent risk factor for adverse events. Careful pre-procedural evaluation, particularly of infectious status and abdominal wall characteristics, is essential to optimize patient outcomes.

eP586 Biliary obstruction due to ampullary neuroendocrine tumor: the value of endoscopy without imaging mass

Authors Espuche Jiménez C[1], Madrigal Bayonas L[1], Ana PL[2], Egea Valenzuela J[2]

Institutes **1** Rafael Méndez Hospital, Lorca, Spain; **2** Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain

DOI 10.1055/s-0046-1821913

Introduction Neuroendocrine tumors (NETs) of the ampulla of Vater are rare, accounting for < 1 % of ampullary neoplasms. Their presentation is often nonspecific, and cross-sectional imaging may miss small or infiltrative lesions, especially when they grow submucosally. Endoscopy plays a critical role when symptoms persist despite unrevealing imaging.

Case Report A 47-year-old woman with a history of cholangiopancreatitis presented with recurrent abdominal pain, nausea, and progressive constitutional symptoms. Previous imaging had shown biliary and pancreatic duct dilation without an identifiable cause. A repeat MRCP demonstrated ampullary obstruction but no mass. ERCP revealed a markedly abnormal papilla, characterized by friability, firmness, erythema, and an unusually en bloc mobility that prevented biliary cannulation. Biopsies were obtained and a prophylactic pancreatic stent was placed [1–5].

Histology demonstrated a well-differentiated grade 3 neuroendocrine tumor (Ki-67 25 %, CK19/CK7 positive). Staging found no metastases, but surgical exploration identified multiple small liver lesions consistent with metastatic NET. Resection revealed a 3-cm ampullary NET infiltrating the pancreatic head with lymphovascular and perineural invasion, as well as regional lymph-node involvement, consistent with pT3 N1 M1 disease. A synchronous well-differentiated grade 2 pancreatic tail NET (1 cm) was also identified, suggesting multifocal disease.

Discussion Ampullary NETs tend to behave more aggressively than other gastrointestinal or pancreatic NETs of comparable size. Reported rates of nodal involvement and liver metastases are high, even in small tumors. This case illustrates the diagnostic limitations of MRCP and CT for detecting early or infiltrative ampullary lesions and reinforces the value of endoscopy as the most sensitive tool for identifying abnormal papillary morphology. Immunohistochemistry confirms neuroendocrine differentiation, while Ki-67 remains essential for grading and prognosis. Management typically requires radical surgical resection. In advanced disease, therapeutic options include somatostatin analogues, targeted agents, peptide receptor radionuclide therapy, or systemic chemotherapy.

Conclusion This case highlights the central diagnostic role of endoscopy in evaluating ampullary lesions that remain occult on imaging. The combination of atypical papillary features, multifocal NETs, and unexpected metastatic disease underscores the aggressive potential of ampullary NETs and the importance of maintaining clinical suspicion in patients with persistent symptoms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP587 Evaluating The Need for Thermal Ablation of Mucosal Defect Margins After Colonic Piecemeal Underwater Endoscopic Mucosal Resection: A Retrospective Analysis

Authors Pacheco T[1], Barros AR[2], Pinto J[2], Pimentel R[2], Silva J[2]

Institutes **1** Unidade Local de Saúde do Tâmega e Sousa, E.P.E., Penafiel, Portugal; **2** Unidade Local de Saúde do Tâmega e Sousa, E.P.E., Guilhufe, Portugal

DOI 10.1055/s-0046-1821914

Aims Several studies have demonstrated that snare tip soft coagulation (STSC) of the resection margins can significantly reduce recurrence rates after conventional piecemeal endoscopic mucosal resection (EMR). However, there is a lack of data regarding the efficacy of STSC in the context of piecemeal underwater EMR (pU-EMR) of large (≥ 20 mm) nonpedunculated colorectal polyps (LNPCPs).

Methods This study aimed to assess the impact on recurrence rates of thermal ablation of the resection margins following pU-EMR. We conducted a retrospective single-center study including all LNPCPs removed by pU-EMR between 2022 and 2024. The primary outcome was endoscopic recurrence at follow-up colonoscopy. Adverse events, including bleeding and perforation, were also recorded.

Results Among 55 LNPCPs resected by pU-EMR (54 patients), 33 lesions underwent follow-up colonoscopy and were included in the analysis (median size, 25 mm; interquartile range, 25–45 mm; right colon location, 57.6 %). Of these, 25 lesions (75.8 %) received STSC of the resection margins. At follow-up colonoscopy (median interval, 6 months; interquartile range, 5–7 months), no recurrence was observed in the non-STSC group (0/8), while a single recurrence occurred in the STSC group (1/25; 4.0 %). No adverse events were reported. The isolated recurrence was effectively managed with repeat endoscopic resection.

Conclusions Recurrence after pU-EMR was rare overall and notably absent in lesions that did not undergo margin ablation. These findings suggest that, unlike conventional EMR, routine snare tip soft coagulation may not be necessary in the underwater setting. Given the small sample size and low event rate, prospective studies with larger cohorts are warranted to determine the true role of thermal margin ablation after pU-EMR.

eP588 Intraoperative FLIP assessment during G-POEM: preliminary results from a prospective single-center cohort

Authors Torres Reyes C[1], Cahyadi O[1], Koc M[1], Stögbauer M[1], Ebigbo A[1]
Institute 1 Catholic Hospital Bochum – St. Josef-Hospital, Bochum, Germany
DOI 10.1055/s-0046-1821915

Aims To assess intraoperative changes in pyloric distensibility during gastric peroral endoscopic myotomy (G-POEM) using the Functional Lumen Imaging Probe (FLIP), and to determine whether FLIP can provide reliable real-time guidance on the adequacy of pyloromyotomy.

Methods A first analysis of a prospectively maintained G-POEM database was performed (n = 9). FLIP measurements at 50-ml balloon volume were obtained immediately before tunnel creation and after completion of the pyloromyotomy. Recorded parameters included distensibility index (DI, mm²/mmHg), minimal luminal diameter (mm) and cross-sectional area (CSA, mm²). All procedures were performed under total intravenous anesthesia. Adverse events and clinical data were documented. Follow-up at 3–6 months included the Gastric Cardinal Symptom Index (GCSI) and the ^{13}C-sodium-octanoate breath test.

Results The DI increased from a mean of 4.5 to 7.8 mm²/mmHg (Δ + 3.3 mm²/mmHg). Minimal diameter increased from 12.8 to 15.2 mm (Δ + 2.4 mm), and CSA from 146 to 210 mm² (Δ + 64 mm²). No intraoperative complications occurred. Mean procedure time was 78 minutes. In one patient (11.1 %), balloon positioning was challenging due to a hook-shaped antrum. Early follow-up data (n = 3) indicate symptomatic improvement accompanied by continued increases in FLIP parameters.

Conclusions Intraoperative FLIP assessment provides a reproducible, quantitative evaluation of pyloric distensibility during G-POEM. The observed increase in pyloric compliance confirms the technical effectiveness of the myotomy. Early follow-up findings suggest a consistent trend toward clinical improvement and further distensibility gain. FLIP may serve as an intraoperative guidance tool and help determine the adequate extent of pyloromyotomy during the procedure. Further data, particularly long-term correlations and protocol standardization, are required

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP589 Endoscopic Ultrasound Elastography, Fractal Analysis, and Colorimetric Assessment in predicting Lymph Node Histology

Authors Terrin M[1], Grizzi F[2, 3], Hegazi MA[2, 3], Spadaccini M[3, 1], Rahal D[4], Fugazza A[1], Colombo M[1], Andreozzi M[1], Marcozzi G[1], Poletti V[1], Maselli R[5, 1, 3], Hassan C[1, 3], Repici A[3, 1], Carrara S[3, 1]
Institutes 1 Gastroenterology and Digestive Endoscopy Unit, Humanitas Research Hospital, Rozzano, Italy; 2 Department of Immunology and Inflammation, Humanitas Research Hospital, Rozzano, Italy; 3 Humanitas University, Milan, Italy; 4 Pathology Unit, Humanitas Research Hospital, Rozzano, Italy; 5 Humanitas San Pio X, Milano, Italy
DOI 10.1055/s-0046-1821916

Aims Accurate lymph node (LN) characterization is crucial for cancer diagnosis and staging. Elastography (E) may improve Endoscopic Ultrasound (EUS) accuracy, while fractal geometry and colorimetric analysis also show promise in oncologic imaging. This study evaluates the diagnostic performance of EUS-E, fractal analysis, and colorimetric analysis in distinguishing malignant from benign LNs [1–4].

Methods In this prospective single-center study (NCT04671784), LNs were evaluated using EUS-E (strain ratio, SR), fractal dimension, and automated colorimetric analysis (mean red, green, blue, RGB, values and channel ratios). Optimal cut-offs were defined by histology, and AUC and accuracy were compared across methods. Final diagnoses were confirmed by cytology, histology, or ≥ 24-month follow-up.

Results From September 2019 to January 2023, 100 patients with enlarged mediastinal or abdominal LNs (50 malignant) were prospectively enrolled. Quantitative E (SR cut-off: 8.7) achieved an AUC of 92 % [95 % CI, 80-100], with 100 % sensitivity and 80 % specificity. Colorimetric analysis showed higher accuracy, with an AUC of 94 % [95 % CI, 81-100], 100 % sensitivity, and 87 % specificity ($p < 0.0001$). Combining both E and colorimetric analysis yielded an AUC of 94.5 % [95 %CI, 83-100], with 100 % sensitivity and 93.3 % specificity ($p < 0.0001$). The addiction of fractal analysis did not improve the accuracy.

Conclusions Our findings demonstrate that EUS-E is highly effective in differentiating benign from malignant LNs. Incorporating colorimetric analysis of elastographic images further improves diagnostic accuracy, while fractal analysis does not contribute significantly. Nevertheless, each modality offers unique and potentially complementary insights into LN pathology.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP590 Unconventional Endoscopic Management of a Postoperative Gastrocutaneous Fistula Using PEG and Duodenal Stent – Case report

Authors Hegedis D[1], Bulic Z[1]
Institute 1 Opća bolnica Pula, Pula, Croatia
DOI 10.1055/s-0046-1821917

Abstract Text

A 70-year-old female patient was undergoing oncological treatment for metastatic, inoperable adenocarcinoma of the antropyloric region of the stomach. Her clinical course was complicated by gastric perforation for which she underwent surgery. In the early postoperative period, the appearance of gastric fluid secretion through the skin sutures raised suspicion of a developing gastrocutaneous fistula. Gastroscopy revealed a fistulous opening at the proximal margin of the pyloric canal and a duodenal bulb stricture that was difficult to traverse, with normal-appearing mucosa distal to the stenosis. A 20 × 60 mm self-expanding metal duodenal stent (SEMS) was placed.

Because the stent did not adequately cover the fistulous opening and the fistula failed to close within a week, an uncommon but practical solution was chosen. Through the external fistula opening, a soft guidewire was introduced into the stomach, allowing placement of a thread for placing a percutaneous endoscopic gastrostomy (PEG) G-tube.

After PEG placement, the patient was given methylene-blue–colored tea to assess for leakage around the PEG insertion site. As no leakage occurred, she began full oral intake (initially enteral formulas and liquids only) and was subsequently discharged home in improved condition. Six months later, the PEG was removed and fistulous tract closed completely.

This case demonstrates how the endoscopist's ingenuity and clinical experience can effectively manage a postoperative complication without the need for surgical intervention.

DOI 10.1055/s-0046-1821918

Aims Eosinophilic esophagitis (EoE) is an immune-mediated inflammatory esophageal disease. In chronic cases, fibrostenotic phenotype manifests, with esophageal stenosis (ES) that benefit from endoscopic dilation as well as optimization of medical treatment. However, recent guidelines do not establish the prevalence of such ES. We wanted to analyze our prevalence of ES, the need of treatment in these patients and how such endoscopic dilation was performed.

Methods We collected retrospective data from our patients with a EoE diagnosis in our hospital since 2020. Their clinical reports and endoscopic reports were reviewed. If an ES was described, the endoscopic report and its images were examined. Patients with Schatzki's rings were excluded, since its pathophysiology and response to treatment differ from ES in the context of EoE [1–3].

Results Out of 186 patients with an EoE diagnosis, 30 patients were initially screened with an ES. After revision, 14 patients were excluded with an endoscopic diagnosis of Schatzki's ring and 16 patients were confirmed to have an ES in the context of EoE (ES-EoE), leading to a prevalence of 8.6 % of patients with EoE in our center. Only 7 patients received endoscopic dilation treatment of their ES, amounting up to 3.7 % of our center's patients.

In 3 of our patients, the diagnosis of EoE was established after the diagnosis and treatment of the ES. Esophageal biopsies were taken after the procedure leading up to EoE diagnosis.

Demographic, clinical and endoscopic characteristics of these patients are summarized in ▶ **Table 1**. There was a predominance of male patients (71.42 %) with a mean age of 41.85 years of age. Both the median and mode were 1-2 sessions of endoscopic dilation. No complications were described and a subjective clinical improvement was reported in all of our patients. All of our patients had a change of treatment after the treatment, with 14 % of them receiving benralizumab with compassive intention and 42.85 % of them receiving topical budesonide, while some patients needed an optimization of proton pump inhibitor (PPI) dosage.

Conclusions ES-EoE amount up to 8.6 % of patients with EoE in our center. 3.7 % of patients with ES-EoE need endoscopic treatment, with clinical response and no adverse effects were described. After endoscopic dilation, 57 % of the patients needed a change of treatment. Endoscopic dilation in ES-EoE is a safe procedure with a small rate of complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

▶ **Table 1**

Patient	Sex	Age	Stenosis	Number of sessions	Dilation method	EoE diagnosis related to ES	Adversse effects	Improvement	Change in treatment
1	M	32	Diffuse Distal <1cm	1	Balloon	Same time	No	Yes	Started benralizumab
2	M	27	Ringed Proximal <1cm	6	Savary-Gilliard	EoE after ES treatment	No	Yes	Started budesonide
3	F	52	Diffuse Distal <1cm	2	Balloon	Same time	No	Yes	Started PPIs
4	M	58	Ringed Medial <1cm	2	Balloon	EoE after ES treatment	No	Yes	Started PPIs
5	M	62	Ringed Distal <1cm	1	Balloon	Same time	No	Yes	Optimization of PPI dosage and budesonide started
6	M	48	Ringed Medial <1cm	1	Balloon	EoE after ES treatment	No	Yes	Started PPIs
7	F	14	Diffuse Proximal >5cm	2	Savary-Gilliard	Same time	No	Yes	Started budesonide

Aims Endoscopic features of Helicobacter pylori (H. pylori) gastritis may reflect bacterial load and mucosal damage, potentially influencing therapeutic response. This study aimed to evaluate the relationship between endoscopic findings and eradication outcomes among patients receiving empirical quadruple therapy in Kairouan, Tunisia.

Methods A retrospective study was conducted including 89 adults with histologically confirmed H. pylori infection who received a 14-day empirical quadruple therapy between January and August 2024. Endoscopic abnormalities (erythema, nodularity, mosaic pattern, erosions, ulcer disease) and histology-based gastritis grading were collected. Eradication was assessed through stool antigen testing, follow-up endoscopy, or clinical improvement. An univariate analysis explored associations between endoscopic features and treatment success.

Results Endoscopy revealed gastric erythema in 92.1 % of patients, nodularity in 21.3 %, mosaic pattern in 15.7 %, erosions in 16.9 %, and gastric or duodenal ulcer in 8.9 %. The overall first-line eradication rate was 69.7 %, and the global eradication rate reached 75.2 %. Patients with ulcer disease showed lower eradication rates (62,5 %) compared with those without ulcers (70,3 %). Nodularity and erosions were more frequently associated with moderate to severe H. pylori density on histology (p = 0,027 and 0,033 respectively), which was itself linked to a higher rate of therapeutic failure (24,07 % vs 34,03 %). In contrast, isolated erythematous gastritis did not significantly affect eradication outcomes (p = 0,67).

Conclusions Specific endoscopic features—particularly nodularity, erosions, and ulcer disease—were associated with lower eradication rates, likely reflecting higher bacterial burden and more advanced mucosal injury. Endoscopic patterns may therefore serve as useful indicators for predicting treatment response and should be considered when tailoring eradication strategies, especially in resource-limited settings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP593 Gastric Atrophy and Intestinal Metaplasia in Helicobacter pylori Infection: Prevalence and Associated Factors

Authors Souilem E[1], Jemai R[2], Houssem H[3], Wafa D[3], Jaziri H[3], Elleuch N[3], Ben Slama A[3], Ksiaa M[3], Braham A[3]
Institutes **1** UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia; **2** Mohamed Taher Maamouri Hospital, Nabeul, Tunisia; **3** Sahloul Hospital, Sousse, Tunisia
DOI 10.1055/s-0046-1821920

Aims*Helicobacter pylori* (H. pylori) infection plays a pivotal role in the development of gastric precancerous lesions. Gastric atrophy and intestinal metaplasia (IM) constitute key stages in Correa's cascade leading to gastric adenocarcinoma. This study aimed to determine the prevalence of these lesions and to identify factors associated with their occurrence among patients with histologically confirmed H. pylori infection.

Methods We conducted a retrospective descriptive and analytical study in the Department of Hepato-Gastroenterology at Sahloul University Hospital (2020–2024). All patients with H. pylori infection confirmed by histology according to the Sydney System were included. Demographic and histologic data were collected. Associated factors were analyzed using Chi-square and Student's t-tests, followed by multivariate logistic regression.

Results A total of 339 patients were included (mean age 48.5 ± 16.7 years; sex ratio M/F = 1.2). More than half (56 %) were older than 45 years, and smoking was reported in 14 %. Gastric atrophy was present in 68 % of patients, predominantly in the antrum (72 %), followed by the fundus (20 %) and pangastric involvement (8 %). Atrophy was significantly associated with higher gastritis activity (p = 0.001) and age > 50 years (p = 0.03).Intestinal metaplasia was identified in 13 % of cases. In multivariate analysis, independent predictors of IM were age > 50 years (OR 1.3; 95 %CI 1.1–1.6; p = 0.01) and severe atrophy (OR 2.2; 95 %CI 1.1–4.5; p = 0.03).

Conclusions Among patients infected with *H. pylori*, gastric atrophy and intestinal metaplasia are frequent and strongly interrelated precancerous lesions. The severity of atrophy emerges as a key predictor of IM, emphasizing the need for early H. pylori eradication and tailored endoscopic surveillance strategies.

eP594 Concurrent Detection of Gastric GIST and Dual Aortic Aneurysms During Endoscopic Ultrasound: A Diagnostic Opportunity

Authors Alioua SA[1, 2], Balamane A[1]
Institutes **1** Department of Hepatology and Gastroenterology, Beni Messous Hospital, Algiers, Algeria; **2** Department of Hepatology and Gastroenterology, Erasme Hospital, Brussels, Belgium
DOI 10.1055/s-0046-1821921

Abstract Text

We report the case of a patient evaluated for a gastric submucosal mass, in whom endoscopic ultrasound (EUS) enabled a comprehensive assessment. Endoscopy revealed a large antral–fundic submucosal lesion.

Transgastric EUS identified a 39.5 × 37 mm hypoechoic tumor arising from the fourth layer, suggestive of a resectable gastric GIST. The examination also revealed two aortic aneurysms: a 41 mm infrarenal aneurysm and a 22 mm supraceliac aneurysm. No additional pancreatic, biliary, hepatic, or hepatic–splenic abnormalities were detected.

This case underscores the broad diagnostic potential of EUS for simultaneous evaluation of gastrointestinal tumors and significant vascular pathology.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP595 Gastric Diffuse large B-cell lymphoma (DLBCL) with pancreatic invasion: A case of Outlet Obstruction and Acute Pancreatitis

Authors Aleksandrowicz A[1], Bartolomé Oterino I[2], Benabdallah R[2], García Martin N[2], Villafruela Cives M[2], Golmayo Flethes C[2], Sierra Morales M[2], Tabernero Da Veiga S[2]

DOI 10.1055/s-0046-1821922

Abstract Text

Non-Hodgkin's lymphoma often involves extranodal sites, but pancreatic infiltration remains exceptionally uncommon. Primary pancreatic lymphoma accounts for less than 0.5 % of all pancreatic tumours. Secondary pancreatic involvement, usually by direct extension from gastric or retroperitoneal lymphomas. We present a case of gastric diffuse large B-cell lymphoma (DLBCL) with contiguous pancreatic extension manifesting as gastric outlet obstruction and acute pancreatitis [1–3].

A 48-year-old man with no significant past medical history presented with a 2-month history of epigastric colicky pain radiating to the back worsening over the past 72 hours, associated with nausea, vomiting and unintended 17-kg weight loss. He reported intermittent low-grade fever. Two weeks earlier, an upper endoscopy had been suspended because of large amounts of retained food. Laboratory tests revealed elevated serum amylase and lipase (3x ULN) and eosinophilia. He was initially managed as mild acute pancreatitis. Abdominal ultrasound demonstrated a well-defined 33 × 34 mm rounded hypoechoic pancreatic lesion.

Repeated upper endoscopy identified a large ulcerated, exophytic lesion involving the incisura and antrum, extending along the greater curvature and into the descending part of the duodenum, causing partial gastric outlet obstruction. Biopsies showed diffuse large B-cell lymphoma, germinal-center phenotype. Staging computed tomography (CT) and endoscopic ultrasound (EUS) revealed a 35–40 mm transmural hypoechoic gastric mass infiltrating all wall layers with direct extension into the pancreatic neck, along with several small perigastric and peripancreatic lymph nodes. Fine-needle aspiration of the pancreatic lesion confirmed a clonal B-cell population. Bone marrow biopsy and flow cytometry showed no infiltration. Final diagnosis was gastric DLBCL, germinal-center type, stage IV. The patient received a pre-phase with cyclophosphamide and dexamethasone, followed by R-EDOCH (rituximab, etoposide, doxorubicin, vincristine, cyclophosphamide, prednisone) immunochemotherapy. Treatment was well tolerated. Interim PET-CT demonstrated marked radiologic improvement with complete metabolic response, consistent with clinical remission. Follow-up endoscopies showed progressive ulcer healing and a persistent fibrotic duodenal stenosis. He is currently without active oncologic treatment and undergoing clinical and endoscopic follow-up.

This case illustrates a rare presentation of gastric DLBCL with contiguous pancreatic invasion mimicking acute pancreatitis. Pancreatic involvement by lymphoma may resemble both pancreatitis and pancreatic carcinoma. Diagnosis relies on imaging, endoscopy, EUS-guided sampling, and histopathology. Immunochemotherapy is the standard treatment and typically induces rapid tumor regression. DLBCL should be considered in the differential diagnosis of pancreatic masses or acute pancreatitis-like presentations, especially when gastric lesions or obstructive symptoms are present. Early histologic confirmation and prompt initiation of immunochemotherapy are essential to avoid delays and unnecessary surgery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP596 Prediction of significant vascular lesions on pan-intestinal capsule endoscopy in patients with suspected gastrointestinal bleeding

Authors Abreu Marques I[1, 2, 3], Cláudia M[1, 2, 3], José C[1, 2, 3], Bruno R[1, 2, 3]

Institutes **1** Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Portugal, Guimaraes, Portugal; **2** Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Guimaraes, Portugal; **3** ICVS/3B's – PT Government Associate Laboratory, Guimaraes, Portugal

DOI 10.1055/s-0046-1821923

Aims Pan-intestinal capsule endoscopy (PCE) is increasingly recognized as a valuable diagnostic tool for patients with suspected mid-lower gastrointestinal bleeding (MLGIB). This study aimed to identify clinical predictors of significant vascular findings on PCE thatmay warrant its early application [1].

Methods The study included 100 consecutive patients who underwent PCE for suspected MLGIB. The primary indications were iron deficiencyanemia (81 %) and overt bleeding (19 %). Clinical data collected included laboratory results, comorbidities and regular medication.

Results The median age was 70 years (IQR 60–78), with 65 % female, and a median Charlson Comorbidity Index 4.0 (IQR 2.0-5.0). CompletePCE was achieved in 76 % of cases and 72 % had adequate bowel preparation. Vascular lesions were detected in 32 % of patients,primarily angioectasias, 43.7 % in the colon, 34,4 % in small bowel and 21.9 % in both. In univariate analysis, older age, highercreatinine levels, atrial fibrillation (AF) were significantly associated with the presence of vascular lesions ($p < 0.05$). A multivariablelogistic regression model was constructed including variables identified as significant in univariate analysis. In the adjusted model,elevated creatinine showed a trend toward independent association (OR 4.49; 95 % CI: 0.99–20.23; $p = 0.051$), while age (OR 1.04; $p = 0.164$) and AF (OR 0.62; $p = 0.530$) were not statistically significant. The final model demonstrated an overall accuracy of 78.1 %,sensitivity of 52.4 %, specificity of 90.7 %, positive predictive value of 73.3 %, and an area under the ROC curve (AUC) of 0.79.

Conclusions Since the accuracy of predicting models based on clinical features is below 80 %, PCE should be used for the diagnosis of small boweland/or colonic vascular lesions in patients with suspected MLGIB, regardless of age, medication or comorbidities.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP597 Improving Colonoscopy Visualization: Impact of Simethicone on Bowel Prep Quality

Authors Bouhdoud N[1], Sadik A[1], Machayi FZ[1], Aouroud H[1], Lairani FZ[1], Nacir O[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute **1** Mohammed VI University hospital marrakech, Marrakesh, Morocco

DOI 10.1055/s-0046-1821924

Aims High-quality bowel preparation is crucial for optimal colonoscopy performance. Simethicone, an anti-foaming agent, may enhance endoluminal visibility by reducing bubbles and foam, facilitating lesion detection and procedural efficiency. The Aim of this study is to evaluate the effectiveness of adding simethicone to a standard polyethylene glycol (PEG) bowel preparation on colon cleansing quality, lesion detection, and procedural performance.

Methods A prospective study was conducted from July to December 2024 in our Gastroenterology endoscopic Unit Eighty patients scheduled for elective colonoscopy were randomly assigned to two groups: Group A (n = 40): Standard PEG 4L preparation Group B (n = 40): Standard PEG 4L + simethicone 300 mg (administered with the last liter of PEG)Bowel preparation quality was assessed using the Boston Bowel Preparation Scale (BBPS). Secondary outcomes included adenoma detection rate (ADR), number of polyps detected per patient, need for intraprocedural lavage, cecal intubation time, and endoscopist satisfaction (Likert scale).

Results The mean age was 52 ± 13 years, with a sex ratio M/F of 1.2. Adequate bowel preparation (BBPS ≥ 6) was achieved in 33 patients (82.5 %) in Group B versus 25 patients (62.5 %) in Group A (p = 0.03). ADR was higher in Group B (28 %) compared to Group A (16 %) (p = 0.04), with a greater mean number of polyps detected per patient (1.8 ± 1.1 vs 1.1 ± 0.9, p = 0.02). The need for intraprocedural lavage was reduced in Group B (12.5 %) versus Group A (30 %) (p = 0.02). Cecal intubation time was slightly shorter in the simethicone group (7.2 ± 2.1 min vs 8.1 ± 2.5 min, p = 0.08), though not statistically significant. Endoscopist satisfaction scores were higher for Group B (median 4.5/5 vs 3.8/5, p = 0.01). No serious adverse events related to simethicone were reported.

Conclusions Adding simethicone to standard PEG bowel preparation significantly improves colonic visibility, increases adenoma detection, reduces intraprocedural lavage, and enhances endoscopist satisfaction. This safe, low-cost intervention is recommended for routine colonoscopy protocols to optimize diagnostic outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP598 Development of an Artificial Intelligence Model for Malnutrition Screening in Patients with Inflammatory Bowel Disease

Authors Souilem E[1], Oussama M[2], Houssem H[2], Jemai R[3], Elleuch N[2], Jaziri H[2], Ben Slama A[2], Braham A[2], Wafa D[2], Ksiaa M[2]

Institutes 1 UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia; 2 Sahloul Hospital, Sousse, Tunisia; 3 Mohamed Taher Maamouri Hospital, Nabeul, Tunisia

DOI 10.1055/s-0046-1821925

Aims Malnutrition is a frequent yet under-recognized complication of inflammatory bowel disease (IBD), negatively impacting therapeutic response, disease course, and prognosis. Artificial intelligence (AI) offers new opportunities for early, accurate nutritional risk stratification. This study aimed to determine the prevalence of malnutrition in IBD patients, identify associated clinical and biological factors, and develop a machine-learning model for non-invasive malnutrition screening.

Methods A cross-sectional analytical study was conducted at Sahloul University Hospital including 224 IBD patients. Malnutrition was defined by a Malnutrition Universal Screening Tool (MUST) score ≥ 2 or ESPEN 2015 criteria (BMI < 18.5 kg/m² or significant weight loss with age-adjusted low BMI). Machine-learning models were developed using the CRISP-DM framework. Model performance was assessed using ROC analysis and predictive accuracy.

Results Among the 224 included patients (157 Crohn's disease; 67 ulcerative colitis), median age was 38 years (IQR 29–48) with a sex ratio M/F of 1.26. The overall prevalence of malnutrition was 25.9 %, with good agreement between MUST and ESPEN criteria (κ = 0.723).In univariate analysis, malnutrition was significantly associated with smoking (p = 0.018), ileocolonic Crohn's disease (p = 0.011), distal ulcerative colitis (p = 0.041), clinical and endoscopic activity (p < 0.001), anemia (p < 0.001), hypoalbuminemia (p < 0.001), elevated CRP (p < 0.001), and absence of azathioprine or biologic therapy (p < 0.001).Multivariate logistic regression identified three independent predictors of malnutrition: clinical disease activity (OR 3.38; 95 %CI 1.51–7.58), elevated CRP (OR 2.51; 95 %CI 1.14–5.53), and hypoalbuminemia (OR 4.03; 95 %CI 1.86–8.70). Among the tested machine-learning models, the Neural Network demonstrated the highest diagnostic performance, with an AUC of 0.90 and a predictive accuracy of 87 %.

Conclusions Malnutrition is highly prevalent among IBD patients and strongly associated with disease activity, systemic inflammation, and hypoalbuminemia. The AI-based Neural Network model showed excellent performance in predicting malnutrition, supporting its potential role as a personalized, non-invasive screening tool to optimize nutritional care in IBD.

eP599 Remimazolam-Esketamine Versus Propofol-Esketamine for Sedation During Gastrointestinal Endoscopy: A Systematic Review and Meta-Analysis of Efficacy and Safety

Authors Elaraby A[1], Bakr A[2], Gamal I[2]

Institutes 1 Faculty of Medicine, Al-Azhar University, Cairo, Egypt; 2 Al-Azhar University, Cairo, Egypt

DOI 10.1055/s-0046-1821926

Aims The optimal sedation regimen for gastrointestinal endoscopy that balances efficacy with patient safety remains undecided. We conduct a systematic review and meta-analysis aimed to compare the efficacy and safety of remimazolam combined with esketamine (RE) versus propofol combined with esketamine (PE) for sedation during gastrointestinal endoscopy

Methods A systematic literature search was conducted in fuor search engines including PubMed, Cochrane Library, Scopus, and Web of Science using the keywords "remimazolam," "propofol," "esketamine," and "gastrointestinal endoscopy." We included only randomized controlled trials (RCTs) comparing RE with PE. The primary outcomes were sedation sucuess rate and induction time and the incidence of adverse events, including hypotension, bradycardia, respiratory depression, tachycardia, injection pain, and nausea/vomiting. Data were pooled using a random-effects model

Results Four RCTs involving a total of 1219 patients (617 in the RE group and 602 in the PE group) were included in the meta- analysis. The sedation success rate was comparable between the two groups (Risk Ratio [RR] 1.00; 95 % CI [0.98, 1.01]).

Compared to the PE group, the RE group showed a significantly longer induction time (Mean Difference 10.97 seconds; 95 % CI [3.12, 18.82]). However, the RE group was associated with a significantly lower incidence of several adverse events. The risk of bradycardia (RR 0.32; 95 % CI [0.11, 0.94]), respiratory depression (RR 0.33; 95 % CI [0.18, 0.58]), and injection pain (RR 0.03; 95 % CI [0.00, 1.05]) was significantly lower in the remimazolam group

There were no statistically significant differences between the groups in the incidence of hypotension (RR 0.60; 95 % CI [0.34, 1.07]), nausea and vomiting (RR 0.95; 95 % CI [0.53, 1.70]), or tachycardia (RR 0.95; 95 % CI [0.09, 10.39]).

Conclusions When combined with esketamine for gastrointestinal endoscopy, remimazolam demonstrates comparable sedative efficacy to propofol. While remimazolam has a longer induction time, it offers a superior safety profile, with significantly lower risks of bradycardia, respiratory depression, and injection pain. These findings suggest that remimazolam combined with esketamine is a safe and effective alternative to the propofol-based regimen

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP600 Fundoplication for GERD: Outcomes beyond symptoms control

Authors Katsila S[1], Kakounis K[1], Dardanis G[1], Mavrikos M[1], Sfougkatakis N[1], Xiromeritou V[1]

Institute 1 Gastroenterology Department, Hippocration Hospital, Athens, Greece, Athens, Greece

DOI 10.1055/s-0046-1821927

Aims Gastroesophageal reflux disease (GERD) is frequently managed surgically with fundoplication in patients with persistent symptoms or abnormal reflux testing. High-resolution manometry (HRM) and pH-impedance monitoring provide objective assessment before and after surgery. This study aimed to

evaluate clinical outcomes, symptoms, and physiological parameters in patients undergoing antireflux surgery

Methods We prospectively analyzed 16 patients (37.5 % female, mean age 56.4 ± 12.5 years, mean BMI 28.1 ± 3.4) who underwent antireflux surgery (62.5 % Nissen, 37.5 % Toupet). Preoperative and postoperative assessments included symptoms, GERD-HRQL score, HRM, and pH-impedance monitoring [1–3].

Results Preoperatively, heartburn (81 %), regurgitation (63 %), and cough (50 %) were most common. At follow-up, heartburn (19 %) and cough (6 %) improved significantly ($p = 0.006$ and $p = 0.016$). Hiatal hernia was identified in 69 % on endoscopy (mean size 2.1 cm) and 56 % on HRM. Barrett's esophagus was present in 12.5 %. GERD-HRQL score improved from 21.6 ± 11.2 to 3.4 ± 7.6 ($p < 0.001$). LES pressure and EGJ-CI increased modestly, while distal latency increased (trend, $p = 0.057$). Total AET (acid exposure time) decreased from 6.2 % to 3.3 % (trend, $p = 0.088$). DeMeester score decreased from 30 (median) to 5.4 ($p = 0.092$), with abnormal values (> 14.8) dropping from 62.5 % to 31.2 %. MNBI improved from 1.95 to 2.40 kΩ, with 43 % of abnormal values normalizing. The number of reflux episodes decreased (trend, $p = 0.055$) and bolus clearance improved significantly ($p = 0.034$). MNBI correlated strongly with AET both pre- and post-operatively ($r = -0.49$ and -0.47). SI and SAP positivity decreased from 7 and 5 patients pre-op to only 2 patients post-op, indicating loss of symptom–reflux association. Correlation analysis showed that EGJ-CI correlated moderately with reductions in acid exposure, suggesting it may better reflect postoperative reflux control.

Conclusions Fundoplication resulted in substantial improvement in physiological, anatomical, and symptomatic markers of GERD. These findings support comprehensive pre-operative physiological assessment for optimizing patient selection and predicting outcomes in antireflux surgery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP601 Digestive hemorrhage secondary to Petersen's hernia

Authors Correa Torres S[1], Suárez Montesdeoca C[1], Iglesias Sobrino C[1], Manso Rodriguez H[1], Negrín Rey J[1], Febles González A[1], Cejas Dorta L[1]

Institute 1 Our Lady of Candelaria University Hospital, Santa Cruz de Tenerife, Spain

DOI 10.1055/s-0046-1821928

Abstract Text

Petersen's hernia is a complication that occurs after gastric bypass surgery and consists of a protrusion of intestinal loops through a defect formed between the alimentary limb and the transverse mesocolon. It has a low incidence, estimated between 0.2 % and 3 % of patients undergoing this surgery. Symptoms are very nonspecific (abdominal pain, vomiting, intestinal obstruction) and are often diagnosed during exploratory laparotomy. Treatment is always surgical [1–4].

We present the case of a 42-year-old woman with a history of gastric bypass surgery 7 years earlier, who presents to the emergency department with a 5-day history of epigastric pain associated with vomiting of food content and one bowel movement containing fresh blood. Upon arrival at the emergency department, she presents with overt rectal bleeding and associated arterial hypotension (BP 60/40 mmHg). Given the suspicion of a rapid transit source, an urgent gastroscopy is performed, which shows no blood residue or lesions likely to bleed. The following day, a colonoscopy is performed, revealing blood remnants throughout all explored segments, appearing more abundant in the left colon and rectum, where some diverticula are observed, although no active bleeding site is identified. Subsequently, the patient develops new rectal bleeding with hemodynamic instability and increased abdominal pain. A CT angiography is performed, showing enterocolitis (jejunum, ileum, and right hemicolon) of probable ischemic etiology in the context of congestion caused by venous thrombosis (portal vein and the ileocolic, middle colic, and right colic branches of the superior mesenteric vein) secondary to a Petersen's hernia. The patient ultimately undergoes surgical intervention with adequate reduction of the herniated contents and closure of the Petersen's space, with good postoperative evolution.

Although presentation as digestive hemorrhage in this condition is rare, in a patient with a history of gastric bypass, inconclusive endoscopic studies, and lack of clinical improvement, this entity must be considered in the differential diagnosis. Delayed diagnosis increases morbidity and mortality in these patients. A multidisciplinary approach with surgeons and radiologists can be useful in guiding management of this condition.

DOI 10.1055/s-0046-1821929

Background: Post-hepatectomy bile leaks are significant causes of morbidity and may rarely progress to complex fistulas, including uncommon bronchobiliary fistulas.

Case: A 52-year-old developed a post operative bile leak with a biloma and a biliobronchial fistula. Initial ERCP with sphincterotomy, stenting, and nasobiliary drainage failed to reduce output (> 500 mL/day), leading to repeat ERCPs with additional drainage and stents placement. Persistent leakage required percutaneous and IR intervention, including transhepatic access, tract dilation, and closure with an 18-mm vascular plug and a glue. A 12-Fr pigtail drain was left for controlled biloma drainage.

Conclusion: A hybrid endoscopic–percutaneous–IR strategy successfully treated this rare post-hepatectomy bronchobiliary fistula.

eP603 Abdominal Corsets in Colonoscopy: A Systematic Review and Meta-Analysis on Cecal Intubation Time and Pain Reduction

Authors Elaraby A[1], Gamal I[2], Bakr A[2]
Institutes 1 Faculty of Medicine, Al-Azhar University, Cairo, Egypt; 2 Al-Azhar University, Cairo, Egypt
DOI 10.1055/s-0046-1821930

Aims Colonoscopy is a critical procedure for colorectal disease screening and diagnosis, but it can be challenging, often causing patient discomfort and procedural difficulties like scope looping. Abdominal corsets have been proposed as a simple, non-invasive intervention to improve procedural efficiency and patient tolerance. This systematic review and meta-analysis aims to synthesize the current evidence on the effectiveness of abdominal corsets in improving key colonoscopy outcomes

Methods A comprehensive systematic literature search was conducted across four major electronic databases: PubMed, Scopus, Web of Science, and Cochrane. We included randomized controlled trials (RCTs) comparing the use of an abdominal corset (experimental group) to standard colonoscopy without a corset (control group). The primary outcomes analyzed were the need for manual compression, cecal intubation time, patient-reported pain scores, and the need for a change in patient position. Four separate meta-analyses were performed using a random-effects model

Results Four RCTs, with a total of 580 patients (283 experimental, 297 control), were included in the final analysis. The use of an abdominal corset did not significantly reduce the need for manual compression (Risk Ratio [RR] 0.46; 95 % CI [0.16, 1.33]; P = 0.15), although significant heterogeneity was present (I^2 = 92 %). However, the meta-analysis demonstrated that corsets significantly shortened the cecal intubation time (Mean Difference [MD] -0.99 minutes; 95 % CI [-1.93, -0.05]; P = 0.04) and significantly reduced patient-reported pain scores (MD -1.55; 95 % CI [-2.35, -0.75]; P = 0.0001). There was no statistically significant effect on the need for changing the patient's position (RR 0.88; 95 % CI [0.36, 2.15]; P = 0.78).

Conclusions This meta-analysis suggests that the use of an abdominal corset during colonoscopy is an effective intervention for reducing cecal intubation time and patient pain. While a definitive effect on reducing the need for manual compression or position changes was not established, the observed benefits support its consideration as a tool to enhance both the efficiency of the procedure and the patient's experience

eP604 Gastric Ulcer as the Initial Presentation of Metastatic Invasive Lobular Breast Carcinoma

Authors Espuche Jiménez C[1], Sánchez Godoy L[2], Bógalo Romero C[3], Alajarín Cervera M[3]
Institutes 1 Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain; 2 Virgen of Arrixaca University Clinical Hospital, El Palmar, Spain; 3 Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain
DOI 10.1055/s-0046-1821931

Introduction Breast cancer is the most common malignancy in women, with invasive lobular carcinoma (ILC) accounting for up to 20 % of cases. Gastrointestinal metastases are rare, reported in 0.04–18 % of cases, with the stomach being the most frequently affected site, followed by colon and rectum. Non-specific symptoms often lead to delayed diagnosis, particularly years after the primary tumor [1–5].

Case Report A 62-year-old woman with a history of right breast ILC (T2N1M0), treated over 10 years ago with surgery, radiotherapy, chemotherapy, and hormone therapy for hormone receptor-positive disease, had previously developed bone and liver metastases managed with systemic therapy. She presented with epigastric pain radiating retrosternally and associated autonomic symptoms. Laboratory tests showed microcytic hypochromic anemia and elevated tumor markers (CA 15-3, CEA).

Gastroscopy revealed a 1-cm excavated ulcer on the greater curvature of the gastric body, posterior wall, with a fibrin-covered base and edematous, congestive borders. Biopsies demonstrated atypical cells positive for estrogen and progesterone receptors, confirming metastatic breast carcinoma.

Discussion Gastric metastases from breast cancer, especially ILC, can occur months to decades after initial diagnosis (reported intervals 3 months–30 years). Clinical manifestations are often subtle, including abdominal discomfort, dyspepsia, or GI bleeding, and mimic primary gastric cancer. Endoscopic evaluation combined with histopathology and immunohistochemistry (ER/PR, GATA-3) is essential for diagnosis. Recent literature confirms the rarity of this entity (~0.04–0.3 % in large cohorts) but highlights its relevance for guiding systemic therapy rather than surgical management. Awareness is crucial to differentiate metastatic lesions from primary gastric malignancies, avoid unnecessary surgery, and initiate appropriate systemic treatment.

Conclusion This case underscores the importance of considering gastric metastases in patients with a history of invasive lobular breast carcinoma presenting with upper GI symptoms, even many years after the primary tumor. Endoscopic biopsy with immunohistochemical confirmation enables accurate diagnosis and informs optimal systemic management, preventing unnecessary surgical interventions and improving patient care.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821932

Abstract Text

Gastric fundal varices are a less common but potentially severe cause of upper gastrointestinal bleeding. A 50-year-old woman with chronic alcohol use presented with hematemesis and melena. She was hemodynamically stable but had acute anemia. Laboratory tests revealed newly diagnosed cirrhosis with acute alcoholic hepatitis. Initial gastroscopy showed a large fundal varix without active bleeding. The patient underwent endoscopic cyanoacrylate injection. Follow-up gastroscopy and endoscopic ultrasound confirmed complete thrombosis of the treated GOV2 varix, with stable other gastric varices. Cyanoacrylate injection provided effective hemostasis for high-risk fundal varices, and early intervention with careful monitoring ensured a positive clinical outcome [1, 2].

eP606 Living With Celiac Disease: Impact on Quality of Life and Determinants of Adherence to a Gluten-Free Diet

Authors Wafa D[1], Souilem E[2], Houssem H[1], Jemai R[3], Elleuch N[1], Jaziri H[1], Braham A[1], Ben Slama A[1], Ksiaa M[1]
Institutes 1 Sahloul hospital, Sousse, Tunisia; 2 UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia; 3 Mohamed Taher Maamouri Hospital, Nabeul, Tunisia
DOI 10.1055/s-0046-1821933

Aims Celiac disease (CD) is a chronic autoimmune disorder whose impact extends beyond the gastrointestinal tract, significantly affecting quality of life (QoL). Adherence to a gluten-free diet (GFD)—the cornerstone of treatment—is essential to prevent complications and improve well-being, yet maintaining strict adherence remains challenging. This study aimed to evaluate QoL in adult patients with CD, assess adherence to a GFD, and identify factors influencing both outcomes.

Methods A cross-sectional descriptive and analytical study was conducted over a three-month period (October–December 2023) among 100 adult members of the Tunisian Celiac Disease Association. QoL was assessed using two validated Arabic questionnaires: the generic SF-12 and the disease-specific Celiac Disease Questionnaire (CDQ). Adherence was evaluated using the Biagi Score, classifying patients into good (score 3–4) versus poor adherence (score 0–2). Sociodemographic, clinical, and socioeconomic factors associated with impaired QoL and poor adherence were analyzed using uni- and multivariate regression.

Results The cohort included 100 patients (mean age 34.5 ± 9.5 years; sex ratio M/F = 0.39). Median age at diagnosis was 11 years and the median disease duration was 21.5 years. Only 27 % reported strict adherence to a GFD (Biagi Score 3–4).QoL was globally impaired, with a mean SF-12 score of 26.0 ± 4.0 and a mean CDQ score of 123.9 ± 29.6. In univariate analysis, impaired QoL was associated with female sex ($p = 0.02$), low educational level ($p < 0.001$), low socioeconomic status ($p = 0.01$), and autoimmune comorbidities ($p = 0.04$). After adjustment, low educational level ($\beta = 0.21$; $p = 0.03$) and low socioeconomic status ($\beta = 0.25$; $p = 0.04$) remained independent predictors of impaired QoL. Good adherence to the GFD was more frequent in older patients (>40 years; $p = 0.025$) and women ($p = 0.04$), although no independent predictors were confirmed in multivariate analysis. Reported barriers included gluten-rich dietary habits, high cost of gluten-free products, limited food availability, and low socioeconomic and educational levels.

Conclusions Celiac disease exerts a substantial impact on quality of life, particularly among patients with low socioeconomic and educational backgrounds. Adherence to a gluten-free diet remains low and is hindered by economic, cultural, and accessibility constraints. These findings underscore the need for a comprehensive care strategy integrating nutritional education, psychological support, and socioeconomic assistance to improve both QoL and long-term therapeutic adherence in patients with CD.

eP607 Back pain to massive GI bleeding: the unexpected discovery of primary gastric squamous cell carcinoma

Authors Abdel-Muhdy Z[1], Alhyari A[2]
Institutes 1 Department of radiology, university hospital of Marburg, Marburg, Germany; 2 Department of Gastroenterology, university hospital of Marburg, Marburg, Germany
DOI 10.1055/s-0046-1821934

Abstract Text

Primary gastric squamous cell carcinoma (SCC) is extremely rare and can resemble adenocarcinoma or submucosal tumors such as GIST, making diagnosis difficult. We report a case that began with isolated back pain and progressed to massive upper GI bleeding, ultimately revealing a primary gastric SCC.

A 66-year-old man presented with several months of thoracolumbar back pain. A CT scan performed for musculoskeletal evaluation incidentally revealed a large gastric mass at the lesser curvature. Upper endoscopy showed an extensive infiltrative, exulcerated lesion with deep ulcerations and a small active bleed. Biopsy was deferred due to dual antiplatelet therapy. Endoscopic ultrasound demonstrated a large heterogeneous lesion arising from the muscularis propria, suggesting a GIST-like submucosal tumor. EUS-guided sampling was performed. After cessation of antiplatelet therapy, repeat endoscopy showed an infiltrating carcinoma, and biopsies confirmed poorly differentiated SCC (CK5/6 positive, p63 positive, CK7 negative). The esophagus appeared normal [1–3].

The clinical course was marked by recurrent malignant bleeding requiring several urgent endoscopies. One procedure showed interval tumor progression without active hemorrhage, whereas later examinations revealed large amounts of hematin and multiple arterial bleeding points. Injection therapy, coagulation and hemostatic powder (TC-325/HaemoSpray) achieved only temporary control. The final endoscopy, performed under intubation, showed the stomach filled with a large volume of blood and a deep necrotic cavity with persistent arterial bleeding. The patient died from hemorrhagic shock.

Further staging with PET-CT showed no evidence of another SCC primary and no esophageal involvement. Together with the extra-cardiac location of the tumor, these findings fulfilled Parks' criteria and supported the diagnosis of primary gastric SCC. The multidisciplinary tumor board classified the tumor as unresectable, and palliative systemic chemotherapy was initiated, but recurrent bleeding ultimately led to a fatal outcome.

This case highlights how primary gastric SCC may present with atypical symptoms and a deceptive GIST-like EUS appearance. It underscores the importance of multimodal evaluation including EGD, EUS, imaging and targeted biopsy in diagnosing rare gastric tumors. The case also demonstrates the limited durability of endoscopic hemostasis in advanced malignant bleeding and the need to consider gastric SCC in ulcerated, subepithelial-appearing lesions when endoscopic, imaging and histologic findings are discordant.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP608 Overweight in Crohn's Disease: A Hidden Driver of Escalation Toward Anti-TNFα Therapy?

Author Souilem E[1]
Institute 1 UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia
DOI 10.1055/s-0046-1821935

Aims Crohn's disease (CD) has long been associated with malnutrition, yet the rising prevalence of overweight challenges this traditional paradigm. Adipose tissue is now recognized as a metabolically active organ capable of amplifying systemic and intestinal inflammation, potentially altering disease course and therapeutic requirements. This study aimed to assess the prevalence of overweight among CD patients and determine whether higher BMI is associated with disease severity, complications, and escalation to anti-TNFα therapy.

Methods A cross-sectional study was conducted at Sahloul University Hospital including 157 adults with confirmed CD. Demographic, clinical, Montreal classification, perianal disease, and biological parameters (BMI, CRP, albumin) were collected. Patients were stratified into overweight (BMI ≥ 25 kg/m²) and non-overweight (< 25 kg/m²). Disease complications (strictures, abscesses,

fistulas, perianal disease), digestive surgery, and treatment strategies (5-ASA, thiopurines, anti-TNFα monotherapy, combination therapy, and optimization) were compared. Logistic regression identified independent determinants of anti-TNFα use.

Results The cohort included 157 CD patients (mean age 38.4 ± 12.7 years; sex ratio 1.2). Mean BMI was 22.1 ± 4.3 kg/m², and 24.2 % were overweight. Overweight patients were older at inclusion (44.7 ± 10.9 vs 36.5 ± 13.0 years; p = 0.03) and more frequently diagnosed after age 40 (Montreal A3; p = 0.01). Disease location (L1/L2/L3), behavior (B1/B2/B3), perianal involvement, CRP, albumin, and digestive complications did not differ significantly between groups (p > 0.05).However, overweight patients had significantly higher use of anti-TNFα agents (38.9 % vs 19.4 %; p = 0.03), with more frequent therapeutic optimization (22.2 % vs 8.7 %; p = 0.02).In multivariate analysis, overweight was the *only* independent predictor of anti-TNFα initiation (OR 2.45; 95 %CI 1.10–5.46; p = 0.028). No association was found between BMI and inflammatory biomarkers.

Conclusions Overweight affects nearly one-quarter of CD patients and is independently associated with increased need for anti-TNFα therapy and more frequent treatment optimization, despite comparable inflammatory markers and complication rates. These findings suggest that adiposity may modulate therapeutic thresholds in CD and highlight the importance of integrating metabolic status into treatment decision-making.

eP609 Flushing-Assisted Saline Immersion ESD (Flushing ESD) Improves Haemostasis with Minimal Haemostatic Forceps Usage

Authors Matthews T[1], Landy J[1], Ban H[2], Toyonaga T[3], Suzuki N[1]
Institutes **1** Wolfson Unit for Endoscopy, St Mark's The National Bowel Hospital, London, United Kingdom; **2** Omi Medical Centre, Kusatsu, Japan; **3** Kobe University School of Medicine, Health Sciences, Kobe, Japan
DOI 10.1055/s-0046-1821936

Aims Controlling intraoperative bleeding is imperative for effective ESD. Flushing-assisted under-saline ESD (Flushing ESD) is a novel adjunct technique in saline immersion therapeutic endoscopy, designed to enhance bleeding prevention and improve haemostatic control. It provides concurrent, energy-synchronised flushing from the endoscopic knife, where effective vessel sealing and coagulation can be achieved with high radiofrequency forced coagulation. We aimed to compare haemostatic performance, bleeding events, and coagulation grasper utilisation between flushing and non-flushing rectal ESD in a UK tertiary referral centre (▶ **Table 1**).

Methods We conducted a single-centre retrospective study comparing 10 rectal flushing with 5 non-flushing ESDs (3 CO_2 and 2 SITE). The Flushing Forced Method used an electrosurgical knife with integrated flushing (FlushKnife BTs, FUJIFILM Corp, Japan) connected to an endoscopic irrigation pump (EIP2, ERBE Corp, Germany). Videos were analysed to document visible vessels, minor bleeding (ooze), major bleeding (red-out), and coagulation grasper activations. Demographic, procedural and histological data were obtained from electronic records. Student's t-tests were used for continuous variables, logistic regression for categorical variables, and Poisson regression for rate outcomes.

Results Baseline demographics, lesion characteristics, and resection outcomes were comparable between groups. Flushing ESD demonstrated significantly higher oozing (rate ratio [RR] 1.55, 95 %CI 1.09–2.23) when scaled per vessel, but not when scaled per lesion area. All oozing events were easily treated with further applications of Flushing Forced coagulation with the knife tip. It required markedly fewer coagulation grasper applications for active bleeding per vessel (RR 0.07, 95 %CI 0.00–0.43, p = 0.02) and per cm² (RR 0.04, 95 %CI 0.00–0.25, p < 0.01). Rates of major bleeding did not differ significantly.

Conclusions Although rates of major bleeding did not differ significantly between flushing and non-flushing ESD, Flushing ESD demonstrated improved haemostatic efficiency, with markedly fewer coagulation grasper activations. Minor bleeding was more frequent when normalised per vessel, but this did not translate into a greater clinical bleeding burden. All minor bleeding episodes were readily controlled with further Flushing Forced coagulation applications. Overall, Flushing ESD facilitated more controlled and efficient intraprocedural haemostasis for rectal ESD.

Abstract Text

A 72-year-old woman with pancreatic adenocarcinoma (pT2N1) treated by pancreaticoduodenectomy with single-loop reconstruction two years earlier developed local recurrence and received chemoradiotherapy. She presented with jaundice, acholic stools, and dark urine. Laboratory tests showed total bilirubin 11.5 mg/dL, direct bilirubin 7.8 mg/dL, and alkaline phosphatase 711 U/L. Magnetic resonance imaging revealed infiltrative recurrence encasing the coeliac trunk and superior mesenteric artery with moderate biliary dilatation secondary to narrowing of the hepaticojejunostomy [1, 2].

Upper endoscopy identified severe malignant stenosis at the gastrojejunal anastomosis with oedematous, infiltrative mucosa. Under fluoroscopic guidance, a 0.035-inch guidewire was negotiated across the pinpoint stenosis. Contrast injection confirmed position in the afferent loop. An ultrathin 4.9-mm gastroscope was advanced through the stenosis, revealing an intact but compressed hepaticojejunostomy with abundant biliary drainage and no intraductal tumour. Two 7-Fr × 7-cm double-pigtail plastic stents were successfully deployed side-by-side across the gastrojejunal stenosis. No biliary stent was placed.

At 7-day follow-up the patient was asymptomatic, bilirubin had fallen to 2.1 mg/dL, and liver enzymes normalised. She was discharged home.

This case demonstrates that endoscopic transmural drainage of malignant afferent loop syndrome using double-pigtail stents across the gastrojejunal anastomosis is feasible, safe, and rapidly effective. The ultrathin gastroscope was key to confirming hepaticojejunostomy patency and avoiding unnecessary biliary intervention.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP611 Ulcerative Colitis-like Crohn's Disease: Endoscopic Diagnostic Challenges and Clinical Characteristics

Authors Tababi R[1], Guediche A[1], Abdelawahed M[1], Jemni I[1], Sabbek A[1], Nciri A[1], Baklouti R[1], Bouhlel W[1], Zakhama M[1], Loghmari H[1], Safer L[1]

Institute 1 Gastroenterology Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia

DOI 10.1055/s-0046-1821938

Aims Crohn's disease (CD) occasionally presents with continuous colonic involvement and endoscopic features resembling ulcerative colitis (UC). This UC-like colonic CD subtype has been reported in a minority of Crohn's colitis cases, yet understanding its endoscopic patterns and clinical characteristics is essential to improve early recognition and guide appropriate therapy.

Methods We conducted a retrospective study including inflammatory bowel disease (IBD) patients followed in our center between 2011 and 2023.

Results Among 106 IBD patients (19 UC and 87 CD), UC-like CD was identified in 27 patients, accounting for 39 % of colonic CD. There was a slight male predominance (M/F ratio = 1.25). The mean age at disease onset was 28.9 years, not significantly different from UC (27.9 years) or other CD (25.5 years).

Endoscopically, all UC-like CD patients showed continuous mucosal inflammation without skip lesions. Granularity, friability, and/or spontaneous bleeding were observed in 78 % of cases. Pancolitis was present in 22 patients (81.5 %), while 5 (18.5 %) had left-sided colitis; the right colon was spared in 37 %.

Histopathology favored UC in 44.4 % of colonic biopsies, while 55.6 % were equivocal. Ten patients underwent colectomy: histologic examination of specimens demonstrated UC features in 6 and CD features in 4 cases.

All 27 cases were ultimately diagnosed as CD rather than UC after a median delay of 53 months (IQR 3–111). Supporting arguments included the development of perianal disease (70 %), ileal involvement (30 %), and subsequent changes in endoscopic (52 %) and histological (37 %) features consistent with CD.

Active smoking was less frequent in UC-like CD than in other CD patients (3.8 % vs 25 %, p = 0.016). However, UC-like CD patients were more prone to develop acute severe colitis (ASC) than other colonic CD patients (55.6 % vs 19 %, p = 0.002). The rate of ASC was comparable between UC-like CD and UC (57.9 %, p = 0.875). There was no significant difference in treatment response or surgery rates between ASC associated with UC-like CD and other ASC cases.

Conclusions UC-like colonic Crohn's disease represents a distinct subtype that closely mimics ulcerative colitis both endoscopically and histologically. Recognition of this subtype is essential, as it may evolve toward typical Crohn's disease features over time and shows a similar risk of acute severe colitis to UC.

eP612 Ergonomy in Endoscopy: Time to think

Authors Triki L[1], Ramdani N[2], Ramdani B[2], Eddahri L[3], Simeti B[3], Sita-Kianzambi W[3], Pirson M[3], Lemmers A[1], Arvanitakis M[1]

Institutes 1 Erasme Hospital HUB, Université Libre de Bruxelles, Brussels, Belgium; 2 Université Libre De Bruxelles / Campus Érasme, Brussels, Belgium; 3 Hospital Erasme, Nurse Department of Endoscopy, Bruxelles, Belgium

DOI 10.1055/s-0046-1821939

Aims Musculoskeletal disorders (MSDs) are caused by repetitive and non-physiological constraints. The primary objective of this study was to determine the prevalence and localization of MSDs among health care professionals (HCPs) in endoscopy units; the secondary objective was to identify risk factors.

Methods Questionnaires were distributed in French-speaking hospitals in Belgium—one for physicians and one for nurses. Collected data included demographics, occupational background, and self-reported MSDs. Correlation tests were performed to assess the association between potential risk factors (sex, hand size, physical and endoscopic activity) and the presence of MSDs

Results A total of 63 physicians and 42 nurses participated, representing a variety of work settings (university hospitals, private practices, retired professionals, and trainees). Among physicians, 84.1 % reported at least one MSD. The most affected anatomical region was the thumb (55.6 %), followed by the lower back (54 %), and hands (42.9 %). Among nurses, 97.6 % reported MSDs, with the lumbar region most affected (85.7 %), followed by the upper back (73.8 %), and the neck and shoulder (69 %).

These symptoms affected work performance, leading to temporary work interruptions. In the physician group, 17.5 % had taken sick leave due to MSDs, mainly attributed to lower-back pain (7.9 %). In the nursing group, 54.8 % reported temporary interruptions, again with the lumbar region being the most frequently involved (35,7 %).

Chi-square correlation tests were performed to evaluate the association between the occurrence of MSD and some risk factors but no statistically significant correlations were identified, probably due to the limited sample size.

Conclusions This observational study reveals a high prevalence of MSDs among HCPs in endoscopy units, leading to a signifiant impact on work performance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP613 Endoscopic Management of Gastrointestinal Foreign Bodies: Outcomes and Independent Predictors of Surgical Intervention

Authors Souilem E[1], Houssem H[2], Wafa D[2], Jemai R[3], Jaziri H[2], Elleuch N[2], Braham A[2], Ben Slama A[2], Ksiaa M[2]
Institutes 1 UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia; 2 Sahloul Hospital, Sousse, Tunisia; 3 Mohamed Taher Maamouri Hospital, Nabeul, Tunisia
DOI 10.1055/s-0046-1821940

Aims Foreign body ingestion is a common emergency. While endoscopy is the primary treatment, some cases require surgery. This study evaluated endoscopic outcomes and predictors of surgical intervention.

Methods We performed a retrospective study (January 2019–July 2025) including all patients undergoing endoscopic removal of gastrointestinal foreign bodies. Demographic, clinical, radiologic, and endoscopic data were collected. Associations were analyzed using Chi-square and t-tests, and independent predictors of surgical intervention were identified through multivariate logistic regression.

Results A total of 63 patients were included (mean age 47.2 ± 13.1 years; range 18–82; sex ratio M/F = 0.9). Urban residence was documented in 80.9 % of cases; 19 % were incarcerated, and 11 % had chronic psychotic disorders.The most frequent symptoms were epigastric pain (61.9 %), dysphagia (38.1 %), hypersalivation (25.4 %), vomiting (14.3 %), and respiratory symptoms (6.4 %). Hematemesis occurred in two cases (3.2 %). Almost all patients underwent preliminary abdominal radiography.The mean delay between ingestion and endoscopic intervention was 9.6 ± 7.9 hours (range 4–26). Foreign bodies included hard bread boluses (22.2 %), plastic objects (20.6 %), chicken bones (14.3 %), poorly chewed food (14.3 %), and sharp or bulky items (12.6 %) such as lighters, metal clips, or dental prostheses.Endoscopic removal was performed via upper endoscopy in 95.2 % of cases and rectosigmoidoscopy in 4.8 %. Common extraction tools included rat-tooth forceps (31.7 %) and snares (27 %). Surgery was required in 6 patients (9.5 %). In multivariate analysis, surgical intervention was independently associated with the presence of a sharp or bulky foreign body (OR 5.84; 95 %CI 1.21–28.13; p = 0.028) and with an extraction delay exceeding 12 hours (OR 4.76; 95 %CI 1.05–21.60; p = 0.042).

Conclusions Endoscopy safely removes over 90 % of gastrointestinal foreign bodies. Sharp or bulky objects and delays > 12 hours independently predict the need for surgery. Early identification and timely endoscopic retrieval are key to reducing complications and improving outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP614 Relationship Between Endoscopic Patterns and Gastric Precancerous Staging (OLGA/OLGIM) in Patients with Helicobacter pylori Infection

Authors Hassine A[1], Khelifi S[1], Bannour R[2], Sboui H[1], Monastiri S[1], Ben Mansour J[1], Hamdi S[1]
Institutes 1 Hospital Ibn El Jazzar, Kairouan, Tunisia; 2 Department of Family and community Medicine, Research Laboratory "LR12ES03", sousse, Tunisia
DOI 10.1055/s-0046-1821941

Aims The OLGA (Operative Link for Gastritis Assessment) and OLGIM (Operative Link on Gastric Intestinal Metaplasia) staging systems stratify gastric cancer risk based on the severity and topography of atrophy and intestinal metaplasia. Endoscopic patterns such as nodularity, mosaic mucosa, erosions, or ulcer disease may correlate with underlying histological severity. This study evaluated the association between endoscopic findings and OLGA/OLGIM histological stages in patients with Helicobacter pylori (H. pylori) infection in Kairouan, Tunisia.

Methods We conducted a retrospective study including 89 adults with histologically confirmed H. pylori infection who underwent upper gastrointestinal endoscopy between January and August 2024. Endoscopic findings (erythema, nodularity, mosaic pattern, erosions, ulcer disease) were collected. Histopathology assessed chronic inflammation, activity, glandular atrophy, intestinal metaplasia, and H. pylori density according to the Sydney system, allowing indirect categorization into OLGA and OLGIM stages. Associations between endoscopic abnormalities and histological severity markers were analyzed descriptively.

Results Erythematous gastritis was the most common endoscopic finding (92.1 %), followed by nodularity (21.3 %), mosaic pattern (15.7 %), erosions (16.9 %), and ulcer disease (8.9 %). Histology showed chronic gastritis in 98.9 %, mild-to-severe inflammatory activity in 91 %, glandular atrophy in 13.5 %, and intestinal metaplasia in 6.7 %. Nodularity and mosaic patterns were predominantly associated with higher H. pylori density and active inflammation—corresponding to early OLGA stages (I–II). Erosions and ulcer disease were more frequently associated with moderate activity and early atrophy, suggesting progression toward intermediate OLGA stage II. Patients with glandular atrophy or intestinal metaplasia (compatible with OLGA/OLGIM II–III) more often exhibited mucosal pallor, loss of folds, or mosaic patterns rather than nodularity. No high-risk OLGA/OLGIM stage IV lesions were identified.

Conclusions Endoscopic findings correlate with key histological components of the OLGA/OLGIM systems. Nodularity reflects high bacterial load and early-stage gastritis, while mosaic patterns, erosions, and mucosal thinning are more frequently associated with atrophy or intestinal metaplasia. Integrating endoscopic patterns with OLGA/OLGIM staging may enhance early risk stratification for gastric cancer in H. pylori–infected patients, particularly in resource-limited settings.

eP615 Predictors of development and endoscopic treatment of achalasia

Authors Babii O[1], Shevchenko B[1], Prolom N[1], Tarabarov S[1]
Institute 1 Institute of gastroenterology of the National academy of medical sciences of Ukraine, Dnipro, Ukraine
DOI 10.1055/s-0046-1821942

Aims In the last years, with the improvement of diagnostics and understanding of the pathogenesis of Achalasia, scientists have been considering a personalised approach to the treatment of esophageal dysmotility [1, 2].
AIM: To identify predictors of Achalasia and evaluate the results of endoscopic treatment.

Methods In the Department of Surgery of Digestive organs of the Institute in may 2024 – september 2025, 29 patients diagnosed with Achalasia were examined and treated. There were 12 men and 17 women. The average age was 28-68 years (39.6 ± 5.3). All patients underwent Eckardt score (dysphagia (0-5), regurgitation (0-5), chest pain (0-5)), X-ray (time barium swallows), endoscopic, EUS and HRM examination, and endoscopic treatment.

Results According to HRM, Achalasia type I (n = 10 /34.5 %), type II (n = 14 /48.3 %), type III (n = 2 /6.9 %), EGJOO (n = 3 /10.3 %) were established. According to EUS with compression elastography, thickening of the lower third of the esophagus ≥ 3 mm and LES ≥ 5 mm were diagnosed in all cases. According to EUS-elastography of the LES, a blue pattern (fibrosis) was determined in 5 (17.2 %) cases, and a green-yellow pattern (hypertrophy) was determined in 24 (82.8 %) cases. Endoscopically, all patients showed esophageal dilation, congestive contents, and resistance to the endoscope when passing through the LES. All patients underwent pneumatic dilation (PD) using 3.5 cm Rigiflex II balloons. The ineffectiveness of the PD course within 12 months was determined in 31.0 %: Achalasia type I (n = 2), type II (n = 3), type III (n = 1), EGJOO (n = 3). In these cases, per oral endoscopic myotomy (POEM) was performed. Histologically, fibrosis was confirmed in cases of type I (n = 2) and type II (n = 3) Achalasia, and muscle hypertrophy was confirmed in cases of type III (n = 1) and EGJOO (n = 3). During the 12-month follow-up period, all patients showed clinical improvement according to the Eckardt score (p < 0.01); according to the time baruim swallows assessment after 1 min, 2 min, and 5 min, a decrease in

Endoscopy 2026; 58: S1–S1041

the diameter of the esophagus ($p < 0.01$), acceleration of passage ($p < 0.01$), and the appearance of a gastric gas bubble ($p < 0.01$) were noted.

Conclusions EUS allows differentiation between LES and esophageal muscle hypertrophy and their fibrotic transformation in Achalasia, which requires myotomy. HRM allows assessment of LES relaxation and esophageal motility, which influences the staging of PD or primary POEM. Reduction in esophageal diameter and LES relaxation are screening criteria in assessing the effectiveness of Achalasia treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821943

Aims Adequate bowel preparation (BP) is crucial for high-quality colonoscopy surveillance in ulcerative colitis (UC), because an inadequate one leads to incomplete colonoscopy and higher rate of missing precancerous lesions, which are usually flat or subtle in this setting. There is conflicting evidence regarding risk factors for inadequate BP when UC patients are in endoscopic and clinical remission; furthermore, data on the optimal PEG-regimen which should be used in this setting are scarce. The aim of this study was to assess which factors influence the quality of BP in this specific setting.

Methods This is a multicentre, cross-sectional, retrospective study carry out it eight centres between January-2021 and December-2022, including UC patients with endoscopic and clinical remission (Mayo endoscopic score = 0) who underwent colonoscopy. Patients with colonic, ileal or abdominal surgery were excluded. The primary outcomes were the rate of adequate preparation, defined as total Boston Bowel Preparation Scale (BBPS) ≥ 6 with all segments scoring ≥ 2 and overall BBPS scores of patients undergoing BP with 1L-PEG-ASC (Plenvu) and 2L-PEG (Moviprep, Clensia), without any specific allocation or instructions. Secondary endpoint was the evaluation of risk factors oof cleansing quality with a multivariable ordinal logistic regression, the right colon cleansing adequacy rate and exam completion rate.

Results Overall, 379 patients (mean age 52 ± 15 years, 159 female) with quiescent UC undergoing colonoscopy stratified by preparation type: 1L-PEG (n = 216) and 2L-PEG (n = 163). Baseline clinical and demographic characteristics were compared. 1L-PEG yielded higher overall BP quality, with a significantly higher median total BBPS compared to 2L-PEG (8, IQR 7–9 vs 6, IQR 6–8, $p < 0.001$). Although rate of adequate preparation was higher in the 1L-PEG group, this difference did not reach statistical significance (92.6 % vs 87.7 %, $p = 0.12$). The 1L-PEG group demonstrated higher rates of exam completion (99.5 % vs. 95.7 %; $p = 0.02$) compared to 2L-PEG, but no differences in overall right colon cleansing adequacy (96.3 % vs 94.5 %, $p = 0.46$). At multivariate ordinal logistic regression adjusted for age, sex, and disease extension, the use of 2L-PEG was associated with significantly lower odds of achieving higher BBPS scores (OR 0.30, 95 % CI 0.20–0.45) compared to 1L-PEG.

Conversely, patient demographics, smoking status, maximum disease extension, history of advanced therapy or presence of pseudopolyps did not significantly affect BP quality ($p > 0.05$).

Conclusions In a relatively unbiased setting, such as UC patients in endoscopic and clinical remission, 1L-PEG demonstrated better BP quality cleansing and higher procedural completion rates. Moreover, it was the primary determinant of BP quality, with neither disease extent nor a history of advanced therapy affecting BP. These findings suggest that 1L-PEG-ASC preparation may be the preferred option for colonoscopy BP in UC patients when not contraindicated.

eP617 Hiatal herniation of the duodenal limb after total laparoscopic gastrectomy: A case report

Authors Hysa A[1], Kola B[2], Dhima A[3], Pemaj X[4], Osmanaj D[4], Sina M[4], Prifti S[4]

Institutes **1** Gastroenterology Department, American Hospital, Tirana, Albania; **2** General Surgery Department, American Hospital, Tirana, Albania; **3** Radiology Department, American Hospital, Tirana, Albania; **4** University Clinic of Gastroenterology/Hepatology, University Hospital Center Mother Teresa, Tirana, Albania

DOI 10.1055/s-0046-1821944

Background: Total gastrectomy with Roux-en-Y esophagojejunostomy is a standard surgical treatment for gastric cancer. While internal hernias are known complications following Roux reconstructions, hiatal herniation of the biliopancreatic (afferent/duodenal) limb is exceptionally rare. Only a few cases have been described in the literature. We present a case of intrathoracic herniation of the duodenal limb causing obstructive symptoms 10 months after total gastrectomy.

Case presentation: A 70-year-old woman with a history of locally advanced gastric cancer treated with neoadjuvant chemotherapy underwent total laparoscopic gastrectomy with Roux-en-Y reconstruction 10 months before presentation. She presented with progressive abdominal pain and unintentional weight loss over one month. Physical examination revealed mild epigastric tenderness without signs of peritonitis. Laboratory results were unremarkable. Contrast-enhanced CT revealed a markedly dilated duodenal (biliopancreatic) limb filled with fluid, herniating through the esophageal hiatus into the thoracic cavity, findings consistent with afferent limb obstruction due to hiatal herniation. An upper endoscopy was performed in an attempt to decompress and reduce the limb. Although endoscopic detorsion has been reported to be successful in selected cases of Roux limb obstruction post-gastrectomy, in this patient, the afferent limb was fixed within the hiatus, and reduction was not possible. After that, the patient was under surgical intervention. A laparoscopic approach was attempted and revealed a grossly dilated afferent limb incarcerated at the hiatus. A hernia detorsion was not possible due to gentle manipulation, so needle decompression with aspiration of enteric contents was performed, allowing successful reduction of the limb back into the abdomen.

The hiatal defect was repaired, and no intestinal resection was required. The patient recovered uneventfully and was discharged on postoperative day 10 [1–3].

Conclusion: Hiatal herniation of the biliopancreatic limb is a rare but important cause of small bowel obstruction following total gastrectomy with Roux-en-Y reconstruction. Non-specific symptoms such as abdominal pain and weight loss may delay diagnosis. In post-gastrectomy patients presenting with such symptoms, even months after surgery, clinicians should consider this entity in the differential diagnosis. Prompt surgical reduction and defect repair can avoid severe complications, provide good outcomes, and prevent further morbidity.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP618 Role of EUS in diagnosis of retroperitoneal masses

Authors Razov Radas M[1], Radas F[2]
Institutes 1 Zadar General Hospital, Zadar, Croatia; 2 Faculty of Medicine, Rijeka, Croatia
DOI 10.1055/s-0046-1821945

Aims The retroperitoneum (RP) is an anatomical space located behind the abdominal or peritoneal cavity. Abdominal organs that are not suspended by the mesentery and lie between the abdominal wall and parietal peritoneum are said to lie within the RP (kidneys, adrenal glands, pancreas, and parts of the aorta, inferior vena cava, duodenum, and colon). Several individual spaces make up the RP. These spaces are the anterior pararenal space, posterior pararenal space, and the perirenal space [1]. Methods for retroperitoneal biopsy include open/laparoscopic surgery, or CT-guided biopsy. We present using of EUS-FNA/FNB trought the duodenum as a new route for accessing the retroperitoneum

Methods We present diagnostic procedure in patient with abdominal pain,diabetes mellitus, weight loosing, and excessive consumption of alcohol. MSCT scan show retroperitoneal mass (RPM) dorsal to the pancreas, which has been pushed ventrally, and partly with infiltration of the head and the initial part of the body of the pancreas, a large expansive infiltrative formation (AP × LL × CC – 51 × 81 × 71 mm). The formation was heterogeneous with cystic lesions, some of which contain calcifications.Transduodenal endoscopic ultrasound (FujiFilm Arietta 850) -guided fine-needle biopsy (EUS-FNB – 22 ga) was second step. Patohystological finding show a regular pancreatic glands and pieces of squamous epithelium without malignant tissue.

Results After consultation with the multidisciplinary team, surgery was performed as follows – pancreatodudenotomy sec Whipple, pancreatojejunostomy, hepaticojejunostomy, GEA, EEA sec. Roux, cholecystectomy, VAC drainage. Patohystological finding show a regular and irregular pancreatic glands without malignant tissue – conclusion – changes caused by recurrent chronic pancreatitis of ethylic etiology.

Conclusions Transduodenal endoscopic ultrasound FNA/FNB for diagnosis of RPM is still only sporadically mentioned in the literature. But this is a powerful diagnostic tool in the hands of an experienced endoscopist.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP619 Diagnostic Accuracy of EUS-Guided Tissue Acquisition for Pancreatic Lesions in a High-Volume Center Without Rapid On-Site Evaluation (ROSE): A Real-World Comparison of FNA versus FNB

Authors Martella M[1], Porta P[2], Fantasia S[3], Donato G[2], Impellizzeri G[2], De Angelis C[4], Laghi L[5], Boldorini RL[6], Pagano N[2]
Institutes 1 Medical Doctor (MD), University of Eastern Piedmont, Novara, Italy; 2 Gastroenterology Unit, Ospedale Maggiore di Novara, Novara, Italy; 3 Gastroenterology Unit – University Hospital, Parma, Italy; 4 Digestive Endoscopy Unit, Azienda Ospedaliero Universitaria di Torino, Turin, Italy; 5 University of Parma – Department of Medicine and Surgery, Parma, Italy; 6 Pathology Department, Ospedale Maggiore di Novara, Novara, Italy
DOI 10.1055/s-0046-1821946

Aims This study aimed to evaluate the diagnostic accuracy of Endoscopic Ultrasound-guided Tissue Acquisition (EUS-TA) for pancreatic lesions in a tertiary referral center without Rapid On-Site Evaluation (ROSE). Secondary objectives pointed to assess the influence of specific variables (lesion size, location, needle gauge, number of passes, and needle type) on the diagnostic yield.

Methods We conducted a retrospective single-center study on 129 patients with 134 pancreatic lesions undergoing EUS-TA between 2020 and 2024. All procedures were performed by experienced endoscopists. Diagnostic yield was calculated based on the definitive result of the most recent procedure; indeterminate cases (Papanicolaou C3/H3) were reclassified based on KRAS mutation analysis. A composite gold-standard (GS) was defined as histological confirmation from surgery or minimum 6-month clinical-radiological follow-up consistent with disease evolution. Univariate analysis (Chi-square test) was performed to evaluate the impact of lesion size, location, needle gauge, number of passes, and needle type (FNA vs FNB) on diagnostic accuracy. McNemar's test was used to analyse the efficacy of repeat biopsies.

Results Out of 134 included lesions, 130 yielded a conclusive result and were included in the performance analysis. Comparison with the GS revealed 107 True Positives, 15 False Negatives, 7 True Negatives, and 1 False Positive. Overall accuracy was 87.7 % (95 % CI: 80.9–92.3). Sensitivity was 87.7 % (95 % CI: 82.1–93.3), Specificity 87.5 % (95 % CI: 65–100) and Positive Predictive Value (PPV) 99.1 % (95 % CI: 94.9–99.8). The Negative Predictive Value (NPV) was 32.0 % (95 % CI: 12.4–52.1). Univariate analysis revealed no significant correlations with lesion location, size, needle gauge, or number of passes. Specifically, no significant difference in failure rates was observed between FNA (9.6 %) and FNB (14.1 %) ($p = 0.43$). However, repeat biopsy significantly improved the diagnostic yield in initially inconclusive cases ($p < 0.001$).

Conclusions EUS-TA without ROSE demonstrates high diagnostic accuracy and an excellent PPV (99.1 %) for pancreatic lesions. Our analysis confirms that diagnostic performance is not significantly influenced by needle type (FNA vs FNB) or other technical variables in this setting. However, in a tertiary setting with a high pre-test probability of disease, the low NPV highlights that EUS-TA does not reliably exclude malignancy, therefore requiring careful evaluation and repeated EUS-TA to resolve diagnostic uncertainty.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims The aim of this study was to evaluate the performance of double balloon enteroscopy (DBE) in general and according to patients' age. Furthermore, preliminary results on the use of the new EN840T enteroscope model were assessed

Methods We conducted a retrospective study of prospectively collected data on patients who underwent DBE in our endoscopy unit between January 2006 and August 2025

Results A total of 592 DBE procedures were included. The overall diagnostic yield was 60 %; vascular lesions were the predominant endoscopic findings (24.8 %), followed by polyps or neoplastic masses (17.4 %). Older patients (≥ 65 years) showed higher rates of clinically relevant findings compared to adult patients (< 65 years) (p = 0.01). Crohn's disease and polyps or neoplastic masses were more frequent in the younger group (p = 0.02 and p = 0.04, respectively), while vascular lesions were the most common findings in the older group (p < 0.001). The rate of endoscopic treatment rates was higher in the older group (p < 0.001). Complications occurred in eight procedures (1.4 %). Sixteen DBE procedures were performed using the EN840T enteroscope. No complications were observed. In transoral procedures, the length of small bowel visualized was greater than with previous models (234 cm vs. 217 cm from the pylorus). The diagnostic yield was 81.2 %, compared to 55 % (p = 0.03) with older enteroscopes.

Conclusions DBE is an effective tool with a high safety profile, particularly in the elderly population. The new EN840T enteroscope, although evaluated in a limited number of procedures, appears to provide improved diagnostic performance with an excellent safety profile

eP621 Pancreatic metastasis of urothelial neoplasia as the origin of upper gastrointestinal bleeding

Authors Crivillen O[1], Zaera De La Fuente C[1], Garrido Gallego F[1], Angel PD[1]
Institute 1 Hospital Universitario Infanta Leonor, Madrid, Spain
DOI 10.1055/s-0046-1821948

Abstract Text

A 72-year-old male patient with a history of urothelial carcinoma treated with chemotherapy. During follow-up, a nonspecific hypodense nodular image measuring 26 mm was observed on CT scan at the posterior margin of the pancreatic head. Concurrent with this finding, the patient developed intermittent melena and anemia. Gastroscopy revealed a 20 mm excavated ulcer in the second portion of the duodenum, oozing blood in a sheet-like pattern, with an infiltrative appearance [1].

An endoscopic ultrasound was performed, revealing a 27 mm heterogeneous, rounded, hypoechoic lesion in the pancreatic head, adjacent to the papilla. Ultrasound visualization showed a duodenal ulcer embedded within the pancreatic lesion. A 22G biopsy needle was used to puncture the lesion, and the histopathological examination was suggestive of urothelial carcinoma metastasis. Following the endoscopic ultrasound examination, adrenaline was injected into the ulcer. At the end of the procedure, an adherent clot was observed without active bleeding. Based on these findings, the treatment was modified. Gastrointestinal bleeding is an uncommon manifestation of pancreatic lesions that is usually associated with a poor prognosis and is refractory to endoscopic treatment. In our case, no further endoscopic treatments were necessary and no complications arose despite the puncture being performed through the infiltrative duodenal ulcer. Furthermore, although pancreatic metastases are becoming increasingly frequent, they remain a very uncommon site of metastasis for urothelial carcinoma; endoscopic ultrasound with biopsy is a fundamental tool for the proper management of these patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP622 Efficacy of antireflux mucoplasty (ARM-P) and antireflux mucoplasty with valve (ARM-PV), and feasibility of a modified ARM-PV approach in patients with PPI-refractory GERD

Authors Iwaya Y[1, 2], Sekita H[1], Ida M[1], Kobayashi Y[1], Ikeuchi H[1], Tsuchiya T[1], Baba S[1], Sawaguchi H[1], Kako S[1], Hirayama A[1], Okamura T[1], Nagaya T[1]

DOI 10.1055/s-0046-1821949

Problem to solve Proton pump inhibitor (PPI) refractory gastroesophageal reflux disease (GERD) remains a therapeutic challenge, and there is an increasing demand for minimally invasive endoscopic options that provide durable symptom relief. Antireflux mucoplasty (ARM-P) is an endoscopic anti-reflux procedure in which mucosal resection is performed at the gastric cardia, followed by immediate endoscopic closure, thereby reshaping the esophagogastric junction. Antireflux mucoplasty with valve (ARM-PV) further incorporates a valvuloplasty concept by creating a mucosal flap and fixing it to the underlying muscle layer with clips before closing the defect, enabling the construction of an antireflux valve. However, in conventional ARM-PV, mucosal flap fixation clips may be embedded and potentially interfere with subsequent endoscopic suturing. Clinical data on ARM-P and ARM-PV, as well as strategies to overcome these clip-related issues, are still limited. We therefore aimed to evaluate the clinical outcomes of ARM-P and ARM-PV for PPI refractory GERD and to assess the feasibility of a modified ARM-PV approach developed to reduce problems related to flap fixation clips.

Innovation To address these clip-related issues, we developed a modified ARM-PV technique that omits clip fixation of the mucosal flap to the muscle layer. This modification was designed to simplify the procedure while preserving the antireflux valve mechanism. We retrospectively reviewed consecutive patients with PPI-refractory GERD who underwent ARM-P or ARM-PV at a single tertiary center. Clinical outcomes, including technical success, adverse events, changes in GERD-related symptoms, and use of acid-suppressive medication, were analyzed. Symptom severity was assessed before treatment and at 1 month using the GERD-Health Related Quality of Life Questionnaire (GERD-HRQL) and the Frequency Scale for the Symptoms of GERD (FSSG).

Results Thirteen consecutive patients with PPI-refractory GERD were treated, including 6 who underwent ARM-P and 7 who underwent ARM-PV, of whom 6 received the modified ARM-PV technique. All procedures were completed successfully without major adverse events (bleeding, perforation, or stricture). In the overall cohort, GERD-HRQL improved from a median of 23 at baseline to 5 at 1 month, and FSSG improved from 29 to 13, all of which were statistically significant. In the subgroup treated with the modified ARM-PV approach, GERD-HRQL improved from 27.5 to 6.5 and FSSG from 31 to 12, also showing statistically significant symptom relief comparable to that observed in the full cohort. Regarding acid-suppressive therapy, all 13 patients were receiving full-dose PPI or P-CAB at baseline. At 1 month, 4 patients (31 %) remained on full dose, 3 patients (23 %) were maintained on half dose, and 6 patients (46 %) were able to discontinue or switch to on-demand use, with a similar pattern seen in the modified ARM-PV subgroup.

Conclusions In this single-center retrospective series, ARM-P and ARM-PV provided significant improvement in GERD-related symptoms and allowed reduction of acid-suppressive medication in patients with PPI-refractory GERD, without major adverse events such as bleeding, perforation, or stricture. The modified ARM-PV technique, which omits mucosal flap clip fixation to the muscle layer, appeared to be a feasible and safe endoscopic innovation that maintained clinical efficacy while potentially mitigating clip-related issues. Larger prospective studies with longer follow-up are warranted to confirm the durability of these outcomes and to further define the role of the modified ARM-PV approach among endoscopic treatments for refractory GERD.

eP623 POEM with preserving of the sling fibers and minimizing the length of esophageal myotomy is an effective method to prevent GERD in patients after peroral endoscopic myotomy. The first study outcomes of the single center of Ukraine

Authors Kiosov O[1], Tkachov V[2], Gulevskyi S[3], Shebela V[4]
Institutes **1** Zaporizhzhia State Medical University, Zaporizhzhia, Ukraine; **2** Zaporizhzhia State Medical and Pharmaceutical University, Zaporizhzhia, Ukraine; **3** University Clinic of Zaporizhzhia State Medical and Pharmaceutical University, Zaporizhzhia, Ukraine; **4** Medical Faculty 2, UzhNU, Uzhhorod, Ukraine
DOI 10.1055/s-0046-1821950

Aims POEM is the first line of treatment for patients with esophageal achalasia, but the development of postoperative GERD remains an actual problem today. To prevent the development of reflux, we modified the conventional technique of peroral endoscopic myotomy which is that we preservation of the sliding fibers of the stomach and the length of the esophageal myotomy [1–3].

Methods 32 patients with achalasia were included in the study. The studied group consisted of 16 men (50.0 %) and 16 women (50.0 %), the average age was 47.72 ± 2.88 (95 %-CI 41.95-53.49) years, the average duration of the disease was 4.33 ± 1.07 (95 %-CI 2.18-6.47) years. All patients were operated on by the modified method of peroral endoscopy myotomy with preservation of sliding fibers and minimizing length of esophageal myotomy. To diagnose postoperative reflux, we used daily esophageal impedance-24pH monitoring and the GerdQ questionnaire (GastroEsophageal Reflux Disease Questionnaire). The effectiveness of treatment results was assessed using the Eckard symptom scale. Assessment of quality of the life parameters (questionnaires ASQ, QLQ-C30 and QLQ-OES18) and the effectiveness of the performed modified peroral endoscopic myotomy of the esophagus.

Results All patients of the study group were operated on by a modified method of oral endoscopic myotomy (POEM). Esophageal myotomy was performed along the back wall, the length of the myotomy was 6-8 cm, and the crossing of the LES with preservation of the sliding fibers was mandatory. The result of the operation was evaluated 3 months after the operation.

According to the assessment of 24-hour pH-metry, based on the quantitative assessment of intraesophageal pH, the performance of POEM is associated with less pronounced manifestations of reflux, although the total time of residence of pH < 4 in this group was implausibly greater than the norm. At that time, the overall average score according to the GerdQ questionnaire in the studied group was 0.78 ± 0.25 (range 0.28-1.29). The obtained results indicate a low severity of GERD symptoms in patients 3 months after modified POEM, which confirms the effectiveness of the procedure in reducing the manifestations of reflux pathology and improving the quality of life of patients.

Conclusions Modified peroral endoscopic myotomy is an effective minimally invasive endoscopic method of treating patients with esophageal achalasia, with a significantly reduced development of reflux disease. The dynamics of changes in quality of the life indicators in patients with achalasia of the cardia 3 months after modified peroral endoscopic myotomy according to the Eckard symptom scales, achalasia-DS QoL (ASQ), EORTC QLQ-C30, EORTC QLQ-OES18 indicate a low percentage of reflux, a statistically reliable positive trend of improvement in quality of life parameters and work capacity

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP624 Submucosal Injection of Rectal Lesions Followed by Timed MRI: A Technique to Identify the Submucosal Plane and More Accurately Assess Depth of Invasion

Authors Boustani C[1], Dibitetto S[2, 3], de Sire R[4], Massimi D[5], Alfarone L[6], Capogreco A[6], Maselli R[7], Hassan C[8], Repici A[9]

Problem to solve Choosing the optimal resection strategy for colorectal lesions depends on morphology/Paris classification, optical diagnosis to characterize the surface pattern (JNET and/or Kudo), and lesion size. However, despite these classification systems in expert hands, there remains a large degree of uncertainty in accurately characterizing the depth of invasion of a lesion, particularly superficial or deep submucosal invasive cancer (SMIC). [1] Notably, both EUS and contrast enhanced MRI have limited reliability in staging rectal lesions (i.e. T1a/T1b vs T2). [2]

Our aim is to determine whether MRI after submucosal injection improves accuracy of differentiating T1 (presence of superficial or deep SMIC) from T2 rectal lesions compared with standard MRI, using histopathology as a reference. This crucial differentiation remains a challenging task and could drastically affect resection strategies and patient outcomes.

Innovation After a rectal lesion is identified on initial colonoscopy that may carry a higher risk of SMIC (size > 2 cm, JNET 2A and/or 2B), patients undergo a baseline MRI followed by submucosal normal saline injection of the lesion during endoscopy. The procedure is to be performed underwater without the use of CO2 to prevent an air-filled colon on imaging. A repeat MRI within 45 minutes provides a clearer view of the submucosal layer, allowing direct comparison with the baseline study.

Results Three rectal lesions (20–45 mm, Paris 0-IIa + Is, JNET 2A–2B) were evaluated and resected via ESD. The post-lift MRI was able to clearly highlight the submucosal plane for the radiologist, allowing them to determine absence of invasion into the submucosal layer or underlying muscularis propria. In comparison, the submucosal layer was not clearly visible in the pre-lift MRI, making the determination of SMIC not possible. Histology after ESD of all three lesions ranged from tubulovillous adenoma with either low- or high-grade dysplasia. Our results reveal that submucosal injection allowed the radiologist to more accurately stage these lesions based on their histology as a reference.

Conclusions Submucosal injection of rectal lesions followed by a timed MRI highlighted a clearly visible submucosal layer, improving staging accuracy in terms of presence of SMIC. In this series, the post-lift MRI correctly identified the absence of submucosal invasion, using histology as a reference. This technique may aid decision making for high-risk lesions where endoscopic (EMR or ESD) versus surgical resection remains in question.

DOI 10.1055/s-0046-1821952

Aims Despite recent guideline recommendations on managing acute upper gastrointestinal bleeding (AUGIB), mortality rates have not substantially improved over the years. We aimed to understand real-life pre-endoscopic assessment and management practices in AUGIB.

Methods We conducted an international survey from April to November 2023. Key domains captured respondents' demographics and clinical practice location, definitions of hemodynamic instability, and pre-endoscopic assessment. We provided descriptive proportions of responses. Secondary analyses explored differences in responses based on years of clinical experience.

Results Among the 533 clinicians who completed the survey, 47.1 % reported using a triage system for AUGIB, and only 60.4 % applied risk stratification scores at the time of presentation. Normal saline and balanced crystalloid fluids were almost equally preferred for initial fluid resuscitation. Hemodynamically unstable patients were typically managed in emergency departments and/or intensive care units. Over 85 % of respondents followed a restrictive blood transfusion strategy in stable patients, but this dropped to 50.3 % in hemodynamically unstable cases. Among respondents, 34.3 % did not routinely use prokinetics, and 27.6 % avoided their use, even in cases of severe bleeding or suspected gastric emptying disorders. The majority (87.1 %) prescribed proton pump inhibitors before endoscopy. For suspected variceal bleeding, 83.7 % reported using vasoactive agents, and 74.3 % reported administering prophylactic antibiotics. Younger clinicians were more likely to follow recent guidelines than those with over 15 years of clinical experience.

Conclusions We found considerable variation in the pre-endoscopic management of individuals with AUGIB. Overall adherence to international guidelines was not uniform, which may adversely impact patient outcomes

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP626 Video quality does not affect submucosal invasive cancer detection in large colorectal polyps: a prospective multicentre study

Authors Poortmans PJ[1, 2, 3], Montori M[4, 1], Argenziano ME[1, 2], Sorge A[1], Badrulhisham F[5], Tornai T[1], Monod A[1], Debels L[3], Hoorens A[1], Lala V[6], Desomer L[7, 1], Tate D[2, 1]

DOI 10.1055/s-0046-1821953

Aims Accurate detection of submucosal invasive cancer (SMIC) in large non-pedunculated colorectal polyps (LNPCPs) is essential for risk stratification. Pre-resection videos are increasingly used for expert review and triage, but it is unknown whether video quality influences diagnostic performance. This prospective multicentre study evaluated the impact of video quality on SMIC detection in LNPCPs by trained endoscopists.

Methods In four tertiary centres, high-definition pre-resection videos of consecutive LNPCPs were recorded by expert endoscopists and optically trained interventional fellows. Videos were uploaded to a web platform and independently reviewed by 9 blinded raters (experts and fellows) not involved in the original procedures. Raters were randomly assigned to videos and classified each lesion for SMIC presence.

Video quality was scored on a 5-point Likert scale (1 = poor, 5 = excellent) following a standardisation meeting defining structural criteria (global white-light overview, systematic inspection with virtual chromoendoscopy, close-up of suspicious areas) and technical criteria (clean lens, adequate washing, steady images). All recording endoscopists had received a brief educational intervention on standardised LNPCP video acquisition to ensure a basic proficiency in pre-resection imaging.

The primary outcome was the association between video quality and diagnostic performance (sensitivity, specificity, accuracy) for SMIC detection as defined by blinded histopathological assessment. Video quality was analysed as ordinal (1–5) and categorically as low (1–3) versus high (4–5). Sensitivity, specificity and accuracy were calculated with 95 % confidence intervals (CI). A mixed-effects logistic regression model with correct SMIC classification as dependent variable and random intercepts for lesion and rater assessed quality impact.

Results We included 268 LNPCPs, yielding 667 video assessments. SMIC was present in 53/268 (19.8 %), HGD in 76/268 (28.4 %), and LGD in 129/268 (48.1 %). Videos were rated as low-quality in 184/667 (27.6 %) and high-quality in 483/667 (72.4 %).

Overall sensitivity, specificity and accuracy for SMIC detection were 70.0 % (95 %CI 61.7–77.4), 83.8 % (95 %CI 80.4–86.7) and 81.0 % (95 %CI 77.9–83.8), respectively. Stratified by quality category, sensitivity was 67.0 % (95 %CI 56.7–76.2) for high-quality versus 73.0 % (95 %CI 55.9–86.2) for low-quality videos (P = 0.648). Specificity was 84.5 % (95 %CI 80.4–87.9) vs 81.0 % (95 %CI 73.7–87.0) (P = 0.399), and accuracy 81.0 % (95 %CI 77.2–84.4) vs 79.3 % (95 %CI 72.8–85.0) (P = 0.720). Lesion demographics are presented for high- and low-quality videos in the table. In the mixed-effects model, each 1-point increase in quality score yielded OR 1.07 (95 %CI 0.70–1.65; P = 0.76) for correct classification, indicating no significant effect (▶ **Table 1**).

▶ Table 1

Characteristic	High quality (Likert 4–5, n = 483)	Low quality (Likert 1–3, n = 184)	P-value
Lesion size (mm), median (IQR)	35 (20)	35 (12.5)	0.647
Non-granular morphology, n (%, 95% CI)	199 (41.2, 36.8–45.7)	74 (40.2, 33.1–47.7)	0.886
Paris classification, n (%, 95% CI)			
- Paris 0-IIa	212 (43.9, 39.4–48.4)	55 (29.9, 23.4–37.1)	**0.001**
- Paris 0-IIa + Is	124 (25.7, 21.8–29.8)	67 (36.4, 29.5–43.8)	**0.008**
- Paris 0-IIa + c	45 (9.3, 6.9–12.3)	15 (8.2, 4.6–13.1)	0.750
- Paris 0-Is	94 (19.5, 16.0–23.3)	43 (23.4, 17.5–30.2)	0.313
- Paris 0-Is + c	8 (1.7, 0.7–3.2)	4 (2.2, 0.6–5.5)	0.902

Conclusions In this multicentre study, SMIC detection on pre-resection LNPCP videos was highly accurate and did not differ significantly between low- and high-quality videos when basic structural and technical criteria were met. These findings support the use of routine pre-resection videos of varying quality for risk stratification and MDT triage by trained endoscopists.

DOI 10.1055/s-0046-1821954

Aims Effective professional education is critical for enhancing the quality and safety of endoscopic practice. This study aimed to objectively evaluate the immediate efficacy of seven distinct specialized endoscopic training courses by comparing participants' knowledge assessment scores before (pre-test) and immediately after (post-test) the educational intervention. The courses covered a broad range of clinically relevant topics, including diagnostic Upper GI endoscopy with separate modules on the stomach and the esophagus, screening colonoscopy, inflammatory bowel diseases (IBD) with an emphasis on endoscopic management, and two advanced endoscopic trainings: one focused on endoscopic submucosal dissection (ESD) and another on endoscopic ultrasound (EUS).

Methods Seven one-day specialized endoscopy trainings were conducted between 25 January 2025 and 25 October 2025 as part of the EndoAcademy continuous medical education program in Ukraine. Each training followed a unified structure that included: a diagnostic pre-test; theoretical sessions with case sharing and discussion led by expert faculty, covering updated diagnostic criteria and pathology correlation; small-group hands-on training using modern equipment focused on key interventional techniques such as polypectomy, EMR, endoscopic hemostasis, as well as other essential procedural skills; and a post-test to measure immediate learning gains. Only participants who completed both assessments were included, yielding 76 paired data sets. For each group, a paired t-test assessed statistical significance, and Cohen's *d* quantified the effect size.

Results 76 participants had completed both tests. Five of the seven trainings demonstrated a statistically significant increase in mean post-training scores ($p \leq 0.003$), with mean improvements ranging from 3.35 to 4.22 points. These five trainings also showed a very large effect size ($d \geq 1.52$), confirming the strong practical impact of the educational intervention.

Two trainings did not show statistically significant improvement ($p > 0.05$), and one of them exhibited a small, non-significant decrease in mean score.

Conclusions The majority of the specialized endoscopic trainings (5 of 7) were highly effective in immediately improving participants' knowledge based on paired test results. These findings support the value of structured, targeted educational interventions. For the trainings that did not demonstrate a significant effect, several factors may have contributed, including a notably smaller sample size in one group and a higher level of difficulty of the test questions, which may have limited measurable score improvement. These aspects warrant further evaluation to refine both the training content and the assessment methodology for future iterations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP628 Diffuse Endoscopic Involvement of the Gastrointestinal Tract by Metastatic Melanoma: A Case Report

Abstract Text

Gastrointestinal (GI) metastases from skin melanoma are rare and often diagnosed lately. Endoscopic identification of lesions in both upper and lower GI tracts is quite exceptional. We present the case of a 63-year-old man with a history of acral melanoma of the right foot (Breslow thickness 3.5 mm, BRAF wild-type) and known hepatic and cerebral metastases on computed tomography imaging. The patient underwent ileocecal resection with regional lymphadenectomy, followed by adjuvant and sequential immunotherapies including interferon-α, nivolumab, ipilimumab, and pembrolizumab. The patient subsequently underwent surgery due to ileal intussusception with creation of an ileostomy. He was admitted to our unit for anemia and vomiting. Therefore the patient underwent upper endoscopy which revealed multiple black-pigmented, vegetating lesions up to 4 cm in the gastric antrum and smaller lesions in the duodenum. Colonoscopy, performed both transanally and via ileostomy, showed dark, sessile lesions in the ileum and a small pigmented plaque in the colon. Histology confirmed metastatic melanoma (Melan-A, HMB-45, S100 positive).

Conclusion. Melanoma may metastasize diffusely to the GI tract even years after primary tumor excision. The endoscopic appearance of pigmented mucosal lesions should always prompt biopsy.

Simultaneous gastric, duodenal, ileal, and colonic metastases from melanoma are remarkably uncommon. This case underlines the crucial role of endoscopy

for diagnosis and staging of disseminated melanoma, even in advanced disease, guiding treatment decisions in complex oncologic scenarios.

eP629 Obscure gastrointestinal bleeding: a diagnostic uncertainty

Authors Sugeac A[1], Mateescu RB[1,2], Puscasu C[1]

Institutes **1** Colentina Hospital, Bucharest, Romania; **2** Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

DOI 10.1055/s-0046-1821956

Abstract Text

Identifying the bleeding source in obscure gastrointestinal bleeding is often challenging, particularly when endoscopic, radiologic, and surgical explorations yield discordant results. We present a case of recurrent bleeding of uncertain etiology, despite extensive investigation and therapeutic interventions.

A 73-year-old male with atrial fibrillation (previously anticoagulated), Child A cirrhosis, and recurrent C. Difficile colitis presented with repeated episodes of hematochezia and melena and moderate microcytic anemia.

Initial EGD revealed only small esophageal varices without signs of recent bleeding. Colonoscopy identified a cecal polyp which was resected, and no evidence of active bleeding. During an episode of hematochezia, we performed emergency videocapsule endoscopy, which showed the presence of blood in the terminal ileum but subsequent angio-CT was negative.

Due to recurrent episodes of clinically significant bleeding, we opted for intraoperative enteroscopy, which identified several small-bowel angiodysplasias, subsequently treated with APC and clipping. However, these lesions were small, of limited bleeding potential, and did not fully correlate with the severity and recurrence of overt bleeding. Recurrent melena persisted despite therapy, requiring multiple transfusions.

Bleeding gradually decreased after supportive management and repeated procedures, and the patient was discharged clinically stable. However, the definitive source of bleeding remained unclear.

Although multiple angiodysplasias were identified, their significance as the primary bleeding source is uncertain. A small-bowel Dieulafoy-type lesion – intermittent and difficult to capture – remains a strong alternative explanation. This case highlights the inherent limitations of current diagnostic modalities in obscure GI bleeding and the need for repeated, multimodal evaluation.

eP630 Age-Stratified Adenoma and Cancer Detection in the Middle East: Results from the First Large Screening Cohort of Asymptomatic Adults in Saudi Arabia

Authors Gardezi SAA[1], Saleh A[1], Alghawi R[1], Alabbasi F[1], Abualsoud S[1], Alomar M[1], Alalwan H[1], Alruwaili AF[1], Muafa F[1]

Institute **1** Johns Hopkins Aramco Healthcare Dhahran, Dhahran, Saudi Arabia

DOI 10.1055/s-0046-1821957

Aims Colorectal cancer (CRC) incidence is rising globally, with a notable shift toward younger-age onset in several regions [1]. However, real-world screening data from the Middle East are almost non-existent. There is currently no national colorectal cancer screening program in Saudi Arabia or, more broadly, across most of the Middle East. Our hospital is one of the few centres offering open-access screening colonoscopy for adults aged ≥ 45 years. This study aims to describe the screening colonoscopy outcomes in asymptomatic adults over four years, quantify adenoma and cancer detection across age groups, and provide foundational data to inform future CRC screening recommendations for Middle Eastern populations [2].

Methods This was a retrospective cohort analysis conducted at a single tertiary centre in Saudi Arabia. All screening colonoscopies performed between January 2022 and January 2025 were included. Eligible participants were asymptomatic adults undergoing screening, with a routine lower age threshold of 45 years. Data collected included demographics, caecal intubation rates (CIR), Boston Bowel Preparation Scale (BBPS) scores, withdrawal times, polyp and adenoma detection, polyp type, and complications. Colonoscopy quality indicators were evaluated according to ESGE standards [3]. Descriptive statistics were used for analysis, and outcomes were stratified by age groups: < 45, 45–60, and > 60 years. Individuals < 45 who underwent colonoscopy likely did so for non-documented opportunistic or external indications (e.g., FIT done elsewhere, incidental imaging findings, or family history).

Results A total of 3,397 screening colonoscopies were included. The mean age was 56.2 years; 61.8 % were male. The overall CIR was 98.1 %. Bowel preparation quality was high, with a mean BBPS of 7.28 and adequate preparation (BBPS ≥ 6) in 93.6 % of procedures. The mean withdrawal time was 9.5 minutes, with 92 % ≥ 6 minutes. The overall polyp detection rate was 37.9 %. Adenoma Detection Rate (ADR) was 15.6 %, varying across age groups as follows: < 45 years (10.4 %), 45–60 years (16.3 %), and > 60 years (14.9 %). Adenomas were identified from age 27 onward. Twenty-two malignant lesions were detected: 1 in < 45 years, 14 in 45–60 years, and 7 in > 60 years, with the earliest cancer detected at age 43. The overall clinical complication rate was 0.06 %, significantly below international benchmarks (▶ **Table 1**).

▶ **Table 1**

Parameter	Result
Total screening colonoscopies	3,397
Mean age (years)	56.2
Gender distribution	61.8 % male, 37.2 % female
Caecal intubation rate (CIR)	**98.1 %**
Mean BBPS score	7.28
Adequate bowel prep (BBPS ≥ 6)	**93.6 %**
Mean withdrawal time (minutes)	9.5
Withdrawal time ≥ 6 min	**92 %**
Polyp Detection Rate (PDR)	**37.9 %**
Adenoma Detection Rate (ADR)	**15.6 %**
ADR by age group	< 45: **10.4 %** 45–60: **16.3 %** > 60: **14.9 %**
Earliest adenoma detection	Age 27
Total cancers detected	22
Cancer distribution by age	< 45: **1** 45–60: **14** > 60: **7**
Earliest cancer detection	Age 43

Conclusions This represents the first large-scale dataset describing screening colonoscopy outcomes from the Middle East. High-quality indicators and very low complication rates demonstrate the feasibility of effective screening delivery in this region. The presence of adenomas and cancers in adults younger than 45 years raises important questions regarding the onset age of colorectal neoplasia in Middle Eastern populations. These findings highlight the need for prospective, population-based studies to determine optimal CRC screening strategies and age thresholds for the region.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP631 A rare case of pancreatic Schwannoma of the uncinate process

Authors Sugeac A[1], Voiosu T[1,2], Mateescu RB[1,2], State M[1,2]
Institutes 1 Colentina Hospital, Bucharest, Romania; 2 Carol Davila University of Medicine and Pharmacy, Bucharest, Romania
DOI 10.1055/s-0046-1821958

Abstract Text

Pancreatic schwannomas are extremely rare benign nerve-sheath tumors. Fewer than ~70 cases have been reported, and diagnostic accuracy prior to surgery is low. Therapeutic approaches remain highly heterogeneous in the literature.
We present the case of a 64-year-old female, who presented with left hypochondrial pain radiating posteriorly. MRI and EUS revealed a ~20 mm, well-circumscribed, hypoechoic, firm lesion at elastography in the pancreatic uncinate process. EUS-FNB biopsy demonstrated spindle-cell proliferation with typical Antoni A/B areas. Immunohistochemistry showed S100 and SOX10 positivity, with CD34, DOG1, GFAP, SMA, AE1/AE3 and chromogranin negativity, Ki-67 < 1 %, consistent with a pancreatic schwannoma.
Given the lesion's small size, its benign histologic profile, and the absence of high-risk features, and considering that the only surgical option is a pancreaticoduodenectomy (Whipple procedure), the patient declined the surgical approach and instead opted to pursue structured imagistic and EUS surveillance.
Pancreatic schwannomas show variable imaging appearances and often mimic neuroendocrine tumors or solid-pseudopapillary neoplasms. Management strategies described in case series range from observation and enucleation to major resections, reflecting a lack of consensus.
This case highlights the rarity of pancreatic schwannoma and the discordance in therapeutic approaches. When histology confirms benign features, close imagistic and EUS follow-up may be a safe alternative to radical surgery, especially for small, well-delimited lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP632V Obscure Gastrointestinal Bleeding Secondary to Jejunal Lymphangiectasia Bleeding: Diagnostic and therapeutic management by single-balloon enteroscopy

Authors Arroyo Argüelles JM[1], Escobar Ortiz J[1], Garrido Gallego F[1], Roldán Fernández M[1], Luisa AM[1], Angel PD[1]
Institute 1 Hospital Universitario Infanta Leonor, Madrid, Spain
DOI 10.1055/s-0046-1821959

Abstract Text

Obscure gastrointestinal bleeding can present a diagnostic challenge.
We report the case of an 84-year-old male with chronic kidney disease and anticoagulated atrial fibrillation, presenting with anemia and recurrent melena [1–4].
Initial endoscopic evaluation, including gastroscopy and colonoscopy, revealed no findings. Capsule endoscopy subsequently identified fresh blood in the proximal jejunum.
Anterograde single-balloon enteroscopy was performed, revealing a 5 mm lymphangiectasia in the proximal jejunum, approximately two meters from the dental arcade, with active oozing at its base, which was treated with the placement of a hemoclip, with good results.
This case highlights the importance of advanced endoscopic techniques in the diagnosis and treatment of obscure gastrointestinal bleeding.

eP633 Tolerability of Sedation with Remimazolam versus Midazolam in Outpatients Undergoing Upper GI or Biliopancreatic Endoscopic Ultrasound in a Non-Anesthesiologist Setting: preliminary results of A Prospective Observational Study (REM-EUS Study)

Authors Pessarelli T[1], Ciccia R[2], De Monti A[1], Pagliarulo M[1], Piagnani A[1], Bergna IMB[1], Boemo C[1], La Milia M[1], Marfinati Hervoso C[1], Alongi S[1], Amato A[1]
Institutes 1 ASST di Lecco, Lecco, Italy; 2 University Hospital Paolo Giaccone, Palermo, Italy
DOI 10.1055/s-0046-1821960

Aims Remimazolam (REM) and midazolam (MID) are currently used interchangeably for sedation in digestive endoscopy, with available literature indicating comparable safety profiles. However, data on patient-reported procedural tolerability are heterogeneous and largely derived from studies in which tolerability was a secondary outcome. Moreover, most evidence comes from anesthesiologist-led settings. The primary aim of this monocentric, prospective observational study was to evaluate and compare patient-reported tolerability of REM versus MID (both administered with fentanyl) during outpatient diagnostic endoscopic ultrasound (EUS) performed in a non-anesthesiological setting [1–3].

Methods Consecutive outpatients undergoing diagnostic EUS under moderate sedation and with American Society of Anesthesiologists class 1 to 3 were enrolled. The choice between REM and MID was made according to routine clinical practice, also considering drug availability. Demographic data were collected. The Modified Observational Alertness/Sedation Assessment (MOAA/S) scale was used to monitor sedation depth and determine the need for supplemental dosing. Vital signs were recorded every 5 minutes throughout the procedure. Recovery time was assessed using the Modified Aldrete score, while procedural tolerability was evaluated with the PRO-STEP scale. Operator satisfaction was measured using a Numeric Rating Scale. The study protocol was approved and endorsed by the anesthesiology department.

Results At the time of this preliminary analysis, 63 patients (46 biliopancreatic and 17 upper GI EUS) had been enrolled (median age 69 years, 44 % female, 63 % ASA class 2), with 31 (49 %) receiving REM. Patients in the REM and MID groups, respectively, did not differ significantly in age (69 vs. 68 median years, p = 0.99), sex (52 % vs. 38 % female, p = 0.81), BMI (24.04 vs. 24.01, p = 0.76), or ASA class distribution (p = 0.54). Supplemental dosing was required in 74 % of REM cases and 63 % of MID cases (p = 0.15). Total fentanyl dose did not differ significantly between groups. Median procedural time was also comparable (25 minutes vs. 18 minutes, p = 0.14). Patient tolerability, as measured by the PRO-STEP score, was similar between REM and MID (1.50 vs. 1.67, p = 0.77), as was operator satisfaction (NRS 9 vs. 9). Awakening and recovery times were significantly shorter in the REM group (p < 0.001). No adverse events were recorded.

Conclusions These preliminary findings suggest that REM and MID, when combined with fentanyl for moderate sedation in diagnostic EUS in a non-anesthesiological setting, provide comparable patient tolerability and operator satisfaction, with excellent safety profiles. REM is associated with a significantly faster post-procedure recovery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP634 The Hidden Burden of Endoscopy: Burnout, Work-Related Injuries, and Emotional Impact of Complications Among Endoscopists in Saudi Arabia

Authors Gardezi SAA[1], Alhamazani S[1], Saleh A[1], Muafa F[1]

Institute 1 Johns Hopkins Aramco Healthcare Dhahran, Dhahran, Saudi Arabia

DOI 10.1055/s-0046-1821961

Aims Endoscopy is a cornerstone of gastrointestinal healthcare, yet the well-being of endoscopists remains largely unexamined, particularly in the Middle East. Burnout, physical strain, and psychological distress after procedure-related complications can have significant implications for clinicians and patient safety [1, 2]. This study *the first of its kind in Saudi Arabia* aimed to determine the prevalence of burnout, musculoskeletal injuries, and emotional consequences following major endoscopic complications among practicing endoscopists. The objective was to quantify the occupational burden, identify contributing factors, and highlight gaps in institutional support systems.

Methods A national cross-sectional survey was conducted from October 2025 to November 2025 among licensed endoscopists across Saudi Arabia. The questionnaire captured demographic information, institutional practice characteristics, workload, burnout indicators, musculoskeletal symptoms, experiences with endoscopic complications, emotional impact, safety culture, and coping strategies. Data were analysed using descriptive statistical methods in Microsoft Excel.

Results A total of 76 endoscopists were included. Most participants were male and between 30–59 years of age, with consultants forming the largest professional group. Endoscopists practiced across all regions of the Kingdom, with Ministry of Health hospitals representing the most common workplace, followed by private and military institutions. High procedural burden was evident, with the majority performing close to 20 procedures weekly and working 41 hours or more. Musculoskeletal discomfort lasting over 24 hours was reported by 65 % of respondents, affecting predominantly the back, shoulders, and neck. Despite high symptom burden, only a small proportion sought medical evaluation or required absence from work. Burnout indicators were common, with 29 % often feeling tired and 17 % reporting emotional exhaustion or feelings of burnout. A significant procedural complication within the previous year was reported by 65 % of participants, most commonly bleeding or perforation. Emotional effects included intrusive thoughts, sleep disturbance, and transient loss of confidence. Over one-third avoided similar procedures after the complication. Formal debriefing or institutional support was inconsistently available, with nearly 60 % reporting no structured response following adverse events. A majority strongly supported the development of a national peer-support program for endoscopists.

Conclusions Endoscopists in Saudi Arabia face substantial physical, emotional, and psychological demands associated with high workloads, musculoskeletal strain, and significant complication-related distress. The lack of ergonomic training and limited debriefing structures underscores important gaps in institutional support. As the first study of its kind in the region, these findings highlight the urgent need for national ergonomic standards, structured debriefing pathways, peer-support systems, and comprehensive wellbeing strategies to safeguard clinician health and ensure sustainable endoscopy services.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP635 Salvage Hemostasis With a Self-Assembling Peptide (Purastat) in Bleeding Duodenal Tumors: A Four-Case Series from Oman Cancer Center

Authors Matar R[1], Sanyour J[1], Al Qarshoubi I[1]

Institute 1 Sultan Qaboos Comprehensive Cancer Care and Research Center, University Medical City, Muscat, Oman

DOI 10.1055/s-0046-1821962

Aims Purastat,is a novel transparent absorbent localized hemostatic agent [1]. It is self-assembling peptide hydrogel, has been increasingly recognized as a helpful tool in controlling non-variceal gastrointestinal bleeding [2], particularly in postprocedural oozing and bleeding from small blood vessels in the gastrointestinal tract [3]. Many studies have documented its effectiveness in spontaneous acute gastrointestinal bleeding [4–6], post-sphincterotomy bleeding, post-papillectomy bleeding [3]. However, evidence supporting its role in malignant upper GI bleeding remains scarce.

Bleeding due to primary or metastatic gastrointestinal (GI) tumors remains clinically challenging. GI-related tumor bleeding accounts for 12-15 % of cases of acute GI hemorrhage [7]

Herein, we report a case series of endoscopic hemostasis using PuraStat as a rescue therapy for bleeding duodenal tumors when standard endoscopic techniques were unsuccessful.

Methods We reviewed four patients who presented with active bleeding from duodenal malignant tumors. In all cases, standard endoscopic techniques including thermal coagulation or mechanical clipping along with epinephrine injection either failed to control the bleeding or were not feasible because of the friable tumor surface. Purastat was then applied as a salvage therapy. The main outcomes evaluated were immediate hemostasis, early rebleeding within 7 days, the need for additional interventions, changes in transfusion requirements, and any procedure-related complications.

Results Diffuse oozing and extremely friable tumor surfaces were present in all lesions, significantly reducing the efficacy of standard endoscopic modalities including epinephrine injection, thermal coagulation, and mechanical techniques. When application of Purastat, immediate hemostasis was achieved without any procedure-related complications. Transfusion requirements decreased after treatment, none of the patients experienced early rebleeding as well as the needed for radiologic or surgical intervention.

Conclusions Our experience indicates that Purastat may be a useful salvage option for Gastrointestinal tumors bleeding, including duodenal tumor bleeding when conventional techniques fails. Purastat was easy to apply, safe, and consistently effective at achieving hemostasis in this small series. These preliminary results support the need for larger prospective studies for Purastat potential role in malignant upper gastrointestinal bleeding

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP636 Precision in the Ducts: Diagnostic Yield of Cholangioscopy-Guided Biopsies for Imaging-Suspected Malignant Biliary Strictures

Authors Mountaki A[1], Khattak MF[1], Kok B[1], Potts J[1], Martin H[1]
Institute 1 Royal Free Hospital, London, United Kingdom
DOI 10.1055/s-0046-1821963

Aims Diagnosing 'indeterminate' biliary strictures remains a clinical challenge. The gold standard is a histological or cytological diagnosis. Conventional endoscopic sampling methods include brush cytology, fluoroscopy-guided endobiliary biopsies, and bile aspiration. These are limited by low sensitivity with frequent false-negative results. These limitations often delay definitive diagnosis and appropriate management. Cholangioscopy-guided biopsies using digital single-operator systems offer direct visual targeting of abnormal mucosa and may improve diagnostic accuracy. This study evaluates the diagnostic performance of cholangioscopy-guided biopsies in patients with biliary strictures previously deemed suspicious for malignancy on cross-sectional imaging [1–3].

Methods This was a retrospective, single-center study including consecutive patients who underwent Endoscopic Retrogade Cholangiopancreatography (ERCP) and cholangioscopy with biopsy between January 2024 and November 2025. All patients had biliary strictures considered suspicious for malignancy based on cross-sectional imaging. Cholangioscopy was performed using the SpyGlass DS II system (Boston Scientific), and all biopsies were obtained under direct visual guidance. Final diagnosis was based on histopathology from cholangioscopy-guided biopsies, or in cases of negative endoscopic sampling, from tissue obtained intraoperatively or through image-guided percutaneous biopsy.

Results A total of 44 patients were included, with a median age of 62 years. 30 (68 %) were male and 14 (32 %) were female. The majority had hilar strictures (n = 30, 68 %), followed by common hepatic duct (CHD) strictures (n = 11, 25 %) and common bile duct (CBD) strictures (n = 3, 7 %). All strictures appeared suspicious for malignancy on cross-sectional imaging. All patients were discussed in malignant Hepatopancreatobiliary multidisciplinary team (HPB MDT). Cholangioscopy with targeted biopsies was performed using the SpyGlass DS II system (with the use of SpyBite Max Biopsy Forceps). Final diagnosis was available for 42 patients; two were excluded due to unknown outcome. Among the 29 patients with a final diagnosis of cholangiocarcinoma, cholangioscopy guided biopsy confirmed malignancy in 20 cases, yielding a sensitivity of 69 %. 5 cases were falsely negative, with malignancy confirmed later via surgical or other sampling. The remaining 4 cases were considered to have malignancy from progressive changes on imaging.
Of the 13 patients without malignancy, biopsy was negative in all, corresponding to complete concordance with the final diagnosis. Median surveillance for patients that were diagnosed with benign disease was 15.3 months.
The overall clinical diagnostic accuracy of cholangioscopy-guided biopsies in this case series was 78.6 % with a sensitivity of 69 % and a specificity of 100 %. These figures compare favorably with conventional ERCP brush cytology, for which large series and meta-analyses consistently report pooled sensitivities in the order of 40–45 % and specificities approaching 100 % for malignant biliary strictures(1-3).
These findings reflect a consistently high diagnostic yield for visually targeted cholangioscopy-guided biopsy in the evaluation of extrahepatic biliary strictures.

Conclusions Cholangioscopy-guided biopsies demonstrate a good diagnostic yield and accuracy in the evaluation of biliary strictures that are suspicious for malignancy. Our findings support the routine use of cholangioscopy-guided biopsy as a reliable tissue acquisition method in the diagnostic work-up of suspected cholangiocarcinoma, while acknowledging that cholangioscopy is likely to be best used as one component of a multimodality endoscopic work-up for indeterminate biliary strictures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP637 Risk-Stratified Safety of Propofol Sedation for Outpatient Colonoscopy in Older Adults: Insights From a 20,041-Case Cohort

Authors Fukuda M[1], Tanabe M[1], Yumi K[1], Daijiro S[1], Hatsuka N[1], Rei M[1], Toshimori A[1], Ito T[1], Uragami N[1], Yokoyama N[1], Inoue H[1]
Institute 1 Showa Medical University Koto Toyosu Hospital, Tokyo, Japan
DOI 10.1055/s-0046-1821964

Aims With the growing elderly population, ensuring the safety of non-anesthesiologist–administered propofol (NAAP) for colonoscopy is increasingly important; however, real-world data in older adults remain limited. This study aimed to identify independent predictors of adverse events and delayed recovery during NAAP-sedated outpatient colonoscopy, particularly in patients aged ≥ 75 years.

Methods This retrospective study evaluated 20,041 consecutive outpatients who underwent colonoscopy with propofol sedation administered exclusively by non-anesthesiologist endoscopists between December 2015 and March 2024. Patients were stratified into three age groups (< 50, 50–74, and ≥ 75 years). Adverse events included hypoxemia (SpO_2 < 90 %), hypotension (sBP < 80 mmHg), bradycardia (HR < 50/min), and delayed recovery, defined as a resting time exceeding 32 minutes. Multivariable logistic regression was performed using age, sex, BMI, cardiovascular disease, procedure duration, and propofol dose as covariates.

Results A total of 20,041 colonoscopies were included (4,766 < 50 years; 11,449 aged 50–74; 3,826 aged ≥ 75). Adverse events increased with age, with hypoxemia, hypotension, and bradycardia occurring most frequently in patients aged ≥ 75 years (6.2 %, 2.6 %, and 2.8 %, respectively; all p < 0.01).
In multivariable analysis of the entire cohort, hypoxemia was independently associated with age (OR 1.03 per 1-year increase), BMI (OR 1.12 per 1 kg/m²

increase), and procedure duration (OR 1.02 per 1-minute increase). Hypotension was independently associated with age (OR 1.05 per 1-year increase) and procedure duration (OR 1.03 per 1-minute increase). Bradycardia was associated with lower BMI (OR 0.93 per 1 kg/m²), cardiovascular disease (OR 2.47), and procedure duration (OR 1.02 per 1-minute increase). Delayed recovery was associated with cardiovascular disease (OR 1.13).

Despite increasing adverse event rates with age, mean recovery time did not differ significantly among the three age groups (26.8, 26.6, and 26.1 minutes; p = 0.909).

Among patients aged ≥ 75 years, hypoxemia was independently associated with higher BMI and longer procedure duration (OR 1.10 per 1 kg/m², 95 % CI 1.07–1.14; and OR 1.02 per minute, 95 % CI 1.01–1.03, respectively). Bradycardia was associated with cardiovascular disease, female sex, and procedure duration (OR 2.72, 95 % CI 1.95–3.79; OR 1.66, 95 % CI 1.02–2.72; and OR 1.02 per minute, 95 % CI 1.01–1.04). Hypotension was associated with cardiovascular disease and procedure duration (OR 1.60, 95 % CI 1.03–2.48; and OR 1.03 per minute, 95 % CI 1.00–1.06). No independent predictors of delayed recovery were identified in this age stratum.

Conclusions In NAAP-sedated colonoscopy, advancing age contributed to an increased risk of cardiopulmonary events; however, physiological and procedural factors—including BMI, cardiovascular disease, sex, and procedure duration—also played important roles in determining overall vulnerability. Despite higher event rates in older adults, patients aged ≥ 75 years demonstrated recovery times comparable to those of younger individuals. These findings highlight the need to assess sedation risk comprehensively, incorporating both age and patient-specific physiological factors, and to apply individualized dosing and monitoring strategies to optimize the safety of NAAP in aging populations.

eP638 Assessing Negative PillSense for Safe Discharge in Patients with Positive Hemoccult and/or Unexplained Anemia

Authors Farooq A[1], Singh G[1], Almujarkesh K[1], Taj S[1], Fawwaz B[1], Naveed M[1], Inayat I[1], Robalino Gonzaga E[2]

Institutes **1** AdventHealth Orlando, Orlando, FL, USA, United States of America; **2** University of Pennsylvania, Philadelphia, United States of America

DOI 10.1055/s-0046-1821965

Aims This study aims to evaluate the safety and diagnostic performance of the PillSense optical blood-detection capsule as a triage tool for hospitalized patients with anemia or positive FOBT but no overt gastrointestinal bleeding. The primary objective was to determine the negative predictive value of a negative PillSense result for excluding active GI bleeding. We hypothesized that a negative PillSense reading would reliably identify patients who could be safely discharged without the need for urgent inpatient endoscopy [1–6].

Methods This was a prospective, single-center, blinded study at a tertiary U.S. hospital. Hospitalized adults with anemia and/or positive FOBT, without overt GI bleeding and without capsule contraindications, were enrolled. After informed consent, patients ingested the PillSense capsule, and results ("Blood Detected" vs "No Blood Detected") were collected by a research team member. Treating endoscopists were blinded to capsule results. Endoscopic evaluation (EGD, enteroscopy, and/or colonoscopy) was performed per standard clinical care. Primary outcome was safety and ability of a negative PillSense result to predict the safe discharge of hospitalized patients with positive hemoccult tests and/or anaemia.

Results Ten patients were enrolled, with a mean age of 59.1 years and 70 % female. PillSense generated a negative signal within the first 10 minutes in 9 of 10 patients (90 %). Among these nine patients, extended monitoring was performed in eight between 4 and 6 hours. Five of these eight patients (62.5 %) later developed a positive signal, while three patients (37.5 %) remained negative throughout prolonged monitoring. In all three cases with persistently negative signals, subsequent endoscopic evaluation confirmed the absence of any identifiable bleeding source, supporting the reliability of the negative result.

Among the five patients who transitioned from an early negative to a delayed positive signal, endoscopic evaluation demonstrated non-actively bleeding lesions. These included a gastric ulcer in the upper gastrointestinal tract, a small-bowel arteriovenous malformation, and a hemorrhoidal source in the lower gastrointestinal tract. In one additional patient who was initially negative at 10 minutes, no further PillSense data could be obtained; endoscopy revealed a non-bleeding gastric polyp and diverticulosis.

Importantly, across all nine patients with a negative PillSense result at 10 minutes, no cases of active upper gastrointestinal bleeding were identified endoscopically, yielding a negative predictive value of 100 % for active UGI bleeding in this cohort. No patient required an endoscopic hemostatic intervention, and no capsule-related adverse events occurred. One patient required an unrelated readmission.

Conclusions In hospitalized patients with anemia or positive FOBT but no overt gastrointestinal bleeding, a negative PillSense result reliably excluded active upper GI bleeding, with an observed negative predictive value of 100 % in this cohort. These findings support the safety of using PillSense as a rapid triage tool to identify patients who may not require urgent inpatient EGD and who can instead be deferred to outpatient evaluation. Because several patients in this study remained admitted solely while awaiting endoscopy, the ability to confidently rule out active upper GI bleeding has the potential to meaningfully reduce unnecessary hospital days, decrease costs, and improve bed utilization in resource-constrained settings.

PillSense also accurately detected the single case of active bleeding and demonstrated that a delayed positive signal, occurring after 4-6 hours, corresponded to clinically relevant lesions in the upper GI tract, small bowel, and even the lower GI tract that had ceased active bleeding. Together, these observations highlight the promise of PillSense as a point-of-care technology capable of both safely ruling out active bleeding early and identifying occult lesions over time, ultimately streamlining care pathways and optimizing resource allocation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP639 Disposable Elevator-Cap Duodenoscopes and the Risk of Post-ERCP Cholangitis: Results from a Prospective Cohort

Authors Kim EJ[1], Kim CH[1], Choi JH[1], Cho IR[1], Lee SH[1], Ryu JK[1], Paik WH[1]

Institute **1** Department of Internal Medicine and Liver Research Institute, Seoul National University Hospital, Seoul, Republic of Korea

DOI 10.1055/s-0046-1821966

Aims Disposable elevator-cap (DEC) duodenoscopes were designed to reduce residual contamination after reprocessing and thereby lower the risk of infection transmission. We compared clinical outcomes of DEC versus conventional duodenoscopes, focusing on post-ERCP cholangitis and multidrug-resistant (MDR) cholangitis in routine practice [1, 2].

Methods In a prospective, single-center cohort, consecutive ERCP patients were followed for post-procedural outcomes. Routine post–high-level disinfection (HLD) surveillance cultures were also performed during the study period.

Results Interim analysis was conducted after enrollment of 1,039 patients (318 in the DEC group and 721 in the conventional group). Technical success was similar (DEC 98.7 % vs conventional 98.2 %), while mean procedure time was shorter with DEC (15.7 ± 9.0 vs 17.5 ± 9.8 minutes; p = 0.003). The incidence of overall post-ERCP cholangitis was comparable between groups (10.1 % in DEC vs 8.0 % in conventional, p = 0.20). After adjustment, no significant difference was observed (OR, 1.28; 95 % CI, 0.80–2.06; p = 0.31). DEC tended to be more protective for MDR cholangitis without statistical significance (OR, 0.74; 95 % CI, 0.27–1.99; p = 0.55). In parallel, post-HLD surveillance cultures revealed microbial contamination only in conventional duodenoscopes, whereas no growth was detected in DEC-equipped duodenoscopes.

Conclusions This interim analysis showed no significant difference in post-ERCP or MDR cholangitis between DEC and conventional duodenoscopes, leading to early study termination. The absence of microbial growth during surveillance in the DEC group supports a potential infection-prevention advantage of the device.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP640 Outcomes of self-expandable metallic stents (SEMS) in post-cholecystectomy biliary strictures – a single-arm meta-analysis

Authors Santo P[1], Awadie H[2], Zoabi A[2], Gralnek I

Institutes 1 Texas Tech University Health Sciences Center, Lubbock, United States of America; 2 Emek Medical Center, Afula, Israel

DOI 10.1055/s-0046-1821967

Aims Endoscopic placement of multiple plastic stents (MPS) is considered first-line therapy for benign biliary strictures. Emerging evidence however, suggests that SEMS may offer advantages, including fewer endoscopic re-interventions (e.g., stent exchanges) needed to achieve clinical success (stricture resolution). However, stratified data on the various specific etiologies of benign biliary strictures such as iatrogenic injury during surgery (most common), chronic inflammatory and infectious conditions, trauma, chemotherapy-induced injury, and autoimmune diseases remain limited. The aim of this meta-analysis was to pool available published data specifically on post-cholecystectomy biliary strictures in order to evaluate the efficacy and safety of SEMS placement for this specific clinical indication (▶ **Table 1**).

Methods This study protocol was published in PROSPERO under the register CRD420251239366. After a systematic review of studies identified from MEDLINE, Embase and Cochrane, we performed a single-arm proportion meta-analysis analyzing the rate of stricture resolution, stricture recurrence, adverse events, stent migration and sucessful stent removal with SEMS. We excluded studies that did not provide stratified data on the specific etiology of the benign biliary stricture. We used a random-effects model to calculate the combined proportion with 95 % confidence interval (CI). Between-study heterogeneity was assessed using I^2 statistics.

▶ **Table 1**

Outcome Evaluated	Number of Patients	Pooled Effect (95 % CI)	Heterogeneity (I^2)
Stricture Resolution	46	82.6 % (68.9-91.1 %)	0 %
Stricture Recurrence	44	20.5 % (11.0-34.9 %)	0 %
Adverse Event	48	30.4 % (16.1-49.8 %)	0 %
Stent Migration	46	3.8 % (0.0-15.7 %)	0 %
Sucessful Stent Removal	38	94.2 % (53.0-99.6 %)	0 %

Results We included 6 studies, comprising 54 patients with a post-cholecystectomy biliary stricture. The rate of SEMS stricture resolution was 82.6 % (95 % CI 68.9-91.1 %; I^2 = 0 %), and the stricture recurrence rate was 20.5 % (95 % CI 11.0-34.9 %; I^2 = 0 %). The adverse event rate was 30.4 % (95 % CI 16.1-49.8 %; I^2 = 0 %), and included cholangitis (n = 10), pancreatitis (n = 1), solid debris in lumen (n = 1), and abdominal pain (n = 1). The rate of stent migration was 3.8 % (95 % CI 0.0-15.7 %; I^2 = 0 %). Successful SEMS removal rate was 94.2 % (95 % CI 53.0-99.6 %; I^2 = 0 %).

Conclusions Previous systematic reviews / meta-analyses have reported that long-term biliary stricture resolution rates with MPS for benign etiologies range from 84 % to 90 %, with stricture recurrence rates varying by underlying cause. In our study, we observed a stricture resolution rate of 82.6 % and a stricture recurrence rate of 20.5 %. Given the non-negligible rate of adverse events (30.4 %), our findings highlight the need for etiology-specific analyses before generalizing the non-inferiority of SEMS across all benign biliary strictures, as the mechanisms and pathogenesis differ and each stricture etiology may require an individualized therapeutic approach. Additionally, it must be mentioned that the included studies analysed different types of SEMS. Although there was no identified between-study heterogeneity, differences in the mechanism of each stent may have played a role in our findings, which should be interpreted with caution. Unfortunately, due to lack of data it was not possible to perform subgroup analyses stratified by SEMS type. Further studies should be conducted that are stratified by benign biliary stricture etiology in order to draw more definitive conclusions.

eP641 Sixteen years single-center experience in flexible endoscopic septotomy for Zenker's diverticulum: a traditional technique in the modern era

Authors Manno M[1], Gualandi N[1], Bonura GF[1], Gabbani T[1], Soriani P[1]

Institute 1 Azienda USL Modena, Modena, Italy

DOI 10.1055/s-0046-1821968

Aims To evaluate clinical and technical efficacy, safety profile, and recurrence rate of flexible endoscopic septotomy (FES) for Zenker's Diverticulum (ZD) in a high-volume referral center.

Methods This retrospective single-center study included all consecutive adults undergoing FES for symptomatic ZD from January 2010 to November 2025. Clinical, endoscopic, and procedural data were collected from electronic records. Septotomy was performed using either a diverticuloscope-assisted or free-hand approach using IT-Knife 2. Clinical follow-up at 1, 6, and 12 months, and thereafter until recurrence, assessed symptom resolution using the Dakkak and Bennett score. Primary outcome was clinical success (score = 0). Secondary outcomes included technical success, recurrence and adverse events rates [1–10]

Results A total of 55 procedures were performed in 50 patients (median age 74 years; 70 % male). Median diverticulum size was 30 mm (range 25–50). Median follow-up was 84 months (range 6–144). Clinical success was achieved in 45/50 patients (90 %). Five patients experienced recurrence at 8, 11, 96, 96, and 144 months; all of these underwent successful re-septotomy with no further recurrence. Technical success was achieved in all cases (100 %), with a mean procedure time of 17 ± 4 minutes. Intraprocedural bleeding occurred in three patients, all managed endoscopically by clip apposing; no post-procedural or late adverse events were observed. Fourty-nine patients (98 %) were discharged within 48 hours

Conclusions FES is a highly effective and safe treatment for ZD, offering excellent long-term symptom-free period. Even in cases of recurrence, repeat endoscopic treatment can be is successfully and safety performed. These findings support FES as a first-line therapy, while highlighting its robust long-term performance in the era of emerging endoscopic techniques

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Over-the-Scope Clips (OTSC) are commonly used for haemostasis and defect closure, but removal may occasionally be required. The standard method is the bipolar cutter system, though no formal guidelines exist. We describe an alternative ESD-based technique when conventional removal fails [1, 2].

An 81-year-old male patient underwent piecemeal EMR for a 35 mm rectal lesion after ESD was aborted due to severe bleeding, requiring OTSC placement. Two years later, recurrence was detected around and within the clip, with biopsies showing adenoma with low-grade dysplasia. Attempts to remove the OTSC with the bipolar cutter system were unsuccessful.

An ESD approach was performed under conscious sedation, using, allowing complete OTSC removal without adverse events. Three-month follow-up confirmed no recurrence.

eP643 Dieulafoy's Lesion of the Right Colon: Report of Two Cases

Authors Georgakopoulou N[1], Kotzagiannidou E[1], Thanos C[1], Ntailianas D[1], Piskopou D[1], Georgiou E[1], Triantafyllou M[1], Tsitsigiannis K[1], Kalakos N[1], Mpraimakis A[1], Michalopoulos G[1], Striki A[1], Argyropoulos T[1], Karoumpalis I[1]
Institute **1** General Hospital of Athens "G. Gennimatas", Athens, Greece
DOI 10.1055/s-0046-1821970

Background Dieulafoy's lesion (DL) is an uncommon vascular anomaly capable of causing severe gastrointestinal bleeding. Although it most frequently occurs in the stomach, colonic localization—particularly in the right colon—is rare and may delay diagnosis and management. We describe two patients, recently diagnosed and treated in our department [1].

Case Reports

Case 1:A 77-year-old woman with a history of atrial fibrillation receiving acenocoumarol presented with anemia (Hgb 9.3 g/dL; Hct 28.7 %; MCV 97 fL) and dark red stools. Acenocoumarol was discontinued, and fluid resuscitation along with PPI therapy was initiated. Upper endoscopy identified a small prepyloric Forrest III ulcer (0.6 cm), deemed insufficient to explain the bleeding. Due to ongoing gastrointestinal bleeding and transfusion requirements, colonoscopy was performed and revealed a capillary bleeding point in the ascending colon consistent with a Dieulafoy's lesion. Argon plasma coagulation (APC) achieved successful hemostasis.

Case 2: An 80-year-old woman with coronary artery disease and atrial fibrillation, on daily clopidogrel and apixaban, presented with severe anemia (Hgb 3.3 g/dL; Hct 10.3 %; MCV 93.7 fL) and dark red stools. Management included PPI therapy, transfusion of red blood cells, fresh frozen plasma, and temporary suspension of anticoagulation. Upper endoscopy showed no source of bleeding. Because symptoms persisted, colonoscopy was performed and revealed a Dieulafoy's lesion in the ascending colon. Hemostasis was achieved using three endoscopic clips. Low-molecular-weight heparin was later restarted without hemorrhagic recurrence.

Conclusion Both patients recovered uneventfully and were discharged in stable condition. These cases illustrate that in patients with ongoing gastrointestinal bleeding and negative upper endoscopy, early colonoscopy should be strongly considered. Prompt evaluation can prevent unnecessary repeated procedures and allows timely diagnosis and effective endoscopic treatment of rare but clinically significant colonic Dieulafoy's lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP644 Dysphagia in Ineffective Esophageal Motility is Not Explained by Evidence of Obstruction or Poorer Peristalsis at High-resolution Esophageal Manometry: Results from a Prospective Study

Authors Adamo G[1], Visaggi P[2], Solinas I[3], Ovidi F[4], Bellini M[5], Savarino E[6], De Bortoli N[5]
Institutes **1** Azienda USL Toscana Nord Ovest, Livorno, Italy; **2** Digestive Endoscopy Unit, Azienda Ospedaliera Universitaria Pisana, Ospedale Nuovo Santa Chiara, Pisa, Italy; **3** Azienda USL Toscana Nord Ovest, Pontedera, Italy; **4** Azienda USL Toscana Nord Ovest, Cecina, Italy; **5** Gastroenterology Unit, Azienda Ospedaliera Universitaria Pisana, Ospedale Nuovo Santa Chiara, Pisa, Italy; **6** Gastroenterology Unit, Azienda Ospedale-Università di Padova, Padova, Italy
DOI 10.1055/s-0046-1821971

Aims Ineffective esophageal motility (IEM) is a rare motility disorder characterized by weak or failed peristalsis at high-resolution manometry (HRM). There is an established association between IEM and gastroesophageal reflux-disease (GERD) symptoms. However, it is unclear why some patients present with dysphagia. In this study we aimed to investigated whether dysphagia in IEM is associated with specific HRM or pH-impedance monitoring (MII-pH) findings.

Methods Adults (≥ 18 y) who underwent HRM for upper gastrointestinal symptoms who were diagnosed with IEM according to Chicago v4.0 between January 2021 and November 2024 were included. Patients' gender, age, symptoms (dysphagia, chest pain, heartburn, regurgitation, belching), response to proton pump inhibitor (PPI) treatment, and HRM data were recorded. All patients underwent MII-pH. Wilcoxon rank sum test, Pearson's chi-squared test and Fisher's exact test were used for comparisons. Significance was set at $p < 0.05$.

Results In the study period, 54 patients were diagnosed with IEM. Of them, 33 (61 %) did not report dysphagia (IEM-GERD), while 21 (39 %) had dysphagia (IEM-DYSPHAGIA). Of note, patients with or without dysphagia had a comparable prevalence of heartburn, chest pain, regurgitation, and erosive esophagitis. In addition, IEM-GERD and IEM-DYSPHAGIA were comparable in age and response to PPI treatment. IEM-GERD and IEM-DYSPHAGIA did not show significant differences in EGJ type, EGJ contractile integral (EGJ-CI), integrated relaxation pressure (IRP), percentage of ineffective or failed swallows, or the rapid drinking challenge (RDC) findings ($p > 0.05$ for all), demonstrating an overall similar pathophysiology of peristalsis and EGJ opening. In terms of MII-pH, there was no statistical difference in GERD-related parameters between IEM-GERD and IEM-DYSPHAGIA, who showed comparable values of acid exposure time (AET), mean nocturnal baseline impedance (MNBI), symptom association indexes, and post-reflux swallow-induced peristaltic wave index (PSPW-I) ($p > 0.05$ for all).

Conclusions We showed that dysphagia in IEM is not explained by impaired EGJ outflow or worse peristalsis. IEM with and without dysphagia have a similar proportion of GERD symptoms, comparable MII-pH findings, and respond similarly to PPI treatment. Our findings suggest that dysphagia in IEM could be a symptomatic manifestation of GERD.

Abstract Text
Recurrent or previously manipulated lesions, especially those involving tattoo ink, are technically challenging due to submucosal fibrosis, obscured dissection planes, and poor lifting, increasing the risk of incomplete resection and adverse events. We present an 82-year-old woman with a 30 mm hemi-circumferential recurrent hepatic-flexure lesion after two prior hot EMRs, with dense tattoo infiltration. Underwater ESD was performed using continuous saline immersion for improved visualization, supported by a thin needle knife with high-pressure waterjet and double rubber-band traction. Amber-Red Color imaging enhanced plane delineation despite heavy pigmentation. Despite an intraprocedural perforation, closed endoscopically, en bloc R0 resection was achieved. This case highlights how combining underwater dissection, waterjet knives, traction, and ACI can enable safe curative ESD in fibrotic tattooed recurrences.

Abstract Text
An 80 year-old man with prior left hepatic lobectomy for hepatocellular carcinoma presented with cholangitis due to biliary stent occlusion. CT scan showed biliary dilation and duodenal stenosis due to progression of a known ampullary adenocarcinoma. ERCP was unfeasible. After placement of an orojejunal tube and distension of the jejunal loop, EUS-GE was created using a 20mm LAMS. Due to the left hepatectomy, a standard transgastric opserative window for EUS-HGS was not found. Hence, a more prepyloric access was selected to access a mildly dilated right intrahepatic biliary tree. EUS-HGS was completed deploying a 10 × 80 mm partially covered metal stent. HGS access was further used to extract stones from the common bile duct (CBD) and to promote antegrade SEMS-in-SEMS stenting. The patient recovered uneventfully, and no further cholangitis occurred during a 3-month follow up.

eP647 5 years tertiary experience in button battery ingestions – Children continue to die from button batteries

Authors Almheiri M[1], Aljabri E[2], Krishnamurthy B[1], Kader A[2], Malik E[3], Almurbati B[2], Tzivinikos C[1]
Institutes **1** Al Jalila Children's Hospital, Dubai, United Arab Emirates; **2** Al Jalila Children's Hospital, Dubai, United Arab Emirates; **3** Al Jalila Childrens' Hospital, Dubai, United Arab Emirates
DOI 10.1055/s-0046-1821974

Aims Button battery ingestion (BBI) in children can lead to lifethreatening complications including death. In 2021, the EuropeanSociety for Pediatric Gastroenterology Hepatology and Nutrition(ESPGHAN) published guidance, aiming to unify the managementfor better outcomes and to assess the compliance to EPSGHAN guidance and the impact ofthis problem in our community including the long termcomplications [1].

Methods Retrospective data collection looking at all pediatric patient whopresented with button battery ingestion in our children's hospitalfrom 2018 – 2023.

Results From April 2018 till November 2024, 40 patients presented with BBI. In our datanoticed increase in number of cases per year, in 2022 we had 18 patients(Fig.1.A). The button battery mainly was in esophagus (52 %, n = 21), and 37 %(n = 15) were in stomach. ESPGHAN recommends removing button battery inesophagus within 2 hours. 14 patients who met the criteria, underwentendoscopy removal within average of 1.5 hours. According to endoscopicclassification of corrosive injuries (Zargar classification) 9 patients had 0 score,but 14 had class IIIa (Fig.1B) . 82 % (n = 33) of patients recovered fully, 3 patientshad short term complications: fever, and one had esophageal perforation .3patients had long term complications including esophageal stricture requiringmultiple dilatations and tracheoesophageal fistula and one died (Fig.1.C).Out of 32 patients who presented < 12h , 14 received honey in emergencydepartment. 15 patients met the indications for further imaging, but13 of themhad either CT or MRI done during the admission.In 18 patients who underwent endoscopic removal of button battery inesophagus, 13 patients had acetic acid irrigation during endoscopy (Fig.1.D).

Conclusions Overall, the majority of patients after 2021 received management as perESPGHAN guidance, most of the patients recovered but the long termcomplications can be life threatening and cause significant morbidity andmortality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP648 Endoscopic intermuscular dissection of possibly submucosa invasive rectal lesions – a prospective register study

Authors Schneider M[1], Veiser T[1], Dertmann T[1], Beyna T[1]

Institute **1** Evangelical Hospital Düsseldorf, Düsseldorf, Germany

DOI 10.1055/s-0046-1821975

Aims Endoscopic intermuscular disection (EID) is an evolving method allowing resection of submucosal invasive rectal neoplasms. In this unicenter prospective register study from a tertiary endoscopy centre we examined the oncological outcomes, procedure associated data also regarding safety under nurse administered sedation and assesed structural requirements for this procedure.

Methods All patients treated with EID for rectal lesions from November 2024 to November 2025 at Evangelisches Krankenhaus Düsseldorf, Germany were included. The primary endpoints were en-bloc-, R0- and curative resection rate. Secondary endpoints were, periprocedural complications and sedation related complications as well as resection speed and duration of hospital stay.

Results A total of 8 patients with an average age of 64,9 years were included in this analysis (male/female 6/2). 3 lesions were previously treated by EMR. All lesions were resected en-bloc. Histopathologically the resected lesions were 5 adenocarcinoma- 3 pT1 with submucosal invasion (1 sm1, 2 sm3) and 2 pT2, 1 high grade dysplasia, 1 low grade dysplasia (with severe submucosal fibrosis) and 1 non- neoplastic lesion (secondary resection after pmEMR of an adenocarcinoma).The R0 resection rate was 83,3 % whereas the curative resection rate was 50 %. Not curatively resected patients underwent surgery in 2/3 cases. In one case there were no vital tumorcells in the specimen and the other one resulted to be a pT3 lesion.The procedures were performed under nurse administered sedation with propofol and midazolam. There were no intraprocedural or sedation associated complications. 1 post procedural bleeding occured that required endoscopic treatment. The average procedure time was 136 minutes. The average specimen size was 1350mm² and the resectionspeed 9,9mm²/min. Patients stayed in the hospital for an average of 3,25 nights. Compared to our prospective ESD data (17,8mm²/min for rectal lesions) the dissection speed was slower among these first EID cases and there was no difference in length of hospital stay.

Conclusions EID appears to be a feasable method, easy to establish in ESD experienced endoscopy centers to treat possibly submucosa invasive rectal lesions or lesions with submucosal firbosis. The method does not require additional measures and can be performed under nurse administered sedation. Continous prospective assesment of the method is necessary to further evaluate its safety profile and long term oncologic outcomes.

DOI 10.1055/s-0046-1821976

Aims Cleanliness of the mucosa has been recently recognized as a key quality indicator of esophagogastroduodenoscopy (EGD). Pre-medication with mucolytic and defoaming agents is an effective method for improving visibility during EGD. One of the possible obstacles in routine pre-medication implementation is the safety concern related to sedation. We aimed to synthesize the available evidence regarding the safety of pre-medication with anti-foaming agents, with or without mucolytic substances, in patients scheduled to undergo sedated upper gastrointestinal endoscopy.

Methods A systematic review across MEDLINE and Cochrane Central Register from 01/01/2019 until 31/12/2024 was performed for all types of trials evaluating the safety of pre-medication with an anti-foaming agent with or without mucolytic substances in patients undergoing sedated upper GI endoscopy. We pooled the AE detected in the two arms: intervention (up to 100 ml of anti-foaming-mucolytic solution) and comparator (either up to 100 ml of water or nil per mouth), and presented the effect size on study outcomes either as the total rate of AE or Odds Ratio (OR) with 95 % confidence interval (CI). The

certainty of evidence was assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

Results Nine studies (eight RCTs and one cohort) with 10283 subjects were included. Overall, there were 27 and 39 AEs in the intervention and the control group, respectively, with a total AEs rate of 0 %, 95 % CI (0-0.01); I^2 = 93 %; there was moderate certainty in the estimates. Focusing only on the studies with nil *per os* as a comparator (3 studies with 1012 patients), no excess of AEs rate in the premedication group was found [OR 0.55, 95 % CI (0.11-2.72); I^2 = 86 %].

Conclusions Utilization of premedication with anti-foaming/mucolytic agents before routine upper GI endoscopy is not associated with an increased rate of AEs during sedated upper GI endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP650 ERCP in patients over 80 years old: experience from a tetriary hospital

Authors Panagaki A[1], Giannakopoulos A[1], Aggelopoulos G[1], Gkolfakis P[2], Tziatzios G[3], Mathou N[1], Kyvelou E[4], Petraki S[1], Delatolas V[1], Aggelogiannopoulou P[1], Paraskevopoulou P[1], Paraskevopoulou A[1], Triantopoulou C[1], Paraskeva K[3]

DOI 10.1055/s-0046-1821977

Aims To present clinical and procedural data of patients over 80 years of age who underwent ERCP.

Methods We retrospectively reviewed a prospectively collected single-center database of adult patients who underwent ERCP between 1/1/2022 and 31/5/2025 in a tertiary Greek public hospital. Data collected included demographic characteristics, indications for ERCP, clinical outcomes., and complications rates both immediate and within 2-week s post procedure. These data were compared with an historical cohort from the same center, consisting of patients under 80 years of age who underwent ERCP between 9/2021 and 12/2023.

Results A total of 1729 ERCP were performed during the study period. Among these 31.1 % (n = 538) were performed in patients aged > 80 years (54.1 % female) and 5.03 % (n = 87). In patients aged > 90 years. These were compared with 695 patients under 80 years from the historical cohort.

The most common indication for ERCP in patients > 80 years was choledocholithiasis 53.5 % (n = 288) percentage similar to the historic cohort 42 % (n = 292), (p > 0.05). The second most common indication was malignant biliary obstruction 19.9 % (n = 107) compared with 28.6 % (n = 199), (p > 0.05). in the younger cohort (p > 0,05). The third commonest indication was acute cholangitis 17.7 % (n = 95) compering with 13.4 % (n = 79), (p > 0.05).

Sphincterotomy was performed in 61.5 % (n = 331) of older patients and 27.1 % (n = 146) had a prior sphincterotomy.

Post ERCP bleeding occurred in 4.87 % (n = 25), including 4 delayed cases, vs 2.73 % in the historic group (p = 0.048). Post ERCP pancreatitis occurred in 1.95 % (n = 10) vs 0.72 % (p > 0.05), cholangitis 1.36 % (n = 7) vs 0.29 % (p = 0.033), cardiopulmonary complications 0.59 % (n = 3) vs 0.83 % (n = 6) (p > 0.05) and death 0.39 % (n = 2).

Completeness of procedure of ERCP was 96.5 % (n = 494). Causes of incomplete ERCP included anatomical reasons (duodenal diverticula, altered anatomy) 56.3 % (n = 9), malignant infiltration 25 % (n = 4) and patient/anesthesia related complications 18.7 % (n = 3).

Conclusions In a tertiary reference center approximately one third of all ERCP procedures were performed in patients over 80 years of age. One quarter of these patients over 80 years had previously undergone sphincterotomy. The most common indication, (> 50 %) is choledocholithiasis did not differ between age groups. Complications rates were generally comparable between patients above and below 80 years, indicating that ERCP is a safe and effective procedure in very elderly patients when performed in an experienced center.

eP651 Endoscopic Intermuscular Dissection at the Anal Verge: Optimizing Oncological and Functional Outcomes Using a Novel Bipolar Scissor Device – a Case Study

Author Triller C[1]

Institute **1** City Hospital Heinsberg GmbH, Heinsberg, Germany

DOI 10.1055/s-0046-1821978

Abstract Text

Endoscopic techniques have emerged as a pivotal component in the treatment of early gastrointestinal cancer. Endoscopic intermuscular dissection (EID) serves as a technique facilitating deeper resection in the rectum to achieve R0 resection of advanced dysplasia, scar tissue adjacent to dysplasia, or T1 cancer [1, 2]. In this case study, we used a novel bipolar endoscopic scissor device to enhance patient outcomes.

Case Presentation: An 89-year-old female presented with lower gastrointestinal bleeding under Apixaban, due to atrial fibrillation and chronic heart failure. Colonoscopy revealed an eroded broad-based 2.5 cm polyp in the distal rectum. During initial intervention, a snare resection was performed. Conventional histology revealed rectal cancer extending to the resection margin (R1). Further immunohistochemical staining confirmed a malignant melanoma. Clinical examination and imaging studies yielded no evidence of additional manifestations. After MDT discussion, we opted for an endoscopic approach to avoid colonostomy for the elderly patient with significant comorbidities. For the second intervention, we used a novel bipolar scissor device „SpydrBlade Flex" by CreoMedical, to facilitate deep intermuscular dissection within fibrotic tissue adjacent to the anal verge. A tapered cap and water irrigation were employed to establish close contact with muscular vessels. After injection of saline and indigo carmine, we started with a circular incision around the former resection ulcer with open jaws. Subsequently, a layer-by-layer underwater dissection was performed, utilizing a grasping, lifting, and pulling technique. The adaptive energy enabled continuous cutting regardless of tissue thickness, without a charring effect. The resection was completed using rubber band traction. Bleeding vessels were coagulated by super-high frequency (SHF) microwave effect without changing the device. The resection plane was adjusted using hemoclips. Further clinical course of the patient was uneventful, with no signs of wound infection or bleeding, and normal bowel movements. Histological examination revealed no residual melanoma, confirming an R0 resection.

Discussion: Endoscopic intermuscular dissection (EID) is an evolving technique aimed at achieving an oncological R0 resection in early rectal malignancy. The novel endoscopic bipolar scissor device with adaptive energy facilitates safe resection in narrow spaces and fibrotic tissue, while microwave coagulation provides adequate hemostasis without changing the device [3].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP652 Video Capsule Endoscopy: Performance, Failures, and Complications in an 8-Year Single-Center Experience

Authors khyat C[1], Serraj I[2], Salihoun M[2], Kabbaj N[2]
Institutes 1 Ibn Sina University Hospital, rabat, Morocco, Rabat, Morocco; 2 Ibn Sina University Hospital, rabat, Morocco
DOI 10.1055/s-0046-1821979

Aims Capsule endoscopy (CE) is a widely used modality for small-bowel evaluation, but its performance may be affected by technical failures, incomplete examinations, or clinical complications such as retention. The aim of this study was to assess the diagnostic yield, technical limitations, and safety profile of CE in routine clinical practice over an eight-year period in a tertiary referral center.

Methods This retrospective study included all patients who underwent CE between 2017 and 2024 in the Digestive and Hepato-Gastroenterological Functional Explorations Department at Ibn Sina University Hospital, Rabat, Morocco. CE was performed using PillCam SB3 or CapsoCam devices following standardized bowel preparation. Indications included obscure gastrointestinal bleeding (overt or occult), suspected or known Crohn's disease, celiac disease, malabsorption syndrome, Rendu–Osler disease, and small-bowel lymphoma. Technical limitations were defined as equipment-related disruptions, and clinical limitations as events related to patient factors or physiological conditions. Data were analyzed using SPSS.

Results A total of 125 patients were included (mean age 56.2 ± 19.6 years; 54.4 % female). Obscure gastrointestinal bleeding was the most frequent indication (76.8 %), followed by Crohn's disease (11.2 %) and celiac disease (7.2 %). CE completion rate, defined by cecal visualization before battery depletion, was 88 %. Median small-bowel transit time was 3 hours and 10 minutes. The overall diagnostic yield was 65 %, with angiodysplasia identified in 32.8 % of patients and small-bowel ulcerations in 17.6 %.

Clinical limitations and complications were observed in a subset of examinations. Incomplete examinations occurred in 11.2 % of patients, mainly due to delayed gastric or small-bowel transit. Capsule retention occurred in 2.4 % of cases. Two patients had strictures related to Crohn's disease requiring surgical retrieval, while one patient with celiac disease passed the capsule spontaneously after corticosteroid therapy. Four cases of gastric retention required endoscopic deployment; three progressed into the small bowel while one remained in the stomach despite multiple attempts.

Capsule ingestion difficulties occurred in four patients, three of whom had pre-existing swallowing disorders, including dysphagia or a history of cerebrovascular accident. In one elderly patient with severe dysphagia, CE could not be performed. Inadequate visualization occurred in 10.4 % of examinations, predominantly due to residual food debris, particularly affecting duodenal and jejunal segments. Blood and clots impaired visualization in six cases, mainly among patients with overt gastrointestinal bleeding.

Technical failures were rare, with a single case (0.8 %) of premature battery depletion in the proximal jejunum.

Conclusions CE demonstrated high diagnostic performance with a low rate of serious complications. The main limitations were related to clinical factors such as incomplete transit, capsule retention, swallowing disorders, and inadequate mucosal visualization, rather than true technical failures. Capsule retention remained infrequent and predictable in high-risk groups. Improving patient selection, optimizing bowel preparation, and ensuring careful evaluation of dysphagia risk may enhance CE performance and safety. Technological improvements, including extended battery life, real-time localization, and better image cleansing algorithms, could further reduce failures and improve diagnostic accuracy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP653 Closure After Full-Thickness Resection of Duodenal Submucosal Tumors Larger Than 25 mm: Learning the Lessons!

Authors Desai PN[1], Mayank K[1], Rajiv M[1], Nandwani S[1], Chintan P[1], Prajapati R[1], Patel N[1], Sethia M[1]
Institute 1 SIDS Hospital & Research Centre, Surat, India
DOI 10.1055/s-0046-1821980

Aims Full-thickness resection (EFTR) of duodenal submucosal tumors (SMTs) is highly challenging due to the thin duodenal wall, proximity to vital structures, and the requirement for a secure closure. Tumors > 25 mm significantly increase complexity and risk. This study aimed to evaluate our experience with free-hand EFTR for duodenal SMTs > 25 mm at a high-volume tertiary endoscopy center in Western India and identify the most effective closure method.

Methods All EFTR procedures for duodenal SMTs > 25 mm were retrospectively analyzed. Every case was discussed at a multidisciplinary meeting (MDT). Procedures were performed under general anaesthesia with a surgeon on standby. Gelofuscin was injected for submucosal lift, and dissection was performed using a Dual J Knife (KD-655U, Olympus). Haemostasis was achieved using a Coagrasper (FD-411UR, Olympus) in soft-coag mode at 40 W. Abdominal decompression was done using a 16G Intracath.

Closure methods used included TTSC, OTSC, Loop-and-Clip, endoscopic suturing, and LECS (laparoscopic–endoscopic cooperative surgery). Endoscopic suturing was attempted in two cases but was technically prohibitive due to awkward scope positioning and concern for adjacent vital structures. A saline-immersion leak test was done post-procedure. All patients received a triple-lumen nasojejunal tube with gastric aspiration. Diet advancement and tube removal were individualized.

Results

Case 1 (Male, 54 years): 28 mm anterior duodenal SMT. Closure with six TTSCs. R0 achieved. Complete closure not achieved. Histology: NET Grade I. Complications: mild fever and small leak. Managed with sponge therapy, NJ tube for 7 days, RTA for 5 days, and antibiotics for 10 days. Length of stay: 10 days.

Case 2 (Female, 58 years): 31 mm postero-inferior lesion. Closure with Loop-and-Clip. R0 achieved but incomplete closure. Histology: NET Grade II. Complications: leak with collection requiring surgery within 24 hours. Additional NJ tube, RTA, antibiotics. Length of stay: 13 days.

Case 3 (Male, 62 years): 30 mm anterior lesion. Closure with LECS. R0 and complete closure achieved. Histology: GIST. No complications. Managed with NBM 48 hours, antibiotics. Length of stay: 6 days.

Case 4 (Male, 65 years): 27 mm antero-superior lesion. Closure with OTSC plus three TTSCs. R0 achieved; complete closure not achieved. Histology: NET Grade I. Complications: pain and delayed perforation. Managed with NBM 10 days, NJ tube for 2 weeks, RTA, antibiotics for 15 days. Length of stay: 10 days.

Case 5 (Female, 48 years): 32 mm antero-superior lesion. Closure with LECS. Complete R0 resection and complete closure. Histology: NET Grade I. Complication: pain. Managed with NBM for 2 days and RTA for 2 days. Length of stay: 5 days.

Case 6 (Male, 61 years): 30 mm posterior lesion. Closure with LECS. R0 and complete closure achieved. Histology: GIST. Complication: pain. Managed with NBM 2 days and RTA 1 day. Length of stay: 5 days.

Case 7 (Female, 59 years): 28 mm postero-inferior lesion. Closure with LECS. R0 and complete closure achieved. Histology: NET Grade I. Complication: pain. Managed with NBM 2 days and RTA 1 day. Length of stay: 5 days.

Discussion This series demonstrates that although free-hand EFTR for duodenal SMTs > 25 mm is feasible, closure remains the most critical and difficult step. TTSC, OTSC, and Loop-and-Clip methods failed to provide complete full-thickness closure for defects > 20 mm, and were associated with leaks, delayed perforation, and prolonged hospital stay. Endoscopic suturing was technically difficult and unsafe. LECS consistently provided secure, watertight closure with minimal complications, faster recovery, shorter NBM duration, early oral feeding, and reduced antibiotic use.

Conclusions Free-hand EFTR for duodenal SMTs > 25 mm is technically demanding. LECS provides the most secure closure with the lowest morbidity. Larger prospective studies are needed to confirm optimal closure strategies in such high-risk duodenal EFTR defects.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP654V Breaking Through Stent Overgrowth: A Step-by-Step Endoscopic Solution

Authors Vadalà V[1], Andreozzi M[1], Spadaccini M[2], Colombo M[3], Fugazza A[1], Hassan C[4], Repici A[5]

DOI 10.1055/s-0046-1821981

Abstract Text

Palliative treatment of malignant esophageal strictures with self-expanding metal stents (SEMS) can be complicated by tissue overgrowth, making retrieval difficult and risky.We present a case of a patient with esophagogastric junction cancer and a double SEMS (stent-in-stent), who developed severe dysphagia due to stent overgrowth.A combined approach was performed: radial incisions with a needle knife on the proximal overgrowth to expose and free the inner stent edge, which was then removed with rat-tooth forceps.For the outer stent, with its distal flange deeply embedded in the gastric wall, dissection using an ESD knife released the flange, allowing safe stent removal.The patient experienced immediate symptomatic relief.This combination of endoscopic techniques enabled safe retrieval of deeply embedded stents, avoiding more invasive procedures [1–5].

eP655 Reliability of surface pattern based histologic prediction in screen-detected colorectal polyps – results from a nationwide cohort study

Authors Fábián A[1], Magyar D[1], Bor R[1], Bősze Z[1], Szántó F[1], Vasas B[1], Bálint A[1], Bacsur P[1], Farkas B[1], Farkas K[1], Iványi E[1], Rutka M[1], Molnár T[1], Szepes Z[1]

Institute **1** University of Szeged, Szeged, Hungary

DOI 10.1055/s-0046-1821982

Aims This nationwide observational cohort study aimed to assess the reliability of optical diagnosis (based on Kudo's pit pattern) compared to histologic results of colorectal polyps removed during screening colonoscopies.

Methods Data regarding Kudo's pit pattern (Kudo I-V), and histologic results were obtained from the prospectively collected registry of Hungarian National Public Health Institute. The correlation between Kudo I-II and non-neoplastic lesions, Kudo III-IV and neoplastic lesions, and Kudo V and submucosally invasive cancer (SMIC) was characterized by Cohen's Kappa coefficient, respectively. The potential effects of polyp size and location, and operator characteristics (adenoma detection rate [ADR], annual screening colonoscopy rate and experience in years) were also evaluated.

Results A total of 8560 lesions (7423 neoplastic [785 SMIC], 1137 non-neoplastic) were registered between 2019 and 2023. Of the 979 serrated polyps 100 contained dysplasia. Kudo I-II and Kudo III-IV demonstrated moderate agreement with non-neoplastic ($\kappa = 0.449$) and neoplastic lesions ($\kappa = 0.528$), respectively, while Kudo V demonstrated substantial agreement ($\kappa = 0.782$) with SMIC. For serrated lesions, Kudo I-II correlated only slightly ($\kappa = 0.143$) with non-neoplastic lesions. Left-sided location resulted in higher levels of agreement for non-neoplastic ($\kappa = 0.489$), and neoplastic lesions ($\kappa = 0.556$), respectively. For lesions larger than 2 cm, levels of agreement were substantial for neoplastic lesions ($\kappa = 0.758$), and near perfect for SMIC ($\kappa = 0.803$). ADR reaching 25 %, and annual screening colonoscopy rate ≥ 100 was associated with slightly better results for both non-neoplastic ($\kappa = 0.454$ and $\kappa = 0.530$), neoplastic lesions ($\kappa = 0.535$ and $\kappa = 0.585$), and SMIC ($\kappa = 0.802$ and $\kappa = 0.804$). This was not observed for ADR reaching 35 %. Operators with less than 10 years of prior endoscopic experience had better results: $\kappa = 0.581$ for non-neoplastic, $\kappa = 0.651$ for neoplastic lesions, and $\kappa = 0.827$ for SMIC.

Conclusions This nationwide cohort demonstrates a moderate and substantial reliability of surface pattern-based identification of neoplasia and SMIC during screening colonoscopies, with better results for left-sided lesions and those larger than 2 cm. Endoscopists with ADR reaching 25 % (but not that reaching 35 %), higher annual rate of screening colonoscopies and those early in their career perform better in optical diagnosis based histologic prediction.

eP656V EUS-guided Hepatico-Gastrostomy followed by Antegrade Digital Cholangioscopy and Laser Lithotripsy for a Large Biliary Stone in Surgically Altered Anatomy

Authors Achemlal A[1], Baware B[1], Mukewar S[1], Mukewar S[1]

Institute **1** MIDAS HOSPITAL, Nagpur, India

DOI 10.1055/s-0046-1821983

Problem to solve Management of biliary stones in patients with surgically altered anatomy (SAA) remains challenging due to the limited endoscopic access to the biliary tree. Enteroscopy-assisted ERCP may fail even in expert hands, and alternative approaches such as percutaneous transhepatic access or surgical revision carry significant risks and morbidity.

We report the case of a young patient with SAA and a large impacted stone at the hepatic duct confluence. Enteroscopy assisted ERCP failed due to inability to reach the anastomotic site. A safe and minimally invasive strategy was required to access, fragment, and clear the biliary stone while avoiding additional surgical morbidity.

Innovation We adopted a three-stage endoscopic strategy combining interventional EUS and Cholangioscopy. EUS-guided Hepatico-Gastrostomy (EUS-HGS) was performed followed by antegrade digital transhepatic cholangioscopy, and then a modified wire-guided cholangioscopy technique that ultimately enabled successful laser lithotripsy and stone clearance.

A)Stage 1 – EUS-guided Hepatico-Gastrostomy

Under linear EUS guidance, the left intrahepatic bile duct was punctured from the gastric body.

A guidewire was advanced antegrade across the obstruction. A 7Fr Cystotome was inserted in the tract.

A partially-covered self-expandable metal stent (PC-SEMS) was deployed, establishing a stable hepatico-gastric fistula.

This provided a secure transluminal route for subsequent cholangioscopy.

B)Stage 2 – Antegrade Digital Cholangioscopy

A digital cholangioscope was advanced through the HGS stent to reach the biliary confluence. However, due to the sharp angulation created by the metallic stent, the scope could not be maneuvered sufficiently to access the bile duct. As a result, laser lithotripsy could not be performed at this stage, and an alternative strategy was required to optimize access and achieve ductal clearance.

C)Stage 3 – Wire-Guided Cholangioscopy after Stent Removal

The PC-SEMS was removed to straighten the tract and reduce the angulation. A sphincterotome with a guidewire was then carefully advanced antegrade into the bile duct. The digital cholangioscope was subsequently railroaded over the guidewire, which provided a stable and aligned path through the hepatico-gastric tract.This maneuver allowed successful advancement of the cholangioscope into the common bile duct, where the large biliary stone was directly visualized. Laser lithotripsy was performed, fragmenting the stone into small pieces, and routine antegrade extraction maneuvers with basket and balloon allowed complete ductal clearance.

Results The three-stage procedure was completed without complications. EUS-HGS provided secure biliary access, and wire-guided cholangioscopy enabled successful visualization and fragmentation of the stone. Laser lithotripsy resulted in complete clearance, and the patient's symptoms resolved rapidly. Liver function tests normalized within days, and no adverse events occurred during recovery.

Conclusions This case highlights the safety, feasibility, and clinical value of a staged endoscopic strategy combining EUS-guided Hepatico-Gastrostomy with antegrade digital cholangioscopy and laser lithotripsy for the management of large biliary stones in patients with surgically altered anatomy.

This innovative approach may represent a minimally invasive alternative to percutaneous or surgical interventions in selected patients with complex biliary stones and altered anatomy. Future studies are warranted to further evaluate long-term outcomes and define optimal procedural timing and stent strategies.

eP657 Safety and Outcomes of EUS-Guided Choledochal Drainage in Patients With and Without Ascites

Authors Agrawal S[1], Godbole S[1], Bhaware B[1], Mukewar S[1], Mukewar S[1]
Institute 1 Midas Multispeciality Hospital Pvt. Ltd., Nagpur, India
DOI 10.1055/s-0046-1821984

Aims Ascites is often considered a relative contraindication of Enndoscopic ultrasound guided choledochal drainage (EUS-CD). This study compared the safety, technical success, and clinical outcomes of EUS-CD in patients with and without ascites (▶ **Table 1**).

Methods A retrospective study of 80 patients (ascites n = 29; no ascites n = 51) compared demographics, drainage indications, technical and clinical success, and adverse events. Ascites was classified as mild, moderate, or severe. Technical success was defined as successful stent placement, and clinical success as radiologic or biochemical biliary decompression.

Results Median age was higher in the ascites group (70 vs. 60.5 years, p = 0.027). Failed ERCP was a more common indication in patients with ascites (75.9 % vs. 52.9 %, p = 0.043). Pancreatic cancer was the predominant etiology in both groups (65 % vs. 63 %). A transduodenal approach was used in > 80 % of cases in both cohorts. Partially covered SEMS (6 cm) was the most frequently used stent type (51.7 % vs. 52.9 %). Technical success was high in both groups (100 % vs. 98.4 %), with similar clinical success rates (96.5 % vs. 96.1 %). Adverse events were comparable (7.1 % vs. 6.7 %), including bile leak (7.1 % vs. 6.7 %, p = 0.938) and mortality (6.9 % vs. 3.9 %, p = 0.674); none reached statistical significance.

▶ **Table 1**

	EUS CD with Ascites (n = 29)	EUS CD without Ascites (n = 51)	p-value
Age (Median, IQR)	70 (55, 17.5)	60.5 (50, 10	0.0272
Male	72.41 %	66.67 %	0.594
Ascites			
Mild	21 (72.41 %)		
Moderate	7 (24.14 %)		
Severe	1 (3.45 %)		
Indication for biliary drainage			
Pancreatic cancer	15 (65 %)	28 (63 %)	0.463
Ampullary cancer	4 (9.1 %)	5 (11.1 %)	0.477
Duodenal cancer	2 (7.1 %)	5 (11.1 %)	0.451
Cholangiocarcinoma	4 (14.3 %)	4 (8.9 %)	0.473
Other	3 (4.3 %)	3 (9.1 %)	0.54
Failed ERCP	22 (75.86 %)	27 (52.94 %) P = 0.043	0.064
Previous plastic stent in bile duct	2 (6.90 %)	2 (3.92 %) P = 0.552	0.498
Location of Stent			
Transduodenal	23 (82.1 %)	42 (93.3 %)	0.137
Transgastric	0 (0 %)	2 (4.4 %)	0.258
Type of stent			
Gioborr	8 (27.6 %)	11 (21.6 %)	0.543
PC-SEMS 6 cm	15 (51.7 %)	27 (52.9 %)	0.917
FC SEMS 6 cm	5 (17.2 %)	10 (19.6 %)	0.794
FC SEMS 4 cm	1 (3.4 %)	3 (5.9 %)	0.631
Lumen Apposing Metal Stent (Axios)	1 (3.4 %)	0 (0 %)	0.182
Technical Success	29 (100 %)	50 (98.4 %)	0.448
Clinical Success	28 (96.5 %)	49 (96.1 %)	0.915
Adverse Events	2 (7.1 %)	3 (6.7 %)	0.938
Bile leak	2 (7.1 %)	3 (6.7 %)	0.938
Bleeding	0 (0 %)	1 (2.2 %)	0.427
Mortality	2 (6.9 %)	2 (3.9 %) P = 0.557	0.674

Conclusions EUS-CD shows comparable technical and clinical success and similar adverse event rates in patients with or without ascites, indicating ascites may not be a contraindication when performed by experienced endosonographers.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP658 Endoscopic Ultrasound-Guided Transmural Biliary Drainage as a Primary Procedure vs. Secondary/Rescue Procedure after Failed ERCP

Authors Agrawal S[1], Bhaware B[1], Godbole S[1], Mukewar S[1], Mukewar S[1]
Institute 1 Midas Multispeciality Hospital Pvt. Ltd., Nagpur, India
DOI 10.1055/s-0046-1821985

Aims The aim of this study was to evaluate the technical success, clinical success, and safety of endoscopic ultrasound-guided choledochal drainage (EUS-CD) in patients with biliary obstruction, comparing its use as a primary procedure versus as a secondary/rescue procedure after failed endoscopic retrograde cholangiopancreatography (ERCP).

Methods A retrospective review was conducted using prospectively maintained records of 75 patients with biliary obstruction who underwent EUS-CD. Among these, 31 patients (41.3 %) underwent primary EUS-CD, while 44 patients (58.7 %) underwent secondary or rescue EUS-CD following failed ERCP. The most common indications for drainage were malignancies, including pancreatic head mass, ampullary cancer, duodenal cancer, and cholangiocarcinoma (▶ **Table 1**).

▶ **Table 1**

Variables	EUS CD Primary (n = 31)	EUS CD secondary/ rescue (n = 44)	P VALUE
Age (Median, IQR)	70, 58-74 years	62, 48.5-76 years	0.2963
Male	20 (64.52 %)	31(70.45 %)	0.5872
Ascites	7(22.58 %)	19(43.18 %)	0.9881
Indication for biliary drainage			
HOP mass	21(67.74 %)	23(52.27 %)	0.1804
Ampullary cancer	1(3.23 %)	9(20.45 %)	**0.0307**
Duodenal cancer	4(12.90 %)	2(4/55 %)	0.1889
Cholangiocarcinoma	2(6.45 %)	7(15.91 %)	0.2146
Lymph nodes	2(6.45 %)	1(2.27 %)	0.3631
BBS stone	2(6.45 %)	5(11.36 %)	0.4715
Previous plastic stent in bile duct	1(3.23 %)	3(6.82 %)	0.4954
Location of Stent			
Transduodenal			
Transgastric			
Type of stent			
Gioborr	6(19.35 %)	10(22.73 %)	0.7255
PC-SEMS 6 cm	15(48.39 %)	25(56.82 %)	0.471
FC SEMS 6 cm	9(31.03 %)	6(13.64 %)	0.101
FC SEMS 4 cm	1(3.23 %)	3(6.82 %)	0.4954
Lumen Apposing Metal Stent (Axios)	0(0.0 %)	1(2.27 %)	0.398
Technical Success	31(100 %)	44(100 %)	NA
Clinical Success	30(96.77 %)	44(100 %)	0.2304
Adverse Events			
Bile leak			
Bleeding			
Mortality	1(3.23 %)	1(2.27 %)	0.8008

Results Technical success was achieved in 100 % of patients in both groups. Clinical success was observed in 96.77 % of patients in the primary EUS-CD group and 100 % in the secondary group, with no statistically significant difference (P = 0.2304). Adverse events were rare and included isolated cases of bile leak, bleeding, and mortality, with comparable rates between the two groups. Overall, there was no statistically significant difference in complication rates between primary and secondary EUS-CD

Conclusions There was no significant difference in success rates or adverse events in performing EUS-CD as a primary procedure vs. secondary/rescue procedure.

Hence the proposed endoscopic ultrasound-guided choledochal drainage (EUS-CD) in biliary obstruction as a rescue procedure after failed ERP is a safe alternative with high technical and clinical success rates and minimum adverse event rate.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP659 Primary Colorectal Signet-Ring Cell Carcinoma with Synchronous Colonic Metastases in an Asymptomatic Patient: Case Presentation

Authors Barboi OB[1], Vulpoi RA[1], Floria DE[1], Vadim R[1], Simiras C[1], Andriescu EC[1], Amitoaie I[2], Drug VL[1]
Institutes 1 "Grigore T. Popa" University of Medicine and Pharmacy, Iași, Romania; 2 Saint Spiridon County Hospital, Iași, Romania
DOI 10.1055/s-0046-1821986

Introduction. Less than 1 % of all colorectal cancers (CRC) are primary colorectal signet-ring cell carcinomas (SRCC), which represent an uncommon and aggressive histological subtype. Synchronous colonic metastases at initial diagnosis are very rare.

Case report. We report the case of a 65-year-old male patient who underwent routine colonoscopy following a positive faecal immunochemical test. The patient had no remarkable medical history and was asymptomatic.

A 3-cm semi-pedunculated polyp (Paris Isp, JNET type 3) and several smaller depressed lesions (Paris 0-IIa + c and JNET type 3) were observed in the descending colon.

Multiple biopsies were obtained. Histopathological examination of the biopsy specimens highlighted the presence of diffusely infiltrating signet-ring cells embedded within a mucinous stroma. Tumour cells were poorly cohesive, with most exhibiting prominent intracellular mucin vacuoles displacing the nuclei peripherally. Immunohistochemical staining of the specimens showed positivity for CK20 and CDX2, supporting a colorectal origin, and negativity for CK7 and GCDFP-15. Additional immunostaining revealed a preserved expression of E-cadherin, though focal loss was observed in infiltrative areas, suggesting a more aggressive biological behaviour. The Ki-67 proliferation index was markedly abnormal at 75 %, and p53 showed strong diffuse positivity. Testing for mismatch repair proteins demonstrated intact expression of MLH1, MSH2, MSH6, and PMS2, indicating microsatellite stability. Further molecular analysis revealed wild-type KRAS and BRAF genes and no evidence of NRAS mutations. There was no sign of extra-colonic metastases on the computed tomography. The endoscopic features, alongside the histopathological assessment and immunochemistry suggest primary colorectal SRCC with synchronous colonic metastases at initial diagnosis. The patient was referred for extensive hemicolectomy, regional lymphadenectomy and adjuvant chemotherapy.

Conclusion. The biological behaviour of SRCC is aggressive and unpredictable. The synchronous occurrence of primary SRCC and metastatic lesions further complicates the clinical management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Endoscopy 2026; 58: S1–S1041

eP660 Endoscopic Ultrasound–Guided Shunt Occlusion: Experience from Three Cases

Authors Agrawal S[1], Bhaware B[1], Godbole S[1], Mukewar S[1], Mukewar S[1]
Institute 1 Midas Multispeciality Hospital Pvt. Ltd., Nagpur, India
DOI 10.1055/s-0046-1821987

Aims To assess the feasibility, safety, and effectiveness of endoscopic ultrasound–guided shunt occlusion as a novel, minimally invasive therapeutic alternative for managing refractory hepatic encephalopathy in patients with large portosystemic shunts who are ineligible for TIPS, BRTO, or liver transplantation.

Methods We retrospectively analyzed three male patients (ages 41–66) with ethanolrelated cirrhosis and recurrent overt hepatic encephalopathy (OHE) despite optimal medical therapy. All had large splenorenal or splenoportal shunts documented on CT, with significant portofugal flow on doppler. Due to financial constraints or high MELD, liver transplantation, BRTO, and TIPS were not feasible. Under deep sedation, an echoendoscope was positioned at the gastric cardia to visualize the splenoportal axis. The afferent feeder to the shunt was identified using Doppler, and a 19G EUS-FNA needle was used for direct puncture. Technique involved deployment of 16–20 mm coils folowed by n-butyl cyanoacrylate glue injection, in single or staged sessions, depending on residual flow. Coil number ranged from 2 to 6 per patient. Post-procedure, patients were monitored for bleeding, ascites, hypoxia, and worsening decompensation. CT portography was repeated after 4–6 weeks. Clinical folow-up included MELD score, HE episodes, and functional status assessment.

Results Case 1 (66-year-old male): Large splenoportal shunt with recurrent HE. Single session EUS guided shunt occlusion with two coils (18mm x 14cm and 20mm x 14cm) and 2 ml glue achieved complete obliteration. No complications. No further HE over 3 months; improved cognition reported.

Case 2 (57-year-old male): Large posterior gastric vein afferent shunt. Initial coil (20mm and 16mm) + and 2ml glue session partially occluded flow. A second session next day achieved complete thrombosis. In the second session, 2 coils of 20mm with 2ml glue was injected. Developed mild hemoperitoneum and ascites, managed with correction of coagulopathy. After discharge, only one minor HE episode occurred at 3 weeks, and none thereafter. CT at 35 days showed complete non-opacification of shunt without thrombus extension.

Case 3 (41-year-old male): a 2cm portosystemic shunt was seen. EUS guided shunt coiling was done using 4 coils of 20mm, 20mm, 18mm and 18mm, alongwith 2ml glue. Mild post-procedure hypoxia occurred, managed conservatively. CT showed partial obliteration of the shunt. No episodes of OHE in the followed up 1 month. Improved sensorium and liver function was noted.

Across all cases, technical success was 100 %, clinical control of OHE was achieved in all three patients, there was no extension of portal vein or systemic thrombus, and no mortality was observed.

Conclusions This case series demonstrates that EUS-guided shunt occlusion is a feasible and effective therapeutic alternative for patients with recurrent HE and contraindications to TIPS, BRTO, or transplantation. The ability to directly visualize and selectively embolize the shunt afferent offers distinct procedural precision over radiologic methods. While mild complications occurred, a were manageable, and neurocognitive improvement was consistent across patients. EUS guided shunt occlusion may represent an emerging interventional paradigm in hepatology, particularly within resource-constrained settings. A multicentric prospective study is needed to establish standardized protocols, optimal coil–glue combinations, and long-term outcomes beyond encephalopathy control, including survival and portal hemodynamics.

eP661 A Prospective Single-Centre Pilot Study on the Impact of a Customised Endoscopy Safety Checklist on Patient Safety Outcomes in a Tertiary Diagnostic and Interventional GI Endoscopy Unit in India

Authors Desai PN[1], Chintan P[1], Mayank K[1], Prajapati R[1], Rajiv M[1], Nandwani S[1], Patel N[1], Sethia M[1]
Institute 1 SIDS Hospital & Research Centre, Surat, India
DOI 10.1055/s-0046-1821988

Aims To evaluate the effectiveness of a customised endoscopy safety checklist in improving patient safety, identifying high-risk conditions, reducing preventable complications, and enhancing team coordination in a high-volume tertiary GI endoscopy unit in India.

Methods This prospective single-centre pilot study was conducted from September 2024 to the present. A customised endoscopy safety checklist was designed, incorporating critical parameters related to patient history, anticoagulation status, NPO duration, airway evaluation, anaesthetic considerations, and cardiopulmonary status. The checklist was completed pre-procedure and verified independently by the endoscopy nurse, resident medical officer, and the endoscopist before scope insertion. All checklist entries and clinical outcomes were prospectively recorded. A total of 5460 endoscopic procedures were performed. Data were analysed for checklist compliance, high-risk patient identification, adverse events, and avoidable complications. The study also recorded the single case in which the checklist was not implemented.

Results A total of 5460 endoscopic procedures were performed, and the checklist was implemented in 5459 cases, yielding a compliance rate of 99.98 %. High-risk factors were identified in 40 patients (0.73 %), resulting in modification, delay, or abandonment of procedures to prevent adverse events. No adverse events occurred in any case where the checklist was used. One preventable fatal adverse event occurred in the single case (0.02 %) where the checklist was not implemented.

Summary of Core Findings Total Endoscopic Procedures — 5460, Checklist Implemented — 5459 (99.98 %) compliance, Procedures WITHOUT Checklist — 1 (0.02 %), High-Risk Patients Identified — 40 (0.73 %), Low-Risk Patients Confirmed — 5419 (99.27 %), Adverse Events WITH Checklist — 0 (0 %), Adverse Events WITHOUT Checklist — 1 (Fatal haemorrhage post-EUS-FNA/FNB), Mortality WITH Checklist — 0(0 %), Mortality WITHOUT Checklist — 1 (Preventable, related to unreported anticoagulant use)

Breakdown of High-Risk Factors Identified:

Risk Factor — Count — % of High-Risk Cohort — % of Total Procedures — Classification

Inadequate NPO Status (< 6 hours) — 15 — 37.5 % — 0.275 % — ESGE aspiration-risk criterion

Severe Trismus (< 3-finger mouth opening) — 11 — 27.5 % — 0.202 % — ASGE/ESGE difficult-airway category

Ongoing Anticoagulant/Antiplatelet Therapy — 10 — 25 % — 0.183 % — ASGE high-risk bleeding category

Severe Cardio-Pulmonary Comorbidities — 4 — 10 % — 0.073 % — ASGE cardiopulmonary risk classification

Conclusions D**iscussion: A**n Indian tertiary setting with high daily workloads, time constraints, inadequate documentation from referring clinicians, and limited patient awareness contribute to missed critical information during routine evaluations. The checklist functioned as a reliable error-prevention tool, ensuring systematic confirmation of risk factors that may otherwise be overlooked.

Conclusions: Implementation of a customised endoscopy safety checklist achieved near-perfect compliance and significantly improved patient safety by identifying high-risk conditions and preventing avoidable procedural complications. No adverse events occurred in any case where the checklist was applied. The checklist promoted teamwork, standardisation of pre-procedure evaluation, and improved communication among staff. Adoption of such struc-

tured checklists is strongly recommended for all diagnostic and interventional endoscopy units, particularly in high-volume centres across India and similar healthcare environments.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP662 Quantifying the environmental cost of diagnostic gastroscopy: a life cycle assessment

Authors García-Castellanos M[1], Matamoros JJ[1], Vilariño-Ferrer G[1], Tort-Ausina I[1], Rodríguez-Hernández JC[1], Pohl H[2], Rodriguez de Santiago E[3], Pons V[4], Lorenzo-Zúñiga V[4], Campillo-Fernandez AJ[1]

Institutes **1** Centre for Biomaterials and Tissue Engineering, CBIT, Universitat Politècnica de València, Valencia, Spain; **2** VA Medical Center, White River Junction, VT, USA, United States of America; **3** Hospital Universitario Ramón y Cajal, Madrid, Spain; **4** La Fe University and Polytechnic Hospital, València, Spain

DOI 10.1055/s-0046-1821989

Aims The healthcare sector is a major contributor to environmental impact, and gastrointestinal endoscopy is associated with substantial resource use and waste generation. This study aimed to conduct a comprehensive life cycle assessment (LCA) of diagnostic gastroscopy—following the E-SPARE guideline and ISO 14040 standard—with a particular focus on the contribution of energy consumption (HVAC, lighting, and medical equipment). A Montecarlo uncertainty analysis is planned to strengthen the robustness of the estimates.

Methods A prospective one-month observational study was carried out at Hospital Universitari i Politècnic La Fe (València, Spain) including all outpatients undergoing diagnostic gastroscopy (n = 143). A cradle-to-grave LCA considered four stages: production, transportation, clinical procedure, and end-of-life. The analysis included medical supplies, gastroscope production and reprocessing, sedation, CO_2 insufflation, staff and patient travel, energy consumption, and waste management. Environmental impacts were quantified using ReCiPe 2016 Midpoint methodology and expressed as GWP-100 ($kgCO_2e$).

Results The carbon footprint of a single diagnostic gastroscopy was 25.17 $kgCO_2e$. The main contributors were patient transport (9.71 $kgCO_2e$, 38.6 %), staff transport (6.95 $kgCO_2e$, 27.6 %), and energy consumption (4.78 $kgCO_2e$, 19.0 %). Medical supplies contributed 2.75 $kgCO_2e$ (10.9 %), while gastroscope production and reprocessing accounted for 0.93 $kgCO_2e$ (3.7 %). The clinical procedure itself (sedation and CO_2 insufflation) had a negligible impact (0.05 $kgCO_2e$, 0.2 %). Within supplies, the most impactful items were surgical gowns, absorbent underpads, and biopsy containers, driven largely by material production (~74 % of total impact).

Conclusions Transportation—particularly patient travel—was the dominant contributor to the carbon footprint of diagnostic gastroscopy, followed by energy consumption. Strategies promoting sustainable mobility and improving energy efficiency could substantially reduce the environmental burden of the procedure.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP663 Corporate Welfare as an Integrative Model to Improve Awareness and Expand Participation in Colorectal Cancer Screening Using FIT

Authors Sereni G[1], Manzotti C[1], Iori V[1], Salardi M[1], Sassatelli R[1]

Institute **1** Gastroenterology and Digestive Endoscopy, AUSL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

DOI 10.1055/s-0046-1821990

Aims To evaluate a corporate welfare–based integrative model aimed at improving awareness of colorectal cancer (CRC) risk factors, expanding participation in FIT-based screening among less commonly involved subjects; to assess the prevalence of personal and familial CRC risk profiles.

Methods Healthcare professionals from the Gastroenterology and Digestive Endoscopy Unit of AUSL-IRCCS Reggio Emilia delivered structured educational sessions to employees of a company in the Lower Reggio Emilia area. The intervention focused on CRC risk factors and the importance of early detection. Participants were invited to complete a standardized questionnaire collecting personal and family medical history to identify CRC and pancreatic cancer risk factors. Individuals reporting a first- or second-degree family history of CRC and/or pancreatic cancer underwent a follow-up telephone interview to further refine their risk profile and evaluate potential hereditary cancer syndromes. FIT-based CRC screening was then offered to all employees who completed the questionnaire, with specific attention to those aged > 40 years and to younger individuals with positive family history.

Results Of approximately 800 employees, 713 (≈ 90 %) attended the educational sessions. Among them, 374 (52.5 %; 88 % male; mean age 43.7 ± 9.9 years, range 21–70) provided presonal information consent and completed the questionnaire.

A family history of CRC was reported by 44/374 (11.8 %), while 15/374 (4 %) reported a family history of pancreatic cancer. Telephone consultations suggested a possible BRCA1 mutation in 2 individuals.

Overall, 280/374 (75 %) agreed to undergo FIT screening: 88/128 participants < 40 years and 192/246 ≥ 40 years.FIT kits were returned by 204 employees (54.5 % of questionnaire respondents; 28.6 % of all participants in the educational sessions). Among them, 37/88 (< 40 years) completed the test, with a positivity rate of 5.4 % (2/37). In the ≥ 40-year group, 167/192 completed the test, with a positivity rate of 0.6 % (1/167). All three FIT-positive participants underwent colonoscopy, which resulted negative in all cases.

Conclusions This corporate welfare–based intervention proved effective in increasing awareness and promoting CRC screening uptake among a working-age population typically underrepresented in conventional public health screening programs. The high participation rates in both educational activities and risk assessment demonstrate the feasibility and acceptability of this integrative model. The approach enabled the identification of individuals with increased familial risk, including suspected hereditary cancer predisposition. Collaboration between public healthcare providers and private companies may represent a valuable strategy to enhance preventive efforts, expand participation in population-based CRC screening, and support early detection in groups that are otherwise difficult to reach.

eP664V Modified Z-POEM for giant Zenker's diverticulum using a tunnel-free approach, undersaline immersion, and mucosal trimming

Authors Mavrogenis G[1], Vogli S[2], Kanoupakis G[1]

Institutes **1** Mediterraneo Hospital, Glifada, Greece; **2** Metaxa Cancer Hospital of Piraeus, Piraeus, Greece

DOI 10.1055/s-0046-1821991

Background & Aims: Large Zenker's diverticula pose technical challenges and higher recurrence risk during Z-POEM.

Methods:A 59-year-old female with severe dysphagia from a 9-cm Zenker's diverticulum and underwent modified Z-POEM. Key steps included mucosal incision over the septum, early undersaline immersion, tunnel-free myotomy for efficient progression, extended septotomy into the esophagus, and mucosal flap trimming to avoid food retention. Clips were used for closure.

Results: The procedure was successful with no adverse events. Imaging confirmed full emptying. At 6 months, the patient tolerated a normal diet without symptoms.

Conclusions: This modified technique appears effective for large and complex Zenker's diverticula.

eP665 Renal safety of Sodium Phosphate boost in patients undergoing Colon Capsule Endoscopy

Authors Carretero C[1], Bojorquez A[1], Sandoval Rico M[1], Redin N[1], Herraiz Bayod M[1]
Institute **1** Clinica Universidad de Navarra, Pamplona, Spain
DOI 10.1055/s-0046-1821992

Aims To assess the renal safety of sodium phosphate used as a boost in colon capsule endoscopy by comparing pre- and post-procedure renal function and electrolytes

Methods We performed a retrospective observational study including consecutive adult patients who underwent colon capsule endoscopy with sodium phosphate used as a boost regimen at a single tertiary care center. Patients were eligible if serum creatinine, estimated glomerular filtration rate (eGFR), sodium and potassium were available within 7 days before and within 1 days after the procedure. Continuous variables were compared using paired statistical tests as appropriate, and statistical significance was set at $p < 0.05$.

Results A total of 76 patients were included in the analysis. Mean age was 73 years (SD 16 years). Paired pre–post comparisons showed no significant changes in renal function after sodium phosphate administration. Serum creatinine remained stable ($p = 0.174$), and estimated glomerular filtration rate (eGFR) also showed no significant variation ($p = 0.111$).

Blood urea levels significantly decreased after the procedure ($p < 0.001$), a finding consistent with hemodilution rather than renal impairment [1].

Electrolyte levels remained largely unchanged. Serum sodium showed no significant pre–post difference ($p = 0.151$). Serum potassium demonstrated a statistically significant decrease ($p < 0.001$), although no clinically relevant hypokalemia was identified.

No patient met KDIGO criteria for acute kidney injury.

Conclusions Sodium phosphate used as a boost for colon capsule endoscopy was not associated with renal function deterioration. Both creatinine and eGFR remained stable after the procedure, and the observed decrease in blood urea was consistent with hemodilution rather than kidney injury. Electrolyte levels were largely unchanged, and the reduction in serum potassium, although statistically significant, had no clinical relevance. No cases of acute kidney injury were identified.These findings support the renal and metabolic safety of sodium phosphate in this setting.

eP666 Rectal Metastasis Revealing Occult Male Breast Cancer: A Case Report Detected During Screening Colonoscopy

Authors Matar R[1], Sanyour J[1], Al Qarshoubi I[1]
Institute **1** Sultan Qaboos Comprehensive Cancer Care and Research Center, University Medical City, Muscat, Oman
DOI 10.1055/s-0046-1821993

Abstract Text

The male breast cancer (MBC) is a rare and represents less than 1 % of all malignancies in men and only 1 % of all breast cancers incident [1]. When it spreads, the gastrointestinal tract is rarely involved, and rectal metastasis is exceptionally unusual [2, 3]. Occult breast cancer (OBC) adds another layer of complexity**.** OBC is defined as a clinically recognizable metastatic carcinoma arising from an undetectable primary breast tumor and was first described by Halsted in 1907 [4]. It is thought that OBC is secondary to microinvasive breast cancer [5].It presents in 0.3–1 % of all breast cancers [6], with first presentation by axillary and cervical lymph node metastases [7]. It is usually identified only after biopsy of a metastatic site, supported by immunohistochemical markers [8].

Here, we report the case of a 43-year-old man with a strong family history of colorectal cancer who underwent a screening colonoscopy despite being entirely asymptomatic. During colonoscopic evaluation, a small erythematous, slightly elevated rectal lesion measuring approximately 10 × 8 mm was incidentally identified at about 7 cm from the anal verge. The lesion showed no ulceration and was surrounded by a mildly thickened rectal wall. Targeted biopsies were obtained.

Histopathological examination, supported by immunohistochemical profiling, revealed adenocarcinoma consistent with metastatic breast origin—an unexpected finding in a male patient with no prior history of breast disease. Subsequent staging with dedicated breast imaging and PET-CT confirmed the diagnosis of occult breast cancer with metastatic involvement of the rectum, regional lymph nodes, and bone.

This case underscores the critical value of colonoscopy not only for colorectal cancer prevention in high-risk individuals but also for detecting unexpected metastatic disease in asymptomatic patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821994

▶ **Table 1** Raw data and composite scores (A–D coding)

Snare	Euros	kgCO_2e	Avg Force (N)	Score 50:30:20	Score 33:33:33	Score 100:0:0
A	11.5	0.445	2.52	6.39	14.46	11.50
B	19.4	0.609	2.77	10.44	22.78	19.40
C	14.0	0.388	4.10	7.94	18.49	14.00
D	21.2	0.324	2.54	11.21	24.06	21.20

Aims In ESGE Days 2025, we reported the first comparative carbon-footprint analysis of four commonly used cold snares. Although relevant for sustainable endoscopy, environmental data alone cannot guide equipment selection. This follow-up study incorporates new elements not previously presented: [1] a functional evaluation based on standardized mechanical performance as a surrogate of clinical efficacy, and [2] a composite sustainability scoring system integrating environmental impact, mechanical performance, and cost.

Methods Four 10-mm cold snares (mdd GmbH, Olympus SnareMaster Plus, Boston Scientific Captivator Cold, Steris Exacto) underwent standardized functional testing on biological tissue (n = 40), including dimensional accuracy and average traction force measured using a calibrated dynamometer. For analysis, snares were randomly assigned codes A–D to avoid brand bias. Environmental impact (kgCO_2e) was extracted from life-cycle inventory data, and price (EUR) was recorded for each device. A multi-criteria scoring system (MCDA) was constructed using min–max normalization and three weighting scenarios aligned with public procurement practice in Spain: 100:0:0, 50:30:20, and 33:33:33 (price–environment–ergonomics). Lower scores indicate a more sustainable device. Given the inherent uncertainty of LCA modelling, the need for Montecarlo simulation to generate 95 % uncertainty intervals is acknowledged (▶ **Table 1**).

Results Dimensional accuracy was consistent (9.10–10.48 mm). Average traction force varied from 2.52 N (A) to 4.10 N (C), indicating poorer ergonomic performance for C. Environmental impact ranged from 0.324 to 0.609 kgCO_2e. Composite results using the corrected dataset demonstrated stable rankings across all weighting schemes, consistently identifying snare A as the most favourable, followed by C, B and D.

Conclusions This work provides the first integrated environmental–mechanical assessment of cold snares. The proposed composite scoring system is transparent, reproducible and aligned with current European and Spanish procurement legislation, supporting the incorporation of environmental and ergonomic criteria into tendering processes. Future studies should incorporate Montecarlo–based uncertainty modelling and clinical outcomes to validate and strengthen this approach.

eP668 Rectal Mucinous Adenomas With High-Grade Dysplasia in Bloom Syndrome: A Seven-Patient Familial Case Series Detected During Screening Colonoscopy

Authors Matar R[1], Sanyour J[1], Al Qarshoubi I[1]
Institute 1 Sultan Qaboos Comprehensive Cancer Care and Research Center, University Medical City, Muscat, Oman
DOI 10.1055/s-0046-1821995

Abstract Text

Bloom syndrome (BS) is an extremely rare autosomal recessive genetic disorder caused by a mutation in the *BLM* gene [1]. The diagnosis of BS should be considered in patients with growth retardation of prenatal onset, a photosensitive rash in a butterfly distribution over the cheeks, and an increased risk of cancer at an early age. [2] Clinical manifestations also include short stature, dolichocephaly, prominent ears, micrognathia, malar hypoplasia, immunodeficiency, type II diabetes, hypogonadism associated with male infertility and female subfertility [3, 4]. The risk of malignancy in Bloom syndrome is 150–300 times greater than in the general population, with around 25 % of patients developing cancer at a mean age of 20.7 years [5, 6]. In BS the risk of colon cancer is significant, affecting around 12 % of patients, with a mean diagnosis age of 35.4 years [7]

In this case series, we describe seven related patients—siblings and cousins, both male and female—with genetically confirmed Bloom syndrome who underwent screening colonoscopy because of their high-risk status. All were asymptomatic, and their mean age was 24.7 years.

Colonoscopy revealed multiple polyps in each patient, several of which were safely removed using cold snare polypectomy. What was particularly striking, however, was that all seven patients had a large sessile rectal lesion, with an average size of 34 × 27 mm. These lesions were completely resected using endoscopic mucosal resection (EMR).

Histopathology showed that every rectal lesion was a mucinous adenoma with high-grade dysplasia. This is highly unusual, as mucinous adenomas are rare overall and even less common in the rectum. Finding this pattern repeatedly within one extended family highlights the unique behavior of colorectal neoplasia in Bloom syndrome.

At six-month follow-up, colonoscopy confirmed no residual lesions in any patient. Due to their increased lifetime risk of both early and advanced colorectal cancer, All seven patients have since continued on annual colonoscopy surveillance.

This case series demonstrates how asymptomatic patients with Bloom Syndrome may experience the early development of significant colorectal lesions. The finding of rectal mucinous adenomas with high-grade dysplasia emphasizes how crucial routine screening colonoscopy is for this high-risk group. Early screening and timely endoscopic management remain essential cornerstones in preventing the progression of colorectal cancer.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP669 Mobile Endoscopy Training in Growing Emerging Markets: Multi-country Experience of a Mobile Training Centre Model

Authors Aboudeif A[1, 2], Hady Ashry M[1, 2], Farghaly M[1, 2], Hamadah OH[1, 2], Ala'a El Khouly S[1], Ahmed A[1], Ismail S[1], Ashraf El-Bieh I[1], Nada M[1], Ibrahim M[2, 3]

DOI 10.1055/s-0046-1821996

Aims Gastrointestinal and liver diseases are a major cause of morbidity and mortality in growing emerging markets (Africa, Middle East, Eastern Europe), where endoscopy capacity and training opportunities remain limited [1, 2]. We describe the implementation and reach of a mobile endoscopy training centre deployed in these regions.

Methods We performed a descriptive analysis of activities delivered by a mobile endoscopy training centre since its inception. Programme records were reviewed to extract: (1) number and type of activities (lectures, workshops on simulators and live cases, fellowships, train-the-trainer courses); (2) numbers and professional profiles of participants; and (3) geographic coverage. We outline a collaboration in Kenya as an example of how the model can support a structured national endoscopy training programme.

Results Over the observation period, the mobile training centre delivered 442 activities and trained more than 8,000 healthcare professionals in gastrointestinal (GI) endoscopy. Faculty from 38 countries delivered activities across multiple centres in Africa, the Middle East and Eastern Europe, combining didactic teaching, simulation-based training and supervised patient procedures. The curriculum covered diagnostic and therapeutic GI endoscopy and quality- and safety-related topics. In Kenya, the model was adapted into a dedicated school of endoscopy with a target to train 100 healthcare workers in its first year.

Conclusions A mobile endoscopy training centre can support multi-country training and development of sustainable local programmes in growing and emerging markets. This model may complement existing initiatives by bringing structured, faculty-supported education directly to underserved regions; evaluation of learning and service outcomes is warranted.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP670 Salvage EUS-Guided Gastrojejunostomy Using LAMS for Malignant Gastric Outlet Obstruction After Failed Surgical Gastrojejunostomy: First Three Cases Reported in Oman

Authors Matar R[1], Sanyour J[1], Al Qarshoubi I[1]
Institute **1** Sultan Qaboos Comprehensive Cancer Care and Research Center, University Medical City, Muscat, Oman
DOI 10.1055/s-0046-1821997

Abstract Text

Malignant gastric outlet obstruction (MGOO) is a complication of advanced gastrointestinal malignancies and contributes significantly to patient morbidity [1]. Traditionally, the two main modalities for treatment of MGOO were endoscopic enteral stenting or a surgical-gastrojejunostomy via either an open or laparoscopic approach [2]. Surgical gastrojejunostomy has been the standard of care for the management of GOO for many years [3].

Endoscopic ultrasound–guided gastrojejunostomy (EUS-GJ) using lumen-apposing metal stents (LAMS) represent a break-through in therapeutic endosonography. In the palliative setting, EUS-GJ demonstrates promising clinical efficacy and fewer adverse events compared to the traditional duodenal stent and/or surgical gastrojejunostomy [4]. Current literature includes only limited case reports describing EUS-GJ following failure of a surgically created gastrojejunostomy due to anastomotic stricture or angulation rather than malignant obstruction.

Here we describe a case series of three elderly patients with stage IV pancreatic adenocarcinoma, all managed in a palliative setting, previously underwent laparoscopic gastrojejunostomy (GJ) for MGOO. The patients returned at a mean interval of 21 days, reporting vomiting, weight loss, and intolerance to oral intake. Endoscopy revealed a markedly angulated and severely narrowed GJ anastomosis, impassable even with a pediatric gastroscope, indicating functional failure of the surgical bypass.

The three patients underwent salvage EUS-GJ rather than repeat surgery A nasobiliary- drain assisted free hand technique was used and placement of a (20x10mm) LAMS. Technical success was achieved in all procedures, with no adverse events reported.

Post-procedural recovery was uncomplicated in all patients. Oral liquids were initiated on the first day without difficulty. Stent patency was confirmed by barium study on the second day. Patients were subsquently advanced to a soft diet, with resolution of vomiting and a clear improvement in their oral intake.

These cases demonstrate the feasibility, safety and significant early clinical benefit of this technique in a palliative oncology setting, They are the first series of salvage EUS-guided gastrojejunostomies performed in Oman.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP671V Endoscopic Removal of Migrated Mesh Sutures 26 Years After Restrictive Gastroplasty

Authors Farghaly M[1, 2], Hady Ashry M[1, 2], Ibrahim M[2, 3]
Institutes **1** Newgiza University, Giza, Egypt; **2** ROEYA Gastroenterology, Hepatology and Endoscopy Center, Cairo, Egypt; **3** Theodor Bilharz Research Institute, Cairo, Egypt
DOI 10.1055/s-0046-1821998

Abstract Text

Restrictive gastroplasty is now obsolete because of long-term complications, including late staple-line and foreign-body problems [1, 2]. A 52-year-old woman who underwent restrictive gastroplasty 26 years ago presented with recurrent vomiting and abdominal discomfort for months. Upper endoscopy revealed severe gastritis, marked esophageal and distal gastric pouch dilatation, and intraluminally migrated mesh sutures at the anastomotic site. We demonstrate stepwise endoscopic release and retrieval of three migrated mesh sutures

using electrocautery and endoscopic scissors, without immediate complications. The patient was monitored for 24 hours without adverse events and remained asymptomatic at six-week follow-up on proton pump inhibitor and dietary counselling. Our case highlights endoscopic mesh removal as a minimally invasive alternative to revisional surgery [3].

DOI 10.1055/s-0046-1821999

Aims Colorectal cancer (CRC) screening has increased the detection of benign polyps. Although most can be safely removed endoscopically, some patients are still referred for surgery due to technical or organizational limitations, resulting in avoidable overtreatment. This study aimed to determine the rate of avoidable surgery within the Catalan CRC Screening Program and to assess territorial variability in a FIT-based screening context.

Methods A retrospective observational study was conducted including all participants aged 50–69 years with a positive fecal immunochemical test (FIT) who underwent colonoscopy between 2010 and 2020. Data from the Catalan CRC Screening Registry were cross-linked with the Catalonian Inpatient Minimum Basic Data Set (CMBD-AEA) using ICD-9 and ICD-10 codes to identify colorectal surgeries performed within 12 months after colonoscopy. Cases with CRC stage > pT1 or surgeries unrelated to screening were excluded. Surgery rates were calculated overall and by geographic area, classified as urban or rural.

Results Among 93,035 colonoscopies (mean age 59.6 ± 5.7 years; 44.3 % women), 1,427 surgeries were performed (1.53 %; 95 % CI 1.46–1.61), including 893 procedures for benign lesions (0.96 %; 95 % CI 0.90–1.02). Across territories, five areas showed rates close to the Catalan average, whereas four deviated markedly, with surgery for benign lesions ranging from < 0.6 % in highly specialized urban areas to 3–4 % in rural regions. Colonoscopy-related complications occurred in 625 procedures (0.67 %; 95 % CI 0.62–0.73), of which 27 (0.03 %) required surgery. CRC-pT1 was diagnosed in 1,378 examinations (1.48 %; 95 % CI 1.41–1.56), with 516 patients undergoing surgery (0.55 %; 95 % CI 0.51–0.60).

Conclusions A non-negligible proportion of surgeries following CRC screening are performed for benign lesions, reflecting territorial inequities and opportunities for improvement. Although the overall rate of overtreatment is low, optimization through advanced endoscopic training and structured referral pathways remains a key goal.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822000

Aims High-quality colonoscopy depends on adequate training. This study aimed to evaluate the impact of a standardized simulator-based colonoscopy training program on low- to moderately experienced gastroenterologists' self-reported confidence, navigation comfort, polyp-detection proficiency, familiarity with quality indicators, and perceived diagnostic and therapeutic challenges three months after the training.

Methods This pre–post study enrolled 218 participants from 13 countries with low to moderate colonoscopy experience. All attended a standardized two-day training course combining lectures with hands-on practice on the Mikoto simulator (R ZERO Inc., Japan) across four difficulty stations (Easy, Standard, Advanced 1, Advanced 2) simulating increasing difficulty and realistic tasks such as cecal intubation and loop management. Pre-course and three-month post-course surveys assessed self-reported colonoscopy confidence, navigation comfort, polyp-detection proficiency, familiarity with quality indicators, and perceived diagnostic and therapeutic challenges. All self-reported competencies were rated on a 3-point scale (1 = low, 2 = moderate, 3 = high). Paired analyses were restricted to the 153 participants (70.2 %) who completed both surveys. Attrition bias was evaluated by comparing baseline scores between responders (n = 153) and non-responders (n = 65). Ordinal outcomes were analyzed using the Wilcoxon signed-rank test and binary challenge variables using

McNemar's test. Effect-modification analyses were performed according to baseline colonoscopy volume and prior endoscopy training. Statistical significance was set at $p < 0.05$.

Results All self-reported competencies increased significantly after training. Confidence scores shifted upward, with the median remaining at 2 but the distribution moving from (IQR 1–2) to (IQR 2–3), navigation comfort from 1 (IQR 1–2) to 2 (IQR 1–3), polyp-detection proficiency from 2 (IQR 2–3) to 3 (IQR 3–3), and familiarity with quality indicators from 2 (IQR 1–3) to 3 (IQR 3–3) (all $p < 0.0001$). Frequency-shift analyses showed upward transitions: 47.7 % improved in confidence, 44.4 % in navigation, 36.6 % in polyp-detection proficiency, and 51.6 % in quality-indicator familiarity, with rare declines (2.6 %). Self-reported diagnostic challenges decreased from 80.9 % to 38.8 %, and therapeutic challenges from 92.1 % to 63.2 % ($p < 0.0001$). Attrition bias assessment showed no meaningful baseline differences between responders and non-responders. Participants who performed < 50 prior colonoscopies showed greater improvement in confidence than those who performed ≥ 51 ($p = 0.0003$), and those without prior formal training showed greater improvement than trained participants ($p = 0.0035$). Navigation changes were not significantly different across subgroups.

Conclusions Participation in a standardized simulation-based colonoscopy training course was associated with higher self-reported confidence, perceived procedural proficiency, and fewer perceived diagnostic and therapeutic challenges three months later. Greater gains among less experienced and untrained participants support the value of structured simulation in early endoscopy training.

Abstract Text

We report an EUS-free LAMS-assisted recanalization of a complete J-pouch afferent-limb stenosis.A 45-year-old man with ulcerative colitis and IPAA had a diverting ileostomy due to a postoperative anastomotic fistula and chronic pouchitis. Endoscopy demonstrated total occlusion of the pouch with no identifiable orifice. Through the stoma injection of saline–methylene blue into the efferent limb resulted in dye appearance within the pouch, confirming a fistulous communication. A guidewire was advanced and a 16 × 20-mm electrocautery-enhanced LAMS was deployed across the stenosis under fluoroscopic control using a colonoscope. LAMS deployment achieved immediate recanalization of the afferent limb and restoration of pouch continuity. Passage through the stent allowed inspection of the afferent limb and confirmed a patent endoscopic re-anastomosis.

Problem to solve Bowel preparation quality is a key determinant of colonoscopy effectiveness, influencing mucosal assessment and lesion detection. The Boston Bowel Preparation Scale (BBPS) is a widely used scoring system, yet its categorical and subjective nature limits granularity and consistency. This study aims to develop and validate a deep learning model for automated, objective, and continuous assessment of bowel cleanliness using real-time image analysis.

Innovation A retrospective dataset of colonoscopy videos from nine international centres (n = 1128; 2020–2022; white light imaging) was used to train a DeepLabV3 + model[1] for seven-class scene segmentation (stool, water, clean mucosa, instruments, borders, shadows, glare). For validation, the trained model was applied to an independent single-centre dataset of colonoscopy videos (n = 428; 2023–2024; white light and narrow band imaging). The model processed these videos by extracting one frame per second and generating a segmentation output for each extracted frame. From these outputs, we derived AI cleanliness metrics: frame-wise fractions of stool, water, and clean mucosa, and a novel Normalised Stool Index (NSI), defined as the proportion of the total mucosa labelled as stool, which is less biased by artifacts than the stool fraction. All metrics were computed only from instrument-free withdrawal frames, matching BBPS scoring conventions, and averaged per procedure. Associations between total BBPS scores from two raters (R1, R2; quadratic weighted $\kappa = 0.22$; inter-rater $\rho = 0.221$; weak inter-rater reliability) and mean stool, water, and clean mucosal fractions, as well as NSI, were assessed (Spearman's ρ with false-discovery-rate correction). Clinical relevance was examined by correlating mean NSI, water fraction, and ΔNSI (difference between withdrawal and insertion) with lesion count and minimum lesion size, and by assessing the ability of the AI cleanliness metrics to predict the presence of at least one adenoma (AUC and logistic regression). Expected behaviour was assessed by examining NSI changes between scope insertion and withdrawal and around automatically detected rinsing events (paired Wilcoxon signed-rank test).

Results The DeepLabV3 + model achieved strong segmentation performance (sensitivity 92.7 %, specificity 98.1 %, mean Dice 93.8 %), enabling reliable extraction of the AI cleanliness metrics. Withdrawal NSI showed the strongest association with BBPS, with significant correlations for both raters (R1: $\rho = -0.21$; R2: $\rho = -0.12$; both $p < 0.02$). Stool fraction showed a similar pattern (R1: $\rho = -0.19$; R2: $\rho = -0.12$; both $p < 0.02$). Water fraction correlated positively with BBPS for R2 only ($\rho = 0.17$; $p < 0.001$), and clean mucosal fraction showed no significant association. Cleanliness metrics showed no significant correlations with lesion count or minimum lesion size (all $|\rho| < 0.12$; $p > 0.10$), and showed no discriminative ability for adenoma presence prediction (AUC ≈ 0.5). Logistic regression yielded non-significant odds ratios (OR) for all tested metrics (ORs 0.92–1.12; $p > 0.2$). NSI decreased significantly after rinsing events (mean ΔNSI = -0.77 %, $p < 0.001$) and improved between insertion and withdrawal (mean ΔNSI = -1.59 %, $p < 0.05$) [1].

Conclusions The segmentation model performed strongly across all classes, enabling reliable extraction of the AI cleanliness metrics. NSI had the strongest association with BBPS, weaker trends were demonstrated for stool and water fractions. These modest correlations are expected given BBPS's limited inter-rater agreement and its selective, segment-based scoring, which does not account for the effects of rinsing. Clinical outcome analysis was constrained by the cohort's high adequacy rate (98 %) and the use of procedure-level averages, which cannot reflect visibility at specific lesion sites. The AI cleanliness metrics behaved as expected, with NSI improving from insertion to withdrawal and decreasing in response to rinsing.

Together, these findings show that the novel AI system provides a continuous and detailed quantification of bowel cleanliness, capturing real-time changes and offering scene context that may support automated reporting and enhance downstream tools such as polyp detection. Further work in procedures with greater variability in preparation quality is needed, but the present results establish a strong foundation for more objective, reproducible, and clinically meaningful cleanliness assessment.

Problem to solve Anastomotic leak after colorectal surgery

Innovation In this context, we describe two consecutive cases of colorectal anastomotic leak managed with VACStent without proximal diversion, providing practical insights into patient selection, technical nuances, the value of synchronized internal–external drainage, and determinants of successful therapy [1–7].

Results A comparative summary of the main clinical, anatomical, and technical differences between the two cases is presented in the table below (▶ **Table 1**).

Conclusions VACStent appears to be a promising minimally invasive option for selected patients with complex colorectal anastomotic leaks, even without proximal diversion. In these cases, VACStent preserved intestinal continuity and avoided major reinterventions, including stoma creation. Technical success depends on precise placement, early vacuum stability, and, when indicated, synchronized external drainage. Larger comparative studies are needed.

▶ **Table 1**

Variable	Case 1	Case 2
Sex / Age	Female, 66 years	Male, 71 years
BMI	60 kg/m²	35 kg/m²
ASA	IV	III
Initial surgery	Open Hartmann for presumed perforated diverticulitis (final pathology: perforated adenocarcinoma). Complicated by prolonged admissionand pulmonary embolism.	Open Hartmann for prepyloric perforation and perforated diverticulitis.Early postoperative complications included colostomy necrosis and evisceration.
Restoration of continuity	Laparoscopic; extensive adhesiolysis; parastomal hernia repair (no mesh)	Open; antegrade colonic lavage; colorectal anastomosis ~10 cm from anal verge. Prior mesh in situ.
Postoperative complications	Early enteric leak, subcutaneous infection, and evisceration	No early complications after restoration of continuity
Time to leak	30 days	3 months
Defect type	<1 cm contained leak with associated collection	Late fistula with chronic cavity in the space of Retzius and subcutaneous extensions
Fistulous opening	Small	Small, partially epithelialized
Proximal diversion	No	No
Previous treatments	None	15 days of TPN; wound care; failed OTSC attempt
Interval to VACStent	Immediate	After outpatient follow-up and readmission
VACStent cycles	1 cycle	4 cycles (7 + 7 + 3 + 3 days)
Negative pressure	–120 mmHg	–300 mmHg initially (pressure-related ulcer), then –120 mmHg
Additional techniques	None	External NPWT ("sandwich technique") in cycles 3 and 4
Tolerance / transit	Well tolerated; transit preserved	Initial disturbance; later normalization
Confirmation of closure	Endoscopy + fluoroscopy	Endoscopy + contrast-enhanced CT
Final outcome	Complete closure	Complete closure
Follow-up	6 months, no recurrence	3 months, no recurrence

Endoscopy 2026; 58: S1–S1041

eP677 A rare pancreatic Schwannoma diagnosed by EUS-FNB

Authors Sparacino A[1], Graceffa P[2], Bracciamà E[1], Cartabellotta F[2], Granata A[2]

Institutes **1** Buccheri La Ferla / Hospital, Palermo, Italy; **2** Ospedale Buccheri La Ferla, Palermo, Italy

DOI 10.1055/s-0046-1822004

Abstract Text

A 40-year-old woman in good clinical condition presented with recurrent abdominal pain. Abdominal computer tomography scan revealed an oval-shaped neoplasm measuring 2.5 x 3.2 cm with regular margins, located between the pancreatic head region, the gallbladder, and the first portion of the duodenum. The lesion exhibited a supradense fluid attenuation, predominantly peripheral enhancement with a partial spoke-wheel pattern, and caused mild compression of the duodenal lumen.Linear endoscopic ultrasound (EUS) showed a solid lesion measuring 2.6×2.7 cm with well-defined, regular margins and predominantly iso-hypoechoic texture, containing multiple internal anechoic areas. Following the intravenous administration of contrast agent, contrast enhancement was observed along with the appearance of some hyperechoic areas. Two passes with a 22- gauge needle were performed for histology of the solid component. Histology of the fine needle biopsy revealed a benign pancreatic schwannoma with immunostaining for S100 and Ki67 1-2%.Pancreatic schwannoma is an extremely rare tumor that originates from Schwann cells of the peripheral nerve sheaths within the pancreas. Less than 1% of pancreatic tumors are of mesenchymal origin, and among these, schwannomas account for only a small fraction. Malignant degeneration is rare but may be suspected in the presence of tumor size greater than 6.9 cm, vascular involvement, or invasion of adjacent organs. Diagnosis of pancreatic schwannoma is challenging due to its tendency to mimic other lesions of the pancreas [1]. EUS-FNB with S100 immunostaining should be considered the best preoperative diagnostic approach [2].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822005

Aims To present the experience regarding the epidemiological characteristics and survival of patients who underwent percutaneous endoscopic gastrostomy (PEG) in our unit.

Methods We performed a retrospective analysis of prospectively collected data from patients who underwent PEG placement between (01/06/2019-01/06/2025). Demographic and clinical characteristics, survival (day 28, 3 months, 6 months and overall) and cause of death were recorded. The primary endpoints were the indication for PEG placement, time to death after PEG and death within 3 months following PEG placement.

Results A total of 119 patients [72 (60.8%) women, mean age 77.7 ± 14.5 years] underwent PEG according to European guidelines indications. The most common indication was dementia-related dysphagia (50.8%), followed by stroke (10.8%) and Parkinson's disease (10.2%). No complications occurred during PEG placement. Overall, survival data (day 28, 3 months and 6 months) were available for 114/119 (95.7%) patients. Median survival time did not differ significantly between indications for PEG placement [135 days 95% CI (37.9-232.1) for dementia, 126 CI95% (39.7-216.2) for stroke and 102 days CI95% (36.1-132.3) for Parkinson's disease, p = 0.27). Survival rates at day, 28, 3 months, and 6 months also did not differ significantly across indications for PEG placement (p = 0.72, p = 0.36, and p = 0.31, respectively).

Conclusions Patient survival after PEG placement does not differ based on the underlying indication for the procedure.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP679 Implementation of a dedicated reporting system for measuring endoscopy quality in the endoscopic unit of a tertiary hospital

Authors Panagaki A[1], Aggelopoulos G[1], Tziatzios G[2], Gkolfakis P[3], Giannakopoulos A[1], Mathou N[1], Kyvelou E[4], Petraki S[1], Paraskeva K[2]

Institutes **1** Konstantopouleio-Patision General Hospital of Nea Ionia, Athens, Greece; **2** Department of Gastroenterology, General Hospital of Nea Ionia "Konstantopoulio-Patision", Athens, Greece; **3** 2nd Department of Gastroenterology, Medical School UoA, ATTIKON University General Hospital, Ath, Greece; **4** Endoscopy Unit, "Konstantopoulio – Patision" General Hospital, Athens, Greece, Athens, Greece

DOI 10.1055/s-0046-1822006

Aims Different quality indicators have been proposed by the European Society of Gastrointestinal Endoscopy (ESGE) guidelines, to measure and evaluate quality in colonoscopy and ERCP. In this study, we aimed to assess the ability to evaluate these performance measures following the introduction of their mandatory documentation within a dedicated reporting system in a tertiary hospital endoscopic unit.

Methods We retrospectively reviewed the electronic database of the Gastroenterology Department of a tertiary hospital and retrieved all colonoscopy (n = 2824) and ERCP reports (n = 453) performed between 30/6/2024 and 1/7/25. ESGE recommended quality indicators were assesses for both procedures.

Results The reporting system enabled systematic recording and measurement of the following colonoscopy quality indicators: adequate bowel preparation (Boston Bowel Preparation Scale [BBPS score ≥ 6]) 93.4 % (95 %CI 92.3 %-94.5 %), indication for colonoscopy 95,8 % (95 %CI 95 %-96,5 %), cecal intubation rate: 96.2 % (95 %CI 95.4 %-97 %), Adenoma detection rate (ADR) based on optical diagnosis 37.7 % (95 %CI 35.4 %-39.9 %), polyp detection rate (PDR): 45.3 % (95 %CI 43 %-47.6 %), appropriate polypectomy technique 94.1 % (95 %CI 92.7 %-95.4 %). However although the reporting system had the capacity to capture additional indicators specifically: complication rates, patients experience and appropriate post-polypectomy surveillance, these fields were not completed by endoscopists, preventing extraction analysis of these measures. For ERCP the following performance measures were measurable: bile duct canulation rate 92.1 % (95 %CI 89.6 %-94.5 %), clearence of common bile duct stones < 10mm, 91.1 % (95 %CI 86 %-96.1 %), stent placement in biliary obstruction 95.9 % (95 %CI 92.2 %-98.9 %). Despite the system's ability to record on other indicators including adequate antibiotics prophylaxis before ERCP, ERCP-related complications and post-ERCP pancreatitis, these fields were not consistently completed by the endoscopists, preventing extraction analysis of these measures.

Conclusions Standardized monitoring of quality indicators for endoscopic procedures (colonoscopy and ERCP) has been incorporated into the electronic database system of the Endoscopy Unit as mandatory fields. Making this fields a prerequisite for report completion by the operating endoscopist, represents an effective strategy for systematically capturing, monitoring and assessing quality indicators. Implementation of this process is expected to markedly improve the quality of services provided and enhance patient safety.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP680 Technical and Clinical Evaluation of a Novel Slim Therapeutic Gastroscope for Third-Space Endoscopic Procedures: Feasibility, Subjective Workload, and System Usability Assessment (The Slim Scop3 Trial)

Authors Cahyadi O[1], Torres Reyes C[1], Ayoub M[1], Quast D[1], Ewald P[1], Ebigbo A[1]
Institute 1 St. Josef-Hospital, Ruhr-University Bochum, Bochum, Germany
DOI 10.1055/s-0046-1822007

Aims Third-space endoscopy, including peroral endoscopic myotomy (POEM) and endoscopic submucosal dissection (ESD), has become an established therapeutic option for various gastrointestinal disorders. A newly developed slim therapeutic gastroscope aims to improve maneuverability and, provide easier access to the submucosal space but also to enhance ergonomic aspects of tedious therapeutic procedures The aim of this study was to evaluate the subjective workload and usability of the novel slim therapeutic gastroscope during third space procedures. Secondary outcomes included technical and clinical performance as well as adverse events.

Methods This was a prospective, single-arm, single-center study comprising 30 patients undergoing third-space endoscopy in a high-volume center in Germany. Subjective workload and usability were assessed with the NASA-Task load index (NASA-TLX) and the System Usability Score (SUS), respectively. Clinical outcomes and adverse events were recorded prospectively (▶ **Table 1**).

Results The slim gastroscope showed a low NASA-TLX and high SUS score which correlates with a low subjective workload and high usability. POEM showed a tendency towards lower NASA-TLX and higher SUS compared to ESD. For ESD, en-bloc and curative R0 resection rate was 100 %. No device-related adverse events occurred.

▶ **Table 1** Summarize the NASA-TLX and SUS scores for all cohorts, as well as E- and Z-POEM, G-POEM and ESD.

		NASA-LTX	SUS
Total	n: 30	1.5 ± 1.1	92.9 ± 7.1
E- and Z-POEM	n: 15	1.2 ± 0.7	95 ± 6.1
G-POEM	n:6	1.7 ± 1	92.7 ± 8.8
ESD	n:9	1.8 ± 1.5	89.4 ± 2.1

The NASA-TLX was very low across the cohorts showing a low subjective workload with the new endoscope with a tendency towards lower score in the ESD cohort compared to E- and Z-POEM. The SUS was very high across the cohorts signaling a high usability of the scope with again higher score for POEM compared to ESD.

Conclusions A novel slim gastroscope offers high usability with a low subjective workload for third space procedures without compromising clinical performance. The slim gastroscope has the potential to reduce the ergonomic strain on endoscopists during complex therapeutic interventions.

DOI 10.1055/s-0046-1822008

Abstract Text

A 28-year-old male with long-standing GERD were referred to Surgery. Laparoscopic Nissen-Rosetti fundoplication was performed. On postoperative day 5 (POD), the patient went to the Emergency department with retrosternal pain and fever. A CT scan revealed an air-fluid collection in the surgical site. Surgical revision was performed, and drains were placed. Finally, on POD 7, due to suspected perforation, a new endoscopic examination revealed a perforation point in the distal esophagus. The patient's condition worsened, requiring admission to the ICU with respiratory distress. A Vac Stent, with an additional replacement, was placed in the distal esophagus using standard technique. The patient experienced significant improvement and the perforation was resolved in a minimally invasive way [1, 2].

DOI 10.1055/s-0046-1822009

Aims This umbrella review aimed to synthesize evidence from systematic reviews and meta-analyses of randomized controlled trials (RCTs) evaluating the effectiveness, safety, and metabolic outcomes of bariatric surgery, endoscopic procedures, and GLP-1 receptor agonists (GLP-1RAs).

Methods Eligible studies included systematic reviews and meta-analyses of RCTs involving adults with obesity (BMI ≥ 30 kg/m²) and assessing at least one of the three intervention classes. Primary outcomes included changes in body weight, BMI, and waist circumference; secondary outcomes included glycemic control, lipid profile, quality of life, and adverse events.

Results A total of 44 systematic reviews with meta-analyses were included, encompassing over 370,000 participants. Most reviews were rated as critically low (59.1 %) or low (29 %) quality, with 20 % using the GRADE approach. Bariatric surgery demonstrated the largest and most durable reductions in body weight (mean differences up to −25.9 kg) and the highest rates of type 2 diabetes remission (60–80 %). GLP-1RAs, particularly semaglutide, showed consistent, dosedependent weight loss (up to −15 %) and significant improvements in glycemic indices. Endoscopic interventions, such as intragastric balloons and endoscopic sleeve gastroplasty, achieved intermediate weight loss (4–12 %) with a favorable safety profile.

Conclusions Bariatric surgery remains the most effective option for substantial weight and metabolic improvements, particularly in severe or refractory obesity. GLP-1RAs offer a potent non-surgical alternative, while endoscopic therapies provide a minimally invasive option for patient's ineligible for or unwilling to undergo surgery. A tiered, individualized approach to obesity treatment; guided by intervention efficacy, safety, and patient characteristics, supported by the current evidence base.

Aims In case of suspicious malignant distal biliary obstruction the most common clinical presentation is jaundice so that pathological confirmation of malignancy and biliary drainage for symptoms palliation are required. Endoscopic ultrasound (EUS) represents the preferred diagnostic technique while endoscopic retrograde cholangiopancreatography (ERCP) is the procedure of choice for drainage. Tissue acquisition can be obtained by means of fine-needle aspiration (FNA) or biopsy (FNB), brushing and/or bile aspiration cytology. The simultaneous EUS and ERCP approach may offer a diagnostic and therapeutic solution using a single sedation/anesthesia, reducing hospital stay, offering a rapid relief of symptoms (jaundice, cholangitis) and a early tissue diagnosis leading to faster oncological planning. Aim of this study is to explore in a real-world setting feasibility and diagnostic effectiveness of EUS-ERCP approach for highly suspicious pancreatobiliary malignancies, valuing the individual role of different tissue acquisition techniques [1–5].

Methods All patients underwent to EUS and ERCP in the same-session in our Endoscopic Department for jaundice in suspicious malignant distal biliary stricture between December 2023 and June 2025 were considered for retrospective analysis. Patients' and procedure characteristics were abstracted. Diagnostic accuracy of each individual techniques and of their combination were analysed.

Results 44 patients resulted eligible (26 M, 18 F, Median age 67.7 IQR 62.8-77.4). Final diagnosis was pancreatic adenocarcinoma in 42/44 cases (95.5 %) and cholangiocarcinoma in 2/44 cases (4.5 %). FNB was carried out in 43/44 (97.7 %), brushing in 43/44(97.7 %) and bile aspiration cytology in 30/44 cases (68,2 %). FNB, performed with the help of macroscopic on site evaluation (MOSE) by the endoscopist, achieved an accuracy of 90.7 %, with sensitivity and specificity respectively 90.48 % and 100 %. Brushing and bile cytology achieved an accuracy, respectively, of 68.18 % and 70 %. Combining all the diagnostic techniques it was obtained a high accuracy (93.33 %, 95 %CI 81.73 %-98.60 %) with sensitivity 93,18 %, specificity 100 % and negative likelihood ratio 0.07 (95 %CI 0.02-0.20). In 3/44 (6.8 %) cases none of these techniques was diagnostic for inadequate samples, requiring a subsequent procedure (EUS in all cases), with success. Simultaneous endoscopic drainage was performed in all cases with ERCP and placement of plastic or self-expandable metal stents. Previous EUS-FNB did not impaired technical success of biliary cannulation. Median time to chemotherapy or to surgery was 27.8 days (IQR, 15-55). No major adverse events occurred, only in 1 case post-ERCP pancreatitis delayed the start of chemotherapy.

Conclusions Same session EUS-guided and ERCP-guided tissue sampling with biliary drainage for symptoms palliation in real world is feasible and safe in case of distal malignant biliary obstruction. It contributes to reduce hospitalization and access time to oncological therapies and should be considered as a standard of clinical practice. In the context of neoplasms with a high cancer-related mortality, combination of sampling techniques may increase significantly diagnostic yields, reducing the need of further procedures (which cause a delay in starting treatments) and, in fact, having a positive impact on disease-specific survival.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP684 Clinical Predictors of Malignancy in EUS-Evaluated Pancreatic Lesions: A Five-Year Saudi Cohort Study

Authors Al-Lehibi A[1], Alshehri M[2], Alanazi A[3], Bawazir A[4]
Institutes **1** Dar Al Uloom University, King Fahad Medical City, Riyadh, Saudi Arabia; **2** King fahad medical city, riyadh, Saudi Arabia; **3** Northren border university, Arar, Saudi Arabia, riyadh, Saudi Arabia; **4** KFMC, riy, Saudi Arabia
DOI 10.1055/s-0046-1822011

Aims his study aimed to characterize the clinicopathological features of pancreatic lesions in a Saudi cohort, identify clinical predictors of malignancy, and evaluate the diagnostic performance of EUS [1–40].

Methods We conducted a retrospective analysis of 351 patients who underwent EUS for pancreatic lesions at a tertiary center in Riyadh, Saudi Arabia, from 2019 to 2023. We collected data on patient demographics, clinical presentation, and imaging findings. The primary outcome was a final diagnosis of benign versus malignant disease. Multivariate logistic regression was used to identify independent predictors of malignancy.

Results A final diagnosis was established in 237 patients, of whom 117 (49 %) had malignant lesions. In univariate analysis, the presence of a solid lesion was the strongest predictor of malignancy (OR 189.0, 95 % CI 72.7-571.0). In a multivariate model of clinical factors, weight loss (OR 9.38, 95 % CI 3.82-26.0), jaundice (OR 3.34, 95 % CI 1.19-10.5), and increasing age (OR 1.05, 95 % CI 1.03-1.08) were independent predictors of malignancy. The visual impression on EUS demonstrated a high specificity of 98 % (95 % CI 0.94-1.00) and a negative predictive value (NPV) of 97 % (95 % CI 0.93-0.99) for diagnosing malignancy.

Conclusions In this large Saudi cohort, the classic clinical predictors of weight loss, jaundice, and older age remain alarming indicators of malignancy. EUS is a highly accurate diagnostic modality, with excellent specificity and NPV, making it an indispensable tool for confidently ruling out pancreatic cancer.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP685V Management of Difficult Intrahepatic Duct Stones Using Cholangioscopy, Lithotripsy, and Basket

Author Al-Lehibi A[1]
Institute **1** Dar Al Uloom University, King Fahad Medical City, Riyadh, Saudi Arabia
DOI 10.1055/s-0046-1822012

Abstract Text

The treatment of difficult intrahepatic duct stones has emerged as a critical area of inquiry due to the high prevalence and complex management challenges of hepatolithiasis worldwide. Epidemiological data indicate that hepatolithiasis affects up to 50 % of patients in East Asia and presents increasing incidence in Western countries, emphasizing the global relevance of effective treatment strategies [1–3](

eP686 Clinical Profile, Management, and Outcomes of Primary Sclerosing Cholangitis in a Saudi Cohort: A Retrospective Study at a Tertiary Care Center in Riyadh

Authors Al-Lehibi A[1], Alhowaish N[2], Alrashedi O[3], Alhubayshi A[2], Bawazir A[4], Aleid A[2]
Institutes **1** Dar Al Uloom University, King Fahad Medical City, Riyadh, Saudi Arabia; **2** king fahad medical city, Riyadh, Saudi Arabia; **3** King fahad medical city, Riy, Saudi Arabia; **4** KFMC, riy, Saudi Arabia
DOI 10.1055/s-0046-1822013

Aims This study aims to characterize PSC in a Saudi cohort, detailing its presentation, diagnosis, and management at a major tertiary center in Riyadh.

Methods This retrospective observational study analyzed PSC patients aged ≥ 14 years at King Fahad Medical City, Riyadh (2013–2024), excluding pregnant, breastfeeding, or incomplete- record cases. Data on demographics, clinical presentation, lab results, imaging, and comorbidities were extracted from EPIC software. Descriptive statistics were performed using SPSS v27. Ethical approval was obtained, ensuring confidentiality and data accuracy through double-checking and standardized protocols [1–41].

Results This study included 93 PSC patients (mean age 41.3 ± 14.7 years, 57 % male, 98.9 % Saudi). Median disease duration was 5 years, with common symptoms including right upper quadrant pain (19.4 %) and pruritus (14 %). Lab findings showed median ALP 188 U/L and bilirubin 11.8 µmol/L. MRCP was the primary diagnostic tool (45.2 %). URSO was the most used treatment (39.7 %). IBD prevalence was 55.6 %, with UC more common than CD. Cholangiocarcinoma and colorectal cancer each occurred in 4.3 %.

Conclusions Early ALP elevation was essential for diagnosis. URSO remains the primary therapy, while novel treatments like oral vancomycin and fibrates show promise. Further research is needed to optimize care and integrate novel bio-

markers with advanced imaging for personalized management in this high-risk population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822014

Aims Small bowel disorders, including obscure gastrointestinal bleeding (OGIB), Crohn's disease, and tumors, requireaccurate diagnostic approaches for effective treatment. Video capsule endoscopy (VCE) and simple balloon enteroscopy (SBE) arewidely used, but each modality has limitations, particularly regarding therapeutic intervention and diagnostic yield [1].

Methods A comprehensive search of four databases (PubMed, Embase, Cochrane Library, and Scopus) revealed over 600 citations for applying capsule endoscopy and balloon enteroscopy for small intestine diagnosis following wall thickening. Following a rigorous assessment of these citations based on a predetermined eligibility criterion, seven moderate-to-high-quality retrospective studies were conducted evaluating the diagnostic performance of VCE and SBE in patients with small bowel disorders. The studies were assessed using QUADAS-2 to evaluate the risk of bias and overall methodological quality.

Results The analysis of seven moderate-to-high-quality retrospective studies revealed comparable overall detection rates for small bowel lesions between Video Capsule Endoscopy (VCE) and Simple Balloon Enteroscopy (SBE). VCE demonstrated superior performance in detecting vascular lesions, with one study reporting 39 cases identified by VCE compared to 30 cases by SBE ($p < 0.05$). Conversely, SBE exhibited higher efficacy in detecting ulcerative lesions, with a statistically significant difference of 28 cases versus 10 cases identified by VCE ($p < 0.01$). The overall diagnostic yield varied across studies, with VCE showing a range of 32-83 % for small bowel bleeding, while SBE demonstrated a higher overall detection rate of 69.7 % compared to 57.6 % for VCE in one study ($p < 0.05$). Notably, SBE showed superior performance in diagnosing Crohn's disease, with a detection rate of 35 % compared to 11.3 % for VCE ($p < 0.001$). The diagnostic concordance between VCE and SBE was influenced by lesion type. Strong agreement was observed for inflammatory lesions ($\kappa = 0.82$, 95 % CI: 0.75-0.89), while moderate agreement was noted for tumors ($\kappa = 0.61$, 95 % CI:0.52-0.70) and angiectasias ($\kappa = 0.58$, 95 % CI: 0.49-0.67). In terms of clinical utility, SBE demonstrated significant advantages in therapeutic intervention, particularly in cases of overt bleeding. One study reported immediate hemostasis achieved in 92 % of cases where active bleeding was identified during SBE (95 % CI: 86-98 %). Patient tolerability was generally higher for VCE, with a completion rate of 95 % (95 % CI: 92-98 %) compared to 85 % for SBE (95 % CI: 80-90 %). However, the capsule retention rate for VCE was reported at 1.4 % (95 % CI: 0.8-2.0 %), necessitating subsequent intervention.

Conclusions VCE and SBE are complementary techniques in evaluating small bowel disorders. While VCE remains the initial test of choice for stable patients with OGIB, SBE should be considered for cases requiring therapeutic intervention. The findings suggest that combining both modalities enhances diagnostic accuracy and patient management. Further research should focus on improving CE interpretation and the ability of SBE to provide comprehensive small bowel exploration.

eP688 Jejunal Fish Bone Perforation Presenting as Recurrent Cholangitis in a Post-Whipple Patient

Authors Rama T[1], Elsayed G[1], Lama M[1], Gadour E[2, 3]
Institutes **1** Mediclinic Middle East Hospital, Abu Dhabi, United Arab Emirates; **2** King Abdulaziz Hospital, Al Mubarraz, Saudi Arabia; **3** King Fahad Specialist Hospital – Dammam., Dammam, Saudi Arabia
DOI 10.1055/s-0046-1822015

Aims: This study aims to report a rare cause of recurrent fever and abdominal pain in a patient with altered gastrointestinal anatomy after pancreaticoduodenectomy (Whipple procedure). The objective is to highlight the diagnostic challenges and emphasize the importance of considering gastrointestinal foreign body perforation in the differential diagnosis of post-Whipple patients presenting with recurrent febrile episodes and abdominal pain [1].

Methods: A case study was conducted involving a 55-year-old female patient with a history of pylorus-preserving Whipple procedure performed 10 years prior for intraductal papillary mucinous neoplasm (IPMN). The patient presented with recurrent fever and severe abdominal pain over one year. Comprehensive diagnostic workup included serial laboratory tests, liver function tests, imaging studies (ultrasound, MRCP, CT KUB), and deep push enteroscopy. Imaging was critically re-evaluated to identify subtle abnormalities. Endoscopic intervention was performed to extract the foreign body.

Results: Initial investigations, including blood tests and liver function tests, remained largely normal, and infectious workup was negative. MRCP revealed a 37-mm linear filling defect in the right intrahepatic duct, initially suspected as intrahepatic lithiasis. CT KUB, upon detailed review, identified a subtle linear hyperdense structure traversing the efferent jejunal limb near the right renal vein, consistent with a fish bone. Deep push enteroscopy confirmed the presence of an embedded fish bone in the jejunal wall, which was successfully extracted endoscopically. Post-procedural intravenous antibiotics led to marked clinical improvement with resolution of fever and abdominal pain. Follow-up demonstrated stable recovery with no recurrence.

Conclusions: This case underscores the significance of maintaining a broad differential diagnosis in post-Whipple patients with recurrent fever and abdominal pain, especially when conventional biliary causes are excluded. Critical re-assessment of imaging and utilization of advanced endoscopic techniques such as deep push enteroscopy are crucial for detecting rare causes like gastrointestinal foreign body perforation. Early multidisciplinary collaboration and vigilant diagnostic approaches can prevent delays in diagnosis and improve

patient outcomes. Future implications include increased awareness of atypical etiologies and the integration of specialized imaging and endoscopic evaluations in complex postoperative cases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP689 The "Biliopancreatic Conundrum" of

Authors Amata M[1], Scimeca D[1], Di Mitri R[1]

Institute 1 Gastroenterology and Digestive Endoscopy, A.R.N.A.S. Ospedali Civico Di Cristina Benfratelli, Palermo, Italy

DOI 10.1055/s-0046-1822016

Aims EUS trans-mural approach can be technically challenging or unfeasible in patients with distal malignant biliary obstruction (DMBO) and < 12 mm common bile ducts (CBD) after ERCP failure [1, 2]. Similarly, intrahepatic route requires ≥ 5mm intrahepatic duct (IHBD) dilatation and ≥ 2.5cm hepatic parenchymal distance to safely create a novel direct access from stomach [3]. EUS-guided rendezvous (EUS-RV) has emerged as an alternative approach in this scenario. However, it require technically challenging steps like biliary puncture using a 19G needle, guidewire manipulation, EUS scope withdrawal and duodenoscope re-insertion, guidewire grasping\traction inside the accessory channel and finally biliary cannulation (BC) using the EUS-placed guidewire by the "along-the-wire" and the "over-the-wire" methods.

Methods This single-center retrospective study aimed to evaluate the feasibility, safety, and efficacy of EUS-RV in patients with < 12mm CBD and DMBO. Patients were enrolled between January 2020 and May 2025, and followed for at least 6 months follow-up. Over a total number of 2838 ERCP performed in our center, approximately one third (1082) were executed for malignant obstruction. Of this subgroup, a DMBO was reported in 785 cases and 91 patients presented a CBD < 12mm. We finally registered all the 12 EUS-RV cases after failed conventional ERCP with standard or advanced cannulation techniques. Technical success, clinical success and adverse events (AEs) were analyzed. All procedures were performed under general anesthesia, using standard linear echoendoscope and ERCP equipment (▶ **Table 1**).

▶ **Table 1**

Patients	12 (6 female – 6 male)
Access ruote	CDB: 8 – IHBD: 3 – Wirsung: 1
Mean CBD diameter	9.8 mm (range: 7,5-11,5 mm)
Wire shearing	0\12 cases
Wire losing	41.6 % (5\12)
Biliary Cannulation	"along-the-wire": 41.6 %(5\12), "over-the-wire" : 58.4 %(7\12)
Procedural time	89,81 ± 29,04 minute
Metallic stent release	100 %
Technical success	100 %
Clinical Success	100 %
AEs	0\12 cases

Results 12 patients were included in this analysis. Access was performed from the bulb to the CBD or from stomach to IHBD (S2 or S3) in 8 and 3 cases, respectively. One case require approach by the main pancreatic duct due to the impossibility of a valid biliary EUS window. Mean CBD diameter was 9.8 mm (range: 7,5-11,5 mm). Wire shearing was never reported. A 10-mm snare was adopted to catch the wire through the duodenoscope. A second operator was systematically located at patient head to collect and facilitate the correct sliding of the 450-mm 0.035inch hydrophilic guidewire. The wire was inadvertently detached, broke or lost during traction in 41,6 % of the cases. In this scenario, BC was performed "along-the-wire" using a standard sphincterotome following the way of the rendezvous wire. In the remained 58,4 % of the cases, the "over-the-wire" BC technique was used. A tubular metal stent was deployed in all the cases. Procedural time was 89,81 ± 29,04 minutes, confirming the high technical complexity of the procedure that require multiple steps. EUS-RV technical success was achieved in all the cases. Clinical success, defined as successful biliary drainage and jaundice resolution, was obtained in 100 % of cases. No AEs were reported.

Conclusions EUS-RV demonstrated favorable efficacy in patients with < 12mm CBD diameter and DMBO when conventional ERCP failed as showed in this single-center retrospective analysis. In this context, EUS-RV constitutes a valid first-line treatment with comparable effectiveness and no AEs, although it necessitates multiple procedural steps that increase technical complexity and procedural time. The lack of dedicated devices necessitated standard ERCP accessories, which may have impacted procedural efficiency and outcomes, particularly wire loss. It can inadvertently occur during scope exchange, guidewire manipulation, or other EUS-RV steps, representing a critical passage that may compromise procedural success. "Along-the-wire" BC represents a useful trick in high-skilled endoscopists facilitating deep papillary access.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP690 Evolution of Gastric Outlet Obstruction Management: Insights from a UK Tertiary Centre

Authors Marrinan A[1], Sriranganathan D[1], Affarah L[2], El Menabawey T[2], Chapman M[3], Phillpotts S[4], Pereira S[1], Johnson G[5], Webster G[4]

Institutes 1 University College London Hospitals NHS Foundation Trust, London, United Kingdom; 2 University College Hospital, London, United Kingdom; 3 UCLH, London, United Kingdom; 4 University College London Hospitals NHS Trust, Department of Gastroenterology, London, United Kingdom; 5 UCL Hospitals, London, United Kingdom

DOI 10.1055/s-0046-1822017

Aims To review the changing trends of endoscopic management of Gastric Outlet Obstruction (GOO) in a large tertiary referral centre in the UK, comparing the outcomes of patients undergoing Duodenal Stenting vs Endoscopic Ultrasound-Guided Gastro-Jejunostomy

Methods We conducted a single centre retrospective analysis reviewing all patients referred for management of GOO between June 2019 and October 2025. Over 300 Electronic Medical Records (EMR) of cases discussed at our MDT were reviewed to select patients subsequently managed with Duodenal Stenting (DS) and/or Endoscopic Ultrasound-Guided Gastro-Jejunostomy (EUS-GJ). EMRs were reviewed to obtain anonymised data related to patient demographics, procedure duration, time to resolution of oral intake post procedure (defined as resumption of oral fluid/food consumption and absence of vomiting), survival, re-intervention rates, complications. We also reviewed our trends of case numbers comparing DS vs EUS GJ procedures per year

Results 71 patients underwent duodenal stenting (31 female/40 male), while 33 underwent EUS GJ (20 female/13 male). Median age of DS group 67 years

old (range 32-91) vs EUS GJ group 66 years old (range 37-86). Median survival of DS cohort 100 days (range 6-604 days) vs median survival of EUS GJ cohort 86 days (range 9-516 days). Median survival of DS cohort 100 days (range 6-604 days) vs median survival of EUS GJ cohort 86 days (range 9-516 days). Re-intervention rate in DS group: 26.7 % (19/71) vs re-intervention rate of EUS GJ group: 6 % (2/33). Median duration of DS procedure 31min (range 13-74min) vs median duration of EUS GJ procedure 49min (range 23-76min). Median time to resolution of GOO: 1 day in EUS GJ group (range 1-2 days) vs 1 day in DS group (range 1-7 days). Over the study period, the number of DS procedures per year has levelled off, while the number of EUS-GJ procedures completed annually has steadily risen year on year since 2022 1-4.

Conclusions Over time, the volume of EUS GJ in our centre has increased steadily, from 1 case in 2022 to 15 cases to date in 2025. The role for DS has changed from the primary endoscopic method of GOO management to one used only in select cases. Re-intervention rates were higher in the DS group, in keeping with prior published experience. In our cohort, 47 % of DS patients who required re-intervention for recurrence of GOO were successfully managed with EUS-GJ. EUS-GJ was seen to be safe, with no major complications noted during the study period, and was highly effective for definitive management of GOO with low rates of re-intervention. This study adds to the growing body of evidence in support of EUS-GJ for patients with malignant GOO.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822018

Aims Precise intraprocedural phase recognition during complex endoscopic procedures like endoscopic submucosal dissection (ESD) could facilitate automatic objective reporting, specific target-oriented training interventions and measurable quality control. Artificial intelligence algorithms have already been applied to phase recognition in laparoscopic operations and peroral endoscopic myotomy successfully. The aim of this study was to develop and validate an algorithm for automated intraprocedural phase recognition during ESD on a single frame basis.

Methods The ESD procedure was divided into 5 macro phases: diagnostics, marking, needle injection, dissection and bleeding. Macro-phases were subdivided into micro-phases, which included scope manipulation, electric current application and injection, leading to a total of 11 phases. A training dataset was compiled from 92 full-length ESD videos (7.930.412 frames) and each frame allocated to one phase. All procedures were performed with the same endoscope system (GIF EZ1500, Olympus, Tokyo, Japan) A video swin transformer was trained in the recognition of the procedural phases. Temporal information was incorporated by uniform frame sampling from past and future of the analyzed frame. The algorithm was validated internally on a validation set (16 ESD procedures, 1.580.394 frames). External validation was performed on 8 ESD procedures (759.346 frames) from a live pig study using a different endoscopy system (GIF H190, Olympus, Tokyo, Japan). In a further evaluation, 2 videos from the external validation set were incorporated into the training data.

Results The overall internal validation yielded an accuracy of 86 % and an F1 score of 86 %. The external validation showed values of 69 % and 70 % for the same parameters. The evaluation for macro phases showed overall accuracies of 89 % and 80 % and F1 scores of 90 % and 80 % for internal and external test sets, respectively. Incorporation of 2 videos from the test set into the training set led to the following results: The accuracy and F1-score for all phase validation were 78 % and 78 %. For macro-phase evaluation, these values were 87 % and 87 %.

Conclusions Automated procedural phase recognition yielded precise overall performance in internal validation. External validation with different image quality, endoscopy series and subject showed lower, but still adequate performance. Incorporation of a very limited number of videos from the test set into the training improved the performance. Adaptation of a core algorithm to local settings by limited retraining may mitigate problems of generalizability in the future. Further research should determine the value of this technology for automatic reporting and quality control.

eP692 What is the optimum duration of hospital admission following colorectal endoscopic submucosal dissection (ESD)?

Authors Looi SJ[1], Narimetla S[1], Ortiz O[2], Ahmad OF[3, 1], Seward E[1], Vega R[1]

Institutes **1** University College London Hospitals NHS Foundation Trust, London, United Kingdom; **2** Hospital Clínic de Barcelona, Barcelona, Spain; **3** Division of Surgery and Interventional Sciences, University College London (UCL), London, United Kingdom

DOI 10.1055/s-0046-1822019

Aims There is no consensus on whether routine hospital admission is required following colorectal ESD, and practice varies internationally. At our institution, patients are typically admitted overnight for observation. We aimed to evaluate post ESD outcomes to identify factors that may guide decision-making on the need for hospital admission.

Methods We conducted a retrospective study of patients undergoing colorectal ESD between October 2019 to October 2025 at a tertiary centre in the United Kingdom. Data were obtained from electronic records. Categorical variables were compared using the Chi-square test, and continuous variables using the T-test or Mann–Whitney U test based on distribution. All procedures were performed using a bipolar radiofrequency/high-frequency microwave device (Speedboat). Procedural complications—defined as perforation, bleeding or post-polypectomy syndrome related to ESD—were classified as immediate (≤ 24 hours) or delayed (> 24 hours). Patients were grouped into uncomplicated and complicated ESD.

Results A total of 225 patients were included; 204 (91 %) were discharged within 24 hours. Extended hospitalisation occurred in 21 patients. Of these, 10 cases (48 %) were due to immediate procedural complications, 7 (33 %) were due to procedure-dependent symptoms such as abdominal pain or raised inflammatory markers, and 4 (19 %) resulted from unrelated issues including

social problems, alcohol withdrawal, or allergic reactions. Fourteen patients required readmission within 30 days; 7 cases (50 %) were attributed to delayed procedural complications, and the remaining 7 cases were due to unrelated conditions such as pneumonia, urinary retention, skin rash, or suspected venous thromboembolism.

We next examined factors associated with complicated ESD (▶ **Table 1**). Anticoagulant use was more common in this group (37.5 % vs 5.7 %, p = 0.001), which also had longer admissions (4 vs 1 day, p < 0.001) and higher 30-day readmissions (43.8 % vs 3.3 %, p = 0.001). As these differences were largely complication-driven, we evaluated event characteristics. Perforation occurred in 2 % (5/225), with only 1 % (3/225) requiring surgery. Post ESD bleeding occurred in 5 % (11/225), and only 2 % (5/225) required intervention. Notably, no perforations occurred in anticoagulated patients, indicating that anticoagulation primarily increases bleeding risk. Indeed, 55 % (6/11) of post ESD bleeds occurred in patients on anticoagulants despite appropriate peri-procedural management in accordance with national guidelines.

▶ **Table 1** Comparison between patients with and without procedural complications

Procedural factors		Uncomplicated ESD N = 209	Complicated ESD N = 16*	p value
Male		118	12	0.27
Mean age (range)		64.4 (25-88)	61.3 (37-81)	0.21
Anticoagulant use, N (%)		12 (5.7)	6 (37.5)	0.001
Previous biopsy/ resection, N (%)		23 (11.0)	4 (25.0)	0.34
Mean size in cm (range)		5.1 (1-18)	5.1 (3-10)	0.98
Location	Rectum, N (%)	96 (45.9)	8 (50.0)	0.98
	Colon, N (%)	113 (54.1)	8 (50.0)	
Mean duration in minutes		167.3	188.4	0.26
Hybrid technique, N (%)		40 (19.1)	4 (25.0)	0.13
Mean admission duration in days		1	4	< 0.001
Out-of-hours medical review, N (%)		9 (4.3)	5 (31.3)	0.008
30-day readmission, N (%)		7 (3.3)	7 (43.8)	0.001

*1 patient had both immediate and delayed complications (bleeding)

Conclusions Colorectal ESD performed with the Speedboat device demonstrates low complication rates, supporting safe discharge within 24 hours for most patients. Anticoagulant use was the only factor significantly associated with complications, leading to extended hospitalisation or readmission. Incorporating anticoagulation status into pre-procedural planning may therefore help identify the minority of patients who would benefit from planned post ESD admission. These findings support a selective, risk-stratified approach rather than routine overnight admission following colorectal ESD.

eP693 Intraprocedural instrument recognition during endoscopic submucosal dissection using artificial intelligence

Authors Scheppach MW[1], Rauber D[2], Büchele C[1], Weber Nunes D[2], Nagl S[1], Probst A[1], Römmele C[1], Palm C[2], Messmann H[1]

Institutes **1** Internal Medicine III – Gastroenterology, University Hospital Augsburg, Augsburg, Germany; **2** Ostbayerische Technische Hochschule (OTH) Regensburg, Regensburg, Germany

DOI 10.1055/s-0046-1822020

Aims The automation of procedure analysis for endoscopic interventions is a prerequisite for the advancement towards automatic reporting, quality assessment and advanced operator assistence systems. A critical aspect of procedure characteristics is the choice and utilization of endoscopic instruments. The endoscopic submucosal dissection (ESD) is a complex resection technique with a slow learning curve and relevant operator dependent risks for procedure related complications such as bleeding and perforation. During ESD, specific instruments such as electrosurgical knives of different shapes or hemostatic forceps are used. The analysis of the utilized endoscopic instruments may facilitate a more profound understanding of procedure characteristics. Therefore, we aimed to develop an algorithm for the automatic detection and delineation of endoscopic instruments during ESD (▶ **Table 1**).

▶ **Table 1**

Class	Sensitivity	Specificity	Dice
Background	0.98	0.91	0.97
Hook knife Shaft	0.92	1.00	0.93
Hook knife Tip	0.78	1.00	0.76
Dual knife Shaft	0.93	1.00	0.95
Dual knife Tip	0.46	1.00	0.54
Flush knife Shaft	0.93	1.00	0.92
Flush knife Tip	0.08	1.00	0.14
Needle Shaft	0.96	1.00	0.91
Needle Tip	0.82	1.00	0.79
Hemostatic forceps Shaft	0.30	1.00	0.41
Hemostatic forceps Tip	0.57	1.00	0.52
Clip Shaft	0.84	1.00	0.84
Clip Tip	0.31	1.00	0.44
Distal Attachment	0.90	0.98	0.93

Methods 65 full length ESD videos (15x rectal, 29x esophageal, 16x gastric, 5x duodenal ESD) were extracted from Augsburg University Hospital database. 8.165 single images from these procedures were used for training. On these images, shaft and tip of endoscopic instruments were delineated by two study investigators using Computer Vision and Annotation Tool. Classes included Hook knife, Dual knife (both Olympus, Tokyo, Japan), Flush knife (Fujifilm, Tokyo, Japan), injection needle, hemostatic forceps, hemostatic clip and transparent distal attachment. Annotated images were used for training of a DeepLabV3 + deep learning algorithm. 5-fold internal cross validation was performed on pixel basis, as well as for instrument detection per image (sensitivity, specificity, F1 score). For the instrument detection, a threshhold of 0.2 for the intersection over union of algorithm prediction and ground truth was used.

Results Internal validation results on pixel basis are shown in the table. For the detection task, F1 scores of 1.00, 0.90, 0.88, 0.65, 0.45, 0.68 and 0.99 were

Endoscopy 2026; 58: S1–S1041

measured for Hook knife, Dual knife, Flush knife, needle, hemostatic forceps, hemostatic clip and distal attachment.

Conclusions In this exploratory study, endoscopic instruments were detected and delineated with varying performance by a deep learning algorithm. This was in part attributed to class imbalances in the training data. However, the incorporation of temporal information may also improve performance. Further research should focus on evaluating this new technology for automatic reporting of ESD procedures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP694 EUS-guided gastroenterostomy as a first-line treatment for malignant and benign gastric outlet obstruction: an international multicenter study

Authors Antonini F[1], Marasco M[2], Zulli C[3], Occhipinti V[4], Greco S[4], Abbatiello C[3], Khoury T[5], Sbeit W[5], Buono T[1], Donnarumma D[1], Galasso D[6]

Institutes **1** Hospital "C. and G. Mazzoni", Ascoli Piceno, Italy; **2** Belcolle Hospital, Belcolle, Italy; **3** Digestive Endoscopy Unit, Mercato San Severino, Salerno, Italy; **4** Endoscopy Unit, Internal Medicine Department, ASST Papa Giovanni XXIII, Bergamo, Italy; **5** Galilee Medical Center, Nahariyya, Israel, Nahariyya, Israel; **6** Hospital Riviera-Chablais, Hospital De Rennaz, Rennaz, Switzerland

DOI 10.1055/s-0046-1822021

Aims Endoscopic ultrasound-guided gastroenterostomy (EUS-GE) has emerged as a minimally invasive alternative to surgical gastrojejunostomy or enteral stenting for the management of malignant gastric outlet obstruction (GOO). This multicenter study aimed to evaluate the outcomes of EUS-GE as a first-line treatment for both malignant and selected benign GOO

Methods We retrospectively analyzed all patients who underwent EUS-GE as a primary treatment between November 2021 and October 2025 across five european referral centers. Primary outcomes were technical success, defined as correct stent placement, and clinical success, defined as improvement in the Gastric Outlet Obstruction Symptom Score (GOOSS ≥ 2). Secondary outcomes included adverse event rates, symptom recurrence, and the need for reintervention.

Results Forty-two patients were included (mean age 71,3 years, range 36-90; 61.9 % male). The main etiologies were pancreatic cancer (16/42, 38.1 %), gastric or duodenal cancer (12/42, 28.6 %), and benign disease (7/42, 16.7 %); carcinomatosis was present in 11 patients (26.2 %). A 20x10 mm lumen apposing metal stent (LAMS) was used in 34/42 (80.9 %) of the cases. Technical success was achieved in 37/42 (88.1 %) cases, and clinical success in 39/42 (92.9 %): in two cases, distal flange maldeployment occurred but was corrected during the same session. Adverse events were reported in 5/42 (11.9 %) patients, primarily due to stent misdeployment, including two surgical intervention and one procedure-related death. During a mean follow-up of 163.7 days (range 15-510), symptom recurrence requiring endoscopic reintervention occurred in one patient (2.4 %).

Conclusions EUS-GE demonstrated high technical and clinical success rates with low adverse event and reintervention rates. Nonetheless, the potential for severe complications underscores the need for careful patient selection and experienced operators. Overall, these findings support EUS-GE as an effective first-line treatment option for malignant and selected benign gastric outlet obstruction

eP695V ESD for an Adenoma of the Bulb: Lessons from this Rare Indication

Authors Alioua SA[1], Verset L[1], Lemmers A[1]

Institute **1** Hospital Erasme HUB, Brussels, Belgium

DOI 10.1055/s-0046-1822022

Abstract Text

Bulbar adenomas with advanced dysplasia are rare and difficult to resect due to limited access and the Brunner gland rich submucosa, which often lifts poorly with EMR.

A 70-year-old man was referred for a 25-mm sessile bulbar adenoma with suspected high-grade dysplasia. Underwater ESD was performed with a distal circumferential incision and deep submucosal dissection beneath the Brunner's gland layer. Gradual saline immersion and dissection from 7 to 3 o'clock helped expose the correct plane.

En-bloc resection was completed in 80 minutes, with minor muscular injuries clipped. Histology confirmed high-grade dysplasia (pTis) with R0 margins, and follow-up was uneventful. This case supports the feasibility and curative potential of ESD for selected duodenal bulb lesions.

eP696 When ERCP Uncovers Hemobilia: Endoscopic Treatment of Choledochal Varices

Authors Siljeström C[1], Curtiaud A[2], Christamnn PY[3], Héroin L[3], Enescu I[1], Mayer P[3]

Institutes **1** Nouvel Hôpital Civil (NHC) de Strasbourg, Place de l'Hôpital, Strasbourg, France, Strasbourg, France; **2** Nouvel Hôpital Civil (NHC) de Strasbourg, Place Hôpital, Strasbourg, France, Strasbourg, France, Strasbourg, France; **3** Nouvel Hôpital Civil (NHC)- Hôpitaux Universitaires de Strasbourg, Strasbourg, France

DOI 10.1055/s-0046-1822023

Background: Hemobilia is an uncommon complication, and when it is related to choledochal varices it becomes exceptionally rare. Diagnosis may be difficult, and management often requires collaboration between endoscopists and interventional radiologists, especially in patients with portal hypertension and complex vascular anatomy [1, 2].

Case Presentation: We describe a 44-year-old patient with multivisceral sarcoidosis who had developed extensive thrombosis of the splenomesenteric axis and portal vein, resulting in cavernoma formation, chronic liver disease, and portal hypertension-related cholangiopathy. The patient initially presented with cholestatic liver test abnormalities. Imaging showed intrahepatic bile duct dilation above a short distal common bile duct (CBD) stricture. ERCP confirmed these findings, and a plastic biliary stent was placed.

One month later, the patient was admitted with acute cholangitis and septic shock due to stent obstruction. During urgent ERCP, removal of the plastic stent immediately triggered significant hemobilia. Given the patient's background, bleeding from choledochal varices was suspected. Balloon sweeps up to 11.5 mm allowed evacuation of clots from the CBD and right intrahepatic ducts. A covered self-expandable metal stent (SEMS) of 10 × 80 mm was placed to achieve tamponade, but bleeding persisted. A second SEMS of the same size was deployed at the biliary confluence, again without satisfactory control.

Because the patient remained unstable, the case was reviewed urgently with interventional radiology and hepatobiliary surgery. No surgical approach was considered feasible, so radiologic management with TIPS was arranged. During the TIPS procedure, injection of contrast into a suprahepatic vein resulted in opacification of the biliary tree, confirming hemobilia. A second angiographic phase showed simultaneous filling of the arterial tree, suggesting the presence of arteriovenous fistulas. TIPS placement was successfully completed, leading to hemodynamic stabilization.

Follow-up imaging demonstrated reduced contrast opacification in both biliary and vascular structures and delineated the cavernoma. The patient improved progressively, and biliary stents were removed without further complications. No recurrent cholangitis or bleeding episodes were observed afterward.

Conclusion: This case illustrates a very unusual source of hemobilia related to choledochal varices in the setting of portal hypertension and complex vascular changes. A combination of endoscopic measures for initial control and radiologic TIPS for definitive management proved essential. Recognizing this possibility is important when hemobilia appears unexpectedly during ERCP in patients with portal hypertension or venous cavernoma.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822024

Aims Colorectal cancer (CRC) remains a leading cause of cancer-related morbidity and mortality worldwide, with incidence steadily increasing across the Middle East. Quality colonoscopy metrics, including adenoma detection rate (ADR), are key determinants of effective CRC prevention, yet regional data remain limited. This multicenter randomized controlled trial aimed to assess whether computer-aided detection (CADe) technology enhances colonoscopy quality indicators—particularly ADR—compared with conventional white-light colonoscopy in Middle Eastern populations [1–3].

Methods This prospective multicenter RCT was conducted between January 2022 and December 2024 across seven tertiary centers in Egypt, Bahrain, Iran, Jordan, Saudi Arabia, and Kuwait. Expert endoscopists performed screening, surveillance, or diagnostic colonoscopies in adults aged 40–80 years using either conventional white-light colonoscopy or AI-assisted colonoscopy equipped with CADe (CAD EYE, Fujifilm). Patients were randomized 1:1 to each arm. The primary outcome was ADR. Secondary outcomes included adenomas per colonoscopy (APC), polyp detection rate (PDR), and polyps per colonoscopy (PPC). Statistical significance was set at $p < 0.05$.

Results A total of 441 patients (mean ± SD age 55 ± 10 years; 46 % female) were included. The CADe-assisted group achieved a similar ADR to the conventional group (34.3 % vs 30.3 %; $p = 0.394$). However, CADe significantly improved overall PDR (60.4 % vs 48.2 %; $p = 0.010$) and detected a greater proportion of diminutive polyps (≤ 5 mm) compared with white-light colonoscopy (51.6 % vs 40.6 %; $p = 0.013$). The mean APC and PPC were also higher in the CADe group.

Conclusions CADe-assisted colonoscopy significantly improved overall polyp detection, particularly for diminutive lesions, demonstrating its value as both a clinical aid and a training tool to enhance endoscopist performance. Although the ADR increase was modest, it aligns with several real-world and nonrandomized studies, reinforcing the consistency of CADe's benefit across diverse settings. As the first multicenter RCT in the Middle East, this study underscores the potential of AI-assisted systems to standardize detection quality and improve diagnostic accuracy in regional populations. Future large-scale studies should focus on optimizing algorithm performance and evaluating its role in endoscopic education and practice integration.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822025

Aims Patients with IBD are at increased risk for dysplasia and colorectal cancer (CRC) often at a younger age than the average population, making early detection essential. Despite routine surveillance colonoscopy, post-colonoscopy CRC rates remain high (28–41 %), partly due to the subtle morphology and rapid progression of IBD-associated lesions, as well as the technical challenges in surveillance colonoscopy. Therefore, simpler and more effective endoscopic techniques are needed to improve dysplasia detection. The role of artificial intelligence (AI) in lesion detection during colonoscopy is well established in patients without IBD, but remains unclear in those with IBD [1–6].
A systematic review has been carried out to assess the diagnostic yield of AI software for detecting dysplasia in patients with IBD, specifically CADe systems designed for dysplasia detection.

Methods A Systematic literature searches was conducted on Medline, Cochrane Library, Web of Science, IEEE, ACM, and Scopus between 2015-2025. All retrieved references were imported to the Rayyan software for assessment for eligibility. The quality of included studies was assessed using the QUADAS-2 tool.

Results The systematic search identified 3032 studies, which were screened through multiple stages. Duplicates (n = 1408) were identified and removed, and a further 1,618 studies were excluded for not meeting the inclusion criteria (e.g., not addressing the study question or not being original research). Ultimately, three studies specifically investigated the detection of dysplasia during surveillance colonoscopy in patients with IBD. However, due to substantial heterogeneity in study design— including prospective real-time lesion detection in colonoscopy videos, image-based lesion detection, lesion classification, and image-based AI model development —the results could not be pooled for a meta-analysis. Therefore, a descriptive analysis was performed instead. An additional three studies explored related topics, including dysplasia classification, polyp detection, and comparisons among different AI filters.
In two studies (Abdelrahim et al. 2024 and Vinsard et al 2023), researchers developed IBD-specific CADe systems by retraining existing CADe models using lesions derived from patients with IBD. Abdelrahim et al validated an IBD-dedicated CADe system using both image-based and real-time validation. In image-based validation, the IBD-specific model demonstrated higher performance compared with a generic CADe system. During real-time evaluation, the system achieved a lesion detection rate of approximately 90.4 %. Vinsard et al validated an IBD-CADe model exclusively using images of IBD-associated

lesions. This system, developed with HDWLE images, demonstrated a higher sensitivity, specificity, PPV, and NPV than the original CADe model.

Another study (López-Serrano, A. et al 2024) performed a cross-sectional non-inferiority comparison of Virtual chromoendoscopy (VCE) iScan with CADe Discovery in ulcerative colitis using histopathology as the gold standard. Among 52 eligible patients, 61 lesions were detected. CADe Discovery demonstrated a lesion detection rate similar to VCE iScan.

Additional studies evaluated multiple AI-based filters to determine the most effective filter to identified IBD-related lesions and polyps, contributing to optimization of AI feature selection for IBD surveillance.

A pilot study assessed the capability of a CADe system to differentiate low-grade from high-grade dysplasia and compared it both expert and non-expert endoscopists performance, providing early evidence for AI-assisted dysplasia grading.

Conclusions Few studies have explored the diagnostic yield of AI for the detection and characterization of dysplastic lesions in IBD surveillance colonoscopy. The lack of standardized protocols and heterogenicity, make comparisons between studies and pooled analyses impossible. Thus, more uniformed study designs are required.

eP699 Neoplasia in advanced chronic pancreatitis: A diagnostic challenge

Authors Crivillen O[1], Zaera De La Fuente C[1], Garrido Gallego F[1], Angel PD[1]

Institute 1 Hospital Universitario Infanta Leonor, Madrid, Spain

DOI 10.1055/s-0046-1822026

Abstract Text

A 48-year-old woman, a smoker of 10 cigarettes a day with a history of COPD and intraductal breast carcinoma, was admitted for acute pancreatitis. A CT scan revealed a prominent pancreatic head with inflammatory changes in the surrounding fat, causing dilation of the pancreatic duct (duct of Wirsung). These findings could be related to a focal area of chronic pancreatitis, although an underlying neoplastic lesion could not be ruled out. An MRI was performed, yielding similar results. An endoscopic ultrasound was then performed, revealing marked signs of chronic pancreatitis, with intraparenchymal and intraductal stones and secondary dilation of the main pancreatic duct. Although no clear lesion was observed in the prominent area in the head, a biopsy was performed, with histology consistent with chronic pancreatitis. Two months later, the patient was admitted for painless jaundice with bilirubin up to 13 mg/dL, which improved spontaneously to 4 mg/dL. During this admission, CT and MRI scans were repeated, which were similar to the previous ones except for now showing dilation of the biliary tract. The echoendoscopy was repeated, without identifying a clear lesion in this exploration either, but a puncture was again performed in the head of the pancreas in the area adjacent to the amputation of the common bile duct, and on this occasion findings compatible with pancreatic ductal adenocarcinoma were observed. Following this, the patient underwent surgery, performing a cephalic duodenopancreatectomy with histology compatible with well-differentiated pT2N1 ductal pancreatic adenocarcinoma with low-grade PanIn in contact with the pancreatic margin; after surgery, treatment was initiated by oncology with FOLFIRINOX, with good clinical evolution.

This case demonstrates how challenging it is to diagnose a pancreatic tumor when it is located within a pancreas with advanced chronic pancreatitis. In our case, jaundice was the alarming sign that made us reconsider the case; a new endoscopic ultrasound with puncture was performed, using the amputation of the common bile duct as a guide when selecting the area to be biopsied, thus resulting in a correct diagnosis with the subsequent establishment of treatment.

DOI 10.1055/s-0046-1822027

Aims Third-space endoscopy generates recognizable postoperative CT changes, yet distinguishing expected findings from true complications remains challenging; this study aimed to define the radiologic signature and identify features linked to clinically relevant events [1].

Methods We performed a single-center retrospective analysis of patients who underwent third-space endoscopy and received standardized postoperative CT within 24 hours. CTs were reviewed using a structured template and quantified with accepted radiologic scales, and categorized as expected or suspected complications. Clinical variables included procedure type, duration, age, and complications requiring management change. Analyses were conducted in R 4.4.2.

Results Of the 91 patients who underwent third-space endoscopy, 79 received postoperative CT imaging and were included. Baseline characteristics and CT findings are summarized in the Table. Thoracic abnormalities were frequent, with pneumomediastinum being the dominant finding. Pleural effusions were mostly small and bilateral; all moderate effusions occurred after esophageal POEM or gastric STER, resolved spontaneously, and were associated with longer procedure duration (90 vs 30 min, $p = 0.0015$). Pericardial effusion showed no association with procedure duration. Radiologic evidence of chronic aspiration was more common in older patients, and atelectasis was highly prevalent. No hydropneumomediastinum, mediastinal collections, or pleural/mediastinal abscess was identified, and all thoracic findings resolved on follow-up imaging. Abdominal findings were mild. Pneumoperitoneum was consistently limited in extent, with occasional retroperitoneal air. Subcutaneous emphysema was common, exclusively after esophageal procedures, and did not correlate with procedure duration. In achalasia cases, esophageal wall thickening at the procedure site showed no relationship to procedural duration, while intramural air and visualized submucosal tunnels were common and fluid-free. No contrast leak, hematoma, or localized collection was observed.A radiologist flagged 13 CTs as suspected complications, but only two reflected clinically relevant

events: a persistent mucosal defect after POEM requiring stenting and a gastrografin leak after gastric STER successfully managed endoscopically, with no leak on next-day imaging (▶ **Table 1**).

▶ **Table 1** Baseline Characteristics and Distribution of CT Findings Across Third-Space Endoscopic Procedures

Demographics	Gender: Male 43 (54.4 %); Female 36 (45.6 %); Age, median (range) 64 (17-87)
Thoracic findings	Pneumomediastinum: Z-POEM 23/29 (86.2 %); POEM 40/42 (95.2 %); Pneumothorax (volume < 30 %): Z-POEM 5/29 (17.2 %); POEM 2/42 (4.7 %); Pleural effusion: Z-POEM 6/29 (20.6 %); POEM 25/42 (59.5 %) G-STER: 2/3 (66.6 %); Hydropneumothorax: Z-POEM 1/29 (3.4 %); Pneumopericardium: Z-POEM 1/29 (3.4 %); Pericardial effusion: Z-POEM 1/29 (3.4 %); POEM 10/42 (23.8 %);
Pulmonary parenchymal changes	Aspiration pneumonitis/ infiltrates: Z-POEM 9/29 (31.0 %); POEM 17/42 (40.4 %); G-POEM 3/3 (100 %); Atelectasis: Z-POEM 13/29 (44.8 %); POEM 36/42 (85.7 %); E-STER 1/1 (100 %); G-POEM 3/3 (100 %)
Peritoneal and retroperitoneal findings	Pneumoperitoneum: Z-POEM 1/29 (3.4 %); POEM 41/42 (97.6 %); G-POEM 2/3 (66.6 %); G-STER 3/3 (100 %); Retroperitoneal air: POEM 8/42 (19.0 %); G-POEM 1/3 (33.3 %); Ascites (minimal – perihepatic fluid collection): POEM 1/42 (2.3 %); Subcutaneous emphysema: Z-POEM 24/29 (82.7 %); POEM 27/42 (64.2 %); E-STER 1/1 (100 %)

Conclusions Post–third-space endoscopy CT shows a consistent pattern of expected changes, while true complications are rare. Multicenter studies are needed to validate these imaging signatures and enhance their diagnostic utility.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP701 Pre-closure High-Resolution Anorectal Manometry to Predict Post-closure Function After Stoma Reversal: a Single-Centre Pilot Study

Authors Dağcı G[1], Yağlı MA[1], Gurbanov A[1], Ağargün BF[1], Telli P[1], Genç Uluçeçen S[1], Çavuş B[1], Kadir D[1], Selman FB[1], Kaymakoğlu S[1], Akyüz F[1]
Institute 1 Istanbul University Faculty of Medicine, Istanbul, Türkiye
DOI 10.1055/s-0046-1822028

Aims Bowel dysfunction after stoma reversal,often captured by the Low Anterior Resection Syndrome (LARS) and Wexner incontinence scores,can impair quality of life. We assessed whether pre-closure high-resolution anorectal manometry (ARM) provides clinically useful discrimination of post-closure functional outcomes [1].

Methods In this single-centre retrospective pilot, ten consecutive adults undergoing planned stoma reversal had pre-closure ARM with anal resting pressure (RP) and maximal squeeze pressure (SP). Post-closure outcomes were LARS and Wexner scores; major LARS was defined as ≥ 30 and major incontinence as Wexner ≥ 11. Continuous data are reported as median (IQR). Discrimination was evaluated with ROC curves.We also explored Pearson correlations and Mann–Whitney U tests, and examined the association between the rectoanal inhibitory reflex (RAIR) and major incontinence (Wexner ≥ 11) using Fisher's exact test.

Results The cohort was 70 % male with a median age of 59 years (48.2–61.8). Surgical indications comprised rectal cancer (6/10), Fournier's gangrene (2/10), Crohn's disease (1/10), and colon cancer (1/10).Median RP and SP were 31 mmHg (22–59) and 77 mmHg (67–98), respectively. LARS categories were < 20 in 1/10, 20–29 in 7/10, and ≥ 30 in 2/10; major Wexner occurred in 4/10. For predicting major LARS, RP showed moderate discrimination (AUC 0.69) with an approximate optimal threshold of 29 mmHg (sensitivity 1.00, specificity 0.50), while SP yielded an AUC of 0.72 with an optimal threshold around 286.5 mmHg (sensitivity 0.50, specificity 1.00). Against major Wexner, discrimination was weaker (RP AUC 0.54; SP AUC 0.60). Pearson correlations between pressures and both LARS and Wexner were not statistically significant, and Mann–Whitney U comparisons showed no significant group differences. RAIR absence tended to coincide with a higher rate of major incontinence (66.7 % [2/3] vs 28.6 % [2/7]); Fisher's exact test gave an odds ratio of 5.0 (p = 0.50). Confidence intervals were wide across analyses, reflecting the small sample and low number of positive events.

Conclusions In this pilot series, pre-closure ARM,particularly resting pressure,offers only modest ability to distinguish patients at risk of post-closure functional impairment, while discrimination against major Wexner incontinence is limited. RAIR absence may signal higher incontinence risk, but the study is underpowered. These hypothesis-generating findings merit confirmation in larger, preferably multicentre, cohorts and may help refine clinically meaningful thresholds for decision-making before stoma reversal.

eP702V Case Study Video of Rare Gastrointestinal Stromal Tumors (GIST) Discovered during a Colonoscopy in a patient in Nigeria

Authors Onabanjo T[1], Adetona A[2], Awosola A[1]
Institutes 1 OUTPATIENT SURGERY AND ENDOSCOPY CLINIC (OSEC), Lagos, Nigeria, Federal Republic of; 2 SYNLAB NIGERIA REFERENCE LABORATORY, Lagos, Nigeria, Federal Republic of
DOI 10.1055/s-0046-1822029

Abstract Text

Gastrointestinal Stromal Tumors (GISTs) is a form of rare mesenchymal tumors and accounts for < 1 % of all gastrointestinal tumors. GISTs are rarer in the colon. A 44-year-old male had irregular bowel movements, rectal bleeding and right iliac fossa pain. Colonoscopy revealed an ileum mass intussusception into the ascending colon. Histology revealed gastric tissue lined by hyperplastic epithelium, proliferating mesenchymal neoplasm composed of atypical epithelioid cells disposed basically in sheets with central nuclei and moderate eosinophilic to clear cytoplasm. > Ten mitoses in 40hpf and focal congestion, necrosis, and hemorrhages seen. Features suggestive of Epitheloid GIST. A hemicolectomy was performed with an oncology review: The patients one year post surgery surveillance colonoscopy was normal. This case underscores the role of colonoscopy in diagnosing rare tumors.

eP703 Effect of Midodrine on Short Term Mortality and Liver Function in Patients with Cirrhosis and Ascites: A Systematic Review and Meta-analysis

Authors Dağcı G[1], Yağlı MA[1], Çavuş B[1], Kadir D[1], Selman FB[1], Kaymakoğlu S[1], Akyüz F[1]
Institute 1 Istanbul University Faculty of Medicine, Istanbul, Türkiye
DOI 10.1055/s-0046-1822030

Aims Midodrine, an α1-adrenergic agonist, has been proposed as a vasoconstrictor therapy to counteract circulatory dysfunction in patients with cirrhosis and ascites. Its potential impact on clinical outcomes, particularly mortality and liver function, remains under active investigation.

Methods A systematic search was conducted for randomized controlled trials comparing midodrine (with or without rifaximin) to standard medical therapy or albumin in cirrhotic patients with ascites. RevMan 5.4 was used to conduct meta-analyses of mortality (binary outcome) and MELD scores (continuous outcome). Heterogeneity was evaluated using I^2 statistics (▶ **Table 1**).

Results Four RCTs, including a total of 729 patients (464 midodrine, 265 control), met the inclusion criteria.Midodrine significantly reduced short-term (12 weeks)mortality compared to SMT (OR: 0.22; 95 % CI: 0.11–0.44; $p < 0.0001$; $I^2 = 29\,\%$).Midodrine was also associated with a greater reduction in MELD score (MD: − 2.49; 95 % CI: − 2.74 to − 2.25; $p < 0.00001$; $I^2 = 0\,\%$).Heterogeneity was low for both outcomes. No serious adverse effects were reported. Mild symptoms such as thirst and abdominal discomfort were noted in two studies. Midodrine was generally used at 7.5–12.5 mg TID. One study combined midodrine with rifaximin.

Conclusions Midodrine is associated with significant improvements in both short-term mortality and liver function, as assessed by MELD score, in patients with cirrhosis and ascites. These findings support the consideration of midodrine as a therapeutic adjunct in selected patients. Further large-scale, multicenter trials are warranted to validate these results.

eP704 Deep Learning Model for Mayo Score Classification from Colonoscopy Images: Validation with CRP, Histological Activity, and Endoscopist Agreement

Authors Dağcı G[1], Yağlı MA[1], Gurbanov A[1], Mammadov S[1], Ağargün BF[1], Telli P[1], Genç Uluçeçen S[1], Çavuş B[1], Ciftcibasi OA[1], Kadir D[1], Selman FB[1], Kaymakoğlu S[1], Akyüz F[1]
Institute 1 Istanbul University Faculty of Medicine, Istanbul, Türkiye
DOI 10.1055/s-0046-1822031

Aims n this study, an artificial intelligence (AI) model was developed that automatically assigns Mayo 0–3 scores to colonoscopy images performed at a single center. The model's performance was compared with CRP, histological activity (Nancy score), and observer assessments.

Methods In this single-center, retrospective study, 4000 colonoscopy images (approximately 1000 frames from each Mayo category) from approximately 150 ulcerative colitis patients were analyzed. An average of 30–40 frames were selected from each patient to represent different colon segments. Data were split into 80 % training and 20 % validation on an episode-by-episode basis. EfficientNet-B0 (ImageNet pre-trained) was used as the model.Model performance was assessed using accuracy, macro-F1, macro-AUC, confusion matrix, and class boundary separations AI_prob_active_M2M3 = p^-(Mayo2) + p^-(-Mayo3), calculated at the episode level, was compared with CRP and Nancy score using Spearman correlation.Human-AI agreement was measured by two independent endoscopists blindly evaluating a subset of samples.

Results The model achieved 61.8 % accuracy on the validation set, macro-F1 = 0.60, and macro-AUC = 0.94. This agreement was similar to the inter-observer agreement at the Mayo 1–2 boundary. The model performed excellently in distinguishing active from inactive (AUROC(0 vs > = 1) = 0.96, AUROC(< = 1 vs > = 2) = 0.99). A significant positive correlation was observed between AI-Mayo and CRP ($\rho = 0.6$, $p < 0.01$). The AI_prob_active_M2M3 value demonstrated high discrimination power (AUROC = 0.85) in the presence of active histology (Nancy > = 1). High agreement ($\kappa = 0.8$) was found between the two observers; model predictions largely agreed with the observers' assessments.

Conclusions The AI model distinguished Mayo 0 from 3 from colonoscopy images with near-human accuracy. The model's high agreement with biochemical and histological activity demonstrates its potential for clinical decision support in the objective and reproducible assessment of mucosal healing.

eP705 Endoscopic drainage of a splenic abscess using a lumen-apposing metal stent: a case report and systematic literature review

Authors Shoval Y[1], Locatelli R[1], Arnoldi C[2], Monteduro C[2], Biancheri P[1], Armellini E[1]
Institutes 1 Digestive Endoscopy Unit, ASST Bergamo Est, Seriate, Italy; 2 Internal Medicine Unit, ASST Bergamo Est, Seriate, Italy
DOI 10.1055/s-0046-1822032

Abstract Text

Splenic abscesses are rare and often refractory to antibiotic therapy. Percutaneous drainage may not be feasible due to limited anatomical access, and surgical treatment is invasive. We report the case of a 62-year-old man with multiple comorbidities including morbid obesity and type II diabetes who was admitted due to sepsis secondary to vertebral osteomyelitis. Contrast-enhanced abdominal CT scan revealed a 44mm well-demarcated fluid collection with a thickened capsule consistent with a splenic abscess. Endoscopic ultrasound (EUS) confirmed a 40mm hypo-/anechoic collection accessible from the gastric body. EUS-guided transgastric drainage was performed using a 10 × 10mm lumen-apposing metal stent (LAMS), resulting in immediate purulent drainage into the gastric cavity. The patient improved rapidly and CT scan confirmed complete resolution of the abscess. LAMS was removed after one week.

We investigated how many cases of EUS-guided splenic abscess drainage have been performed so far. We conducted a systematic literature review on PubMed using the searching terms “splenic abscess” AND “endoscopic drainage” or “lumen-apposing metal stent”. We included all studies and case reports describing a comparable scenario to the presented case.

Our search retrieved eight publications describing a total of ten cases of EUS-guided splenic abscess drainage. Three abscesses were drained with a plastic stent and four using a pigtail stent. Only three of the previously described cases involved LAMS placement.

Regardless of the etiology and predisposing factors, EUS-guided drainage using LAMS is a safe, effective, and less invasive treatment option compared to surgical or percutaneous drainage.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP706 Diagnostic accuracy of detective flow imaging endoscopic ultrasound in pancreatic lesions: a systematic review and meta-analysis

Authors Antonini F[1], Balducci D[2], Vinci A[3], Stigliano S[4], Di Matteo FM[4], Montale A[5], Valvano M[5]
Institutes 1 Hospital "C. and G. Mazzoni", Ascoli Piceno, Italy; 2 Clinic of Gastroenterology, Hepatology, and Emergency Digestive Endoscopy, UNIVPM, Ancona, Italy, Ancona, Italy; 3 Tor Vergata University Polyclinic Emergency Room, Roma, Italy; 4 Bio-Medico Campus University Hospital, Rome, Italy; 5 Galliera Hospital, Genova, Italy
DOI 10.1055/s-0046-1822033

Aims Pancreatic diseases are diagnostically challenging due to overlapping imaging features and variable lesion vascularity. While contrast-enhanced harmonic EUS (CH-EUS) improves microvascular visualization, its use is limited by cost and contraindications. Detective flow imaging EUS (DFI-EUS) is a novel, contrast-free Doppler technique with enhanced sensitivity for detecting fine vascular structures and slow blood flow. However, current evidence is limited to small, single-center studies with methodological variability, and its role relative to CH-EUS remains unclear. This meta-analysis aims to evaluate the diagnostic performance of DFI-EUS in pancreatic lesions.

Methods we have conducted a systematic review and meta-analysis including MEDLINE (via PubMed), Scopus, and the Cochrane Library (Central Register of Controlled Trials), covering all available records up to 30 September 2025 (protocol registered on PROSPERO; registration number CRD420251086026).

Results At the end of the selection process, four studies comprising a total of 267 patients were included in the meta-analysis. DFI demonstrated a pooled sensitivity of 0.93 (95 % CI: 0.83–0.98) and a pooled specificity of 0.91 (95 % CI: 0.47–0.99). Among these, two studies evaluated CE-EUS and eFLOW, reporting pooled sensitivity and specificity estimates of 0.96 and 0.94 for CE-EUS, and 0.84 and 0.69 for eFLOW, respectively.

Conclusions This meta-analysis supports the diagnostic value of DFI-EUS for pancreatic lesions. These findings indicate that DFI shows robust discriminatory performance across the included datasets, although further validation with additional data would strengthen the generalizability of these results

eP707 Feasibility of Single-Operator Cold and Hot Snare Endoscopic Resection Using the HOLDFINGER Device: Initial Clinical Experience

Authors Adamo G[1], Leonardi G[1], Solinas I[1], Ovidi F[1], Lapenna L[1], Bronzini F[1], Sostilio A[1], Manta R[1]
Institute 1 Azienda USL Toscana Nord Ovest, Livorno, Italy
DOI 10.1055/s-0046-1822034

Aims Endoscopic removal of colorectal polyps is central to colorectal cancer prevention, with techniques ranging from cold snare polypectomy (CSP) for smaller lesions to hot snare polypectomy (HSP) for selected larger or pedunculated polyps. ESGE guidelines recommend tailoring technique selection to lesion size, morphology, and location. Although effective, these procedures generally require an assistant to actuate the snare. The HOLDFINGER device is a finger-mounted stabilizing system designed to secure the snare handle and may enable autonomous single-operator polypectomy. This study aimed to assess the feasibility and safety of single-operator CSP and HSP using the HOLDFINGER device.

Methods Seven consecutive patients underwent snare polypectomy with the HOLDFINGER device. Procedures were performed autonomously by experienced endoscopists, except one case requiring assistance for submucosal injection and clip placement during HSP of a 20 mm Paris 0-IIa lesion. No patient was on chronic antiplatelet or anticoagulant therapy.Lesions included three flat polyps (two < 10 mm; one 20 mm), one sessile polyp (< 10 mm), and three pedunculated polyps with heads < 15 mm. CSP was used for flat and sessile lesions; HSP for pedunculated lesions and for the 20 mm flat lesion. Locations included three sigmoid, two transverse, and two right-colon lesions. Outcomes included en-bloc and R0 resection, assistance needed, procedure time, and complications.

Results All lesions were resected en-bloc with R0 margins. Mean procedure time was 6 minutes. One intraprocedural bleeding event during HSP of a pedunculated polyp was controlled with clip placement, with no other intraprocedural or delayed bleeding. Assistant involvement was limited to lifting and clip deployment. No perforation or additional complications occurred.

Conclusions Single-operator CSP and HSP using the HOLDFINGER device appeared feasible and safe in this small series. Larger studies are required to confirm these findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP708 Surveillance of high-risk individuals for pancreatic cancer in the Czech Republic

Authors Krivinka J[1, 2], Kunovsky L[1, 3, 4, 2], Urban O[1, 2], Tacheci I[5], Sembera S[5], Hucl T[6], Macinga P[6], Mares J[6], Stepan M[7], Vitek P[8], Prochazka R[9], Balihar K[10], Mareš K[11], Kraus M[12], Falt P[1, 2]

University, University Hospital, Hradec Kralove, Czech Republic; 6 Institute of Clinical and Experimental Medicine, Prague, Czech Republic; 7 Nemocnice AGEL Ostrava-Vítkovice a.s., Ostrava, Czech Republic; 8 Beskydy Gastrocentre, Frydek-Mistek, Czech Republic; 9 Jablonec nad Nisou Hospital, Jablonec nad Nisou, Czech Republic; 10 University Hospital in Pilsen, Plzeň, Czech Republic; 11 Na Homolce Hospital, Prague, Czech Republic; 12 Ostrava City Hospital, Ostrava, Czech Republic
DOI 10.1055/s-0046-1822035

Aims Pancreatic ductal adenocarcinoma (PDAC) remains a highly lethal disease. The Czech Republic ranks 6th globally in PDAC mortality. This study reports the baseline findings from the first year of a prospective, multicenter surveillance program in the Czech Republic.

Methods In this prospective cohort study, we enrolled asymptomatic high-risk groups with an increased risk of developing pancreatic cancer. These groups included individuals with positive family history of PDAC, hereditary chronic pancreatitis, or confirmed genetic mutations (BRCA1/2, Lynch syndrome, Peutz-Jeghers syndrome, etc.).

Surveillance consisted of annual endoscopic ultrasound (EUS), magnetic resonance imaging (MRI) and blood sampling for analysis of fasting glucose, glycated hemoglobin (HbA1c) and potentially tumor markers (CA 19-9, CEA). The data are subsequently entered into an eCRF and statistically evaluated.

Results Between 2023 and 2025, a total of 373 high risk individuals (HRIs) were enrolled across nine centres from the Czech Republic (59.2 % were female; the mean age was 56 years with range 19 – 80 years). Based on the indication criteria, most HRIs were included due to positive family history of PDAC (264 patients, 70.8 %) and BRCA2 positivity (59 patients, 15.8 %).

The baseline EUS examination was performed in 316 patients with identifying 108 pathological findings (34.2 %). These included 69 cystic lesions (21.8 % of all EUS performed), 20 cases of chronic pancreatitis (6.3 %) and 4 solid lesions (1.3 %). The solid lesions consisted of 1 PDAC and 3 pancreatic neuroendocrine tumors (NETs). Main pancreatic duct dilatation was observed only in 2 cases (0.6 %) and other findings in 13 cases (4.1 %)- mostly anechogenic lesions.

Baseline MRI/MRCP was performed in 282 patients detecting 58 pathological findings (20.6 %), including 41 cystic lesions (14.5 %), 8 cases of chronic pancreatitis (2.8 %) and other findings in 9 cases (3.2 %).

The study demonstrated excellent patient adherence within the long-term surveillance registry. Out of the total cohort of 373 HRIs enrolled across the nine Czech centres, a low number of participants, specifically 10 patients (2.7 %), declined further continuation of the follow-up program and were subsequently lost to follow-up.

Conclusions Baseline data from the HePaCaS registry demonstrate that surveillance in HRIs successfully detected premalignant and malignant lesions, specifically one adenocarcinoma and three neuroendocrine tumors. These findings support the utility of a structured surveillance program, though long-term follow-up is required to confirm survival benefits.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP709 A Rare Cause of Dysphagia: Oeosophagal stenosis due to IgG4 Disease From diagnosis to management

Authors Triki L[1], Verset L[2], Ilzkovitz M[3], Beun A[1], Eisendrath P[1]
Institutes 1 CHU Saint-Pierre, Bruxelles, Belgium; 2 Hospital Erasme HUB, Brussels, Belgium; 3 Hospital Erasme, Bruxelles, Belgium
DOI 10.1055/s-0046-1822036

Abstract Text

IgG4-related disease (IgG4-RD) is a recognized systemic fibro-inflammatory condition characterized by a dense lymphoplasmacytic infiltrate rich in IgG4-positive cells and storiform fibrosis. Although initially described in pancreatic affections in 2001 and 2003, it is now known to affect virtually every organ, including the biliary tract, salivary glands, pancreas, kidneys, lungs for example, and rarely, the esophagus.

Diagnosis relies on a constellation of criteria: elevated serum IgG4 levels , characteristic histopathology (lymphocytic infiltration, obliterative phlebitis, and storiform fibrosis with organ-specific diagnostic criteria), and location.

We report the case of a 47-year-old female patient with a medical history including three episodes of acute pancreatitis, two episodes of pyelonephritis, and insulin-requiring type 2 diabetes. She presented for evaluation of dysphagia that had been evolving over two years. Endoscopy revealed a benign appearing stricture impassable by an adult endoscope. An upper gastrointestinal series and an abdominal CT scan confirmed the presence of marked esophageal wall thickening and a regular stricture in the middle third of the esophagus. A subsequent PET-CT scan showed an isolated hypermetabolism of the esophageal walls, suggestive of an oncological or an inflammatory process.

Endoscopic ultrasound (EUS) was performed due to parietal mucosal thickening, followed by submucosal wall tissues acquisition with fine needle biopsy (FNB). Histological results from the FNB demonstrated a lymphoplasmacytic infiltrate with an IgG4 quantification of 22 cells per 40x high-power field (HPF), highly suggestive for the diagnosis of IgG4-RD. Screening for other organ involvement revealed suspected renal and myocardial affection. Treatment with corticosteroids (dose?) was significantly delayed due to the presence of latent tuberculosis infection and poorly controlled diabetes, which was further dyregulated by the use of corticosteroids. A concomitant corticosteroid-sparing regimen with azathioprine was attempted in view the adverse effects associated with corticosteroid treatment but did not lead to clinical improvement. Ultimately, treatment with Rituximab was initiated after 9 months, resulting in the beginning of symptomatic improvement.

This case highlights, a rare cause of dysphagia (esophageal IgG4-RD) and, the significant difficulty in managing this condition due to the patient's complex comorbidities (diabetes, latent tuberculosis). The certainty of the diagnosis and the follow-up of the treatment in this case necessitate a multidisciplinary approach and close cooperation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP710 Differences in the outcomes of patients with gastrointestinal bleeding according to admission ward: a 25-years population-based study in the Veneto Region, Italy (2000-2024)

Authors Germanà B[1], Meneghel P[1], Dal Pont E[1], Girardi G[2], Salmaso L[3], Russo N[1], Galliani E[1], Giacomin A[1], Menini M[4], Hassan C[5], Saia M[3]
Institutes 1 UOC Gastroenterologia ed Endoscopia Digestiva, Belluno, Italy, Belluno, Italy; 2 University of Padua, Padua, Italy, Padua, Italy; 3 UOC Governo Clinico Azienda Zero, Padova, Italy, Padua, Italy; 4 Humanitas Research Hospital, Cascina Perseghetto, Italy; 5 IRCCS Humanitas Research Hospital, Milano, Italy
DOI 10.1055/s-0046-1822037

Aims Gastrointestinal bleeding (GIB) remains one of the leading causes of emergency hospital admission for gastrointestinal disorders and continues to represent a major source of morbidity and mortality. Yet, there are limited data on the effect of the specialist care setting on the outcomes of the GIB hospitalized patients. In the present study, we aimed to assess the main care process and clinical indicators of hospitalized GIB patients in the Veneto Region from 2000 to 2024, according to the admission ward.

Methods A retrospective analysis based on the anonymous regional Hospital Discharge Records database was carried out including all discharges from hospitals operating under the National Health Service in the Veneto Region in the period 2000-2024 with a Diagnosis-Related Group (DRG) code equal to 174 ("Gastrointestinal Haemorrhage with Complications") or 175 ("Gastrointestinal Haemorrhage without Complications"), or any surgical DRG with a principal discharge diagnosis indicative of GIB. Selected cases were stratified into the site of bleeding (upper, lower, unspecified), the admission area (medical, surgical or other) and, for those hospitalized in the medical area, into gastroenterology ward or different ward (e.g., internal medicine). The mean length of

stay (LOS) among patients discharged alive and the in-hospital case-fatality risk (CFR) were calculated. Multivariate logistic regression models were used to assess the association between the admission ward (gastroenterology vs other medical ward) and the in-hospital CFR.

Results During the 25-year observation period, 99,731 patients were hospitalized for GIB in the Veneto Region: 57.4 % in medical area, 39.6 % in surgical area and 3.0 % in other wards. Males represented 55.2 % of them and accounted for the most in each area. The mean age of GIB hospitalized patients was 70.6 ± 18.1 years and they were older in medical area (73.7 ± 15.2 years) than in surgical area (69.2 ± 16.7 years). Upper GIB was the most represented site of bleeding among patients admitted to the medical area (53.0 %), whereas lower GIB prevailed among patients admitted to the surgical area (52.5 %).

The overall in-hospital CFR was 5.0 % and the mean LOS was 9.3 ± 8.3 days. Both indicators were higher among patients admitted to the medical area compared with those hospitalized in a surgical ward: the CFR was 5.4 % and 4.0 %, respectively, whereas the mean LOS was 9.9 ± 8.2 days and 8.5 ± 7.8 days, respectively.

Among GIB patients cared for in the medical area (n = 57,204), the mean LOS was 7.1 ± 5.9 days in the gastroenterology wards compared to 10.7 ± 8.6 days in other wards. Inside the medical area, significant difference emerged also for the in-hospital CFR, which was 2.3 % in gastroenterology wards and 6.4 % elsewhere. After adjustment for all the other examined variables (sex, age, calendar year and need for surgery), the adjusted odds of in-hospital death decreased by more than half among patients with upper GIB admitted to a gastroenterology ward compared to those admitted to a different medical ward (Odds Ratio 0.48, 95 % CI 0.40 to 0.58, p < 0.0001), and about two-thirds among patients with lower (Odds Ratio 0.33, 95 % CI 0.25 to 0.43, p < 0.0001) or unspecified GIB (Odds Ratio: 0.34, 95 % CI 0.27 to 0.43, p < 0.0001).

Conclusions The management in a gastroenterology ward appears to be associated with improved care process and clinical outcomes, irrespective of the site of bleeding. These findings may provide guidance to both health policymakers and clinicians involved in the management of patients presenting with GIB.

eP711V Successful Application Of Argon Plasma Coagulation For Duodenal Dieulafoy's Lesion In Very Low Birth Weight Premature Neonate

Authors Tzivinikos C[1], Alsarhan A[1], Kanannari F[1], Shankar S[1], Robins J[1], Siddiqui A[1]
Institute 1 Al Jalila Children's Hospital, Dubai, United Arab Emirates
DOI 10.1055/s-0046-1822038

Abstract Text

A male baby, born at 29 weeks with a birth weight of 1.2kg,at week 4, he presented with recurrent hematemesis and melena, leading to shock. Treatment included repeated blood transfusions, octreotide infusions. An upper GI endoscopy revealed a Dieulafoy's lesion in the first part of the duodenum. Local injection of epinephrine 1:1000 failed to prevent recurring bleeding.Forty-eight hours later, a second endoscopy with a GIF XP190 video-gastroscope was performed and targeted APC (30W, 1L/m) was applied to the lesion, successfully stopping the bleeding without recurrence.Our case is the only reported instance of successful endoscopic management of a duodenal Dieulafoy's lesion in the duodenum in a preterm baby with very low birth weight.

eP712 Twenty-Five-Year Trends in Hospitalizations for Gastrointestinal Bleeding in the Italian Veneto Region (2000–2024)

Authors Germanà B[1], Menini M[2], Hassan C[3], Meneghel P[1], Russo N[1], Salmaso L[4], Giacomin A[1], Galliani E[1], Dal Pont E[1], Girardi G[5], Saia M[4]
Institutes 1 UOC Gastroenterologia ed Endoscopia Digestiva, Belluno, Italy, Belluno, Italy; 2 IRCCS Humanitas Research Hospital, Milano, Italy, Milan, Italy; 3 IRCCS Humanitas Research Hospital, Milano, Italy; 4 UOC Governo Clinico Azienda Zero, Padova, Italy, Padua, Italy; 5 University of Padua, Padua, Italy, Padua, Italy
DOI 10.1055/s-0046-1822039

Aims Gastrointestinal bleeding (GIB) remains one of the leading causes of emergency hospital admission for gastrointestinal disorders and continues to represent a major source of morbidity and mortality, particularly in aging populations, where widespread use of antithrombotic and anticoagulant agents increases bleeding risk. Long-term population-based data on GIB hospitalizations in Europe are limited. This study assessed 25-year trends in hospitalization rates for upper (U-GIB), lower (L-GIB), and undefined GIB (UN-GIB) in the Veneto Region, in Northeastern Italy.

Methods All GIB admissions from 2000 to 2024 were identified through regional Hospital Discharge Records using ICD-9-CM codes. Age- and sex-standardized hospitalization rates (HRs) per 100,000 residents were calculated annually. Temporal trends were evaluated using Joinpoint regression and expressed as average annual percent change (AAPC).

Results A total of 99,731 GIB admissions were recorded, including 46.6 % U-GIB, 39.5 % L-GIB, and 13.9 % UN-GIB. The standardized hospitalization rate (HR) decreased from 122.4 to 55.0 per 100,000 population (AAPC − 3.6 %; 95 % CI − 3.9 to − 3.4; $p < 0.001$) from 2000 to 2024. U-GIB declined from 76.3 to 20.1 per 100,000 (AAPC − 5.98 %; 95 % CI − 6.46 to − 5.50; p < 0.001), L-GIB from 30.7 to 28.0 per 100,000 (AAPC − 0.92 %; 95 % CI − 1.31 to − 0.53; p < 0.001), and UN-GIB from 15.3 to 6.8 per 100,000 (AAPC − 3.64 %; 95 % CI − 4.26 to − 3.02). L-GIB exceeded U-GIB from 2011 onwards, in 2008 among females and 2018 among males. Hospitalization rates were consistently higher in males across all bleeding sites. Age-specific rates rose progressively with age, with L-GIB surpassing U-GIB in individuals aged ≥ 85 years and earlier in females (65–74 years).

Conclusions GIB hospitalizations in the Veneto region declined by more than half over 25 years, driven by a steep reduction in U-GIB and a modest decrease in L-GIB. L-GIB has become the most frequent bleeding site, with clear age- and sex-related differences. These long-term trends indicate a shifting epidemiologic burden that should guide future preventive and diagnostic strategies.

eP713 Sex- and Age-Specific Trends in In-Hospital Mortality from Gastrointestinal Bleeding: A 25-Year Study in the Veneto Region

Authors Germanà B[1], Meneghel P[1], Menini M[2], Hassan C[3], Salmaso L[4], Russo N[1], Galliani E[1], Giacomin A[1], Dal Pont E[1], Girardi G[5], Saia M[4]
Institutes 1 UOC Gastroenterologia ed Endoscopia Digestiva, Belluno, Italy, Belluno, Italy; 2 Humanitas Research Hospital, Cascina Perseghetto, Italy; 3 IRCCS Humanitas Research Hospital, Milano, Italy; 4 UOC Governo Clinico Azienda Zero, Padova, Italy, Padua, Italy; 5 University of Padua, Padua, Italy, Padua, Italy
DOI 10.1055/s-0046-1822040

Aims Gastrointestinal bleeding (GIB) remains one of the leading causes of emergency hospital admission for gastrointestinal disorders and continues to represent a major source of morbidity and mortality. Its burden is particularly relevant in aging populations, where widespread use of antithrombotic and anticoagulant agents increases bleeding risk. We aimed to conduct a comprehensive, methodologically consistent, population-based analysis of GIB in

Endoscopy 2026; 58: S1–S1041

hospital-mortality in the Veneto Region (Northeastern Italy) over a 25-year period.

Methods A retrospective analysis based on the anonymous regional Hospital Discharge Records database was carried out including all discharges from hospitals operating under the National Health Service in the Veneto Region in the period 2000-2024 with a Diagnosis-Related Group (DRG) code equal to 174 ("Gastrointestinal Haemorrhage with Complications") or 175 ("Gastrointestinal Haemorrhage without Complications"), or any surgical DRG with a principal discharge diagnosis indicative of GIB. Moreover, selected cases were stratified into upper, lower or unspecified GIB, based on the site of bleeding. Crude in-hospital Case-Fatality Risks (CFR) were calculated among all GIB patients and expressed per 100 patients. Annual trends were analysed in terms of Annual Percentage Change (APC) and Average Annual Percent Change (AAPC).

Results During the 25-year observation period, 99,731 patients were hospitalized for GIB in the Veneto Region. Upper, lower, and unspecified GIB accounted for 46.6 %, 39.5 %, and 13.9 % of cases, respectively. The mean age of patients was 70.6 ± 18.1 years. Males represented 55.2 % of all GIB cases and were significantly younger than females (67.0 ± 18.2 vs. 75.1 ± 16.9 years, respectively; p < 0.001).

Crude in-hospital CFR for GIB was 5.0 % during the 25-year observation period and it was higher in females than in males (5.6 % vs 4.5 %; crude OR 1.26; 95 % CI 1.19 to 1.33). It was 2-fold higher in unspecified GIB (8.8 %) than in upper GIB and lower GIB (4.4 % each). Overall, CFR decreased from 5.4 % in 2000 to 4.4 % in 2018 (APC -0.71 %, 95 % CI − 4.29 to + 0.06, p = 0.056) but increased again in the latest years of the study (APC + 3.42 %, 95 % CI − 0.14 to + 14.15, p = 0.062), peaking at 5.9 % in 2021. Considering the 25-year period, only unspecified GIB showed a significantly decreasing trend in the crude in-hospital CFR (AAPC -1.31 %, 95 % CI − 2.55 to − 0.27, p = 0.019).

Conclusions Despite an aging population and a progressive shift toward outpatient management of low-risk cases, the crude in-hospital CFR showed only a slight reduction in the Veneto Region from 2000 to 2024.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP714 Navigating the uncharted cross roads: Endoscopic solutions for Tracheoesophageal Fistula: 15 case series

Authors Donapati VR[1], Dr HKG[2], Ravi SB[1], Guduru RSR[1], Rakesh KA[1], Anil KM[1], Bongu SS[3], Prasad BT[2], Sreekanth CN[4]

Institutes **1** Yashoda Hospitals – Secunderabad, Secunderabad, India; **2** Yashoda Hospitals | Secunderabad, Secunderabad, India; **3** Yashoda Hospitals, Secunderabad, India; **4** Yashoda hospital secunderabad, Hyderabad, India

DOI 10.1055/s-0046-1822041

Aims To describe real-world outcomes of endoscopic management of Tracheo-Esophageal Fistula(TEF) across varied etiologies and to suggest a practical, algorithm-based approach to intervention selection [1–9].

Methods We present a retrospective series of 15 consecutive TEF cases managed at Yashoda Hospital, Secunderabad, India, a tertiary care centre, seen from December 2022 till November 2025 (▶ **Table 1**).

▶ **Table 1** Suggested Algorithm for TEF Management

1. Confirm Diagnosis: Imaging, Scopies, Characterise- Size, location, cause
2. Airway Management + /- Airway Stenting
3. Nutrition management and Assess fitness for Surgery
4. Endoscopic Options

Results We hereby share our experience of 15 cases of TEF. According to the etiology, two main groups have been identified- Malignant and Benign causes of TEF (▶ **Table 2**).

▶ **Table 2**

Malignant TEF	Benign TEF
Esophageal SEMS + /- Tracheal Stenting	Defect < 5mm: Clipping + /- APC of edges
	5-10mm: OTSC/ ASD Closure Device
	10-12 mm: ASD Closure Device/ EndoSuture
	> 12 mm: Dual Stenting/ Surgery
	Defect > 15mm: Surgery

1. **Malignant TEF** (n = 6) due to Carcinoma Esophagus: All underwent partially covered esophageal SEMS placement, achieving good technical and clinical success.
2. **Benign Causes of TEF** (n = 9): According to the etiology again, 3 subgroups were identified:

i) **Post-intubation TEF** (n = 4):
- ASD closure device placement: 2 patients (successful).
- Tracheal stent + OTSC: 1 patient (successful).
- OTSC alone: 1 patient (partial dislodgement at 2 months → PEG for feeding; planned surgery).

ii) **Tracheostomy Tube-related TEF**-Post thyroid cancer laryngectomy (n = 2):
- ASD closure device placement: 1 successful case.
- Cervical covered SEMS: 1 case with stent-related erosion → stent removal → spontaneous healing of Erosion over 2 weeks; PEG-J feeding provided.

iii) **Tuberculosis-related TEF** (n = 3):

a) *Small defect*: Anti Tuberculosis Therapy(ATT) + NG feeding, successful.

b) *Larger defects:*
- Esophageal covered stent + proximal clipping of stent (1 case), clinically successful.
- APC margin cauterization + multiple hemoclips (1 case), successful.

Overall, endoscopic therapy for TEF in our series demonstrated high technical and clinical success across varied etiologies. We recommend the following approach to the management of this complex disorder.

Conclusions Tracheo Esophageal Fistula(TEF) is a complex entity requiring a multidisciplinary, individualized approach. Endoscopic therapy—particularly stenting—remains the cornerstone for malignant TEF, while benign TEF may benefit from tailored interventions including clipping, cauterization or device closure. Larger defects may require surgical intervention. Our experience with good number of cases suggests that endotherapy offers favorable outcomes when guided by defect characteristics, patient condition and an algorithmic treatment strategy.

eP715V Complete Circumferential Endoscopic Submucosal Dissection for a Long segment Esophageal Dysplasia

Authors Mukewar S[1], Khaldi A[2], Godbole S[3], Bhaware B[3], Mukewar S[3]
Institutes **1** Midas Hospital, Nagpur, Nagpur, India; **2** MIDAS HOSPITAL, Nagpur, India; **3** Midas Multispeciality Hospital Pvt. Ltd., Nagpur, India
DOI 10.1055/s-0046-1822042

Abstract Text

Endoscopic submucosal dissection (ESD) for an extensive circumferential esophageal lesion can be challenging. 56-year-old female who presented with dysphagia since 2 months. On esophagogastroduodenoscopy, circumferential irregular mucosa from proximal to distal esophagus was seen with high definition-narrow band imaging showing abnormal Intra-Papillary Capillary Loop (IPCL) pattern – B1. Circumferential ESD of the entire segment was succesfully performed using a J knife. Steroid injections at base of defect followed by esophageal covered stent placement and oral steroids were given to prevent stricture. Histopathology showed a R0 resection, verrucous proliferation with low-grade squamous intraepithelial lesion at the site of nodular lesion. Despite this, patient developed stricture requiring dilations and stricturotomy with ultimately successful resolution.

eP716 Green Endoscopy: Insights from the Middle East

Authors Omar M[1], Al Ghamdi SS[2], Ghaith J[3], Bukhari M[4], Abdullah M[5], Fakhry S[6], Luo X[7], Dua K[8]
Institutes **1** New Mowasat Hospital, Salmiya, Kuwait; **2** King Abdulaziz University, Jeddah, Saudi Arabia; **3** Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; **4** Dr Sulaiman Al Habib Medical Group, Dubai, United Arab Emirates; **5** Ibn Al Nafees Hospital, Manama, Bahrain; **6** King's College Hospital London, Dubai, United Arab Emirates; **7** South Medical University Nanfang Hospital, Guangzhou, China; **8** Medical College of Wisconsin, Milwaukee, United States of America
DOI 10.1055/s-0046-1822043

Aims Healthcare systems, especially digestive endoscopy (DE) procedures, add significantly to climate change. Data on environmental awareness within DE units, especially in the Middle East remain limited. This study aimed to assess DE healthcare professionals' knowledge of climate-change concepts, understanding of environmental sustainability in endoscopy, and attitudes toward green-endoscopy practices in the Middle East.

Methods From July 2025 to October 2025, a cross-sectional study was conducted. An electronic survey (Qualtrics) was distributed to endoscopists, nurses, technicians, and trainees across 11 Middle Eastern countries. The questionnaire evaluated climate-change knowledge, environmental awareness within healthcare, understanding of green-endoscopy principles (13 questions), as well as beliefs and attitudes toward sustainability practices (17 questions). Another section of the questionnaire was on participants' demographic and work data (12 questions). Descriptive statistics and mean-rank data were used for analysis.

Results 130 participants completed the survey: endoscopists 72 (55.4 %), nurses/technicians 58 (44.6 %); male 66 (50.8 %), female 64 (49.2 %). 77 of 130 (59.2 %) respondents correctly defined climate change as long-term shifts in temperature and weather patterns, and 50 (38.5 %) attributed it to human activity. Knowledge of greenhouse gases was mixed: 73 (56.2 %) answered correctly, while 27 (20.8 %) selected gases essential for life and 13 (10 %) associated it with ozone depletion. Hospital carbon emissions contributors were frequently misidentified, with 86 (66.2 %) selecting waste disposal as the major source. Awareness of endoscopy units' contribution to hospital waste was limited, as only 55 (42.3 %) correctly ranked endoscopy units third, and 40 (30.8 %) were unsure. Understanding of carbon footprint was low: 69 (53.1 %) equated it as a measure for waste generation, whereas only 31 (23.8 %) correctly identified greenhouse-gas emissions. In contrast, recognition of green endoscopy was high 120 (92.3 %), although only 77 (59.2 %) correctly identified that high-quality curative services are not a pillar of green endoscopy. Knowledge related to water use varied: 54 (41.5 %) reported that filtered water is allowed for high-level disinfection, and 80 (61.5 %) indicated that potable tap water is not permitted for mucosal irrigation.
Concern about climate change was high (n 116, 89.2 %). Most participants acknowledged healthcare's negative impact on the environment (n 71, 54.6 %) but perceived limited institutional action. Most respondents (n 86, 66.2 %) perceived single-use endoscopes and accessories as a major contributor to the procedure's environmental burden. In total, 84 respondents (64.6 %) believed that adopting a "reuse" approach could compromise patient safety. The majority (n 92, 70.8 %) of respondents believed that financial models tied to procedural volume hinder the adoption of environmentally sustainable practices in endoscopy. There was strong support for mandatory training on waste management (n 115, 88.5 %), minimizing patient visits when feasible (n 103, 79.2 %), and integrating environmental criteria into purchasing decisions (n 101, 77.7 %). Almost all respondents expressed interest in further education on sustainable endoscopy (n 123, 94.6 %).

Conclusions Healthcare professionals across Middle Eastern endoscopy units demonstrated strong concern for climate change and high support for sustainable practices. However, substantial knowledge gaps existed regarding greenhouse gases, carbon footprints, hospital carbon emission sources, and endoscopy-related environmental impact. Moreover, institutional supportive actions were limited. Present data provide guidance to develop focused, tailored educational programs, clear protocols, and practical policies to help endoscopy teams implement greener, more environmentally responsible practices in the Middle East.

eP717V EUS-guided drainage of an infected pancreatic cyst complicating FNA

Authors Borahma M[1], Kadiri M[2], Ajana FZ[1], Lagdali N[1]
Institutes **1** Mohammed V University, Rabat, Morocco; **2** UM5, Rabat, Morocco
DOI 10.1055/s-0046-1822044

Abstract Text

A 62 old-year-male, with no medical history, was admitted for jaundice. The clinical examination noted cholestatic jaundice and scratching lesions. CT scan showed a pancreatic head cyst with upstream dilation of the common bile duct and intrahepatic duct. Biochemical examination showed acute cholangitis with total bilirubin at 16 mg/dL. Endoscopic ultrasound examination showed a cystic lesion at the head of the pancreas with multiple septation inducing upstream dilation of the common bile duct. FNA of the cyst showed clear liquid (dosage of ACE, glucose, and amylase requested). the patient presented 24 hours later

with fever and tenderness of the abdomen. Re-EUS examination demonstrated a muddy aspect of the cyst suspecting an infection. we decided to perform a drainage with two double pigtail stents. the evolution was very favorable.

DOI 10.1055/s-0046-1822045

Introduction Whipple's disease, caused by *Tropheryma whipplei*, is a rare multisystem infection. Although classically presenting with malabsorption or arthralgia, atypical manifestations may mimic hematologic disorders, leading to diagnostic delay. Accurate diagnosis relies on integrating clinical, biochemical, imaging, histologic, and molecular findings [1]. We report a case of Whipple's disease in which diffuse lymphadenopathies and marked inflammation initially raised concern for a lymphoproliferative disorder.

Case Description A 39-year-old woman with perinatal hypoxic brain injury was referred for persistent systemic inflammation associated with chronic peri-umbilical pain, vomiting and a 20 kg weight loss over two years. Laboratory investigations demonstrated CRP up to 120 mg/L, ESR 115 mm/h, polyclonal hypergammaglobulinemia, elevated vitamin B12. Autoimmune work-up showed an elevated rheumatoid factor, while anti-CCP was negative and C3/C4 levels were within normal range. Infectious work-up including blood cultures and Quantiferon was negative.

CT and PET-CT revealed multiple supraclavicular, mediastinal, mesenteric, and retroperitoneal lymphadenopathies with hypermetabolic activity suggesting lymphoma. Peripheral blood immunophenotyping identified a monoclonal B-cell population compatible with marginal zone lymphoma. Supraclavicular lymph node biopsy was unremarkable.

EUS showed a cluster of hyperechoic retroperitoneal mesenteric lymph nodes, the largest 2 cm near the SMV, sampled using FNB. Endoscopy revealed a brownish, atrophic duodenal mucosa with suspected lymphoid infiltration. Duodenal biopsies and lymph node FNB demonstrated numerous PAS- and PAS-diastase–positive macrophages. Molecular analysis and PCR on paraffin-embedded material confirmed *Tropheryma whipplei*, establishing disseminated Whipple's disease.

The patient was initiated on intravenous ceftriaxone for 14 days, followed by long-term oral doxycycline for 12 to 24 months.

Conclusion This case illustrates an uncommon presentation of Whipple's disease mimicking lymphoma and underlines the important role of endoscopy providing histology and PCR testing for *Tropheryma whipplei* in unexplained systemic inflammation and atypical lymphadenopathy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP719 Comparative Analysis of Efficacy and Tolerability of Bowel Preparations for Colonoscopy: A Multi-Center Prospective Study in Lebanon

Authors Issa I[1], Issa T[2]

Institutes **1** Harley Street Medical Center, Abu Dhabi, United Arab Emirates; **2** University of Nicosia, Nicosia, Cyprus

DOI 10.1055/s-0046-1822046

Aims Adequate bowel preparation is essential for high-quality colonoscopy, yet comparative data on preparation efficacy and tolerability in Middle Eastern populations remain limited. We compared commonly used bowel preparations in Lebanese clinical practice

Methods This prospective, multi-center observational study enrolled 600 patients undergoing elective colonoscopy at three Lebanese hospitals over six months. Patients received polyethylene glycol 4L (Klean-prep, n = 124), polyethylene glycol 2L with ascorbic acid (Moviprep, n = 317), sodium picosulfate/magnesium citrate (Picoprep, n = 136), or other preparations (n = 23). Primary outcome was preparation quality assessed by the Boston Bowel Preparation Scale (BBPS). Secondary outcomes included patient compliance (≥ 80 % consumption), adverse effects, and willingness to repeat the same preparation. Chi-square tests and logistic regression identified factors associated with adequate preparation (BBPS ≥ 6 with all segments ≥ 2).

Results Overall, 91.3 % of patients achieved adequate preparation with no significant difference in mean BBPS scores between Moviprep (7.52 ± 1.63), Picoprep (7.60 ± 1.55), and Klean-prep (7.51 ± 1.64, p = 0.283). However, low-volume preparations demonstrated superior compliance (97.8 % vs 87.9 %, p < 0.001) and patient acceptance. Willingness to repeat was significantly higher for Moviprep (86 %) and Picoprep (74 %) versus Klean-prep (25 %, p < 0.001). Split-dosing improved compliance (p < 0.001) but did not significantly affect BBPS scores (p = 0.283). Independent predictors of inadequate preparation included constipation (p < 0.001), multiple comorbidities (p < 0.001), and regular laxative use (p < 0.001). Unexpectedly, inpatient status was associated with superior preparation quality (p < 0.001) [1–6].

Conclusions While all preparations achieved high adequacy rates, low-volume PEG-based formulations offer superior patient tolerability and acceptance, which may enhance long-term screening adherence. Patient-specific factors including comorbidities and dietary compliance significantly impact preparation quality

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822047

Aims We showed that sugar augmented radiofrequency ablation (SARFA) applied to the pancreatic perivascular tissue in an ex vivo pancreas swine model showed controlled necrotic ablation due to induced sugar better heat conductivity using specific settings for 300 joules of energy [1–5].

Our aim is to show that endoscopic ultrasound SARFA (EUS-SARFA) performed in pancreatic perivascular space in a live swine model using specific RFA settings established in a previous ex-vivo experiment, allows a controlled necrotic ablation without increasing perioperative morbidity and mortality related to pancreatic surgery (duodenopancreatectomy and left pancreatectomy).

Methods EUS-SARFA was performed in the pancreatic parenchyma adjacent to the mesenteric and splenic vessels applying 300 joules of energy using different settings of power (Watts = w) and time (sec = s) in a live swine model.

In group 1 (n = 1) and group 2 (n = 4), EUS-SARFA was compared with EUS-saline-RFA and EUS-RFA. These groups without survival had tested different settings with same energy. In group 3 (n = 3) with survival time of 2, 4 and 7 days (D2, D4 and D7) respectively, used EUS-SARFA was carried-on with prefered settings selected during the previous experiments. Then, surgery was performed starting with duodenopancreatectomy followed 1 hour later by left pancreatectomy.

In group 4 (n = 1) only surgery was performed.

CT scan 3 acquisitions and 1.5 Tesla magnetic resonance imaging (MRI) were carried-out before and after therapeutic EUS procedures. Each pancreatic specimen was harvested separately at the end of the procedures for histopathological examination.

Surgery was assessed with a pancreatic surgery difficulty score index and compared with the control group 4 (n = 1) including duodenopancreatectomy followed by left pancreatectomy.

Results All procedures were successfully completed. CT-scan and MRI performed immediately after EUS-SARFA showed normal splenic and mesenteric vessels with a clear hypodense and non-enhancing demarcated area between them and the pancreatic gland due to ischemia of the perforant vessels. Histopathological examination showed largest necrotic ablation volumes with SARFA at 40wx7.5sec and 30wx10sec (300 joules) in non survival specimens when compared with saline-RFA and RFA alone. The survival group surgery at D4 and D7 showed pancreatic local necrosis, adiponecrosis and inflammatory reaction with focal venous thrombosis of small capillaries with more pronounced early fibrosis observed in at D7. Also, surgery at D7 was scored more difficult than surgery at D4 because of incipient fibrosis.

Finally, intraoperative or immediate postoperative complications for EUS-SARFA where non observed, also EUS-SARFA did not increase perioperative morbidity and mortality related to duodenopancreatectomy at D4 and D7 when compared with the control group 4. In the swine with surgery at D2 acute pancreatitis was confirmed after EUS-SARFA and total pancreatectomy was performed due to acute necrotic inflammation.

Conclusions Pancreatic perivascular EUS-SARFA with specific settings at 300 joules perfomed the same day before pancreatic surgery was an efficient and safe technique enabling a controlled necrotic ablation. This technique could be promising for treatment of pancreatic cancer.

Abstract Text

Hybrid polypectomy techniques offer a practical balance between safety, efficiency, and high-quality resection for intermediate and large colorectal lesions. We present two rectal polyp cases demonstrating complementary hybrid approaches. The first case features a 3-cm Paris Is, NICE 2 rectal polyp removed using the Precut-EMR technique: after submucosal injection, a circumferential incision is created with the tip of the snare, allowing placement of the snare into the groove and achieving en bloc resection. The second case shows a 2-cm LST-G-NM, NICE 2 lesion resected by Tip-in EMR, where a small mucosal incision on the oral side serves as an anchor to prevent slippage and facilitate en bloc capture. These hybrid methods are technically simpler than ESD, time-efficient, improve en bloc resection rates compared with conventional EMR, and are particularly useful for 15–30 mm polyps [1–3].

eP722 Long-term proton pump inhibitor requirements in patients treated with POEM

Authors Rojo E[1], Muñoz González R[2], Resina E[1], Casabona-Francés S[1], Pérez T[1], Santander C[1], Miranda P[1]
Institutes **1** Hospital de La Princesa, Madrid, Spain; **2** Hospital Germans Trias i Pujol, Badalona, Spain
DOI 10.1055/s-0046-1822049

Aims Peroral endoscopic myotomy (POEM) is the treatment of choice for achalasia; however, the development of gastroesophageal reflux disease (GERD) after the procedure is considered a limitation. In that regard, the aims of this study were:

a) To assess the proportion of patients treated with POEM who require long-term proton pump inhibitor (PPI) therapy (>12 months).
b) To evaluate the rate of GERD during post-POEM follow-up.

Methods We conducted a retrospective study of patients who underwent POEM between June 2018 and June 2024 in our center (terciary referral hospital for achalasia). We only included patiens with a minimum follow-up of 12 months. GERD was defined as the presence of: a) typical symptoms, b) erosive esophagitis on endoscopy (Los Angeles Classification grade ≥ B), and/or c) abnormal pH monitoring (acid exposure time ≥ 6 % combined with manual interpretation consistent with acidic reflux) [1].

Results A total of 85 patients were included (57 % male; mean age 54 ± 15 years). The baseline Eckardt score was 7 ± 2, decreasing to 1 ± 2 post-POEM (median follow-up 20 months, interquartile range (IQR) 13–37). Mean esophageal myotomy length was 6 ± 2 cm and gastric myotomy 2 ± 1 cm. Long-term, 37 % of patients did not require PPIs, 34 % were on standard-dose PPIs, and 29 % on double-dose PPIs (mean follow-up 26 ± 16 months). Indications for maintaining PPI therapy were: abnormal pH monitoring and/or esophagitis without GERD symptoms (49 %), abnormal pH monitoring and/or esophagitis with GERD symptoms (40 %), and symptoms alone without esophagitis or abnormal pH monitoring (11 %).A pathological pH monitoring result was documented in 48 % of patients during follow-up. At 3 months post-POEM, the esophagitis rate was 31 % (20 % grade B, 10 % grade C, 1 % grade D), but it decreased to 13 % long-term (11 % grade B, 2 % grade C; mean follow-up 22 ± 14 months).

Conclusions More than one-third of patients do not require long-term PPI therapy after POEM. Post-POEM GERD is generally mild, minimally symptomatic, and tends to decrease over time.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP723 Feasibility of patient-controlled sedation with remimazolam in outpatient colonoscopy

Authors Davodi J[1], Møller AM[1, 2], Vilmann P[2, 3], Steenholdt C[4, 5], Sloth S[3], Kovacevic B[3]

DOI 10.1055/s-0046-1822050

Aims Remimazolam is a novel, short-acting benzodiazepine with organ-independent metabolism, offering rapid onset and fast recovery, making it well-suited for outpatient procedures. Its pharmacokinetic properties also make it an attractive candidate for patient-controlled sedation (PCS), enabling patients to self-titrate sedation within predefined limits for optimized, individualized dosing (Davodi J, et al. Journal of Patient Safety and Risk Management 2025). In this proof-of-concept study, we aimed to evaluate, for the first time, the feasibility, safety, and patient satisfaction of PCS with remimazolam during outpatient colonoscopy.

Methods Ten randomly selected patients (median age 61 years, range 53–71; 50 % female) scheduled for outpatient colonoscopy were enrolled. Indications included colorectal cancer screening due to positive fecal occult blood test (n = 7), inflammatory bowel disease surveillance (n = 2), and adenoma surveillance (n = 1). PCS was delivered via an infusion pump (CADD-Solis, ICU Medical, San Clemente, USA), with an initial bolus of 5–7.5 mg remimazolam combined with 1 mg of alfentanil, followed by patient-activated 2.5 mg boluses with a 2-minute lockout period. Vital signs (oxygen saturation, heart rate, respiratory rate, and non-invasive blood pressure) were continuously monitored. Any adverse events were classified according to the international reporting tool on adverse events in sedation. Patient satisfaction was assessed post-procedure using a validated 5-point Likert scale.

Results All ten colonoscopies were completed successfully. The median number of remimazolam boluses was 3.5 (range 0–7), corresponding to a median total dose of 14.0 mg (range 5.0–27.5 mg). The median procedure duration was 41 minutes (range 23–105). The safety profile of remimazolam was favorable, and no serious adverse events occurred. Only minimal adverse events were observed in three patients (30 %), consisting of brief and transient oxygen desaturation, which resolved spontaneously. No clinically relevant effects on hemodynamic parameters were noted throughout the procedures, and no patients required airway support or reversal agents. One patient was transferred to the recovery room as a precaution due to subcutaneous infiltration at the infusion site; all others were discharged directly from the endoscopy room.

Overall patient satisfaction was high across all participants. All participants reported high or very high satisfaction with the sedation quality (median 5.0), pain relief (median 5.0), and anxiety reduction (median 5.0). Notably, all patients expressed high satisfaction with the ability to control their sedation levels, which is reflected in some patients opting to use fewer or no boluses than others. Satisfaction also appeared to be higher than what we have previously observed with nurse-administered propofol sedation (NAPS) in our earlier study, which used identical questionaries (Steenholdt C, et al. Clinical Gastroenterology and Hepatology 2022; 559-568). Feedback from the endoscopists indicated that the sedation regimen provided satisfactory working conditions without compromising procedural quality.

This pilot experience also highlighted inter-patient variability in sedation needs. Some patients required few boluses, while others required more frequent dosing, suggesting that a standardized protocol may not fit all. Factors such as anxiety level, frailty, previous procedural experience, or body weight may influence sedation demand, emphasizing the adaptability of PCS to individual needs.

Conclusions PCS with remimazolam is a feasible, safe, and well-tolerated option for outpatient colonoscopy. The setup is straightforward, and the built-in lockout mechanism provides an inherent safety feature that helps prevent over-sedation. An antidote is also available if needed. This approach may reduce staff workload by allowing nurses to focus more on procedural assistance rather than manually titrating sedatives. Unlike propofol, which is generally contraindicated in high ASA patients, PCS with remimazolam may be a promising option for frail individuals or patients who prefer to remain partially conscious during the procedure. Our proof-of-concept observations support the rationale for controlled trials to evaluate PCS with remimazolam as a potential alternative to current standards in endoscopic sedation.

eP724V Salvage circumferential endoscopic submucosal dissection with concomitant stricture resection for recurrent, strictured Barrett's neoplasia following multiple endoscopic mucosal resections

Authors Nagl S[1], Messmann H[2]
Institutes **1** Internal Medicine III – Gastroenterology, University Hospital Augsburg, Augsburg, Germany; **2** Internal Medicine III – Gastroenterology, University Hospital Augsburg, Augsburg, Germany
DOI 10.1055/s-0046-1822051

Abstract Text

A 76-year-old patient was referred to our center with Barrett`s esophagus (C14M14), esophageal stricture and recurrent early neoplasia. Prior to referral, she had undergone multiple endoscopic mucosal resections (EMR) for early Barrett`s neoplasia and subsequently developed a non-traversable mid-esophageal stricture. A circumferential endoscopic submucosal dissection (ESD) of the entire Barrett`s segment including stricture resection was performed (Video 1). Histopathology revealed adenocarcinoma pT1a (m3), pNx, L0, Vo, G1, R0. The patient was discharged 48 hours on soft diet and oral prednisolone. Follow-up at 8 weeks demonstrated complete stricture resolution without cancer recurrence. In this case, residual multifocal dysplasia and early cancer after EMR was treated with salvage ESD. Concomitant stricture resection during ESD led to complete resolution of stenosis.

eP725 Biliary cast syndrome: a rare case in non-transplanted patient

Authors Pelloux E[1], Siljeström C[2], Christamnn PY[1], Héroin L[1], Mirabella J[2], Mayer P[1]
Institutes **1** Nouvel Hôpital Civil (NHC)- Hôpitaux Universitaires de Strasbourg, Strasbourg, France; **2** Nouvel Hôpital Civil (NHC)- Hôpitaux Universitaires de Strasbourg, Strasbourg, France, Strasbourg, France
DOI 10.1055/s-0046-1822052

Background: Biliary cast syndrome (BCS) is a rare entity characterized by solid, branching casts conforming to the biliary ducts [1]. It is classically seen after liver transplantation [2], and its occurrence outside the transplant setting is particularly uncommon, with only isolated reports in patients with suspected or confirmed primary sclerosing cholangitis (PSC) [3, 4]. In these cases, the diagnosis can be challenging, especially when patients present with cholangitis.

Case Presentation:A 50-year-old man was admitted for acute cholangitis in the context of newly suspected PSC. MRI showed discreet hepatic dysmorphia and a pruned-tree appearance of the biliary system, prompting endoscopic assessment.

Endoscopic Ultrasound (EUS):EUS revealed mildly dilated intrahepatic ducts and an irregular common bile duct containing dense, adherent material extending from the papilla to the biliary confluence. The exact nature of this material—stones, inflammatory debris, or cast-like elements—could not be clearly distinguished, but the extensive involvement suggested significant ductal inflammation. The pancreas and papilla appeared normal, and a small amount of perihepatic ascites was noted.

ERCP: Selective cannulation of the bile duct was easily achieved. The cholangiogram revealed a pronounced pruned-tree appearance of the intrahepatic ducts with numerous filling defects involving both lobar ducts and the main bile duct, raising suspicion for a mixture of stones and biliary casts. A sphincterotomy was performed, and multiple stones and debris were successfully extracted using an extraction balloon. However, clearance remained incomplete, particularly in the intrahepatic ducts. To ensure sufficient drainage, plastic stents (7 Fr × 15 cm) were placed in both the left and right hepatic ducts, and an 8.5 Fr × 12 cm stent was positioned in the main bile duct. A second ERCP with cholangioscopy and lithotripsy was scheduled to complete ductal clearance.

Outcome: The patient improved clinically with resolution of cholangitis under antibiotic therapy and biliary drainage. He was discharged with planned follow-up and staged therapeutic management.

Discussion: Although BCS is rare in non-transplant patients, it should be considered in individuals with suspected PSC presenting with severe or recurrent cholangitis. In this case, EUS and ERCP together clarified the intraductal pathology and allowed partial clearance with effective decompression. Staged endoscopic therapy is often required, particularly when intrahepatic disease is extensive.

Conclusion: This case highlights a rare non-transplant presentation of biliary cast syndrome in a patient with suspected PSC. Endoscopic evaluation played an important role in establishing the diagnosis and providing initial management, while planned staged treatment remains essential for complete biliary clearance and prevention of recurrence.

DOI 10.1055/s-0046-1822053

Abstract Text

A 67-year-old woman with prior right adrenalectomy for pheochromocytoma (2021; clear margins, low proliferation) presented with elevated plasma metanephrines. F-18-DOPA PET/CT revealed a low-attenuating, DOPA-avid lesion in the left adrenal gland, suspicious of a pheochromocytoma. To avoid adrenal insufficiency, multidisciplinary evaluation favored EUS-guided radiofrequency ablation as an organ-preserving approach. EUS-RFA was performed using a dedicated system (EUSRA, Taewoong Medical, South Korea), with three energy applications. A transient hypertensive response occurred (systolic BP to 240 mmHg), successfully managed with vasodilators. The patient remained hemodynamically stable and was discharged the next day after uneventful recovery. This represents one of the first reported uses of EUS-RFA for this indication. Biochemical and radiologic follow-up outcomes will be presented at the conference.

eP727 Beyond Acute Cholecystitis: Expanding the Role of EUS-Guided Gallbladder Drainage

Authors Achemlal A[1], Baware B[1], Mukewar S[1], Mukewar S[1]
Institute 1 MIDAS HOSPITAL, Nagpur, India
DOI 10.1055/s-0046-1822054

Aims This study aims to assess and compare the outcomes of EUS-GBD in patients presenting with acute cholecystitis (AC) versus those treated for non-cholecystitis indications (NC).

Methods We conducted a retrospective single-center study including all consecutive patients who underwent EUS-GBD for any indication (AC or NC) between May 2020 and October 2025. We compared technical success—defined as appropriate LAMS placement within the gallbladder confirmed by EUS—clinical success (based on clinical and laboratory improvement), adverse event (AE) rates, and mortality between the AC and NC groups. All procedures were performed by an endoscopist (S.M) with advanced training in interventional EUS. Statistical analyses were performed using Jamovi software version 2.3.

▶ **Table 1** Baseline Characteristics and procedural results of patients who underwent EUS-GB procedures

Varaible	Value n(%)
Age (Years,Mean ± SD)	67.2 ± 15.3
Gender, male	25(65.8)
Indication	
AC	25(65.8)
NC	13(34.2)
Symptomatic gallstones	6(15.8 %)
Malignant biliary obstruction	2(5.3)
Symptomatic common bile duct stones	1(2.6)
Gallstone pancreatitis	1(2.6)
Comorbidities	
Cardiopathy	11(28.9)
Advanced Age	10(26.3)
Hepatopathy	5(12.2)
Other	6(15.8)
Material	
Nagi 16mm	2(5.3)
Axios 10mm	18(47.4)
Axios 15mm	13(34.2)
Taewoong 16mm	5(13.2)
Location of the stent	
Gastric wall	34(88.8)
Duodenum	4(11.2)
Adverse events	7(18.4)
AC	5(13.2)
NC	2(5.3)
Clinical Success	36(94.7)

Results A total of 38 patients underwent EUS-GBD; 65.8 % were male, with a mean age of 67.2 ± 15.3 years. Overall, 65.8 % were treated for AC. NC indications included symptomatic gallstones (15.8 %), malignant biliary obstruction (5.3 %), symptomatic common bile duct stones (2.6 %), and gallstone pancreatitis (2.6 %). Most stents were deployed via a transgastric approach (88.8 %), with the remainder placed transduodenally (11.2 %). Technical success was 100 % in both groups. AEs occurred in 18.4 % of cases: 13.2 % in the AC group and 5.3 % in the NC group (p = 0.728). Clinical success was achieved in 84.2 % of the cohort (▶ **Table 1**). One patient died within one month of follow-up; both belonged to the NC group and had malignant biliary obstruction. Another patient, from the AC group, died within one month of follow-up.

Conclusions EUS-GBD demonstrated excellent technical success and favorable clinical outcomes across both acute cholecystitis and non-cholecystitis indications. AE rates were low and comparable between groups. Overall, EUS-GBD appears to be a safe, effective, and versatile drainage strategy not only for acute cholecystitis but also for selected non-cholecystitis conditions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP728 Bowel obstruction in a patient with prior large bowel resection and newly confirmed Crohn's disease: A rare case of primary true enterolithiasis resolved endoscopically

Authors Bukovnik N[1], Nikolić S[1, 2], Ocepek A[1, 2]
Institutes 1 Maribor University Medical Centre, Maribor, Slovenia;
2 University of Maribor, Faculty of Medicine, Maribor, Slovenia
DOI 10.1055/s-0046-1822055

Abstract Text

Background: Enterolithiasis refers to the formation of hard intraluminal masses within the gastrointestinal tract and may lead to obstruction. Enteroliths are categorized as primary or secondary. Primary enteroliths originate within the bowel and are classified as *true* or *false*, depending on their composition and formation. True enteroliths arise in areas of anatomical alteration and stasis, and their chemical composition depends on location—distal small bowel stones typically contain calcium phosphate or oxalate. They are most frequently associated with prior intestinal surgery or stricturing Crohn's disease (CD). Although rare, enteroliths can cause acute large bowel obstruction [1–3].

Case presentation: A 58-year-old female presented with a four-week history of diarrhea, nausea, and acute onset of fever and chills. She had previously undergone partial large bowel resection with a caeco-sigmoid anastomosis due to obstruction caused by multiple intramucosal lipomas, followed by balloon dilatation of the anastomosis five years later for symptomatic stenosis. Clinical examination revealed fever and abdominal distension with diffuse tenderness and hyperactive bowel sounds. Abdominal X-ray showed a 6 cm colonic loop in the right lower quadrant, borderline dilated small bowel loops, and a ~40 mm calcified pelvic mass. Computed tomography (CT) confirmed cecal obstruction and identified an additional 20 mm calcified lesion, without signs of perforation. Suspecting anastomotic stenosis, colonoscopy with planned balloon dilation was performed. It revealed a stenotic anastomosis with an 8 mm lumen, successfully dilated to 12 mm. Advancement of the therapeutic gastroscope allowed visualization of a large enterolith. Ulcerations were observed at the ileocaecal valve and terminal ileum; biopsies were taken. The enterolith was identified as the likely cause of obstruction, and endoscopic lithotripsy was attempted. Fragmentation was challenging due to the stone's hardness, resulting in multiple lithotriptor wire failures. The second calcified lesion was not detected endoscopically. Following the procedure, symptoms rapidly resolved, and the patient was discharged on day four. Stone analysis confirmed calcium phosphate composition. Histology of ileal biopsies demonstrated features consistent with CD. At three-week follow-up, the patient remained asymptomatic, and a second colonoscopy was arranged to treat the remaining stone.

Conclusion: This case illustrates a rare presentation of primary true enterolithiasis causing large bowel obstruction in a patient with a history of bowel resection and newly diagnosed CD. Endoscopic intervention successfully relieved the obstruction and avoided surgical management. Given the anatomical alteration and underlying CD, recurrence risk remains significant. Careful endoscopic follow-up is warranted. Prompt recognition of enterolithiasis, especially in post-surgical or CD patients, is essential, as timely endoscopic therapy may provide a minimally invasive and effective treatment alternative.

eP729 Feasibility and diagnostic yield of an ultra–low-volume bowel preparation in acute lower gastrointestinal bleeding: a real-world cohort study

Authors Aversano A[1], Corder F[2], Budel M[1], Macor D[1], Zucchi E[1], Carbone M[1], Marino M[1], Colombo A[1], Rebuzzi L[2], Cannizzaro R[3], Berretti D[1]

DOI 10.1055/s-0046-1822056

Aims Urgent colonoscopy is recommended during hospitalization for acute lower gastrointestinal bleeding (LGIB), but current guidelines still advocate large-volume polyethylene glycol (PEG) lavage (4–6 L), which is often poorly tolerated in elderly or frail patients. Evidence supporting low- or ultra–low-volume regimens in this setting is scarce. This study aimed to evaluate the feasibility, bowel cleanliness and diagnostic performance of an ultra–low-volume preparation in patients undergoing urgent colonoscopy for acute LGIB. We also assessed whether bowel preparation quality differed across demographic subgroups and analysed the impact of colonoscopy timing (≤ 24 h vs > 24 h) on diagnostic yield.

Methods We conducted a retrospective real-world cohort study including all consecutive patients who underwent urgent colonoscopy for acute LGIB at the Gastroenterology Unit of Santa Maria della Misericordia Hospital, Udine, from September 2024 to September 2025. The bowel preparation consisted of a rapid ultra–low-volume regimen (1-L PEG/ascorbate regimen). Demographics, comorbidities, haemoglobin, Shock Index, Oakland score, timing of colonoscopy, bowel cleanliness (Boston Bowel Preparation Scale, BBPS) and endoscopic outcomes were extracted from electronic records. Bowel preparation adequacy was defined as BBPS ≥ 6. Statistical analyses included χ^2/Fisher's exact test, Mann–Whitney U test, and multivariable logistic regression to identify predictors of bowel cleanliness and diagnostic yield.

Results Eighty-nine patients were included (median age 74 years; high comorbidity burden in 87.6 %; antithrombotic therapy in 39.3 %). Colonoscopy was performed < 12 h in 29.2 %, 12–24 h in 22.5 %, and > 24 h in 48.3 % of cases. Bowel cleanliness was adequate in 56/85 patients (65.9 %), with a median BBPS of 6. Toilettes were comparable across age groups, including patients > 80 years (p = 0.666), and across BMI categories (p = 0.209). Comorbidities were associated with a higher rate of inadequate preparation (adequate 100 % in patients without comorbidities vs 61 % with comorbidities; Fisher p = 0.014), although this association lost significance in multivariate analysis.Bowel cleanliness did not differ significantly between colonoscopies performed ≤ 24 h and > 24 h (BBPS median 6 vs 6; p = 0.346).The overall diagnostic yield was 68.5 %, and endoscopic therapy was performed in 24.7 %. In unadjusted analyses, procedures performed > 24 h appeared more frequently positive; however, after adjustment for haemoglobin and clinical severity, colonoscopy ≤ 24 h was independently associated with higher diagnostic yield (OR ≈ 3.5; p = 0.049). Bowel preparation quality did not significantly influence the ability to deliver endoscopic therapy (p = 0.432).

Conclusions Ultra–low-volume bowel preparation was feasible and generally effective in a real-world population of elderly and comorbid patients with acute LGIB, achieving adequate cleanliness in two-thirds of cases and maintaining stable performance across age and BMI subgroups. Importantly, early colonoscopy (≤ 24 h) improved diagnostic yield without compromising bowel cleanliness. Compared with standard high-volume lavage and conventional low-volume PEG regimens, the ultra–low-volume preparation demonstrated comparable feasibility and acceptable cleanliness in a frail, highly comorbid population, suggesting that reduced-volume strategies may offer a practical and better-tolerated alternative in the urgent LGIB setting without compromising diagnostic performance. Prospective comparative studies against standard and low-volume PEG regimens are warranted.

eP730 Beyond Hamartomas: Revealing Pancreatic Malignancy in Peutz–Jeghers Syndrome

Authors Hassine A[1], Triki L[1], Teles de Campos S[1], Pezzullo M[2], Lucidi V[3], Verset L[4], Van Laethem JL[1], Fernandez y Viesca M[1], Arvanitakis M[1]

DOI 10.1055/s-0046-1822057

Introduction Peutz–Jeghers syndrome (PJS) is traditionally managed with structured endoscopic surveillance targeting hamartomatous polyposis and the prevention of small-bowel obstruction. Conversely, despite a markedly elevated lifetime risk of pancreatic ductal adenocarcinoma (PDAC), pancreatic screening practices remain heterogeneous, and consensus on optimal imaging modalities or surveillance intervals is lacking. This discrepancy may lead clinicians to focus predominantly on gastrointestinal polyp management while inadvertently underrecognizing the pancreatic component of the syndrome [1].

Case Presentation A 44-year-old patient with PJS was initially diagnosed following segmental small-bowel resection for acute intestinal obstruction, with pathology confirming multiple hamartomatous polyps > 2 cm. Serial colonoscopies, upper endoscopies, and double-balloon enteroscopies over subsequent years consistently demonstrated recurrent hamartomatous polyps in the jejunum, duodenum, and colon without dysplasia. Entero-MRI examinations some years later showed jejunal polyps < 2 cm with no suspicious features. The patient presented with mild acute pancreatitis. Laboratory workup ruled out biliary, alcoholic, metabolic, autoimmune, and viral causes. CT confirmed acute edematous pancreatitis. A dedicated pancreatic MRI demonstrated dilation of the main pancreatic duct with abrupt corporeo-caudal stricture, secondary duct ectasia and focal parenchymal signal alteration. CA 19-9 raised up to 442 kU/L Endoscopic ultrasound identified a 20-mm hypoechoic lesion in the pancreatic body causing ductal narrowing with mild upstream dilatation, along with several distal microcysts. Fine-needle biopsy confirmed PDAC. Retrospective review of prior abdominal imaging (entero-MRI) revealed 2 cystic lesions in the pancreatic body suggestive of branch-duct IPMN. The patient underwent left pancreatectomy with splenectomy. Histopathologic staging showed pT-2N1M0 PDAC, BRCA wild-type and KRAS-mutated. Postoperative management included adjuvant FOLFIRINOX chemotherapy

Conclusion This case illustrates how the dominant focus on hamartomatous polyposis in PJS may mask the substantial risk of PDAC, leading to delayed recognition of pancreatic malignancy. The absence of harmonized, evidence-based pancreatic surveillance protocols persists despite the well-established high-risk profile of these patients. Our case underlines the need to re-evaluate existing surveillance frameworks and supports the integration of structured MRI- and EUS-based pancreatic screening to enable earlier detection and ultimately improve outcomes in individuals with PJS.

DOI 10.1055/s-0046-1822058

Aims Vedolizumab is an established treatment for inflammatory bowel disease (IBD). Loss of response is occasionally encountered. Data regarding dose intensification are limited[1]. Aim of the study was to evaluate the effectiveness of interval shortening for intravenous vedolizumab (300mg/4 weeks).

Methods Data were collected retrospectively from patients' medical records, in two Greek tertiary centers. All patients received IV vedolizumab every 4 weeks. Endoscopic and biochemical response was evaluated at 12 months. The intervention was considered successful if treatment was maintained, whereas failure was defined as the need to either switch or operate.

Results Twenty-one patients [14 (66.7 %) men, median age 53 years (range: 25-85 years)] were included. 15 (71.4 %) with ulcerative colitis (UC), 4 (19.1 %) with Crohn's (CD) and 2 (9.5 %) with pouchitis. UC patients: 10 (66.6 %) with left-sided colitis (E2) and 5 (33.3 %) with extensive disease (E3). All CD patients had ileocolitis (L3), whereas two (50 %) had stenotic phenotype and two (50 %) perianal involvement. Previous treatments: 5-ASA and corticosteroids (95.2 %), immunosuppressants (38.1 %) and biologics (57.1 %). Vedolizumab was offered as 1st, 2nd and 3rd line treatment in 9, 3 and 9 patients, respectively. Dose intensification was employed after a median duration of 33 months for UC (IQR: 41) and 19.5 months for CD (IQR: 35) ($p = 0.41$). The intensified scheme was applied for a median of 9 months in CD [IQR: 24.5, range 3–48] and 7.5 months in UC [IQR 10, range 3-58, ($p = 0.98$)]. Endoscopic Mayo score decreased from 2.35 to 0.88 and the effect was significant ($p = 0.001$, $r = 0.79$). The mean CRP value decreased significantly from 1.42 to 0.44 ($p = 0.007$). Intensification was successful in fourteen (66.7 %) cases (11 UC, 2 CD and one pouchitis). Seven patients failed and switched to another biologic. None underwent surgery. No treatment-related adverse events were observed.

Conclusions Vedolizumab intensification scheme was successfully maintained for the majority of IBD patients, beyond six months. The endoscopic and biochemical responses were both significant.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP732 Endoscopic ultrasound-guided drainage of a peripancreatic pseudocyst in a patient with ductal disconnection syndrome using a new lumen-apposing metal stent (LAMS): the Z-EUS IT Hanarostent "free-hands" model

Authors Moya-Valverde E[1], Gala-Moreno I[1], Trueba-Collado C[1], Marco-Blázquez MC[1], Ambite-Pérez I[1], García MAL[1], Tabernero Da Veiga S[1]

Institute **1** Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

DOI 10.1055/s-0046-1822059

Introduction Endoscopic ultrasound (EUS)-guided drainage of peripancreatic collections has become the standard approach following the development of lumen-apposing metal stents (LAMS). Until now, only a single "free-hands" deployment model of this type of stent was available; the Z-EUS IT model by Hanarostent has been recently commercialized.

Case Report We present the case of a 60-year-old male with an episode of severe necrotizing acute pancreatitis and subsequent development of an 80 x 100 mm peripancreatic pseudocyst in the body of the pancreas, which was communicating with the main pancreatic duct. A cholangio-MRI also showed compression of the splenic vein and ductal disconnection syndrome.

Endoscopy EUS was performed, confirming the well-defined wall of the pseudocyst and the absence of interposed vessels along the needle path. EUS-guided cystogastrostomy was performed using a 14 x 20 mm Z-EUS IT lumen-apposing metal stent via a "free-hands" technique, under endoscopic ultrasound and fluoroscopic guidance, confirming its successful deployment. Abundant liquid content was observed draining into the stomach. Subsequently, a 7 Fr x 5 cm double pigtail plastic stent was telescopically placed inside the LAMS without complications, and the patient was discharged 24 hours later.

A control MRI performed at 4 weeks showed complete resolution of the pseudocyst, and the LAMS was removed using the stent retrieval thread with forceps, without incidents. Three months later, we confirmed no pseudocyst recurrence performing a CT scan.

Comment The new "free-hands" Z-EUS IT lumen-apposing metal stent is easy to use and effective for EUS-guided drainage of peripancreatic collections. Different sizes are available than those previously commercialized, what can be useful in selected patients. Additionally, it has a retrieval thread to make easier its removal.

eP733 Dual site rapid urease test improves Helicobacter pylori detection in dyspeptic patients and those on Proton Pump Inhibitors

Authors Pal S[1], Mohta S[1]

Institute **1** Narayana RN Tagore Hospital, Mukundapur, Kolkata, India

DOI 10.1055/s-0046-1822060

Aims *Helicobacter pylori* is a common infection linked to dyspepsia, peptic ulcer disease, and gastric cancer. The rapid urease test (RUT) is widely used for diagnosis, but its accuracy is influenced by proton pump inhibitor (PPI) use and site of gastric sampling. This study aimed to evaluate the effect of PPI use on RUT positivity, compare detection rates between corpus and incisura, and determine the incremental value of dual-site sampling.

Methods We conducted a single-center observational study of 503 adult patients undergoing upper gastrointestinal endoscopy for dyspepsia. RUT was performed from the gastric corpus and incisura using identical kits. Clinical data, including PPI use, demographics, and symptoms, were recorded. Statistical analyses included Chi-square tests, McNemar's test, Cohen's kappa, and logistic regression.

Results Overall *H. pylori* prevalence by RUT was 25.4 %. Positivity was 22.7 % from corpus, 18.9 % from incisura, and 25.4 % when either site was positive. Corpus positivity was significantly higher than incisura (McNemar's $\chi^2 = 6.89$, $p = 0.009$). Dual-site sampling significantly increased detection compared to corpus alone (25.4 % vs 22.7 %, McNemar's $\chi^2 = 12.07$, $p = 0.0005$). If only corpus was sampled, 10.9 % of positive cases would have been missed; if only incisura was sampled, 25.8 % would have been missed. Agreement between corpus and incisura was good ($\kappa = 0.717$). PPI use reduced incisura positivity ($p = 0.02$) but not corpus ($p = 0.09$). On subgroup analysis, the incremental benefit of dual-site sampling was more pronounced in PPI users ($p = 0.023$). RUT positivity was associated with male gender ($p = 0.038$) and younger age ($p = 0.046$).

Conclusions Dual-site RUT sampling improves detection of *H. pylori*, especially in patients on PPIs, and reduces false negatives compared with single-site testing. Corpus alone performs better than incisura, but dual-site testing should be considered in routine clinical practice to maximize diagnostic accuracy.

eP734 Gastric Neuroendocrine Neoplasms: Insights From a 15-Year Cohort

Authors Aversano A[1], Budel M[1], Macor D[1], Zucchi E[1], Carbone M[1], Marino M[1], Colombo A[1], Rebuzzi L[2], Josefina P[1], Cannizzaro R[3], Berretti D[1]
Institutes **1** Gastroenterology, Azienda Sanitaria Universitaria Friuli Centrale (ASUFC), Udine, Italy; **2** Scuola di spec. in Malattie dell'apparato digerente, Università degli Studi di Trieste, Trieste, Italy; **3** Oncological Gastroenterology Unit, Centro di Riferimento Oncologico (CRO) IRCCS, Aviano, Italy
DOI 10.1055/s-0046-1822061

Aims Gastric neuroendocrine neoplasms (g-NENs) include heterogeneous entities with distinct etiological, biological and clinical profiles. Type 1 g-NENs are classically associated with autoimmune chronic atrophic gastritis, whereas type 3 lesions behave more aggressively with higher metastatic potential. Long-term European real-world data remain limited. This study aimed to describe the epidemiology, autoimmune background, treatment strategies and outcomes of g-NENs diagnosed over 15 years at a high-volume Italian tertiary center, and to compare risk factors for recurrence and metastatic spread.

Methods We performed a retrospective observational cohort study including all consecutive patients diagnosed with g-NENs at the Gastroenterology Unit, Santa Maria della Misericordia Hospital, Udine (Italy) between 2010 and 2025. Clinical, biochemical, endoscopic, histological and therapeutic data were retrieved from electronic records. Variables included demographics, autoimmune markers (APCA), presence of autoimmune atrophic gastritis (AAG), tumor location, size, Ki-67, grading, treatment modality, recurrence, lymph-node involvement and distant metastasis. Statistical analyses included chi-square/Fisher's exact test, Mann–Whitney U test and odds ratios with 95 % confidence intervals.

Results Thirty patients were included (66.7 % male; mean age 68.8 ± 11.3 years). Autoimmune disorders were present in 54.2 %, AAG in 36.7 % and APCA positivity in 36.7 %. Strong associations emerged between type 1 g-NENs and AAG (10/11 with AAG; $p < 0.001$; OR 10.0) as well as APCA positivity (10/11 APCA +; $p = 0.002$; OR 28.0). Half of the cohort had type 1 g-NENs (n = 15) and half type 3 (n = 15). Type 1 patients were significantly younger than type 3 (64.7 ± 10.6 vs 72.9 ± 10.5 years; $p = 0.019$).Overall, 63.6 % of tumors were G1, 22.7 % G2 and 13.6 % G3/NEC. Mean lesion size was 12.7 ± 8.4 mm (median 10 mm). Lymph-node metastases occurred in 3/30 patients (10 %), and distant metastasis in 1 patient (3.3 %), exclusively in tumors with very high Ki-67 (90–100 %; $p = 0.024$) and larger size ($p = 0.018$).Treatment consisted of endoscopic resection in 55.6 % and surgery in 29.6 %; type 1 lesions showed a non-significant trend toward less surgery ($p = 0.678$). Local recurrence occurred in 3/29 patients (10.3 %), all intragastric and manageable endoscopically. No tumor-related deaths were observed during available follow-up.

Conclusions This long-term experience confirms the distinct biological behaviors of gastric NENs, with indolent type 1 lesions linked to autoimmunity and more aggressive type 3 tumors associated with high proliferative index and metastatic risk. The strong link between AAG/APCA positivity and type 1 g-NEN supports the role of autoimmune biomarkers in diagnostic classification. Endoscopic therapy was effective and safe in most low-risk lesions, while high-grade or large type 3 tumors required surgical management. Recurrence was infrequent and locally manageable.These findings align with current ENETS guidance and highlight the need for structured long-term endoscopic surveillance in AAG-associated type 1 NENs, and for early multidisciplinary evaluation in type 3 disease. Prospective multicenter studies with standardized follow-up intervals are warranted to refine prognostic stratification and optimize treatment pathways.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP735 Permanent EUS-gallbaldder drainage in high-risk patients after acute cholecystitis: a double center experience

Authors Conti CB, Redaelli AE[1], Occhipinti V[2], Mulinacci G[1], Maino M[1], Frego R[1], Ripamonti I[1], Greco S[2], Dinelli ME[1]
Institutes **1** San Gerardo Hospital Monza, Monza, Italy; **2** Endoscopy Unit, Internal Medicine Department, ASST Papa Giovanni XXIII, Bergamo, Italy
DOI 10.1055/s-0046-1822062

Aims Therapeutic endoscopic ultrasonography (EUS) has become an essential tool in the management of gallbladder diseases. EUS-guided gallbladder drainage (EUS-GBD) using lumen-apposing metal stents (LAMS) have demonstrated efficacy and safety in the treatment of acute cholecystitis (AC) in patients unfit for surgery. With the progressive aging of the population and the rise of complex comorbidities, the number of individuals unfit for cholecystectomy is increasing. The role of permanent EUS-GBD remains insufficiently defined. We aim to describe a double center experience with permanent EUS-GBD following at least one episode of AC, in patients unfit for cholecystectomy [1–3].

Methods Observational study. We prospectively collected data from all patients undergoing permanent EUS-GBD between 2023 and 2025. Demographics, comorbidities, technical, clinical outcomes and follow-up data were collected. Descriptive analyses were performed by reporting mean and standard deviation for continuous variables and frequencies with percentages for categorical variables.

Results A total of 41 patients were included (44 % female). All had experienced one or more episodes of AC prior to the procedure. EUS-GBD was performed within 3 days of the AC episode in 76 % of patients, and within one month in the remaining 24 %. Two patients (6 %) underwent EUS-GBD following percutaneous drainage. LAMS size were 10 x 10 mm or 10 x 15 mm. 21 patients (51 %) required ERCP for cholangitis:10 in the same week as EUS-GBD, 5 within the preceding month, and 6 more than one month before the procedure. We reported one case of LAMS maldeployment (2 %) that was successfully, conservatively managed.

Comorbidity burden was high: 37 % of patients were ASA IV, 54 % ASA III, and 9 % ASA II. Mean age was 78 ± 11.2 years, 34 % of the patients were > 85 years old, including all the ASA II patients. Five people (12 %) had Child-Pugh B or C cirrhosis, 29 % NYHA III stage, 34 % advanced neoplasia, and 15 % had severe obesity. 30-days mortality was 0 %. Three patients (7 %) developed cholecystitis between 30 and 60 days after LAMS placement, in all cases conservatively treated.

Conclusions Permanent EUS-GBD represents a safe and effective therapeutic option for patients not candidates for cholecystectomy due to severe conditions. It can be performed during the acute phase of AC or in an elective setting after clinical resolution. Despite of the need of longer follow up and larger series, data support the consideration of EUS-GBD as a long-term management strategy in presence of advanced age, severe comorbidities, high ASA class.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP736 A Subepithelial Lesion at the Gastroesophageal Junction Presenting as Primary B-Cell MALT Lymphoma: A Rare Case Report

Authors Galanopoulos M[1], Giakoumis M[1], Papadomichelakis M[1], Kyriakos N[1], Liatsos C[1]
Institute **1** 401 General Military Hospital of Athens, Greece, Athens, Greece
DOI 10.1055/s-0046-1822063

IntroductionPrimary mucosa-associated lymphoid tissue (MALT) lymphoma rarely arises at the gastroesophageal junction (GEJ). Subepithelial presentation is particularly uncommon and often misclassified as a mesenchymal tumor. Because GEJ subepithelial lesions are frequently presumed to represent GISTs or leiomyomas, lymphoid neoplasms may escape early consideration. We present a rare case of a GEJ subepithelial lesion originating from the muscularis mucosae, ultimately diagnosed as primary MALT lymphoma, emphasizing the diagnostic value of EUS-guided deep-tissue sampling [1–5].

Case DescriptionA 68-year-old man was evaluated for an incidentally identified GEJ subepithelial lesion. Endoscopy demonstrated a smooth, intact mucosal surface over a well-defined 23 × 10 mm mass. Endoscopic ultrasonography revealed a homogeneous, hypoechoic lesion confined to the muscularis mucosae, without perigastric lymph nodes. The differential diagnosis included gastrointestinal stromal tumor, leiomyoma, neuroendocrine tumor, and lymphoid neoplasia. EUS-guided tissue acquisition was performed using a 22-gauge fine-needle biopsy (FNB).

Histopathology revealed dense CD20(+)/CD3(–) B-cell infiltration, LCA(+), with absence of epithelial or neuroendocrine markers (Pankeratin–, Chromogranin A–, CD56–). Hematopathology demonstrated a monomorphic population of small B-cells expressing CD20 and bcl-2, negative for CD5, CD23, and Cyclin-D1, with a low proliferative index (Ki-67 ≈ 10 %). These findings supported a diagnosis of primary MALT lymphoma. Staging CT identified no systemic disease, consistent with localized lymphoma.

DiscussionMALT lymphoma at the GEJ is exceptionally rare, and subepithelial morphology poses a diagnostic pitfall because EUS features may overlap with GIST or leiomyoma. High-resolution EUS is essential for characterizing the layer of origin, while FNB provides adequate deep-tissue samples crucial for immunophenotyping. The immunoprofile—CD20(+), bcl-2(+), Cyclin-D1(–), CD5(–), CD23(–)—allows differentiation from mantle cell and follicular lymphomas. Early diagnosis is clinically relevant, because localized disease carries an excellent prognosis and can be managed with organ-preserving therapeutic strategies.

ConclusionThis case illustrates a rare GEJ MALT lymphoma mimicking a mesenchymal subepithelial lesion. Accurate diagnosis required correlation of endoscopic appearance, EUS characterization, and targeted FNB with detailed immunohistochemistry. Lymphoid neoplasms, although rare, should be included in the differential diagnosis of GEJ subepithelial lesions, particularly those arising from the muscularis mucosae.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP737 Accuracy of MRI for identifying endoscopically resectable early rectal cancer: a retrospective institutional study

Authors Looi SJ[1], Plumb AA[1], Taylor SA[1], Hameed M[1], Stephenson J[1], Ortiz O[2], Ahmad OF[3, 1], Seward E[1], Vega R[1]
Institutes **1** University College London Hospitals NHS Foundation Trust, London, United Kingdom; **2** Hospital Clínic de Barcelona, Barcelona, Spain; **3** Division of Surgery and Interventional Sciences, University College London (UCL), London, United Kingdom
DOI 10.1055/s-0046-1822064

Aims Increasing numbers of early rectal cancers are detected due to improved screening. MRI can assist in selecting lesions suitable for endoscopic resection [1]. At our institution, all suspicious rectal lesions undergo MRI assessment. We aimed to evaluate the accuracy of MRI in predicting the depth of submucosal invasion in early rectal cancers.

Methods We conducted a retrospective study of T1/2 rectal cancers managed by endoscopic submucosal dissection between October 2019 and October 2025. Each MRI scan was independently reviewed by two radiologists, both blinded to endoscopic and histological findings. Radiologists assigned T-stage based on predefined MRI criteria: absence of submucosal invasion (T0); submucosa ≥ 1mm with intact muscularis propria (MP) (T1 sm1/2); submucosa < 1mm but with ≥ 1mm intact MP (T1 sm3/early T2); or deep invasion characterised by < 1mm intact MP or extension beyond it (deep T2/T3). Radiological staging was compared with final histology and Japan NBI expert team (JNET) or Kudo based optical assessment. Categorical variables were analysed using χ^2 testing, continuous variables with the Mann–Whitney U test, and inter-radiologist agreement using Cohen's kappa (κ).

Results Of the 21 cases identified, 13/21 (63 %) had at least one technical issue. Motion artefact was the most common issue (8/13, 62 %), followed by inadequate distension (3/13, 23 %), absence of a true short-axis imaging (3/13, 23 %), incomplete coverage (3/13, 23 %) and faecal residue (1/13, 8 %). However, this did not appear to affect diagnostic performance: MRI correctly staged 6/8 (75 %) scans without technical issues and 11/13 (85 %) with issues. Overall, one or both radiologists correctly staged 17/21 cases (81 %). All radiologists correctly identified lesions with ≥ 1mm preserved MP which is a key determinant for endoscopic resectability. Staging concordance between radiologists was 13/21 (62 %) consistent with moderate agreement (κ = 0.48).

Optical assessment was then compared with MRI and histology. JNET 2B lesions were all T1 on histology except one T2 case, yet MRI overstaged 4/7 cases (57 %), indicating a conservative bias for superficial disease. JNET 3 lesions showed strong alignment between all modalities, with MRI correctly staging 5/6 cases (83 %). Kudo IV lesions were heterogenous, including overstaging of one Tis lesion. Among Kudo V lesions, histological depth varied; MRI correctly staged 5/6 cases (83 %) and overstaged one case with no understaging. Overall, optical assessment correlated more closely with histology for superficial disease, but MRI performed best for lesions with deeper invasion. MRI tended to overstage disease compared with final histology (9/21; 43 %), with no instances of understaging (▶ **Table 1**).

▶ **Table 1** summarises clinical and procedural characteristics stratified by MRI accuracy.

		MRI Staging		p value
		Correct N = 17	Incorrect N = 4	
Age (median)		67.5	65.0	1.00
Sex	Male, N (%)	10 (58.8)	3 (75.0)	0.50
	Female, N (%)	7 (41.2)	1 (25.0)	
Lesion size in mm (median)	32.5	40.5	1.00	
Location	Upper rectum, N (%)	7 (41.2)	1 (25.0)	0.66
	Lower rectum, N (%)	10 (58.8)	3 (75.0)	
Morphology	LST-NG, N (%)	9 (52.9)	1 (25.0)	0.59
	LST-G mixed nodular type, N (%)	8 (47.7)	3 (75.0)	
Procedural duration in minutes (median)		133.5	178.0	0.09

There were no identifiable predictors of correct staging (all $p > 0.05$).

Conclusions MRI demonstrated high accuracy in identifying early rectal cancers suitable for endoscopic resection, with excellent sensitivity for detecting preserved MP. Accuracy was unaffected by frequent technical issues, although inter-radiologist agreement was moderate and MRI consistently overstaged disease. Optical assessment corresponded more closely to histology for superficial disease, whereas MRI performed best for deeper lesions. MRI is a safe and conservative staging tool, with scope for improvement through targeted MDT feedback.

eP738 When a single stone causes major obstruction: Bouveret's syndrome treated by ElectroHydraulic Lithotripsy (EHL)

Authors Kaya E[1], VandenDriessche V[2], Yengue P[1], Lefebvre M[1]
Institutes 1 Centre Hospitalier de Wallonie Picarde (CHwapi), Tournai, Belgium; 2 Hôpitaux universitaires de Bruxelles – Hôpital Erasme, Brussels, Belgium

DOI 10.1055/s-0046-1822065

Abstract Text

Bouveret's syndrome (BS) is a rare form of gallstone ileus that can result in benign gastric outlet obstruction (GOO). It occurs when a gallstone migrates through the cystic wall, forming a cholecystoenteric fistula with subsequent impaction of the calculous material in the duodenal lumen. [1–3]

We report the case of an 80-year-old woman presenting with chronic abdominal pain, weight loss, and sudden-onset vomiting. Initial evaluation was challenging due to cognitive impairment and early dementia. However, blood tests and computed tomography (CT) imaging revealed a 50 mm gallstone impacted in the duodenal bulb, associated with acute cholecystitis. CT additionally showed gastric dilation secondary to duodenal obstruction. Although BS has traditionally been managed surgically, often requiring laparotomy and limited small-bowel resection, the patient's frailty prompted a multidisciplinary decision to pursue a less invasive endoscopic approach. [4]

Initial management included nasogastric decompression and intravenous proton-pump inhibitor therapy. Subsequent upper gastrointestinal endoscopy confirmed the presence of food debris in the stomach and a 50 mm impacted gallstone obstructing the pyloric outlet. Electrohydraulic lithotripsy (EHL) was performed under direct endoscopic visualization using a high-power setting (pulse level 15) to facilitate fragmentation.

Given the substantial size and calcified consistency of the stone, all eight EHL probes available in our center were used during the first session, achieving partial fragmentation and permitting advancement of the endoscope into the second portion of the duodenum. A second procedure was performed 48 hours later, resulting in complete fragmentation. Stone debris and fragments were extracted using a polyp retrieval net and standard polypectomy snare. The cumulative procedure time was approximately three hours, requiring a total of 12 probes. After stone extraction, two large, round Forrest III ulcers were identified on the lateral wall of the duodenal bulb, while the opening of the cystic duct with adjacent cholecystic mucosa was visualized on the medial wall. Clinical and endoscopic follow-up at ten days confirmed complete symptom resolution, successful clearance of all stone material, and healing of the duodenal ulcers. This case demonstrates successful endoscopic management of duodenal Bouveret's syndrome in a frail, surgically ineligible geriatric patient.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP739 Untutored colorectal endoscopic submucosal dissection: learning curve of a single operator in a non-academic European center

Authors Kogias D[1], Papadopoulos V[1], Vogli S[2], Mavrogenis G[3]
Institutes 1 Democritus University of Thrace, Alexandroupolis, Greece; 2 Metaxa Cancer Hospital Piraeus, Pireas, Greece; 3 Mediterraneo Hospital, Glifada, Greece

DOI 10.1055/s-0046-1822066

Aims Colorectal endoscopic submucosal dissection (ESD) allows en-bloc removal of early neoplastic lesions but remains technically demanding in Western non-academic settings, where exposure to high-volume training is limited. This study aimed to evaluate learning progression and performance determinants of untutored colorectal ESD in a European non-academic center.

Methods This retrospective cohort included all consecutive colorectal ESD procedures performed by a single operator from March 2016 to October 2025. Demographic, lesion, and procedural data were prospectively collected. Learn-

ing-curve assessment used case-by-case speed analysis and linear regression. The operator's concurrent experience with additional third-space endoscopy procedures was also considered. Adverse events were classified by ASGE severity criteria and categorized as mild, moderate, severe, or fatal and immediate or delayed.

Results A total of 114 colorectal ESDs were performed (mean age 66.5 ± 12.0 years; 56.5 % male). Key outcomes included: median lesion size 11.2cm (range 0.36–89.25), median max diameter 4.0cm (range 0.6— 10.5), median dissection speed 7.5cm /hour (range 1–48), high en-bloc and R0 resection rates (97.3 % and 93.8 %) and overall complication rate 13.2 % (3.6 % perforation rate), including two macro-perforations (the only treated surgically), two micro-perforations, four early and two delayed bleeding events and three strictures. The learning curve showed speed increasing progressively from cases 20–60 and peaking at 70–90 (cumulative experience from additional third-space endoscopy procedures, ~70 and ~50 cases during these respective periods). Dissection speed reached above 9 cm /hour after 30 colorectal ESD cases and became consistent after 60-70. Significant location-based differences were observed in lesion size ($p = 0.036$), dissection speed ($p = 0.02$), circumferential involvement ($p = 0.001$), and perforation rates ($p = 0.04$), with rectal and sigmoid lesions showing higher adjusted speeds and right-sided lesions being more challenging. En-bloc and R0 rates did not differ by location. Complications clustered between cases 15–30 before declining after case 35, reflecting an initial learning-curve vulnerability followed by sustained proficiency.

Conclusions In this single-operator European cohort, colorectal ESD exhibited a clear learning curve, with early variability progressively replaced by stable improvements in dissection speed and procedural efficiency, while en-bloc and R0 rates remained consistently high. When colorectal ESDs were combined with other ESD-related procedures, the broader technical exposure likely accelerated skill acquisition. Consequently, the true proficiency threshold for colorectal ESD is likely higher than the apparent cutoff observed here, with at least 100 procedures required to achieve an expert level.

eP740V Afferent limb syndrome (ALS) after DPC and Roux-en-Y reconstruction. Endoscopic resolution with jejuno-jejunal LAMS

Authors Viejo-Almanzor A[1], Alía Verdejo T[1], Rendón Unceta P[1], Rodriguez Ramos C[1]

Institute **1** Hospital Universitario Puerta del Mar, Cádiz, Spain

DOI 10.1055/s-0046-1822067

Abstract Text

A 65-year-old woman with pancreatic adenocarcinoma s/p Whipple and Roux-en-Y reconstruction developed locoregional recurrence on palliative chemotherapy. She presented with cholangitis; PTBD improved infection but clamping caused symptom recurrence, suggesting afferent limb syndrome (ALS).

Therapeutic EUS with afferent limb distension (saline/methylene blue/contrast via PTBD) confirmed ALS and revealed an enterolith. Safe access was obtained from the efferent jejunal limb; a 15 × 10 mm Hot-AXIOS LAMS was placed free-hand with a coaxial double-pigtail stent to prevent obstruction/dislodgment. Cholangiography later showed hepaticojejunal anastomosis stenosis, treated with an uncovered 10 × 60 mm SEMS. The patient achieved complete clinical and laboratory recovery, and was discharged.

DOI 10.1055/s-0046-1822068

Abstract Text

ESGE guidelines recommend prophylactic endoloop placement before resecting large pedunculated colonic polyps, but positioning the loop can be technically demanding and may affect procedural safety.

This video presents three cases of endoloop-assisted underwater resection of large pedunculated colonic polyps. Underwater immersion provides buoyancy, lifting the polyp and facilitating accurate endoloop placement. This approach improves stability, precision, and safety, helping reduce the risk of post-polypectomy bleeding. In some cases, water irrigation alone achieved adequate colonic distension, overcoming spasm and rapid CO_2 expulsion.

In conclusion, underwater immersion simplifies endoloop placement and enhances snare capture and resection of large pedunculated colonic polyps.

eP742 Determinants of Procedural Duration in Colorectal Endoscopic Submucosal Dissection and a Validated Score for Identifying Prolonged Cases

Authors Kogias D[1], Papadopoulos V[1], Vogli S[2], Mavrogenis G[3]

Institutes **1** Democritus University of Thrace, Alexandroupolis, Greece; **2** Metaxa Cancer Hospital Piraeus, Pireas, Greece; **3** Mediterraneo Hospital, Glifada, Greece

DOI 10.1055/s-0046-1822069

Aims Procedure duration is a key determinant of safety, resource utilization, and scheduling in colorectal endoscopic submucosal dissection (ESD). Although several lesion- and patientrelated factors have been associated with procedural difficulty, a validated model for predicting prolonged duration is lacking. This study aimed to identify independent predictors of procedure duration in colorectal ESD and quantify their relative contribution through categorical regression (CATREG), and develop and validate a clinically applicable risk score to predict prolonged procedures.

Methods We retrospectively analyzed 114 consecutive colorectal ESDs recorded in a prospectively maintained database. Procedure duration was the primary outcome. Normality testing demonstrated significant deviation from normality, so non-parametric statistics were employed. Variables with $p < 0.05$ were entered into a multivariable CATREG model with optimal scaling and ridge regularization (tolerance ≥ 0.40). Independent predictors were used to construct a weighted risk score based on normalized CATREG F-statistics. The score was validated against prolonged duration (≥ 1.5 hours) using receiver operating characteristic (ROC) analysis.

Results Duration correlated positively with age, lesion size, maximal axis and circumferential involvement (all $p < 0.001$). No significant differences were observed for sex, location, type of sedation, antithrombotic use, bleeding, perforation, en bloc resection, clip and band traction or underwater technique, even if the last two substantially contributed to the procedure effectiveness. Significantly longer procedures occurred in cases with complications ($p = 0.001$), fibrosis ($p = 0.023$), tunnel technique ($p = 0.001$), LST-G morphology ($p = 0.028$), previous interventions ($p = 0.007$), intermuscular involvement ($p < 0.001$), and R1 resection ($p = 0.014$). Multivariable CATREG identified seven independent

predictors which were used to construct a weighted risk score (range 0–22 points) for predicting prolonged procedures with excellent performance. The predictors included: circumferential involvement ($p < 0.001$, 9 points) lesion size ($p < 0.001$, 4 points), age ($p = 0.001$, 3 points), complications ($p = 0.011$, 3 points), intermuscular involvement ($p = 0.010$, 2 points) LST-G morphology ($p = 0.037$, 1 point) and previous interventions ($p = 0.046$, 1 point). CATREG-derived optimal cutoffs included: size ≥ 12 mm, age ≥ 70 years, circumference ≥ 180 °.

Conclusions Colorectal ESD duration is driven primarily by lesion complexity—particularly circumferential extent and lesion size—with additional contributions from age, intermuscular dissection, complications, LST-G morphology, and prior interventions. An ESD risk score incorporating these factors reliably predicts prolonged procedures and offers a practical tool for preprocedural planning. Prospective validation is warranted.

eP743 VAC therapy as rescue treatment of a big esophageal perforation after endoscopic submucosal dissection in eosinophilic esophagitis

Authors Conti CB[1], Mulinacci G[2], Dinelli ME[2]
Institutes **1** Interventional Endoscopy, IRCCS San Gerardo dei Tintori, Monza, Italy; **2** San Gerardo Hospital Monza, Monza, Italy
DOI 10.1055/s-0046-1822070

Abstract Text

A 74-year-old woman presented with dysphagia. Upper endoscopy revealed eosinophilic esophagitis (EoE) and two squamous lesions: a 15-mm lesion in the upper esophagus with low-grade dysplasia (LGD) and a 30-mm lesion in the mid–lower esophagus with high-grade dysplasia (HGD). We prioritized endoscopic resection before initiating steroid therapy [1–3].

After multidisciplinary discussion, we elected to resect the smaller lesion first to minimize the risk of complications. Endoscopic mucosal resection yielded an 18-mm specimen with confirmed LGD and R0 margins. No complications occurred.

We then performed endoscopic submucosal dissection (ESD) of the distal lesion, obtaining a 35 × 30 mm specimen, HGD, R0, without immediate adverse events.

Twenty-four hours later, the patient developed dyspnea and oxygen saturation dropped to 70 %. A CT scan revealed mediastinitis with a large esophageal perforation. Thoracic surgeons performed mediastinal washout and placed three drains.

During endoscopy, we observed that the esophagus had become detached from the stomach along one-third of its circumference over a length of 7 cm, while the resected area showed no perforation; the breach had occurred laterally.

We elected to reconnect the esophagus and stomach using a VAC-stent system. The patient stabilized, and after three days the stent was replaced. Remarkably, the previously open segment had reapproximated.

Six days later, we placed a fully covered 12-cm metal stent, which was kept in place for one month. The patient recovered well and was discharged after one month.

A follow-up gastroscopy two months later revealed a stricture at the mucosectomy site in the upper esophagus, with fragile mucosa along all the organ, but no recurrent lesions. Five months later, the patient is eating normally and remains on PPI therapy. Re-evaluation and management of the underlying EoE are pending.

Only a few cases of ESD in patients with EoE have been reported in the literature, and perforation appears to be a common complication in this setting. In our patient, the perforation site was unusual, underscoring both the technical challenges of resection and the difficulty in predicting complications in these patients. Nonetheless, the rapid mucosal healing achieved with VAC therapy was remarkable. We believe that in such cases a careful choice between ESD and mucosal resection is essential, and that VAC therapy may represent a valuable option when severe complications occur in these patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP744 Case report: Endoscopic Submucosal Dissection of Gastric Heterotopia in the Rectum

Authors Tranquillini C[1], Landy J[1], Tyson L[1, 2], Suzuki N[1]
Institutes **1** Wolfson Unit for Endoscopy, St Mark's Hospital, London, United Kingdom; **2** Department of Hepatology, St Mary's Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom
DOI 10.1055/s-0046-1822071

Background: Gastric heterotopia (GH) is the presence of gastric mucosa outside its normal anatomical location. Although commonly reported in the upper gastrointestinal tract, GH in the rectum is rare, with fewer than 100 cases documented. GH may be congenital (heteroplasia) or acquired (metaplasia) and can present with nonspecific gastrointestinal or anorectal symptoms. Furthermore, the risk of transformation of heterotopic gastric mucosa to malignancy is currently unknown, but cases of malignant transformation are described in the literature.

Case Presentation: We report the case of a 19-year-old man presenting with chronic abdominal burning, bloating, early satiety, and constipation. Initial investigations were unremarkable. A colonoscopy revealed a well-demarcated, granular lesion with rolled borders in the distal rectum, biopsied and confirmed as gastric heterotopia. The lesion was successfully resected en-bloc via endoscopic submucosal dissection. Histopathology confirmed gastric heterotopia without dysplasia or malignancy. At six-month follow-up, there were no signs of recurrence, and patient reported partial improvement of the symptoms.

Conclusion: Rectal gastric heterotopia is a rare entity that can mimic other anorectal conditions and has a yet unknown risk of transformation to malignancy. Diagnosis requires histopathological confirmation. Endoscopic resection via ESD is an effective and minimally invasive treatment option. Awareness of this condition can facilitate timely diagnosis and appropriate management.

eP745 Per-oral plication of the (neo)esophagus (POPE) for end-stage achalasia and delayed gastric conduit emptying after esophagectomy: a systematic review of case reports and case series

Authors Uchima H[1, 2, 3, 4], Benites Goñi HE[5], Wong L[6], Muñoz González R[6], Guarner-Argente C[7], Albéniz E[8], Kahaleh M[9]
Institutes **1** Germans Trias i Pujol Hospital, Badalona, Spain; **2** Teknon Medical Center, Barcelona, Spain; **3** Institut de Recerca Germans Trias i Pujol, Badalona, Spain; **4** Centro de investigación Biomédica en Red Enfermedades Hepáticas y Digestivas (CIBEREHD), Badalona, Spain; **5** Hospital Nacional Edgardo Rebagliati Martins, Lima, Peru; **6** Hospital Germans Trias i Pujol, Badalona, Spain; **7** Gastroenterology Department, Barcelona, Spain; **8** Navarra Hospital Complex – Navarra Hospital, Pamplona, Spain; **9** Foundation for Interventional & Therapeutic Endoscopy, New Jersey, United States of America
DOI 10.1055/s-0046-1822072

Aims To evaluate the feasibility, clinical effectiveness, and safety of per-oral plication of the esophagus (POPE) in patients with sump-related refractory esophageal emptying due to end-stage achalasia or delayed gastric conduit emptying (DGCE) after esophagectomy. Evidence remains limited to case reports and small series [1–9].

Methods A systematic review was conducted in PubMed, Embase, Scopus, and Web of Science through July 2025. We included case reports and case series reporting extractable clinical information on POPE performed for end-stage achalasia or DGCE after esophagectomy. Clinical and endoscopic data were collected. Study selection followed PRISMA guidelines (▶ **Table 1**).

▶ **Table 1** Demographic data, clinical outcomes, and adverse events

	Total = 59 patients	
Country of study		
USA	58	88.89
Spain	1	11.11
Gender		
Female	31	52.54
Diagnosis prior to treatment		
End-stage achalasia	48	81.36
DGCE after esophagectomy	11	18.64
Clinical response		
End-stage achalasia	43/48	89.58
DGCE after esophagectomy	8/11	72.73
Intraprocedural adverse events	4	6.78
Mucosal perforation	3	5.08
Bleeding	1	1.69
Late adverse events	6	8.47
Bleeding	1	1.69
Pain	1	1.69
Aspiration pneumonia	2	3.39
Gastric obstruction that required gastrostomy tube placement	1	1.69

Results Nine publications were identified (4 case series, 3 case reports, 2 conference abstracts), comprising 59 patients aged 28–86 years (mean 70 years). Forty-eight patients were treated for end-stage esophageal achalasia with sump formation and 11 for DGCE after esophagectomy. All achalasia patients had undergone previous interventions at the esophagogastric junction (endoscopic and/or surgical); in the DGCE group, 72.7 % had undergone pyloromyotomy or pyloroplasty before POPE. Technical success was 100 % with a mean procedure time 71.4 minutes (Range 48-97). Clinical improvement (complete or partial) was reported in 89.6 % of end-stage achalasia cases and 72.7 % of DGCE cases, with overall clinical benefit in 86.4 % of the pooled population. Re-intervention (Re-POPE) was required in 22 % of patients to maintain symptom response. Adverse events were uncommon and generally mild. Intraprocedural events included three mucosal perforations and one bleeding event, all successfully managed endoscopically. Post-procedural events consisted mainly of aspiration pneumonia (n = 2), mild delayed bleeding, or transient pain. No related mortality was reported. Hospital stay was typically ≤ 3 days. Mean reported follow-up across publications was 13.5 months, ranging from 4 months to 6 years.

Conclusions POPE appears to be a feasible and safe endoscopic option for patients with refractory esophageal sump formation due to end-stage achalasia or DGCE after esophagectomy. Clinical improvement was frequent and the technique was repeatable, with low rates of significant adverse events. Given that all available evidence originates from uncontrolled case reports and small series, these findings should be interpreted as exploratory. Prospective studies with standardized outcomes and long-term follow-up are needed to validate the durability and comparative effectiveness of POPE.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Anastomotic leaks remain a serious complication after ileal pouch–anal anastomosis.We report the case of a 53-year-old male patient who underwent laparoscopic subtotal colectomy with ileal pouch for ulcerative colitis. On the fifth postoperative day, the patient developed fever and purulent output from the surgical drain and computed tomography demonstrated an anastomotic leak. The patient was referred to the gastroenterology department for endoscopic management. During endoscopy, a leak approximately 20 mm in diameter was identified near the dentate line and was completely closed using the X-Tack Helix suturing system. Follow-up endoscopy at four and twelve months after the procedure demonstrated the X-Tack system in place. The patient showed clinical improvement soon after the endoscopic closure and remained asymptomatic through the 12-month follow-up.

eP747 Z-POEM, a safe and effective approach for Zenker's diverticulum: a single center experience

Authors Porta P[1], Grassini MV[1], Mosconi M[2], Impellizzeri G[1], Donato G[1], Ferraro R[1], De Angelis C[3], Pagano N[1]
Institutes 1 Ospedale maggiore di Novara, Novara, Italy; 2 Hospital San Giovanni Battista, Foligno, Italy; 3 Azienda ospedaliero universitaria Torino, Torino, Italy
DOI 10.1055/s-0046-1822074

Aims Endoscopic Zenker Peroral Endoscopic Myotomy (Z-POEM) is beginning to establish itself as a valuable, minimally invasive treatment option for Zenker's Diverticulum (ZD). However, the available evidence regarding this approach is still growing. This study aims to assess the technical and clinical performance of endoscopic Z-POEM for ZD, specifically evaluating technical success rates, clinical efficacy, the length of hospitalization, and the occurrence of adverse events.

Methods We included all patients that underwent Z-POEM for Zenker's diverticulum in our Center from February 2022 to August 2025, collected through a prospectively maintained database. The primary outcome we evaluated was clinical success, measured by symptomatic improvement based mainly on the resolution of dysphagia and defined by a Kothari-Haber score < 3 at 3 months, and for the patients with a long enough follow up, at 1 year. As for secondary outcomes, we evaluated technical success, length of hospital stay, and incidence of adverse events.

Results In total, 30 patients were treated with Z-POEM (males 66 %, mean age 73,7 ± 7,6 years), all with Zenker diverticula and one with concomitant esophageal spasm; we excluded 4 patients with exclusive esophageal spasm without presence of a diverticulum. Most patients were naïve, while 4 had already undergone treatment for ZD, 2 of them through a surgical approach and 2 endoscopic, experiencing symptom recurrence a few years post treatment. The average pre-procedural Kothari-Haber score in our population was 5,73 (± 1,8), with all patients presenting with dysphagia and many experiencing daily regurgitations along with weight loss and halitosis. The mean size of the diverticulum was 2,16 cm. Technical success was observed in 100 % of cases and clinical success was achieved in 100 % of patients, with a post-procedural Kothari-Haber score ≤ 1 in all patients at 3 months post treatment. For the 21 patients treated until September 2024 the Kothari-Haber score was still ≤ 1 at the 1 year follow up, and no patient suffered from symptom recurrence. The average duration of hospitalization was 2,03 days. No patient experienced post-procedural adverse events, which we also documented by contrast X-ray performed at 24 hours before attempting refeeding. All patients restarted oral feeding without complications before discharge.

Conclusions Endoscopic Z-POEM is a feasible and effective treatment for Zenker's diverticulum, showing optimal rates of technical and clinical success, and resulting in a short hospital stay. This procedure represents a safe and minimally invasive option for patients with ZD, including those with recurrence of symptoms after a previous surgical or endoscopic intervention.

Background: Gastric outlet obstruction (GOO) in oncologic patients is usually attributed to malignant duodenal infiltration or peritoneal carcinomatosis. However, careful imaging review in mandatory in the context of profound cachexia because rarely benign extrinsic compression of the third portion of the duodenum may closely resemble malignant obstruction. International guidelines increasingly recognize EUS-guided gastroenterostomy (EUS-GE) with lumen-apposing metal stents (LAMS) as a minimally invasive alternative to surgical bypass in both malignant and selected benign GOO, particularly when performed in high-expertise centers [1–9].

Case: We report a 72-year-old woman with metastatic ductal breast carcinoma and severe cachexia presenting with non-traversable duodenal stenosis in a context of normal duodenal mucosa. Endoscopy and computed tomography showed obstruction of the third duodenal portion without clear malignant infiltration. Despite initial PEG–PEJ placement for decompression and nutrition, symptoms persisted. Following multidisciplinary evaluation, an EUS-guided gastroenterostomy using a 15 × 10 mm LAMS was performed, resulting in rapid symptom resolution, restored enteral continuity, and nutritional improvement.

Conclusion:EUS-GE is a valuable minimally invasive therapeutic option for benign or indeterminate GOO in oncologic patients, particularly when the distinction between malignant and benign etiologies is challenging. Current ESGE and ASGE guidelines, supported by recent meta-analyses, endorse its use in expert centers.

eP749V Endoscopic Submucosal Dissection for a Giant Ulcerated Gastric Lipoma Presenting with Acute Bleeding: A Video Case Report

Authors Leonardi G[1], Adamo G[1], Solinas I[1], Ovidi F[1], Bronzini F[1], Lapenna L[1], Sostilio A[1], Manta R[1]
Institute 1 Azienda USL Toscana Nord Ovest, Livorno, Italy
DOI 10.1055/s-0046-1822076

Abstract Text

Gastric lipomas are rare benign tumors, and acute bleeding from these lesions is exceptionally uncommon, usually occurring in large ulcerated antral lipomas. A 65-year-old high-risk patient presented with melena, syncope, and acute anemia. Endoscopy revealed a giant ulcerated subepithelial mass in the antrum, and EUS confirmed a well-defined hyperechoic submucosal lesion consistent with a lipoma. After stabilization, the patient underwent ESD. ESD enabled complete en bloc removal without complications, with rapid clinical recovery and stabilization of hemoglobin. Histology confirmed a large submucosal lipoma with ulceration. ESD is a safe and effective minimally invasive treatment for large or bleeding gastric lipomas, even in comorbid patients, offering a valid alternative to surgery.

DOI 10.1055/s-0046-1822077

Aims Dermatological findings are commonly observed among patients with IBD and significantly impact their quality of life. These skin-related issues, including pyoderma gangrenosum, erythema nodosum, and psoriatic rashes, often become during the active phases of the disease. Recently, new biomarkers have been identified as being correlated with inflammatory bowel disease (IBD) activity and complications . Activin-A, a member of the Transforming Growth Factor-beta (TGF-β) superfamily, stands out as a noteworthy molecule [1, 2].

Methods The present study was an observational investigation that enrolled 34 patients with ulcerative colitis who were receiving treatment. The patients underwent a dermatological evaluation and their serum activin A levels were measured (▶ **Table 1**).

Results There was no significant difference in activin-α levels between the patients with and without dermatological involvemen
Normally distributed numerical variables are presented as means ± standard deviations, and categorical variables are presented as numbers (%). Numerical variables that are not normally distributed are presented as medians (minimum-maximum).

Conclusions The role of activin-A in managing dermatological involvement in UC appears to be limited. Clinically, a broader panel of biomarkers should be used to assess the inflammatory status in these patients

▶ **Table 1** Age, sex, activin-a levels and dermatologic findings among the group

Parameters	Patient (n = 34)
Age	43.7415.16
Sex	
Male	23 (%67.6)
Female	11 (%32.4)
Serum Activin-a	527.34 (231.68-2134.54)
Dermatologic involvement	
Yes	21(%61,8)
No	13(%38,2)

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822078

Aims The aim of our study was to assess the frequency of digestive and extra-digestive cancers in IBD and to identify associated risk factors.

Methods We conducted a retrospective–prospective monocentric cohort study based on hospitalization records from the Department of Gastroenterology at CHU Mohamed Lamine Debaghine.All patients with a confirmed diagnosis of IBD—Crohn's disease (CD) or ulcerative colitis (UC)—hospitalized between 2000 and 2025 were included [1–4].
For each patient, a standardized data sheet recorded demographic characteristics, disease features, and any cancer that occurred during follow-up. We calculated the overall frequency of digestive and extra-digestive cancers as well as the frequency of each cancer type. We also analyzed potential risk factors. Data entry and analysis were performed using Epi-Info 6.

Results A total of **724 patients** were included: **513 (70.9 %) with Crohn's disease** and **209 (28.9 %) with ulcerative colitis**.Overall, **428 patients (59.1 %)** had long-standing IBD (> 10 years), with a mean disease duration of **13.05 ± 7.82 years**.

Thirty-five patients (4.8 %) developed cancer. Cancers were distributed as follows: **Colorectal adenocarcinoma:** 2.34 % (n = 17), **B-cell lymphoma:** 0.82 % (n = 6), **Cholangiocarcinoma:** 0.27 % (n = 2), **Anal cancer:** 0.27 % (n = 2), **Small bowel adenocarcinoma:** 0.13 % (n = 1), **Non-melanoma skin cancer:** 0.13 % (n = 1), **Breast cancer:** 0.41 % (n = 3), **Lung cancer:** 0.13 % (n = 1), **Others:** 0.27 % (n = 2)
We observed a significantly higher frequency of cancer in:**UC patients** ($P < 0.008$),**IBD diagnosed after age 40** ($P < 10^{-6}$),**IBD associated with PSC** ($P < 0.0004$),**Patients exposed to immunosuppressants** ($P < 0.01$).No significant association was found with:Sex ($P = 0.3$),Duration of IBD ($P = 0.6$),Exposure to combination therapy ($P = 0.4$),Exposure to anti-TNFα (Infliximab or Adalimumab) ($P = 0.8$).

Conclusions In our hospital-based series, colorectal cancer was the most frequently observed malignancy.IBD diagnosed after age 40, UC phenotype, associated PSC, and exposure to immunosuppressive therapy were the main risk factors for cancer development in IBD patients

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP752 Budesonide for Celiac-like Enteropathy in Common Variable Immunodeficiency

Authors Lazaridis LD[1], Sachtouris G[1], Patsea E[2], Emmanouil T[3]

Institutes 1 METROPOLITAN GENERAL, Cholargos, Greece; 2 Pathology Dept, Metropolitan General, Cholargos, Greece, Athens, Greece; 3 METROPOLITAN GENERAL HOSPITAL , CHOLARGOS ATHENS Greece

DOI 10.1055/s-0046-1822079

Introduction: Impaired immunoglobulin production is linked to Common Variable Immunodeficiency (CVID), which can be manifested as autoimmune or celiac-like enteropathy. Distinguishing between CVID-related enteropathy and true celiac disease can be difficult especially when there are no serological markers [1, 2].

Case Description: A 52-year-old man who had been previously treated for lung adenocarcinoma and had a history of CVID on immunoglobulin replacement therapy was assessed for persistent diarrhea. Lower limb edema and hypoalbuminemia were found during the initial work-up and paraneoplastic etiology was ruled out by imaging. The patient underwent upper and lower GI endoscopy which showed scalloping of the duodenal folds and histology consistent with celiac disease.

After initial response to strict gluten-free diet the patient developed relapse with severe weight loss and protein loosing gastroenteropathy. Under the suspicion of CVID-related enteropathy rather than refractory celiac disease he was successfully treated with oral budesonide.

Conclusion: Although celiac-like enteropathy in CVID may resemble classical celiac disease, it frequently exhibits no IgA serological response and may only partially respond to gluten-free diet. It is important to distinguish between CVID-associated enteropathy and true celiac disease especially in patients who continue to experience symptoms despite strict gluten withdrawal since they can successfully respond to immunomodulatory treatment like budesonide.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP753 Evaluation of the Global Polypectomy Assessment Tool (GPAT) in Endoscopic Training: Insights from a Single-Center Experience

Authors Petrucci G[1], Chiappetta MF[1], Ciuffini C[1], Papparella LG[1], Vadalà Di Prampero SF[1], Borrelli De Andreis F[1], Costamagna G[1], Simonelli I[1], Bulajic M[1]

Institute 1 Ospedale Isola Tiberina Gemelli Isola, Roma, Italy, Roma, Italy

DOI 10.1055/s-0046-1822080

Aims Validated performance metrics for colonoscopic polypectomy remain limited. The ESGE Training Curriculum Taskforce has recently introduced the Global Polypectomy Assessment Tool (GPAT). We aimed to evaluate GPAT in real-life endoscopic training by assessing a GI trainee's learning curve and interobserver agreement among raters with different levels of experience.

Methods We conducted a prospective single-center study at Isola Tiberina–Gemelli Isola Hospital from January to October 2025. Thirty colorectal endoscopic resections (polypectomy and endoscopic mucosal resection, EMR) were included: 10 performed by a GI trainee under supervision and 10 performed by each of two expert endoscopists. All procedures were video-recorded and independently evaluated using GPAT by all three raters. The trainee's learning curve was assessed by comparing mean GPAT scores in the first 5 versus the last 5 trainee cases (t-test). Interobserver agreement was measured using intraclass correlation coefficients (ICC), with $p < 0.05$ considered statistically significant.

Results Thirty procedures in 23 patients were analyzed (median lesion size 25 mm; 90 % conventional EMR; 57 % piecemeal resection). Adverse events included 3 delayed bleedings (10 %) and no perforations. GPAT demonstrated progressive improvement in the trainee's performance, with convergence of scores after the 6th case (▶ **Fig. 1**). Overall interobserver agreement for GPAT was weak (ICC = 0.33, 95 %CI 0.09–0.57). Agreement between the two experts was poor (ICC = 0.21, 95 %CI − 0.08 to 0.50; p = 0.086). Agreement between the trainee and expert 1 was also poor (ICC = 0.38, 95 %CI 0.03–0.64; p = 0.017), while agreement between the trainee and expert 2 was fair (ICC = 0.44, 95 %CI 0.01–0.72; p = 0.022). When analyzing only the trainee-performed videos, agreement among the three raters remained poor (ICC = 0.24). Interobserver agreement was weak for expert 1-performed cases (ICC = 0.39) and fair for expert 2-performed cases (ICC = 0.41).

Conclusions GPAT offers a structured and practical method for assessing polypectomy competency during endoscopic training. Nevertheless, the low inter-rater reliability observed in real-world conditions highlights the need for improved standardization in the interpretation and scoring of the tool. Structured training in score application, together with refinement of specific scoring criteria, may be required to enhance consistency and validity. Larger multicenter studies are warranted to establish GPAT as a reliable standard for competency assessment in colonoscopic polypectomy.

eP754 Gel Immersion Endoscopic Mucosal Resection (GIEMR) using food thickener for non-pedunculated duodenal and colorectal polyps: a pilot study

Authors Maisterra S[1, 2, 3], Joana BS[1, 3, 2], Castro-Torres S[1, 3, 2], García-Ibañez E[1, 3, 2], Quintana-Carbó S[1, 2, 3], Tutusaus-Arroyo M[2, 3, 1], Golda T[4], Gornals JB[2, 3, 1]

Institutes 1 Endoscopy Unit, Digestive Diseases Department, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, Spain; 2 Bellvitge Biomedical Research Institute (IDIBELL), L'Hospitalet de Llobregat, Barcelona, Spain; 3 University of Barcelona (UB), Barcelona, Spain; 4 Colorectal Surgery Unit, General and Digestive Surgery Department, L'Hospitalet de Llobregat, Barcelona, Spain

DOI 10.1055/s-0046-1822081

Aims In recent years, underwater endoscopic mucosal resection (UEMR) has gained widespread popularity. However, intestinal fluids, bubbles, or bleeding may impair visibility. Gel immersion endoscopic mucosal resection (GIEMR) has

been reported in some Asian series. The use of an electrolyte-free gelling agent may offer advantages over UEMR due to its higher viscosity, and transparency, providing luminal stability, requiring smaller volumes, and ensuring a clearer visual field by displacing particles while limiting dilution with blood. Moreover, its greater weight favours bleeding control through a "slowing effect".
The main objective of the study was to evaluate the use of a food thickener (xanthan gum), as a gel easily prepared in the endoscopy room, for performing ft-GIEMR of non-pedunculated duodenal and colorectal polyps.

Methods A longitudinal, observational, single-centre pilot study was conducted. Consecutive cases prospectively collected in a dedicated database, from January 2024 to June 2025 were retrospectively analysed. Lesions treated with ft-GIEMR (food thickener) were included. The primary endpoint was feasibility and improvement of the visual field. Secondary endpoints included complete and en bloc resection, adverse events and procedure duration. Recurrence data are pending.

Results Among 180 complex lesions resected by EMR, UEMR, EFTR, or ESD, 29 patients (58 % male; median age:70.3 years [IQR: 60–81]) with 29 lesions were selected for GIEMR. Lesion locations included duodenum (n = 2) and the colon and rectum (n = 27), with a median size of 43.5 mm (IQR:32.5–55). Paris classification included Is, 0-IIa, or Is + 0-IIa morphologies. Colorectal lesions were classified as LST-G homogenous (37 %, n = 10), LST-G nodular-mixed (37 %, n = 10), and LST-NG elevated (26 %, n = 7). Gel volumes ranged from 100 to 400 mL per procedure. Median overall procedure time was 87 minutes [IQR:45–120]. Complete resection was achieved in 93 % (27/29), with piecemeal in 27 vs. en bloc resection in 2. One intraprocedural arterial bleed required conversion to CO_2 insufflation and prolonged procedure time. Post-procedure bleeding occurred in 3 cases. No intra or delayed perforations were observed.

Conclusions The use of food thickener for GIEMR appears feasible, effective, and safe, with high complete resection rates (93 %) and no perforations. Prospective comparative studies with UEMR are warranted to confirm these preliminary findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP755 COLON-AI: Evaluating the Reliability and Readability of AI Chatbots in Colonoscopy Counseling

Authors Antuofermo L[1], Apolito P[2], Landi S[2], Schiumerini R[2], Tamanini G[2], Longo NP[2], Librizzi R[2], Ghersi S[2], Bassi M[2], Cennamo V[2]

Institutes **1** Università Bologna, Bologna, Italy; **2** Gastroenterology and Interventional Endoscopy Unit, Local Health Authority of Bologna, Bologna, Italy

DOI 10.1055/s-0046-1822082

Aims Adequate bowel preparation critically depends on the delivery of clear and comprehensible pre-procedural information. Although a recent study has assessed the effectiveness of AI chatbots (GoogleGemini and ChatGPT) in providing colonoscopy instructions, comparative evidence including the most widely disseminated chatbot, Meta, is still lacking, and no data are available concerning the readability of these systems. The objective of the present study was to systematically evaluate the performance and readability of the most widely accessible AI chatbots in generating patient-facing colonoscopy preparation instructions [1–7].

Methods We conducted a prospective, single-center observational study at Maggiore Hospital Bologna between August and September 2025, in accordance with the METRICS checklist. Frequently asked questions (FAQ) regarding colonoscopy were collected from Italian hospital websites and Quora, and subsequently submitted to MetaAI, ChatGPT, and Google Gemini. The chatbot-generated responses were independently evaluated by five gastroenterologists, who were blinded to the chatbot platform, using a 1–5 Likert scale to assess accuracy, completeness, clarity, evidence-based content, and the absence of irrelevant information. Text readability was assessed using Readability Formulas (FRES score), expressed on a 0–100 scale.In addition, a subgroup performance analysis was conducted by categorizing questions into pre-procedural (e.g., split-dose bowel preparation), intra-procedural (e.g., how polypectomy is performed), and post-procedural aspects (e.g., post-sedation precautions).

Results GoogleGemini achieved the highest overall performance, with mean scores for accuracy (3.14), completeness (3.12), clarity (3.13), evidence-based content (2.91) and relevance (2.99), outperforming ChatGPT and MetaAI. The most satisfactory results were observed for pre-procedural questions compared to intra- and post-procedural ones, especially for accuracy, completeness and relevance. ChatGPT ranked second, with slightly lower yet consistent values for accuracy (2.96), completeness (2.93), clarity (2.95), evidence-based content (2.80) and relevance (2.93), particularly in delivering accurate intraprocedural responses. Conversely, MetaAI showed the weakest performance, with significantly lower scores for accuracy (2.62), completeness (2.56), clarity (2.62), evidence-based content (2.60) and relevance (2.66). Regarding readability, ChatGPT (13.68) generated more understandable texts than GoogleGemini (6.35) and MetaAI (4.21). Post-procedural questions yielded more accessible answers with ChatGPT showing the best readability scores (17.17), followed by GoogleGemini (12.00) and MetaAI (6.50). In contrast, intra-procedural queries produced the least satisfactory results with ChatGPT, GoogleGemini, and MetaAI scoring 11.00, 1.86 and 2.71, respectively. Overall, GoogleGemini provided the best response quality, ChatGPT slightly lower performance but better readability and MetaAI globally less favorable results (▶ **Table 1**).

▶ **Table 1**

	ChatGPT					MetaAI					Gemini				
	Accuracy	Completeness	Clarity	Evidence-based content	Relevance	Accuracy	Completeness	Clarity	Evidence-based content	Relevance	Accuracy	Completeness	Clarity	Evidence-based content	Relevance
Pre-procedure	2,96	2,88	2,99	2,79	2,97	2,49	2,37	2,49	2,41	2,59	3,22	3,18	3,18	2,94	3,1
Intra-procedure	3	3,05	3	2,79	2,95	2,67	2,62	2,67	2,64	2,64	3,12	3,17	3,19	2,98	2,93
Post-procedure	2,92	2,86	2,86	2,83	2,86	2,69	2,69	2,69	2,75	2,75	3,08	3,03	3,03	2,81	2,94
Overall	2,96	2,93	2,95	2,8	2,93	2,62	2,56	2,62	2,6	2,66	3,14	3,12	3,13	2,91	2,99

Conclusions This is the first study to evaluate both the accuracy and readability of colonoscopy-related information generated by the most widely used chatbots. Further studies involving patient participation are warranted to confirm the clinical applicability of these models in real-life settings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822083

Aims The aim of our study was to describe the epidemiological, clinical, endoscopic, and outcome-related characteristics of UGIB [1–7].

Methods We conducted a prospective, descriptive, single-center study at Bab El Oued University Hospital between January 2023 and August 2025. All patients admitted to the emergency units for overt upper gastrointestinal bleeding and referred for upper endoscopy were included. Clinical, biological, endoscopic, therapeutic, and outcome data were collected and analyzed using SPSS 23.0.

Results A total of **281 patients** were included, of whom **57.3 % were men**, with a mean age of **65.50 ± 16.16 years**. The main comorbidities were **portal hypertension (48.2 %)**, **ischemic heart disease (22.5 %)**, and **end-stage renal disease (17.4 %)**. Anticoagulant therapy was documented in **21.1 %** and antiplatelet use in **3.9 %** of cases.

UGIB presented as isolated hematemesis (32.4 %), isolated melena (37.7 %), hematemesis combined with melena (21.7 %), melena with hematochezia (5.7 %), and massive hematochezia (2.1 %). The mean Glasgow-Blatchford score was **10.56 ± 4.04**. Endoscopy revealed: peptic gastroduodenal ulcer disease(**33.3 %)**, gastroesophageal variceal rupture(**26.9 %)**, ulcerative esophagitis (**16.5 %)** , neoplasia(**5.8 %)** ,angiodysplasia(**5.4 %)** ,mallory-Weiss syndrome(**4 %)** ,erosive gastritis (**7.1 %),** dieulafoy's lesion(**1.3 %)** ,GAVE(**0.6 %)** and no lesion identified (**9.3 %)**

A blood transfusion was required in **64.8 %** of patients. Endoscopic hemostasis was performed in **25.6 %**, including band ligation (21.8 %), biological glue (2.5 %), APC (10.1 %), adrenaline injection (1.3 %), and hemostatic clips (2.5 %). Surgical intervention was necessary in **1.13 %** of cases. During hospitalization, **rebleeding occurred in 8.4 %** of patients, and **mortality was 2.1 %**.

Conclusions In our experience, peptic ulcer disease and esophageal variceal rupture remain the leading causes of UGIB. Despite a low rate of surgical intervention and a relatively low in-hospital mortality, the rebleeding rate remains significant. These findings highlight the need for early, optimized management and further studies to identify predictive factors for recurrence

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP757 Impact of Artificial Intelligence on Polyp and Adenoma Detection: A Retrospective Real-World Study from a Private Hospital

Authors Lazaridis LD[1], Sachtouris G[1], Emmanouil T[2]

Institutes **1** METROPOLITAN GENERAL, Cholargos, Greece; **2** METROPOLITAN GENERAL HOSPITAL , CHOLARGOS ATHENS Greece

DOI 10.1055/s-0046-1822084

Aims To assess the impact of adopting an artificial intelligence computer-aided detection system, namely GI Genius by Medtronic, on the detection of polyps and adenomas during routine colonoscopy in real-world clinical practice

Methods A retrospective analysis was conducted, including all colonoscopies performed over a period of three months before and three months after AI implementation at a private hospital. Demographic data, the indication of colonoscopy (screening, surveillance, diagnostic), and endoscopist experience (1 year, 3 years, > 10 years) were recorded. The number, size, location, morphology according to Paris classification, and histology (adenoma, advanced adenoma, hyperplastic) of the detected polyps were documented for each examination. Categorical variables were analyzed using Chi-square testing, while continuous variables were analyzed using the Mann–Whitney U test [1].

Results A total of 240 patients were included, of whom 55.4 % were male, with a mean age of 58.93 ± 13.88 years; 136 procedures (56.7 %) were performed

with AI. There were no differences in sex and age of patients between groups. In the AI-assisted cases, the presence of adenomas was significantly higher in screening colonoscopies (16.3 % vs 0 %, p = 0.018). There were no differences between the two groups regarding total polyp count, size, or morphology. Among endoscopists with 3 years of experience, AI significantly increased the detection of Paris Is polyps (40 % vs 18.9 %, p = 0.047) and right-sided polyps (27.7 % vs 8.1 %, p = 0.022). In the overall cohort, no significant differences were observed in the total number of polyps, size, morphology, or histology.

Conclusions AI significantly increased adenoma detection in screening colonoscopies and improved the performance of intermediate-experience endoscopists, especially for Paris Is and right-sided lesions. While overall polyp burden and histological findings were similar between the two groups, these results indicate the selective benefit of AI-assisted colonoscopy in enhancing examination quality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP758 Rectosigmoid Phytobezoar Caused by Diospyros lotus: A Rare Case Mimicking IBS

Author Ayyildiz T[1]

Institute **1** Ondokuz Mayis University School of Medicine, Samsun, Türkiye

DOI 10.1055/s-0046-1822085

Abstract Text

Phytobezoars are concretions of indigestible plant materials in the gastrointestinal tract. While Diospyros lotus-related bezoars are typically found in the stomach or small intestine, rectosigmoid localization is rare. Such bezoars may mimic other gastrointestinal conditions, including irritable bowel syndrome (IBS).A 48-year-old male presented with abdominal bloating, pain, and a sense of incomplete defecation for several weeks. He had no known systemic disease or regular medication use. He reported consuming large quantities of Diospyros lotus fruit from a tree in his garden shortly before symptom onset.Colonoscopy revealed two bezoars, each 3–4 cm in diameter, located in the rectum and sigmoid colon. These were fragmented and removed using a snare and basket catheter. A small number of Diospyros lotus seeds were identified within the bezoars. At follow-up, the patient was symptom-free.Rectosigmoid bezoars are uncommon and usually linked to seed ingestion (e.g., pumpkin, watermelon). Diospyros lotus typically causes gastric phytobezoars or small bowel obstruction. In this case, bezoar formation in the lower colon likely resulted from impaired passage due to anatomical narrowing. The symptom pattern resembling constipation-dominant IBS adds clinical complexity and underscores the need for thorough evaluation in similar cases.This rare case highlights that Diospyros lotus can cause phytobezoars beyond the stomach, including the rectosigmoid colon. Clinicians should consider bezoars in the differential diagnosis of chronic constipation-like symptoms, especially with a relevant dietary history [1].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822086

Aims Functional lumen imaging probe (FLIP) panometry was developed for real time assessment of esophagogastric junction opening and esophageal body contractile response during index endoscopy. Despite its proven value in functional esophageal disorders and its potential to reshape diagnostic pathways in Neurogastroenterology, substantial heterogeneity persists in catheter selection, procedural protocols and exam interpretation. In 2025 the Dallas Consensus provided standardized guidance on indications, performance, interpretation and reporting, yet exam interpretation remains complex and largely confined to high expertise centers. Artificial intelligence offers a pragmatic opportunity to simplify interpretation and support broader adoption of FLIP panometry in lower volume settings. This study aimed to develop an AI model capable of automatic interpretation of motility patterns during FLIP panometry according to the Dallas Consensus, with the goal of enabling more consistent and accessible use in clinical practice [1].

Methods 123 exams from 5 centers from both the European and American continents and performed with both 8- and 16-centimeter catheters were used for model development. Each procedure was classified with a two-expert based consensus decision according to the latest Dallas Consensus. Several machine learning models were trained and tested for evaluation of the esophagogastric junction opening and esophageal body contractile response. Data was divided in training and testing datasets with a 80 %/20 % patient split design, using 5-fold cross validation in the training dataset. Models' performance was evaluated with the testing dataset trough their accuracy and area under the receiver-operating characteristic curve (AUC-ROC).

Results Disorders of esophagogastric junction opening were detected by CatBoost with 96.6 % accuracy and an AUC-ROC of 0.989. Regarding disorders of contractile response, they were detected by XGBoost with 78.2 % accuracy and an AUC-ROC of 0.913. Pathological planimetry patterns according to Dallas Consensus were identified by LightGBM with a mean accuracy of 92.1 % and AUC-ROC of 0.955.

Conclusions This study represents the first application of AI analysis to FLIP panometry, incorporating data from multiple probe types and heterogeneous demographic contexts while adhering to the most recent Dallas Consensus criteria, demonstrating robust accuracy in identifying pathological planimetry patterns. Subsequent research will refine these findings through dedicated validation efforts and explore the capacity to discriminate among distinct motility abnormalities. The integration of AI into FLIP panometry has the potential to meaningfully advance the diagnostic evaluation of suspected esophageal disorders during endoscopy by improving interpretative precision, reinforcing procedural standardization and expanding access beyond specialized centers, thereby contributing to more timely and effective patient management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP760V Closure of a choledochoduodenostomy presenting with refractory reflux cholangitis

Authors Perez-Cuadrado-Robles E[1], Lukenga L[1], Tenorio Gonzalez E[2], Perrod G[1], Benosman H[1], Cellier C[1]
Institutes **1** European Hospital Georges Pompidou, Paris, France; **2** Henri-Mondor University Hospital, PARIS, France
DOI 10.1055/s-0046-1822087

Abstract Text
A 75 years-old patient with metastatic pancreatic cancer presented with cholangitis and asymptomatic duodenal stenosis. An endoscopic ultrasound (EUS)-guided choledochoduodenostomy using a 6x8mm lumen apposing metal stent (LAMS) was decided. The patient presented with reflux cholangitis despite the use of coaxial stenting by plastic and fully covered metal stents. The recurrent cholangitis with significant cholestasis affected the oncological plan.
A closure of the choledochoduodenostomy by EUS-guided antegrade stenting combined with a hepaticogastrostomy assisted by a 7 French catheter in the intrahepatic bile duct through the LAMS was performed. A EUS-guided gastrojejunostomy was also performed in the same time.

eP761 Spontaneous gastrointestinal fistula after necrotising pancreatitis: Presentation and Management

Authors Asari S[1], Agarwal K[2]
Institutes **1** RMLIMS, Lucknow, India; **2** SGPGI Hospital, Lucknow, India
DOI 10.1055/s-0046-1822088

Aims Spontaneous gastrointestinal (GI) fistula is an uncommon but serious complication of necrotising pancreatitis, associated with significant morbidity and mortality. Early identification is crucial, yet published data on its presentation and management remain limited [1].
Methods We retrospectively analysed a prospectively maintained database of 146 patients with acute pancreatitis who developed pancreatic fluid collections. Clinical presentation, imaging findings and management outcomes of patients with pancreatoenteric fistula were reviewed.
Results Spontaneous pancreatoenteric fistula was identified in 5.3 % of patients using contrast enhanced CT with oral/rectal contrast and/or gastrointestinal endoscopy. The most common clinical presentation was worsening or recurrent abdominal pain with intermittent fever, observed in 5 patients (50 %). Gastrointestinal bleeding occurred in 4 patients (40 %). Most patients were managed successfully with minimally invasive approaches: percutaneous drainage in 6 patients (60 %) and EUS guided cystogastrostomy in 2 patients (20 %). Only one patient required surgical intervention.
Conclusions Spontaneous gastrointestinal fistula should be suspected in patients with necrotising pancreatitis who develop new or worsening abdominal pain, sepsis, or GI hemorrhage. Minimally invasive management including percutaneous drainage and EUS guided interventions forms the mainstay of treatment, while surgery should be reserved for patients who fail conservative management or show rapid clinical deterioration.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822089

Aims Stent occlusion represents a major cause of recurrent biliary obstruction (RBO) after biliary stent placement. Whether ursodeoxycholic acid (UDCA) can reduce stent occlusion remains uncertain. This study aimed to evaluate the efficacy of UDCA following biliary stenting for RBO.
Methods We performed a retrospective analysis of patients with RBO who underwent ERCP between January 2021 and December 2023 and required at least one reintervention within 36 months after initial stent placement. A total of 531 patients previously treated with either plastic or metallic stents were screened and included in the study cohort.
Results Of the 492 eligible patients, 348 (70.7 %) received UDCA and 144 (29.3 %) did not. Overall stent patency was longer in the UDCA group (median 90 days, IQR 60–150) compared with non-UDCA patients (median 90 days, IQR 60–90) (p = 0.03). Cholangitis at re-intervention occurred in 181/348 (52.0 %) UDCA users versus 58/144 (40.3 %) non-users (p = 0.02). In patients with plastic stents (n = 320), patency was similar between groups (median 90 days, IQR 60–120 for both; p = 0.55), as were cholangitis rates (51.3 % vs. 45.6 %; p = 0.42). In contrast, among patients with self-expandable metallic stents (SEMS; n = 81), patency was significantly longer with UDCA (median 180 days, IQR 120–180) than without (median 180 days, IQR 60–180) (p = 0.045), while cholangitis rates remained comparable (73.4 % vs. 64.7 %; p = 0.68). Sphincterotomy, performed in 92.7 % (455/492) of cases, showed a non-significant trend toward prolonged patency (median 90 vs. 60 days; p = 0.10).
Conclusions UDCA improved overall stent patency, particularly in patients with metallic stents, supporting its role as a useful adjunct after ERCP. Although cholangitis rates were unchanged, the patency benefit suggests added value in the management of recurrent biliary obstruction
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP763 Artificial intelligence as the new reference standard for accurate polyp size measurement

Authors Gerritsen D[1], Von Renteln D[2], Koch AD[1], Rijckborst V[1], Siersema PD[1]
Institutes **1** Erasmus MC Cancer Institute, University Medical Center, Rotterdam, Netherlands; **2** Montreal University Hospital Research Center, Montreal, Canada
DOI 10.1055/s-0046-1822090

Problem to solve The best reference standard for size measurement after polypectomy so far is caliper-based size measurement. However, this is time-consuming and may be inaccurate because of polyp fragmentation, distortion, or other deformations due to piecemeal resection, retrieval-related damage, inappropriate compression, or folding. This underscores the need for novel measurement tools.
Innovation MAGENTIQ-COLO (MAGENTIQ EYE, Haifa, Israel) is an AI-based system that offers real-time polyp size assessment during colonoscopy or retrospective video evaluation. A video-based validation study was performed to assess the accuracy of this AI system compared to caliper-based size measurement of colorectal polyps.
Results A total of 77 polyps was measured in 55 patients (male sex, n (%): 29 (52.7 %), age median, interquartile range (IQR): 67 (13)). Colonoscopy indica-

Endoscopy 2026; 58: S1–S1041

tions were surveillance in 38 (69.1 %), screening in 7 (12.7 %), and diagnostic in 10 patients (18.2 %). Of the 77 polyps, the majority of polyps were adenomas (n = 52; 67.5 %). Polyps were equally distributed through the colon. The AI-based system correctly identified size in 37/46 polyps (80.4 %) as ≤ 5 mm and 5/6 polyps (83.3 %) as ≥ 10 mm (▶ **Table 1**). The system had a mean accuracy of 0.80 for ≤ 5 mm polyps (n = 46), 0.88 for 6-9 mm polyps (n = 25), and 0.83 for ≥ 10 mm polyps (n = 6), with a total mean accuracy of 0.84. Accounting for the skewed number of polyps per size category, the weighted accuracy was 0.83, with a weighted sensitivity and specificity of 0.83 and 0.92, respectively. The system reliably estimated polyp size, with a slightly higher accuracy for > 5 mm polyps compared to ≤ 5 mm polyps. From initial polyp detection to showing size, median latency was 5 frames (± 0.17 seconds).

▶ **Table 1** Confusion matrix of ground truth polyp size by caliper and predicted polyp size by the AI-based system

	AI system (≤ 5 mm)	AI system (6-9 mm)	AI system (≥ 10 mm)
Caliper (≤ 5 mm)	37	9	0
Caliper (6-9 mm)	1	22	2
Caliper (≥ 10 mm)	0	1	5

Conclusions The novel AI-based system demonstrated a high accuracy compared to the reference standard of calipers, signifying that the AI system correctly identified most polyps within their true size categories with a low risk of size misclassification. Furthermore, colonoscopy time only slightly increased, allowing timely size assessment. This system could well replace the caliper as the reference standard for in-vivo size measurement of polyps during colonoscopy, but further prospective studies are needed.

eP764V A Multi-Method Explainability Framework for Segmentation in Pancreatic EUS: Enhancing Transparency, Clinical Trust and Diagnostic Safety

Authors Gruionu L[1, 2], Udriștoiu AL[2, 3], Gheorghe EC[4, 2], Gruionu G[2], Bang JY[5], Varadarajulu S[5], Saftoiu A[6, 7, 2]

Institutes **1** Faculty of Mechanics, University of Craiova, Craiova, Romania; **2** Medical Softverse srl, Craiova, Romania; **3** Faculty of Automation, Computers and Electronics, University of Craiova, Craiova, Romania; **4** University of Medicine and Pharmacy of Craiova, Craiova, Romania; **5** Center for Advanced Endoscopy, Research and Education, Orlando Health Digestive Health Institute, Orlando, United States of America; **6** Carol Davila University of Medicine and Pharmacy, București, Romania; **7** Elias Emergency University Hospital, București, Romania

DOI 10.1055/s-0046-1822091

Problem to solve Artificial intelligence systems for endoscopic ultrasound (EUS) increasingly achieve high diagnostic accuracy for detecting pancreatic masses [1], yet their "***black box***" nature limits clinical acceptance. Clinicians must understand ***why*** and ***where*** an AI model identifies a lesion, yet existing explainability techniques (e.g., CAM-based methods) were designed for image classification, not for segmentation-based object detection. When applied to EUS, these methods often highlight irrelevant features such as depth markers, calipers or acoustic artifacts, producing misleading interpretations and reducing trust. As no dedicated explainability approach exists for segmentation models in abdominal EUS, there is a need for a reliable, clinically meaningful framework that provides anatomically accurate and artifact-free explanations.

Innovation We developed a dedicated explainability framework for the PANCRAIEUS model segmentation architecture used in pancreatic EUS, based on the initial training data of 32713 frames recorded in 202 patients[1]. The framework integrates several adapted methods (GradCAM, EigenCAM, occlusion analysis and class-specific attention) technically optimized for the multi-scale, segmentation-based design. Building on this, we introduced two new segmentation-guided strategies. The ***Hard Mask*** method restricts heatmaps strictly to detected structures, ensuring that explanations correspond only to pancreas, tumor or cyst regions. The ***Soft Focus*** method maintains overall anatomical context while gradually reducing irrelevant areas, producing fluid, intuitive visualizations suitable for real-time interpretation. Both methods were systematically assessed for anatomical fidelity, artifact suppression and clinical interpretability (▶ **Table 1**).

▶ **Table 1**

Method	Focus on Relevant Anatomy	Artifact Avoidance	Clinical Usefulness
GradCAM	Moderate	Low	Moderate
EigenCAM	Moderate–High	Moderate	Moderate
Occlusion	High	High	Lower (slow)
Hard Mask	*Very High*	*Very High*	*Excellent*
Soft Focus	*High*	*High*	*Excellent (best visual continuity)*

Results When applied to representative EUS images and videos, standard CAM-based techniques frequently produced activations on image text, bright acoustic interfaces or shadow boundaries. In contrast, the segmentation-guided methods consistently generated precise, clinically coherent explanations. ***Hard Mask*** offered the strongest anatomical specificity, sharply delineating lesion borders and fully eliminating artifact-driven activations, making it useful for documentation and regulatory purposes. ***Soft Focus*** produced smoother gradients that preserved situational awareness while still suppressing irrelevant regions, making it more intuitive for teaching and potential live use. Across cases, the combined multi-method approach provided a more complete understanding of model behavior than any single technique alone.

Conclusions This work presents the first ***explainability framework*** tailored to segmentation in pancreatic EUS and demonstrates its ability to produce accurate, clinically trustworthy visual explanations. By integrating multiple adapted techniques with two novel segmentation-guided approaches, the framework enhances transparency, supports safer clinical implementation of AI, and aligns with emerging regulatory expectations for model interpretability. Further work will explore real-time integration and prospective clinical evaluation.

Aims Delayed perforation after colonic endoscopic resection has been thought to be fatal and could lead to serious adverse events. However, with the development of endoscopic techniques, endoscopic intervention may avoid the need for emergency surgery. To validate the feasibility of aggressive endoscopic intervention for delayed perforation after colonic endoscopic resection.

Methods Three cases with delayed perforation experienced from April 2023 to March 2024 were enrolled in this retrospective case series. Patients' backgrounds, procedure-related factors, and outcomes were extracted from medical records, and the feasibility of intensive endoscopic intervention was assessed.

Results The median age of the patients was 34 (range 15-49). Two of them were male. Two of them underwent endoscopic submucosal dissection (ESD) and one underwater endoscopic mucosal resection (UEMR). The median tumor size is 27mm (range 20 –33mm). The treated sites were sigmoid in two cases and the transverse colon in one. The median time to delayed perforation after endoscopic resection was 57 hours (range 20-69). All of them had no apparent perforation during endoscopic resection and showed severe abdominal pain and free air on abdominal CT, and no findings of peritonitis or septic shock. Emergency colonoscopy under sedation using midazolam and opioid analgesics was performed for all cases. The perforation site was confirmed endoscopically in two cases. One delayed perforation was closed with endo-clips, and the other two perforations were covered with polyglycolic acid sheets. Diet was resumed at a median of 9 (range 4-13) days after the aggressive endoscopic intervention.

Conclusions Aggressive endoscopic intervention may be feasible for delayed perforation after colonic endoscopic resection, although an appropriate patients selection would be mandatory.

eP766 Feasibility of differentiating serrated pathway polyps (GCHP, MVHP and SSL) based on endoscopic appearance using deep learning

Authors Jans A[1, 2], Callaerts B[3, 4], Sinonquel P[1, 2], Sagaert X[5], Demedts I[1, 2], Roelandt P[2, 1], Eelbode T[4, 3], Maes F[3, 4], Tejpar S[2, 6], Bisschops R[1, 2]
Institutes **1** Department of Translational Research in Gastrointestinal Diseases (TARGID), KU Leuven, Leuven, Belgium; **2** Department of Gastroenterology and Hepatology, University Hospitals Leuven, Leuven, Belgium; **3** Department of Electrical Engineering (ESAT/PSI), KU Leuven, Leuven, Belgium; **4** Medical Imaging Research Center (MIRC), University Hospitals Leuven, Leuven, Belgium; **5** Department of Pathology, University Hospitals Leuven, Leuven, Belgium; **6** Department of Oncology, Laboratory of Digestive Oncology, KU Leuven, Leuven, Belgium
DOI 10.1055/s-0046-1822093

Aims Recent molecular studies have suggested a biological link between hyperplastic polyps (HPs) and sessile serrated lesions (SSLs), as early serrated features and BRAFV600E-mutations are frequently found in specific HP subtypes: goblet cell-rich HPs (GCHPs) and microvesicular HPs (MVHPs). This supports the hypothesis that GCHPs, MVHPs and SSLs belong to the serrated neoplasia pathway. In previous work, we demonstrated that deep learning can differentiate GCHPs from MVHPs based on their endoscopic appearance. The present study builds further on this finding by investigating whether deep learning can also distinguish GCHPs, MVHPs and SSLs.

Methods High-quality white light and i-scan virtual chromoendoscopy videos of polyps, acquired in our center with Pentax EC38-i20c and EC34-i10 endoscopes, were retrospectively collected, together with their histopathological analysis. Expert pathologists reviewed all cases and reclassified HPs into GCHPs and MVHPs, resulting in a dataset of 260 polyps from 194 patients: 138 GCHPs, 54 MVHPs, and 68 SSLs. The dataset was split into training (70 %), validation (10 %) and test (20 %) sets. Three binary classifiers (GCHP vs MVHP, GCHP vs SSL and MVHP vs SSL) and one ternary classifier (GCHP vs MVHP vs SSL) were trained identically using an EfficientNet B0 backbone with a single video frame as input. Oversampling was applied to balance underrepresented classes. When applying these models to the test cases, predictions for different video frames were aggregated using majority voting.

Results The test set contained 28 GCHPs, 14 MVHPs and 15 SSLs. The binary GCHP-MVHP model scored 82.7 % AUC and 71.4 % sensitivity for both classes. The GCHP-SSL model performed similarly with 82.1 % AUC and sensitivities of 64.3 % and 86.7 % for GCHP and SSL respectively. The MVHP-SSL model achieved the highest performance with 87.6 % AUC and sensitivities of 71.4 % and 80 % for MVHP and SSL respectively. In contrast, the ternary model yielded sensitivities of 25 %, 64.3 % and 60 % for GCHP, MVHP and SSL respectively, with GCHP mostly misclassified as MVHP and SSL as GCHP.

Conclusions Our findings demonstrate that deep learning can differentiate GCHPs, MVHPs and SSLs based on their endoscopic appearance using binary models. The consistently high sensitivity for SSL across the binary models suggests that SSLs have more distinct endoscopic features while differences between GCHP and MVHP are more subtle. The ternary model struggled to reliably discriminate the three classes directly, likely due to the complexity of the task and the limited dataset used. Overall, this study highlights the potential of AI to support endoscopists in recognising a broader spectrum of serrated polyp types, further enhancing diagnostic precision.

eP767 Evolving the Approach: From Conventional to Pancreaticoscopy-Guided Removal of Migrated Pancreatic Duct Stents – A Single-Centre Experience

Authors Chavan R[1], Chaiti G[1], Solanki R[1], Patel M[1], Rajput S[1]
Institute **1** Ansh clinic, Ahmedabad, India
DOI 10.1055/s-0046-1822094

Aims Pancreatic stent migration is a recognized complication of therapeutic endoscopy, often posing significant technical challenges for retrieval. Migrated stents can lead to ductal obstruction, pancreatitis, or infection if not removed promptly. While several endoscopic accessories are available, there is limited prospective data comparing their utility in real-world scenarios. The aim of this prospective study was to evaluate the feasibility, safety, and success of different endoscopic techniques for removal of migrated pancreatic stents in a small cohort of patients, highlighting the role of pancreatoscopy and adjunctive laser-assisted methods [1].

Methods Between January 2024 and April 2025, eight consecutive patients presenting with migrated pancreatic stents were prospectively enrolled. Demographic data, clinical presentation, and procedural details were recorded. All procedures were performed under conscious sedation.

A stepwise approach was adopted, beginning with conventional endoscopic accessories (rat tooth forceps, stone retrieval balloon, hurricane balloon, sohendra stent retrieval) and escalating to advanced Spy glass pancreatoscopy – guided methods (SpyBite max forceps, Spyglass retrieval snare, and laser-assisted fragmentation) when conventional techniques failed. Each patient's final successful retrieval technique was documented. Procedural success was defined as complete removal of the migrated stent without need for surgical intervention (▶ **Table 1**).

Endoscopy 2026; 58: S1–S1041

▶ **Table 1**

No.	Age	Gender	Diagnosis	Duration of stent	Use of spy	Procedure duration (in min)
1	37	M	CCP	8 years	yes	124
2	45	M	CCP	4 months	yes	144
3	65	M	CBD stone	2 months	No	11
4	48	M	CBD stone	Immediately during prophylactic pd stent placement	No	66
5	19	F	CCP	3 months	yes	59
6	47	M	CCP	6months	No	28
7	28	M	CCP	8 months	Yes	88
8	35	M	CCP	1 year	Yes	80

Results The cohort consisted of seven male patients and one female patient, with ages ranging from 19 to 65 years (mean age 40.5 years). All eight patients underwent successful endoscopic removal of the migrated pancreatic stent. Conventional techniques were effective in three patients: one with rat tooth forceps and two with a stone retrieval balloon. In five patients, advanced Pancreatoscopy-guided methods were required. SpyGlass-guided retrieval combined with SpyBite max forceps was successful in one patient, while SpyGlass with laser fragmentation followed by Spyglass retrieval snare or SpyBite max forceps was required in four patients. Laser guided fragmentation of stent was performed in four patient as the ends of stent were impacted in the side branch. No major complications such as perforation, severe bleeding, or pancreatitis were observed. Procedure times varied depending on technique, with mean procedure time was 75 minutes.

This prospective series demonstrates that while conventional accessories may suffice in select cases, migrated stents often necessitate advanced visualization and retrieval tools. The SpyGlass system, particularly when combined with laser fragmentation, provided enhanced ductal visualization and facilitated safe removal in complex scenarios.

Conclusions This prospective series demonstrates that while conventional accessories may suffice in select cases, migrated stents often necessitate advanced visualization and retrieval tools. The SpyGlass system, particularly when combined with laser fragmentation, provided enhanced ductal visualization and facilitated safe removal in complex scenarios.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Colorectal cancer (CRC) screening reduces incidence and mortality, yet participation rates remain suboptimal worldwide. Large language models (LLMs), such as ChatGPT, may help overcome communication barriers by providing accessible, multilingual information. However, their performance across different languages and cultural contexts has never been systematically evaluated. This study aims to assess ChatGPT's accuracy, completeness, and comprehensibility in answering colorectal cancer screening questions across 23 languages and 28 countries, and to evaluate cross-linguistic variability in performance.

Methods Between April and June 2025, we conducted a cross-continental study involving 28 countries and 23 languages. A standardized set of 15 CRC screening–related questions was manually translated by native researchers to preserve linguistic accuracy and cultural nuances. Translated questions were submitted to ChatGPT (GPT-4o), and the generated responses were independently assessed by 140 senior gastroenterologists (five per country). Each response was rated for accuracy, completeness, and comprehensibility using a 5-point Likert scale. Statistical analyses included t-tests, Chi-square tests, and two-way ANOVA.

Results The study collected 2,100 expert ratings across six continents. Overall mean scores (± SD) were 4.1 ± 1.0 for accuracy, 4.1 ± 1.0 for completeness, and 4.2 ± 0.9 for comprehensibility. High-quality performance (score ≥ 4) was observed in 73.9 %, 86.9 %, and 82.6 % of languages for the three domains, respec-

tively. Italian, Turkish, Swahili, and Japanese achieved the highest ratings, while Traditional Chinese, Dutch, and Greek consistently showed lower performance across all domains. Significant differences between languages were found for each metric ($P < 0.001$).

Subtle intra-language variability was also observed in languages spoken in multiple countries (e.g., Dutch in Belgium vs. the Netherlands; English in the UK, US, and Australia), although without statistically significant differences. Question-level analysis revealed a broad score dispersion across languages, with most ratings ranging between 3 and 5.

Conclusions ChatGPT showed strong ability to answer CRC screening questions across multiple languages, supporting its promise as a multilingual patient education tool. However, a significant variability in performance across different languages was demonstrated, highlighting the need for language-specific validation prior to widespread clinical implementation.

eP769 Endoscopic findings in patients with positive FIT test within the Greek National Colorectal Cancer Screening Program: A single-center experience

Authors Rizos E[1, 2], Papanikolaou I[3]

Institutes **1** Private Endoscopic Outpatient Clinic, Athens, Greece; **2** Lefkos Stavros 'The Athens Clinic', Ath, Greece; **3** B Gastroenterology Clinic, National Kapodistrian University, Attikon University General Hospital, Athens, Greece

DOI 10.1055/s-0046-1822096

Aims In October 2024, a national screening program for colorectal cancer using the fecalimmunochemical test (FIT) for hemoglobin detection in stool was implemented for the firsttime in Greece. The aim of the present study is to describe colonoscopy findings inindividuals with a positive FIT test [1–3].

Methods This is a retrospective observational study including patients aged 50–70 years in the Atticaregion who were referred for colonoscopy due to a positive FIT test. Patients werecategorized based on prior endoscopic evaluation, and colonoscopy findings were recorded:adenomas, advanced adenomas (size ≥ 10 mm), and cancer.

Results A total of 140 patients were included. Of these, 96 (68.6 %) had never undergonecolonoscopy, 11 (7.9 %) had been examined more than 10 years earlier, and 2 (1.4 %) had ahistory of incomplete endoscopy. Adenomas were detected in 73 patients (52.1 %), of whom37 (26.4 %) had advanced features. Of the advanced adenomas, 30 (81.1 %) were located inthe left colon. Among the 41 patients with advanced adenomas or cancer, one (2.4 %) hadundergone a recent prior colonoscopy (3 years earlier), representing an interval advanceadenoma. Colorectal cancer was diagnosed in 4 patients (2.8 %), all stage I according to theTNM classification.

Conclusions The implementation of the FIT test within the national screening program appears tosuccessfully target a population without prior adequate endoscopic evaluation and achievesneoplasia detection rates comparable to international reports. The high proportion of early-stage detections supports the importance of expanding and establishing the program at anational level.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP770 Diagnostic Yield of EUS-FNB in Solid Pancreatic and Extrapancreatic Lesions: single center Age-Stratified Analysis

Authors Fantin A[1], Santangelo P[2], Di Somma A[3], Cristofori C[3], Pezua Sanjinez AMS[2], Morbin T[3], Albergati IV[3], Kitenge MP[3], De Simoni O[4], Gruppo M[5], Cataldo I[6]

Institutes **1** Unit of Gastroenterology, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy; **2** Gastroenterology Unit, Veneto Institute Of Oncology, IOV-IRCCS,, Padova, Italy; **3** Gastroenterology Unit, Veneto Institute of Oncology, IOV-IRCCS, Padova, Italy; **4** Unit of Surgical Oncology of Digestive Tract, Veneto Institute of Oncology, IOV-IRCCS, Padova, Italy; **5** Unit of Surgical Oncology of Digestive Tract, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy; **6** Unit of Pathological Anatomy and Histology, Veneto Institute of Oncology, IOV-IRCCS, Padova, Italy

DOI 10.1055/s-0046-1822097

Aims To evaluate the Diagnostic Yield (adequacy rate) of Endoscopic Ultrasound-Guided Fine Needle Biopsy (EUS-FNB) in a cohort of patients with solid pancreatic (NP) and solid non-pancreatic (OTHER) lesions, stratifying the results across four age groups (< 50, 50-70, 71-80, > 81 years).

Methods A single-center, retrospective analysis was conducted on data collected over an extended period, between May 2019 and August 2025, to ensure technique homogeneity. The study included 398 patients who underwent EUS-FNB of solid lesions; cystic lesions and pancreatic cysts were excluded from the analysis. Diagnostic Yield was calculated as the proportion of Adequate samples (Positive or Negative result, 1 + 3) relative to the total number of procedures, distinguishing between Pancreatic Neoplasm (NP) and Other Diagnoses (OTHER) (▶ **Table 1**).

▶ **Table 1**

Age Group	NP (n)	NP Adequate	OTHER (n)	OTHER Adequate
< 50 yrs	**22**	**95.5 %**	**20**	**95.0 %**
50-70 yrs	**106**	**93.4 %**	**41**	**92.7 %**
71-80 yrs	**121**	**99.2 %**	**31**	**96.8 %**
> 81 yrs	**47**	**93.6 %**	**10**	**80.0 %**
Total	**296**	**95.9 %**	**102**	**93.1 %**

Results The overall Diagnostic Yield (Adequate) for EUS-FNB was 95.2 % (379/398). The age-stratified analysis yielded the following adequacy rates indicated in the table.

Conclusions EUS-FNB for solid lesions provides an excellent and stable Diagnostic Yield (> 93 %) for Pancreatic Neoplasm across all ages, aligning with the highest reported rates from high-volume centers in the literature. The procedure is confirmed to be robust, and its effectiveness is not compromised by patient age. However, the risk of obtaining a non-adequate sample is concentrated particularly in patients over 81 with solid non-pancreatic lesions, emphasizing the need for further studies and optimized protocols for EUS-FNB in this frail population and challenging anatomical locations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Endoscopy 2026; 58: S1–S1041

eP771 Reliability and validity of Texture and Colour Enhancement Imaging (TXI) in assessing mucosal inflammation in Ulcerative Colitis

Authors John S[1], Subhaharan D[1], Kakkadasam Ramaswamy P[1], Pillai S[1], Jones M[2], Dong-Hoon Y[3]

Institutes **1** Gold Coast University Hospital, Southport, Australia; **2** Bond University, University Drive, Robina, QLD, Australia, Southport.QLD, Australia; **3** University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea

DOI 10.1055/s-0046-1822098

Aims Accurate endoscopic assessment of mucosal inflammation is critical in managing Ulcerative Colitis (UC). Mayo endoscopic score (MES) and Ulcerative Colitis Endoscopic Index of Severity (UCEIS) have significant interobserver variability. The role of Texture and Colour Enhancement Imaging (TXI) in assessing inflammation is uncertain. We aimed to assess the reliability of TXI in UC.

Methods A multicentre international survey-based study was designed with 20 sets of high-definition white light (HDWLE) images or videos matched with TXI. Each set had varying severities of inflammation as determined by Nancy and Picasso histopathology scores. The MES and UCEIS were rated along with confidence level (high vs low). To assess interobserver variability, we used percentage agreement and Kappa score with 95 % confidence intervals stratified by imaging modality and scoring system. A mixed logistic regression model was constructed to assess accuracy.

Results 30 gastroenterologists from 4 centres were included. 19 (63.3 %) were experts and 10 (33.3 %) had prior TXI experience. Interobserver variability was moderate overall with percentage agreement between 66-70 % and Kappa scores between 0.51-0.58. There was no difference in interobserver variability between HDWLE and TXI. Agreement was slightly higher for UCEIS than MES (▶ **Table 1**). 75 % reported high confidence prediction with confidence consistent across histological severity. Participants rated severity accurately 75 % of the time using MES with accuracy increasing with increase in histological severity. Results for UCEIS were similar with accuracy of 74 %. There was no evidence of a difference in accuracy between the two imaging modalities irrespective of the index used for scoring.

▶ **Table 1** Interobserver variability results

Imaging modality	Mayo	UCEIS
HDWLE	Percent agreement = 68 % Kappa = 0.56 (0.45, 0.67) *	Percent agreement = 66 % Kappa = 0.51 (0.40, 0.63) *
TXI	Percent agreement = 67 % Kappa = 0.55 (0.44, 0.66) *	Percent agreement = 70 % Kappa = 0.58 (0.45, 0.70) *

*95 % confidence interval

Conclusions Interobserver variability remains a challenge in accurately assessing inflammation in UC despite advances in technology and validated scoring systems. Our study suggests that TXI achieves moderate interobserver agreement with accuracy of 75 % and is not superior to HDWLE.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP772 Diagnostic and Therapeutic Value of Over-The-Scope Clip-Assisted EFTR for Indeterminate Small Upper GI Subepithelial Tumors: A "Total Biopsy" Approach

Authors Lu CC[1], Chen HY[1]

Institute **1** Division of Gastroenterology, New Taipei City Hospital, Sanchong Branch, New Taipei City, Taiwan

DOI 10.1055/s-0046-1822099

Aims Small subepithelial lesions (SELs) in the upper gastrointestinal tract present a diagnostic challenge; endoscopic ultrasound (EUS) often struggles to definitively differentiate between gastrointestinal stromal tumors (GISTs) and leiomyomas. This study evaluates the diagnostic yield and therapeutic efficacy of endoscopic full-thickness resection (EFTR) using a suction-based over-the-scope clip system as a definitive "total biopsy" strategy for indeterminate SELs.

Methods We retrospectively analyzed data from 28 consecutive patients with gastric or duodenal SELs who underwent device-assisted EFTR at a regional public hospital between January 2022 and October 2024. The procedure utilized a suction-based over-the-scope clip (Padlock Clip; Steris, USA) and involved routine mucosal incision to facilitate clear tumor exposure prior to clip deployment. The primary outcome was the definitive histological diagnosis rate, and secondary outcomes included the R0 resection rate, procedure time, and adverse events.

Results A total of 28 patients (median age 57 years) were included. Lesions were located in the stomach (n = 24) and duodenum (n = 4), with a median size of 7 mm. The technique achieved a 100 % technical success and R0 resection rate. Histopathological analysis provided definitive diagnoses for all cases, revealing low-grade GIST in 50.0 % (14/28), leiomyoma in 42.9 % (12/28), and ectopic pancreas in 7.1 % (2/28). This distinction was crucial as half of the cohort harbored lesions with malignant potential (GIST) that required distinct management compared to benign leiomyomas. The median procedure time was 29 minutes. One patient (3.6 %) experienced delayed bleeding, managed endoscopically, with no perforations or other serious adverse events observed.

Conclusions Suction-based over-the-scope clip-assisted EFTR is a safe and effective technique that serves a dual role in diagnosis and therapy for small upper GI SELs. By providing a full-thickness specimen, it enables precise histological differentiation between GISTs and benign mimics, ensuring appropriate risk stratification and curative treatment in a single session.

eP773V Refractory diverticular bleeding: a never ending case

Authors Petruzziello L[1], Vagnarelli S[2], Burrelli Scotti G[3], Masoni L[4], Hassan C[5]

Institutes **1** Paideia International Hospital, Via G. Fabbroni, 6, 00135, Rome, Italy; **2** San Giovanni-Addolorata Hospital; Paideia International Hospital, Rome, Italy; **3** Sapienza University of Rome; Paideia International Hospital, Roma, Italy; **4** San Carlo di Nancy Hospital; Paideia International Hospital, Rome, Italy; **5** IRCCS Humanitas Research Hospital, Milan; Paideia International Hospital, Italy, Rome, Italy

DOI 10.1055/s-0046-1822100

Abstract Text

A 50-years-old man presented with rectal bleeding and anemia. CT scan suggested left colic diverticular bleeding. During the first colonoscopy a suspicious diverticulum was clipped. Three days later, the patient had recurrent bleeding and syncope. A second colonoscopy identified the bleeding diverticulum, treated with 5 endoclips. Rebleeding the following day required a third colonoscopy with hemostasis using an over-the-scope clip (OTSC). After 4 days the peridiverticular mucosa grasped by the OTSC bled and was treated with coagrasper. Recurrent bleeding required two superselective arterial embolizations, which finally stopped it after 13 days. Diverticular bleeding can be refractory despite repeated endoscopic and radiological interventions. The use of OTSC as a res-

cue therapy can fail, as bleeding in the responsible diverticulum may exceed its haemostatic capacity.

eP774 Comparative Effectiveness Of Computer-Aided Detection (CADe) Systems For Adenoma Detection: A Network Meta-Analysis Of Randomized Controlled Trials

Authors Maida M[1,2], Calabrese G[3], Lau LH[4,5], Vitello A[1,2], Bonomo F[2], Capodicasa L[2], Sferrazza S[6], Facciorusso A[7]

Institutes **1** Department of Medicine and Surgery, University of Enna 'Kore', Enna, Italy; **2** Gastroenterology Unit, Umberto I Hospital, Enna, Italy; **3** Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy; **4** The Chinese University of Hong Kong, Hong Kong, Hong Kong; **5** Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong; **6** Gastroenterology and Endoscopy Unit, A.R.N.A.S. Ospedali Civico Di Cristina Benfratelli, Palermo, Italy; **7** Gastroenterology Unit, Department of Experimental Medicine, University of Lecce, Lecce, Italy

DOI 10.1055/s-0046-1822101

Aims Multiple artificial intelligence (AI) computer-aided detection (CADe) systems have been developed to improve adenoma detection rate (ADR) during colonoscopy. However, their comparative effectiveness remains uncertain. This network meta-analysis aims to compare the efficacy of different AI-based CADe systems in increasing ADR.

Methods We systematically searched MEDLINE, Embase, Scopus, and the Cochrane Library for randomized controlled trials (RCTs) comparing any CADe system with standard high-definition colonoscopy or with another CADe system. The primary outcome was ADR, expressed as risk ratio (RR) with 95 % confidence interval (CI). A random-effects network meta-analysis (DerSimonian and Laird method) was performed to synthesize direct and indirect evidence. The relative ranking of all interventions was estimated using the surface under the cumulative ranking curve (SUCRA). Methodological quality was assessed with the Cochrane risk-of-bias (RoB2) tool.

Results The network included standard colonoscopy and 12 CADe systems (*CAD EYE FujiFilm, CADe Henan, CADe LPIXEL, Deep2 FujiFilm, Eagle-Eye, ENDO-AID Olympus, Endoangel, Endoscreener, Endovigilant, GI Genius, MAGENTIQ-COLO, SKOUT, YOLOv3*). Compared with standard colonoscopy, most CADe systems significantly increased ADR, with the highest effect estimates observed for *YOLOv3* (RR 1.76; 95 %CI 1.35–2.30), *CADe Henan* (RR 1.64; 95 %CI 1.31–2.04), *Endoangel* (RR 1.55; 95 %CI 1.15–2.08), *Deep2 FujiFilm* (RR 1.37; 95 %CI 1.06–1.76), *ENDO-AID Olympus* (RR 1.25; 95 %CI 1.14–1.38) and *GI Genius* (RR 1.13; 95 %CI 1.06–1.21). On the other hand, *Eagle-Eye, SKOUT, CADe LPIXEL, MAGENTIQ-COLO*, and *Endovigilant* did not reach statistical significance. SUCRA-based ranking showed *YOLOv3, CADe Henan, Endoangel, Deep2 FujiFilm*, and *ENDO-AID Olympus* as the top-performing systems, while *Endovigilant* ranked lowest. Most RCTs were of moderate or high risk of bias due to inability to blind endoscopists to the intervention.

Conclusions This network meta-analysis provides a comprehensive comparative assessment of the relative efficacy across all currently evaluated CADe systems, with *YOLOv3*, *CADe Henan*, *Endoangel*, *Deep2 FujiFilm*, and *ENDO-AID Olympus* emerging as the most effective. These findings may help endoscopy units prioritize AI solutions according to expected diagnostic yield and comparative performance.

DOI 10.1055/s-0046-1822102

Aims Gastric outlet obstruction (GOO) is a late complication of several malignancies, markedly impairing quality of life. Surgical gastroenterostomy (S-GE) has long been the palliative standard, but outcomes are variable and morbidity remains considerable. Endoscopic ultrasound-guided gastroenterostomy (EUS-GE) has emerged as a minimally invasive alternative. We conducted a systematic review and meta-analysis comparing EUS-GE and S-GE, with a specific focus on malignant GOO.

Methods MEDLINE, Embase, Scopus, and the Cochrane Library were searched through September 2025. Eligible studies directly compared EUS-GE and S-GE and reported clinical success (CS), adverse events (AEs), severe AEs, and recurrence/reintervention. Pooled odds ratios (OR) with 95 % confidence intervals (CI) were calculated using random-effects models.

Results Thirteen studies (2 RCTs, 11 retrospective; 1,611 patients) were analyzed. Overall, EUS-GE achieved higher CS (OR 2.69; $p = 0.007$), fewer AEs (OR 0.21; $p < 0.001$) and severe AEs (OR 0.54; $p = 0.05$) compared to S-GE, with no significant difference in recurrence/reintervention rate (OR 0.54; $p = 0.22$). In malignant GOO, CS (OR 1.90; $p = 0.12$) and recurrence/reintervention rate (OR 0.68; $p = 0.50$) were comparable, while overall AEs remained lower with EUS-GE (OR 0.26; $p < 0.01$).

Conclusions In malignant GOO, EUS-GE provides comparable clinical efficacy to S-GE with fewer overall AEs. These data support EUS-GE as a preferred minimally invasive option in selected patients.

3 Digestive Endoscopy, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; 4 Policlinico Universitario Monserrato "Duilio Casula", Monserrato, Italy
DOI 10.1055/s-0046-1822103

Aims Endoscopic Endovacuum Therapy (EVT) is a safe and efficient method for treating post-surgical collections communicating with the gastrointestinal (GI) tract [1], but it requires longer hospitalization and repeated treatments. We aim to identify clinical factors that could predict the success or failure of EVT in treating post-surgical collections (▶ **Table 1**).

Methods We retrospectively analyzed patients treated with EVT in the last 2 years, comparing 2 different centers (Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; A.O.R.N. Moscati, Avellino, Italy). To avoid bias, we considered only patients who had oncological surgery of the rectum, with a diagnosis of colorectal dehiscence communicating with an extraluminal collection, and treated exclusively with EVT. The Endosponge (B. Braun Surgical) was used in all patients, with a negative continuous aspiration between 100 and 125 mmHg; the sponges were exchanged every 72 ± 24 hours. All patients had a colostomy or ileostomy, as allowed adjuvant treatment. The success of EVT was defined as total drainage of the collection and closure of the dehiscence (▶ **Table 2**).

▶ **Table 1** Demographic characteristics

Sex (M/F)	7/10 (70 %)	7/9 (77,7 %)
Mean age (years)	62.6 ± 10.8	64 ± 18
Malignant disease	10/10 (100 %)	9/9 (100 %).
Type of Surgery:		
Anterior rectal resection	8/10 (80 %)	6/9 (66,7 %)
Ultra low rectal resection	1/10 (10 %)	1/9 (11,1 %)
Sigma resection	1/10 (10 %)	2/9 (22,2 %)
Neoadjuvant treatment (CHT ± RT)	5/10; (50 %)	5/9 (55 %)

M: male; F: female; CHT: chemotherapy; RT: radiotherapy

▶ **Table 2** Clinical characteristics

Intestinal diversion	10/10; 100 %	9/9; 100 %
Mean size of the collection (mm)	82.7 ± 61.5	38,8 ± 41,6
Median time from diagnosis to start EVT (days)	16.5 (11–65)	7 (1-21)
Mean duration of EVT (days)	24.8 ± 15.0	17,5 ± 10,1
Mean number of sponge replacements	7 ± 3.2	4 ± 1,3
Successful outcome of EVT	5/10 (50 %)	8/9; (88,8 %)
Complications	0; (0 %)	0; (0 %)

Results A total of 19 patients were analyzed (10 vs 9). Age, sex, and neoadjuvant treatment were comparable (62 vs 64 years; 7/10 vs 7/9 males; 5/10 vs 5/9 patients treated). The outcome was different: 50 % (5/10) vs 88.8 % (8/9) had complete collection drainage and dehiscence closure. Significant differences were found in timing from diagnosis of the dehiscence to the start of EVT (median of 16.5 vs 7 days), the collection's dimensions (mean 38,8 ± 41,6 mm vs 82.7 ± 61.5mm), and the treatment's duration (mean 24.8 ± 15.0 vs 17,5 ± 10,1 days). No complications observed due to EVT.

Conclusions Late start of EVT and larger collection size could negatively impact the outcome of EVT. Longer treatment duration doesn't seem to improve the results.

eP777 EUS Tissue Acquisition: "Two Are Better Than One, for If They Fall, One Will Lift Up His Companion"

Authors Desai PN[1], Prajapati R[1], Chintan P[1], Mayank K[1], Rajiv M[1], Nandwani S[1], Patel N[1], Sethia M[1]

Institute 1 SIDS Hospital & Research Centre, Surat, India
DOI 10.1055/s-0046-1822104

Aims This study aimed to evaluate the comparative effectiveness of conventional fine-needle aspiration (FNA), fine-needle biopsy (FNB), and combined cytology–histology sampling (FNAB) using Franseen needles, and to determine whether a dual-modality sampling strategy enhances diagnostic accuracy across diverse pathologies

Methods Background: For EUS guided tissue acquisition in the diagnosis of gastrointestinal, pancreatobiliary, and mediastinal diseases, Franseen-tip needles have shown superior tissue architecture preservation and improved histology adequacy but evidence regarding their overall impact on diagnostic yield remains mixed. Furthermore, whether cytology and histology obtained concurrently using the same needle—an approach now increasingly adopted—improves diagnostic performance is not fully established.

Methods: We conducted a retrospective review of all patients who underwent EUS-guided tissue sampling at a tertiary referral center in Surat, India. Between January 2015 and March 2025, tissue acquisition predominantly involved FNA using 22G or 25G needles with slow-pull suction (Group A), and FNB using 22G ProCore needles when histology was required. From 2019 onward, Franseen needles were adopted as standard, and combined cytology and histology sampling (FNAB) without stylet or suction became routine (Group B). Variables analyzed included tissue adequacy, sensitivity, specificity, malignancy prediction, and disease-specific diagnostic yield. A propensity-matched analysis compared Groups A and B to control for confounders.

Results A total of 989 patients were included; 631 (63.8 %) had malignant disease. The most common sampling sites were lymph nodes (n = 381), pancreatic lesions (n = 354), bile duct (n = 81), periampullary region (n = 45), gallbladder (n = 39), luminal wall (n = 42), and others. Franseen needles were used in 816 (82.5 %) procedures, while FNB was performed in 748 (75.5 %). Overall cytology adequacy was 92.5 %, while histology adequacy was 87.0 %. Cytology achieved a sensitivity of 92.4 % and specificity of 95.3 %. When combining cytology and histology with Franseen needles (FNAB), adequacy significantly improved (97.4 % vs 91.9 % with non-Franseen FNA; p = 0.0012), as did specificity (94.8 % vs 87.7 %; p = 0.042). Sensitivity and PPV were higher with FNAB, though differences were not statistically significant. In malignant lesions, FNAB provided the highest adequacy (98.9 %) and sensitivity (96.4 %), significantly outperforming both standalone FNA (adequacy 94.1 %; p = 0.0004) and FNB (91.6 %; p < 0.001). In benign lesions, FNAB also demonstrated superior adequacy (98.7 % vs 87.4 % with FNA; p = 0.0048) and higher sensitivity (95.5 % vs 88.8 %; p = 0.0374). Disease-specific analysis revealed the greatest advantage of FNAB in pancreatic carcinoma (adequacy 98.9 % vs 89.4 % with FNB;

p = 0.0003) and tuberculosis (adequacy 98.7 % vs 91.0 % with FNA; p = 0.0048), particularly in lesions with fibrosis, necrosis, or firm tissue consistency. Propensity-matched comparison of Groups A and B showed no significant difference in overall diagnostic adequacy (92.3 % vs 95.4 %; p = 0.36) or sensitivity (93.3 % vs 92.9 %; p = 1.00). Discordance between cytology and histology was low (3.7 %), with moderate agreement (κ = 0.49), indicating complementary contributions rather than redundancy.

Discussion:Franseen needles, propensity-matched analysis showed that needle type alone does not determine diagnostic yield; rather, synergistic combination of cytology and histology enables optimal outcomes.

Conclusions FNAB using Franseen needles offers the most robust diagnostic performance among all tissue acquisition approaches evaluated. The strategy provides higher adequacy and superior sensitivity in both malignant and benign diseases, with particular benefit in pancreatic cancer and tuberculosis. Incorporating both cytology and histology into routine

eP778 Oesophageal Self-expanding Metal Stent Migration: A Single-Centre Audit of Fixation Strategies

Authors Zhang D[1], Yousaf A[1], Malik J[1], Prateek P[1], Mylonas I[1], Wadsworth C[1], Ahmed W[1], Simon D[1]

Institute 1 Imperial College Healthcare NHS Trust, London, United Kingdom

DOI 10.1055/s-0046-1822105

Aims Self-expanding metal stent (SEMS) migration is the most common complication of oesophageal stent placement. A recent systematic review reported an overall migration rate of 17.2 %, with rates varying by indication. [1–3] To mitigate risk, fixation techniques have been deployed such as over the scope clips (OTSC), endoscopic suturing, and through the scope (TTS) clips. A recent meta analysis demonstrated that fixation significantly reduces migration compared to non-fixation, with all fixation techniques superior to non-fixation. [4] However, real world efficacy remains uncertain due to a lack of guidance in indication for stent fixation. This audit aimed to identify clinical and anatomical predictors of migration in routine clinical practice.

Methods Consecutive patients who underwent oesophageal SEMS placement under direct radiological screening between January 2022 and October 2025 were reteroscpectively analysed. The primary outcome was stent migration by 45 days in patients with and without fixation. Secondary outcomes included time-to-migration, migration rates by indication, age, lesion distance, lesion length, and crossing of the gastro-oesophageal junction (GOJ). Statistical analysis was performed using Fisher's exact test, Chi-Square test and Mann-Whitney U test. Multivariable logistic regression was used to assess independent associations with migration.

Results Sixty-six (66) patients were identified aged 33-88. Indications included post operative leaks/ perforations, benign strictures and malignant strictures. Overall migration rate was 9 % (n = 6). Stent fixation was not significantly associated with a change in migration rate: 15.4 % with fixation (2/13) compared with 7.5 % without fixation (4/53), OR = 2.23, p = 0.337. Migration rates varied by fixation method: OTSC 10.0 % (1/10), Suture 33.3 % (1/3), clip 0 % (0/1), and no fixation 7.7 % (4/52). Patient numbers were not large enough to elucidate statistical significance. Six migration events occurred in stents crossing the GOJ 15.0 % (6/40) compared with zero migration events in stents not crossing the GOJ 0 % (0/26), p = 0.074. Indication influenced migration risk: benign stricture 23.1 % (3/13), malignant stricture 5.0 % (2/40), OR = 5.70, p = 0.088; post-operative leaks/perforation 8.3 % (1/12). Mean age was similar in migrated (69.8 years) and non-migrated (66.6 years) groups (p = 0.55). Mean time to migration was longer with fixation (mean 39 days) than without (mean 15 days), with patient numbers too low to draw statistical significance. Fixation was selectively used in higher risk indications: malignant 2.5 % (1/40), benign 23.1 % (3/13), post-operative leaks/perforation 75.0 % (3/12). Multivariable regression showed fixation was not independently associated with migration (OR = 2.18, p = 0.523) after adjusting for indication.

Conclusions This audit demonstrates that SEMS GOJ crossing is the strongest anatomical predictor of stent migration, with all migration events occurring in this context. Benign indication carries significantly higher migration risk than malignant disease, consistent with literature implicating the role of tumour anchoring.[1–3] In this cohort, stent fixation was preferentially used in inherently higher risk cases and we do not show that stent fixation was associated with reduced migration. We postulate that crude rates in fixation may reflect selection bias; fixation seems preferentially performed in inherently higher risk cases, benign and post-operative leaks/perforation. Limitations included the lack of uniformity in endoscopy report documentation and the subjective interpretation of SEMS positioning using radiology. These findings show varying real world practice. Further prospective research and larger sample sizes are required to interrogate the benefit of various stent fixation modalities, across all indications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822106

Aims Endoscopic resection for superficial pharyngeal carcinoma has been reported as a minimally invasive therapeutic option; however, the pharyngeal space is anatomically narrow, making the procedure technically challenging. We developed the underwater ESD with Water Pressure Method (WPM), which utilizes endoscopic waterjet pressure under immersion to facilitate submucosal entry, and previously reported its usefulness in pharyngeal ESD. In the narrow working space of the pharynx, a thin therapeutic endoscope may provide additional technical advantages. This study evaluated the short-term treatment outcomes of pharyngeal ESD performed using WPM with a thin therapeutic endoscope.

Methods We retrospectively reviewed lesions treated with pharyngeal ESD using WPM and a thin therapeutic endoscope under general anesthesia with laryngeal exposure at our institution between March 2022 and May 2025. Short-term outcomes were assessed. The submucosal dissection speed was compared with that of lesions treated during the same period using a conventional-diameter therapeutic endoscope.

Results During the study period, 27 pharyngeal ESD procedures were performed, of which 10 patients with 11 lesions were treated using the thin therapeutic endoscope. All lesions were located in the hypopharynx: 3 in the pyriform sinus, 1 in the post-cricoid area, and 7 on the posterior wall. The median tumor diameter was 20 mm (range, 5–40 mm). Both the en bloc resection rate and procedural completion rate were 100 %, and the histological R0 resection rate was 82 %. The median procedure time was 14 minutes (range, 5–67 minutes). The median hospital stay was 6 days (range, 6–8 days).

During the same period, 17 patients with 20 lesions underwent ESD using a conventional-diameter therapeutic endoscope. The median dissection speed was faster with the thin therapeutic endoscope than with the conventional endoscope (22.7 vs. 15.5 mm^2/min). No adverse events—including laryngeal edema, postoperative bleeding, or aspiration pneumonia—were observed.

Conclusions In the anatomically narrow pharyngeal region, WPM-assisted ESD using a thin therapeutic endoscope enabled safe and efficient dissection, achieving a faster dissection speed compared with conventional-diameter endoscopes. This approach appears particularly useful for pharyngeal ESD in limited working spaces.

eP780 Papilla Morphology as a Predictor of Post-ERCP Pancreatitis: A Retrospective Cohort

Authors Tsitsigiannis K[1], Thanos C[1], Georgakopoulou N[1], Ntailianas D[1], Piskopou D[1], Georgiou E[1], Triantafyllou M[1], Kalakos N[1], Mpraimakis A[1], Kotzagiannidou E[1], Striki A[1], Michalopoulos G[1], Varbobitis I[1], Argyropoulos T[1], Karoumpalis I[1]

Institute **1** General Hospital of Athens "G. Gennimatas", Athens, Greece

DOI 10.1055/s-0046-1822107

Aims Papilla morphology has been proposed as an anatomical determinant of difficulty in ERCP cannulation and in post-ERCP pancreatitis (PEP) risk, but evidence regarding its predictive value remains inconsistent. We examined whether papilla type and the presence of periampullary diverticulum are associated with PEP in a large cohort of ERCP-naïve patients [1, 2].

Methods A retrospective analysis was conducted on 891 ERCPs that were performed on ERCP-naïve patients at General State Hospital of Athens " G. Gennimatas '' during a three-year span. We included only ERCP-naïve patients with non-pathologic papillae; papillary adenomas and inflammatory or distorted ones were excluded from the study. Papillae were classified according to the Haraldsson classification as type I (normal), type II (small), type III (protruding) and type IV (creased/ridged). The diagnosis of PEP was determined according to the ESGE diagnostic criteria. Logistic regression assessed the association between papilla type and PEP while Chi-Square (χ^2) tests were used to evaluate differences in PEP incidence across papilla types and the effect of diverticulum presence on PEP risk. Statistical analyses were performed using SPSS v.23.

Results The papillae type distribution was: Type 1 = 83.4 %, Type 2 = 8,1 %, Type 3 = 7,4 % and Type 4 = 1,1 %. Overall PEP incidence was 6.6 %. Chi-square analysis demonstrated a statistically significant overall difference in PEP incidence across the four types ($p = 0{,}026$). Post-hoc pairwise comparisons showed that Type 3 papillae differed significantly from Type 1 and Type 2 (both $p < 0.05$). The Type 3 vs Type 4 comparison could not be reliably assessed by χ^2 due to sparse data (only 1 PEP case in Type 4). After logistic regression it was shown that Haraldsson type 3 papilla independently increased the odds of PEP ($p = 0.009$; OR 2.83, 95 % CI 1.31–6.16). Presence of periampullary diverticulum was recorded in 11.7 % of cases, but it was not associated with PEP ($p = 0.94$).

Conclusions In this large ERCP-naïve cohort, Haraldsson Type 3 papilla emerged as a significant predictor of PEP, whereas periampullary diverticulum had no impact on risk of PEP. These findings support evidence stating that differences in papilla morphology are linked with alterations in cannulation complexity and PEP. Papilla morphology may represent a simple, visually accessible parameter to enhance pre-procedural risk stratification and guide PEP-prevention strategies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822108

Aims This study evaluates the efficacy, safety, and oncologic outcomes of colorectal Endoscopic Submucosal Dissection (ESD) at two tertiary care centers in Saudi Arabia.

Methods We conducted a retrospective observational cohort study of patients undergoing colorectal ESD from January 2024 up to November 2025 at King Fahad Medical City and Security Forces Hospital. Inclusion criteria comprised all patients with colorectal neoplasms resected via ESD. The primary outcome was the en bloc resection rate. Secondary outcomes included R0 resection (negative lateral/vertical margins), curative resection, adverse events (bleeding, perforation), and local recurrence. Statistical analysis was performed using the R statistical programming language [1–8].

Results A total of 47 patients (mean age 59.5 ± 15.6 years; 52.2 % male) underwent ESD. The cohort had a moderate comorbidity burden (ASA Class II: 70.2 %). Lesions were mostly located in the rectum (46.8 %) and sigmoid colon (17.0 %), with a mean tumor size of 37.6 ± 17.1 mm. Preoperative imaging was performed in 60.9 % of cases. The classic ESD technique was employed in 89.4 % of cases, frequently using a Dual Knife (31.9 %). En bloc resection was achieved in 93.6 % (44/47) of patients. Histopathology revealed adenomas in 71.7 % and early carcinomas (Tis/T1) in 10.9 %. R0 resection was confirmed in 91.3 % for lateral margins and 89.1 % for deep margins. Among evaluable cases, 93.3 % achieved curative resection. The safety profile was favorable, with 95.7 % of patients experiencing no adverse events. Complications occurred in 4.3 % (2/47), comprising one intra-procedural bleeding event managed conservatively and one delayed perforation requiring surgical intervention. Over the follow-up period, surveillance colonoscopy identified local recurrence in 6.4 % (3/47) of patients.

Conclusions Colorectal ESD is a safe and effective modality in Saudi tertiary care settings, achieving high en bloc rates (93.6 %) and low recurrence (6.4 %) comparable to international benchmarks, supporting broader regional implementation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822109

Abstract Text

Esophageal perforation is a rare but serious complication of pneumatic dilation for achalasia, occurring in 1 %–3 % of procedures. Early recognition and rapid endoscopic management are crucial to prevent severe consequences such as mediastinitis or sepsis. We report a case of iatrogenic perforation diagnosed immediately after dilation and successfully managed with endoscopic stenting [1–4].

A **58-year-old woman** with **type II achalasia** underwent her first pneumatic dilation using a **30-mm balloon** inflated for one minute under sedation. Post-dilation endoscopic assessment revealed a **3-cm anterolateral tear**. Shortly afterward, the patient developed severe epigastric pain. A thoraco-abdominal CT scan confirmed a **10-mm esophageal defect** with mediastinal fat infiltration, consistent with perforation.

An early endoscopic intervention was performed, consisting of the placement of a **fully covered self-expandable metal stent (SEMS)** across the tear, secured with **two clips** to avoid migration. Supportive care included **enteral feeding** via a nasogastric tube, **intravenous antibiotics**, and **proton pump inhibitors**. The patient remained clinically stable, without signs of sepsis or subcutaneous emphysema. A control CT scan at **48 hours** showed correct stent positioning and absence of mediastinal leakage. Oral intake was progressively resumed after one week. The stent was removed **two weeks** later, and follow-up endoscopy confirmed **complete healing** of the perforation.

This case highlights the importance of **systematic post-dilation endoscopy** and prompt imaging in symptomatic patients, allowing early diagnosis of perforation. **Endoscopic stent placement with secure fixation** is an effective, minimally invasive therapeutic option that can prevent surgical intervention and reduce morbidity. Early detection and rapid endoscopic management remain key factors in achieving favorable outcomes in iatrogenic esophageal perforation following pneumatic dilation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP783 Sedationist-Endoscopist Model Using Capnography and High Flow Nasal Oxygen in ERCP and Advanced HPB Endoscopy

Authors Lam WL[1], Prawiradiradja R[1], Jivanjee S[1], Javed N[1], Durkin D[1], Lau K[1], Hebbar S[1]
Institute **1** Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom
DOI 10.1055/s-0046-1822110

Aims Most ERCPs in the UK are performed under conscious sedation, yet increasing complexity and duration in HPB endoscopy can challenge patient tolerance. Deep sedation or general anaesthesia is recommended but not consistently available. This study assessed the safety and feasibility of higher-dose conscious sedation delivered through a sedationist–endoscopist model supported by capnography and high flow nasal oxygen [1–3].

Methods We conducted a retrospective review of all ERCPs, combined EUS – ERCPs, EUS-BD, EUS-GE, ampullectomies and cholangioscopies performed between 1 July 2024 and 30 June 2025. All eligible procedures during that period were included. All patients received high flow nasal oxygen with continuous monitoring of oxygen saturation, heart rate and capnography. All patients received midazolam and fentanyl in increments of 1mg for Midazolam and 25µg for Fentanyl. This was administered by the sedationist (either trainee or trainer) while the other performed the endoscopy. Sedation doses were compared with JAG age-based thresholds. Outcomes included completion rates, need for reversal and sedation-related adverse events.

Results Across 527 ERCPs, mean midazolam and fentanyl doses were 4 mg and 176.6 µg (median 4 mg and 150 µg). Thresholds were exceeded in 53.9 % and 83.3 % of patients. No ERCP was incomplete due to sedation. In 244 advanced HPB procedures, mean doses were 4.6 mg and 231.5 µg (median 4 mg and 200 µg). Thresholds were exceeded in 65.1 % and 93.4 % of cases. Three procedures (1.2 %) were incomplete due to sedation. Maximum doses reached 12 mg midazolam and 850 µg fentanyl. No patient had hypoxaemia requiring intervention, no reversal agents were used and no sedation related adverse events were recorded.

Conclusions This sedationist–endoscopist model with capnography and high flow nasal oxygen allowed higher dose conscious sedation to be used safely for ERCP and advanced HPB endoscopy. Completion rates were high and no sedation related complications were observed. This approach provides a practical option where deep sedation or general anaesthesia is limited.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP784 Endoscopic detection of migrated coils: A case series

Authors Wehling C[1, 2], Wichmann D[3], Caca K[4], Wannhoff A[4], Koschny R[1, 2]
Institutes **1** University Hospital Heidelberg, Department of Gastroenterology, Endoscopy Unit, Heidelberg, Germany; **2** University Hospital Heidelberg, Translational Endoscopic Research, Heidelberg, Germany; **3** University Hospital Tübingen, Endoscopy Unit, Tübingen, Germany; **4** RKH Klinikum Ludwigsburg, Department of Internal Medicine, Gastroenterology, Ludwigsburg, Germany
DOI 10.1055/s-0046-1822111

Aims Placement of coils and embolism material by interventional radiology is crucial for the management of vascular bleedings caused by gastric varices, arterial aneurysms or gastrointestinal ulcers. In rare cases these particles migrate through the gastrointestinal wall and become visible during endoscopy. Here a series of 7 patients with migrated coils was analyzed regarding their management and outcome.

Methods Seven patients were retrospectively identified in 3 German tertiary hospitals in the years 2020-2024. Data on age, gender, indication of coil placement, time to detection and anatomic location of migration, complications, and their management was collected.

Results The 2 female and 5 male patients had a mean age of 64.7 ± 16.7 years at the time point of embolization by interventional radiology. Active bleeding necessitated interventional radiology in 4 patients, 3 of which were located in the duodenum and one from a pseudoaneurysm from the right hepatic artery. Prophylactic treatment reasoned the placement of embolism material in 2 patients with varices located in the gastric fundus and esophagus and in one patient with a pseudoaneurysm of the splenic artery. The mean time to detection of migration was 483 ± 523 days including two early migrations within the first 5 days. All patients were alive at the last follow-up after a mean of 619 ± 649 days. Location of migration was the duodenum in 3 cases, the stomach in 2 cases and the jejunum and pancreatic duct in one case each. In 6 of 7 of cases migrated material was left in place as patients remained asymptomatic. The patient with coil migration into the pancreatic duct presented with a pancreatitis 47 months after placement of 19 coils. In this specific case coils were applied for treatment of the dissection of a pseudoaneurysm of the splenic artery and coeliac trunk. Surgical resection of the left pancreas was performed to retrieve coil material which by itself was complicated by pancreatic fluid leakage from the resection margin resulting in EUS-guided drainage.

Conclusions Coil migration represents a rare complication after vascular embolization by interventional radiology. Our case series supports conservative management in the cases of migration into the lumen of the gastrointestinal tract. Penetration into the pancreatic duct was documented in one case requiring surgical and endoscopic treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP785 Technical systematic review and meta-analysis of randomized controlled trials in malignant distal biliary obstruction

Authors Chapelle N[1], Elmunzer J[2], Forbes N[3], Al-Alawi S[4], Peng YN[5], Ahmed N[1], Faucher-Jabado G[1], Benmassaoud A[1,6], Jacques J[1], Martel M[6], Barkun A[1], Chen YI[7]

Institutes **1** Division of Gastroenterology and Hepatology, McGill University Health Centre, Montréal, Canada; **2** Wake, Salem-win, United States of America; **3** Division of Gastroenterology and Hepatology, University of Calgary, Calgary, Canada; **4** MUHC – McGill University Health Centre (Glen Site), Montréal, Canada; **5** Division of Experimental Medicine, McGill University Health Centre, Montréal, Canada; **6** Research Institute of the McGill University Health Centre, Montréal, Canada; **7** McGill University, Montréal, Canada

DOI 10.1055/s-0046-1822112

Aims Malignant distal biliary obstruction (MDBO) is a common complication of peri-ampullary cancers associated with significant morbidity and mortality. Although, recent advances such as endosonography guided biliary drainage (EUS-BD) have emerged, methodological rigorous trials are needed to validate these promising developments. **We aim** to evaluate the quality of published randomized control trials (RCTs) on drainage of MDBO. Our findings are intended to a guide subsequent consensus on a methodological framework for clinical trials in MDBO.

Methods We conducted a systematic review of RCTs assessing biliary drainage in patients with MDBO (PRISMA 2020). We included RCTs published in full that compared at least two biliary drainage modalities or stents in MDBO. Studies involving hilar obstruction were excluded. A systematic search was conducted in MEDLINE, Embase, CENTRAL, and Web of Science from database inception to Jan. 9, 2025. Study quality was assessed using the revised risk of bias (ROB 2.0).

Results Overall, 4,663 citations were identified with 71 trials ultimately selected. These RCTs compared ERCP stent types in 67.6 % with the remaining comparing different modalities of drainage including EUS-BD, percutaneous drainage, and surgery. Most trials assessed patients with unresectable or locally advanced cancer (87.3 %). A hypothesis statement was explicitly stated in only 22.5 % of the studies. A sample size estimate was lacking in 26.8 % of the RCTs. In terms of randomization, timing was missing in 43.7 %, with 56.3 % of the studies having no consort randomization diagram. Moreover, information on blinding was not described in 47.9 % of the trials. In study results, key baseline characteristics such as performance status and comorbidity index were reported in only 29.6 % and 11.3 % of the studies, respectively. The definition of biliary obstruction was heterogeneous with 12 different definitions identified. In terms of outcomes, stent dysfunction was the most common; however, a precise definition was missing in 19.7 % of the studies while 42 different definitions of stent dysfunction were used. Technical and clinical success were defined in only 40.8 % and 47.9 % of the studies, respectively. Although adverse events were ubiquitously reported, only 36.6 % of the trials used a standardized lexicon for reporting. Hospital length of stay and quality of life data were reported in only 21.1 % and 11.3 % of the trials, respectively. According to the ROB2, 85 % of the trials were at high-risk of bias in the measurement of outcomes (▶ **Table 1**).

▶ **Table 1**

	N (%), N = 71
Reports Performance status	21 (29.6 %)
Co-morbidity index included (ASA score)	8 (11.3 %)
Reports liver metastasis	9 (12.7 %)
Reports rate of GOO	9 (12.7 %)
Outcomes	
Reports definition for stent dysfunction	57 (80.3 %)
Reports definition for technical success	29 (40.8 %)
Reports definition for clinical success	34 (47.9 %)
Uses Standardized definition for adverse events	26 (36.6 %)
Reports quality of life data	8 (11.3 %)
Reports hospital length of stay	19 (26.8 %)
Reports mortality/survival	67 (95.7 %)
Reports chemotherapy data	18 (25.4 %)
Reports surgical resection rate	14 (19.7 %)
Reports 30-days complication of pancreaticoduodenectomy	2 (22.2 %)

Conclusions Our review highlights the methodological deficiencies and heterogeneity of current published trials in MDBO. A methodological framework and standardized definitions of outcomes are urgently needed to improve evidence-based medicine for the management of MDBO

eP786V Single scope transhepatic rendezvous for biliary drainage in hilar cholangiocarcinoma

Authors Akerkar S[1, 2, 3], Havre R[2, 1, 3], Pham KDC[3, 1]
Institutes **1** Bergen Research Group for Advanced Gastrointestinal Endoscopy (BRAGE), Bergen, Norway; **2** Department of Clinical Medicine, University of Bergen, Bergen, Norway; **3** Haukeland University Hospital, Bergen, Norway
DOI 10.1055/s-0046-1822113

Abstract Text

Effective biliary drainage is critical in unresectable cholangiocarcinoma (CCA). The patient, a 53-year-old male, underwent several ERCP sessions for stent revisions and intraductal RFA. During the recent intervention with a novel linear EUS scope (EG-740UT, Fujifilm, Tokyo, Japan), a dilated duct in segment II was punctured using a 19G FNA needle, and a 0.025" curved-tip guidewire was advanced antegradely into the duodenum. The guidewire was retrieved with a pediatric biopsy forceps, achieving a single-scope transhepatic rendezvous. Using the same scope, multiple biliary branches were accessed, RFA was performed, and four 8F plastic stents were placed for optimal drainage. This case highlights the principle of single scope rendezvous with a novel linear EUS scope, which offers stability and momentum for retrograde and antegrade instrumentation to overcome complex hilar strictures.

eP787 Improving Upper GI Endoscopy Safety and Success in Patients on GLP-1 Agonists

Authors George R[1], Saramosing J[2], Akbar S[3], Lourenco F[3], Browne H[1], Kumar M[2], Mawdsley J[3], Haji A[1], Gulati S[1], Emmanuel A[1], Hayee B[1]
Institutes **1** King's College Hospital NHS Foundation Trust, London, United Kingdom; **2** Princess Royal University Hospital, Orpington, United Kingdom; **3** Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom
DOI 10.1055/s-0046-1822114

Aims The increasing use of Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) presents a significant challenge for upper gastrointestinal endoscopy (OGD) due to their effect on delaying gastric emptying. Standard fasting protocols are frequently inadequate, leading to limited views and requiring repeat procedures. This study aimed to identify the key demographic, clinical and procedural predictors of endoscopic success in patients on GLP-1 RAs and evaluate strategies for optimizing outcomes.

Methods We conducted an analysis of a prospective audit database including patients on injectable GLP-1 RAs undergoing OGD in a 6 month period from January to June 2025, across three sites in the UK. Data analysed included demographics, clinical status (diabetes, insulin use, indication), GLP-1 RA type and procedural variables (preassessment, sedation, Nil By Mouth (NBM) duration). Multivariate logistic regression was employed to determine independent predictors of poor views as described by the endoscopist. Outcomes and NBM durations for initial and repeat procedures were compared.

Results The analysis included 223 initial procedures. Poor mucosal views were demonstrated in 19 %(43/223) of cases. For the initial procedures, 98 % of patients followed a standard 6-hour fast. Multivariate analysis demonstrated that demographic factors, BMI, type of GLP-1 RA (Tirzepatide, Semaglutide and Liraglutide), indication and the presence of diabetes with or without insulin therapy were not significant predictors of obstructed views during diagnostic gastroscopy in individuals taking GLP- 1 RA.

Procedural factors showed strong protective trends with the utilization of sedation (OR 0.51; 95 % CI [0.24–1.09]; P = 0.082) and completion of a dedicated preassessment (OR 0.47; 95 % CI [0.20–1.09]; P = 0.078) reducing the odds of poor views by approximately 50 %.

Thirty-four patients required repeat endoscopy and nine did not as their indication was achieved on index endoscopy. The strategy for the second attempt involved significantly extending the mean NBM duration from 6.19 hours to 14.62 hours (P < 0.0001). 91 % (31/34) of patients fasting for atleast 12 hours achieved good mucosal views.

Conclusions In patients taking GLP-1 RAs, standard 6-hour fasting is inadequate in one-fifth of cases, irrespective of patient demographics or metabolic status. The key to ensuring successful endoscopy lies in meticulous procedural optimization rather than patient selection. Dedicated preassessment and critically, extending the NBM duration to at least 12 hours are recommended to ensure adequate visualization and minimize the need for repeat procedures in this high-risk cohort.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP788V Laser therapy for ablation of an embedded biliary metalic stent

Author Mukewar S[1]
Institute **1** Midas Hospital, Nagpur, Nagpur, India
DOI 10.1055/s-0046-1822115

Abstract Text

Embedded stents in gastrointestinal tract can be challenging to remove. When standard methods such as traction, compression necrosis or radiofrequency ablation fail, surgery maybe needed. Our case is of a 25-year-old man who presented with a common hepatic duct stricture following cholecystectomy for cholelithiasis. He underwent placement of a fully covered metal stent via percutaneous transhepatic biliary drainage (PTBD). Stent removal with standard methods with traction and radiofrequency ablation was unsuccessful. Patient declined surgery. ERC with Cholangioscopy was performed which showed stent embedded in the bile duct wall. Cholangioscopy guided laser ablation (30 watts for 40 minutes) was performed to ablate the tissue overgrowth and fragment the embedded portion of the stent. Ultimately the stent could be removed succesfully.

Video http://data.process.y-congress.com/ScientificProcess/Data//106/660/1670/509c1468-4f76-4b67-b4ff-76b6db8ccba4/Uploads/19978_Embedded_metal%20stent.mp4

eP789 Endoscopic ultrasound-guided drainage of the gallbladder (EUS-GBD) in patients with acute calculous cholecystitis who are “definitely” unfit for surgery. Experience at a referral center

Authors Arese D[1], Giudici G[1], Poshnjari A[2], Spandre M[1], Rizzi F[1], Coppola F[1]
Institutes **1** ASL Città di Torino – Ospedale San Giovanni Bosco, Torino, Italy; **2** University of Turin, Torino, Italy
DOI 10.1055/s-0046-1822116

Aims In patients with calculous acute cholecystitis who are not candidates for surgery, gallbladder drainage represents an effective strategy to control infection and prevent complications. Among the available options, endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) stands out as a minimally

Endoscopy 2026; 58: S1–S1041

invasive, safe, and effective approach for frail patients.Despite its established efficacy, EUS-GBD requires specialized expertise available only in a limited number of centres, underscoring the need for a standardized approach to this technique. Moreover, the long-term management of lumen-apposing metal stents (LAMS) remains a matter of debate and lacks shared guidelines [1–8].

Methods This single-centre retrospective study describes the experience in frail, high-risk surgical patients (Charlson Comorbidity Index Age-adjusted, A-CCI ≥ 5), evaluating the efficacy and safety of EUS-guided gallbladder drainage and proposing a potential long-term management algorithm for these patients (▶ **Table 1**).

▶ **Table 1**

	N = 19 (%)
Hot Axios	13 (68.4)
Trans-duodenal	16 (84.2)
Technical Success	19 (100)
Intraprocedural AEs	2 (10.5)
Long-term Clinical Success	18 (95)
Hospital Stay (Median)	13 (1-68)
LAMS removal with gallbladder clearance	6 (31.6)

Results EUS-GBD procedures performed at a hub centre between November 2023 and September 2025 were considered. In 19 patients (median A-CCI 8; ASA III–V 100 %), technical success was 100 % and clinical success 95 %, with a mean follow-up of 30 weeks. A transduodenal access was used in 84 % of cases and a transgastric access in 16 %. LAMS types included HOT AXIOS in 68 % and HOT SPAXUS in 32 % of procedures. One duodenal perforation occurred and was managed endoscopically during the same session. No bleeding events or buried LAMS syndrome were observed. Median hospital stay was 13 days. During long-term follow-up, three complications were recorded, all successfully treated endoscopically. Long-term mortality was 37 %, mainly due to non-biliary causes. Stent removal was performed in 32 % of patients after approximately 51 days, following complete gallbladder clearance, resulting in definitive treatment.In the most fragile patients, the LAMS was left in place, no complications related to its permanence were observed.

Conclusions EUS-GBD is a safe and effective definitive treatment option for patients with calculous acute cholecystitis who are not candidates for surgery. Planned LAMS removal is recommended in patients who experience recovery of performance status after the procedure and achieve complete gallbladder clearance, whereas in frail patients the stent can be safely maintained in place. The study highlights the importance of a tailored approach that balances safety, efficacy, and patient tolerance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP790 Optical diagnosis accuracy and use of artificial intelligence systems for diminutive polyps in clinical practice: a nationwide Italian survey

Authors Gibiino G[1], Frazzoni L[2], Antonelli G[3], Marasco G[4], Spada C[5], Portincasa P[6], Hassan C[7], Fuccio L[4], Fabbri C[8]

Institutes **1** Gastroenterology and Digestive Endoscopy Unit, Forlì-Cesena Hospitals, AUSL Romagna, Forlì-Cesena, Italy; **2** Gastroenterology and Digestive Endoscopy Unit, AUSL Romagna, Rimini, Italy; **3** Gastroenterology and Digestive Endoscopy Unit, Castelli Hospital, Roma, Italy; **4** Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; **5** Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; **6** University of Bari Aldo Moro, Bari, Italy; **7** Department of Biomedical Sciences for Health, Milan, Italy; **8** Gastroenterology and Digestive Endoscopy Unit, Forlì-Cesena Hospitals – University of Bologna, Forlì-Cesena, Italy

DOI 10.1055/s-0046-1822117

Aims The prevalence of competence standards for the optical diagnosis of diminutive colorectal lesions (SODA competence standards) is unknown. We aimed to define the knowledge and adoption of these criteria and the role of artificial intelligence (AI) systems in this setting.

Methods We conducted a survey during a nationwide event on quality in colonoscopy held in Verona, Italy in May 2025 by a self-administered questionnaire. Descriptive analysis was conducted [1–3].

Results 50 out of 58 endoscopists (28/50 F/M) attended the survey, with mean age of 52 years and equal distribution of age, regions and public or private

practice. Most of participants (82 %) perform colonoscopy within a specific program for screening of colorectal cancer. Over 90 % stated real-time in-vivo diagnosis of diminutive colorectal polyps, usually by virtual chromoendoscopy, respectively with Narrow Band Imaging (NBI, 73 %), i-scan (14 %) and Blue Light Imaging (BLI, 13 %). The competence is mainly based as self-training.

82 % reports to monitor diagnostic accuracy and 77 % knows SODA criteria; however, most of them is unable to define its own sensitivity and sensibility in clinical practice. AI availability was confirmed in less than 30 %; its role is expected to improve future monitoring of appropriateness and quality standards of colonoscopy.

Conclusions We found a general lack of adoption of SODA competence standards. Acquiring sensitivity and specificity in the optical diagnosis commonly performed in this setting should be the first step towards improving "resect and discard" or "leave in-situ" strategies in clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP791 Diagnosis of Intestinal Lymphoma Using Capsule Endoscopy and Enteroscopy: Essential Tools for Hard-to-Locate Lesions

Authors Moreira H[1], Sergio P[1], Romo P[1], Farrais S[1], Spigarelli IM[1]

Institute 1 Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

DOI 10.1055/s-0046-1822118

Introduction The gastrointestinal tract is the most frequent site of extranodal lymphomas; however, primary intestinal lymphomas (1–4 %) remain uncommon and represent a diagnostic challenge. The small bowel, given its length, location, and limited accessibility, is particularly difficult to evaluate using conventional techniques such as standard endoscopy or radiological imaging. As a result, advanced modalities including video capsule endoscopy (VCE) and enteroscopy have become indispensable for assessing suspected small-bowel disease. These tools allow high-resolution visualization, detection of subtle mucosal abnormalities, and targeted tissue sampling, thereby improving diagnostic accuracy in complex cases [1–7].

Clinical case We describe the case of a 68-year-old woman undergoing surveillance for previously surgically treated oral melanoma. She had no gastrointestinal symptoms and no significant medical history that could suggest small-bowel pathology. A PET-CT scan performed during routine follow-up revealed abnormal radiotracer uptake in the small intestine, a finding not correlated with the abdominopelvic CT, which showed no evident lesions. Given the inaccessibility of the suspected segment by conventional upper or lower endoscopy, a VCE was performed. The study identified an exophytic, ulcerated, and infiltrative lesion located in the proximal jejunum.

To further characterize the finding, single-balloon enteroscopy was carried out. This technique made it possible to reach the lesion directly, enabling precise localization, endoscopic marking for potential future interventions, and collection of multiple biopsies. Additional samples were also obtained from an edematous area in the duodenum. Histopathological examination confirmed the diagnosis of primary intestinal follicular lymphoma (PI-FL).

Conclusions PI-FL is a rare subtype of lymphoma (1–3.6 %), most commonly arising in the duodenum and often demonstrating multifocal involvement throughout the small bowel. Endoscopically, it may present as nodular, polypoid, plaque-like, or ulcerated lesions. Because these abnormalities can be subtle and may not produce luminal distortion, they often remain undetected on standard imaging such as CT scans. This case highlights the diagnostic value of VCE and enteroscopy, which proved crucial for identifying and sampling a lesion that would otherwise have remained inaccessible.

These advanced endoscopic techniques are more sensitive and specific for evaluating small-bowel lymphomas, allowing accurate diagnosis and guiding appropriate therapeutic planning. Following confirmation of PI-FL, the patient was referred to Hematology for specialized management and longitudinal follow-up.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP792 Role of Low-Volume, Same-Day Polyethylene Glycol (PEG) Regimen in Small Bowel Cleansing Before Capsule Endoscopy: A Single-Center Study

Authors De Lisi S[1], Carmagnola S[1], Randazzo AM[1], Schettino M[1], Toppeta A[1], Martelletti C[1], Belli LI[2, 1], Pavan F[2, 1], Salerno R[1]

Institutes 1 Gastroenterology Unit, ASST Fatebenefratelli Sacco, Milano, Italy; 2 Gastroenterology Unit, University of Milan, Milano, Italy

DOI 10.1055/s-0046-1822119

Aims The optimal protocol for small bowel (SB) cleansing in capsule endoscopy (CE) remains controversial. This study aimed to evaluate differences in SB cleansing quality between two low-volume polyethylene glycol (PEG) regimens.

Methods Patients eligible for CE were prospectively enrolled in this single-center, open-label study. All patients followed a low-fiber diet for three days and fasted for 12 hours prior to CE. They were randomly assigned to receive either 1 L of PEG 12 hours before CE (Group A) or 1 L of PEG 3 hours before CE (Group B). All CEs were reviewed by a single endoscopist. SB transit times (SBTT) were measured. Patients tolerability and side effects PEG related were recorded. SB cleanliness was assessed using the Small Bowel Cleansing Assessment and Report (SB-Clear) score and the Brotz score [1, 2].

Results Between October 2024 and October 2025, 29 consecutive patients were prospectively enrolled. Thirteen patients (44.8 %) were randomly assigned to group A, sixteen patients (55.2 %) to group B. 55.2 % were males, 69 % were outpatients. The main indication to CE was obscure gastro-intestinal bleeding (16 patients, 55.2 %). No differences in compliance of the two PEG regimens were found; all patients received the whole volume of PEG without side effects. The main lesions observed were vascular ones (13 patients, 44.8 %).

There were no statistically significant differences in age (mean 65.4 ± 18.4 SD group A vs 55.1 ± 21.9 SD group B) and sex between the two groups. Overall SB cleansing was adeguate in 27 patients (93.1 %). Cleansing scores were significantly higher in group B (SB-CLEAR mean 7.38 ± 0.9 SD vs 6.38 ± 1.4 SD, t-test p = 0.04; Brotz QI mean 6.18 ± 1.2 SD vs 5.07 ± 0.6 SD, t-test p = 0.008), no differences were found in Brotz QE and overall adequacy assessment (OAA). No statistically significant correlations were found among SBTT and SB cleansing scores, even if in Group 2 a shorter SBTT was correlated to higher quality SB cleansing scores (SB-CLEAR Pearson r -0.220 p = 0.412; Brotz QI Pearson r -0.209 p = 0.437). No statistically significant differences were found between detection of vascular lesions and SB cleansing scores. Multivariate analysis were no reliable because of small sample size.

Conclusions A low-volume, same-day PEG regimen is associated with improved small bowel cleansing scores compared with a day-before PEG regimen.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP793 Is There a Particular Feature of Portal Hypertension in Myeloproliferative Neoplasms ?

Authors Essadiqi S[1], Ziane M[1], Belabbes F[2], Delsa H[2], Ben El Barhdadi I[2]

Institutes **1** Mohammed VI University of Sciences and Health, Gastroenterologist, Casablanca, Morocco; **2** Cheikh Khalifa International University Hospital, Mohammed VI University of Sciences and Health, Casablanca, Morocco

DOI 10.1055/s-0046-1822120

Aims Clinically significant portal hypertension (PH) is defined as an elevation of the portal pressure gradient above 10–12 mmHg. While cirrhosis remains its most common cause, several non-cirrhotic forms exist, particularly in thrombotic conditions. Among these, myeloproliferative neoplasms (MPNs) represent a rare but important etiology of non-cirrhotic PH because of their chronic prothrombotic state.

The aim of this study was to describe the clinical and endoscopic features of PH associated with MPNs and to evaluate the impact of hematologic treatment on the evolution of complications.

Methods This retrospective descriptive study spanned a four-year period. Included were adult patients with confirmed PH whose etiology was an MPN diagnosed either through the presence of JAK2, CALR, or MPL mutations, or through consistent bone marrow biopsy (BMB) findings. Clinical presentation, laboratory results, imaging, endoscopic features, and treatment outcomes were collected and analyzed.

Results Of the 220 patients diagnosed with PH, 9 individuals (4.1 %) had an underlying myeloproliferative disorder. The mean age was 62.2 years (range 40–84), and males predominated (66 %, male-to-female ratio 3:1).

The most common presenting symptom was upper gastrointestinal bleeding (44.4 %), followed by anemia-related symptoms (33.3 %) and abdominal pain (22.2 %). Splenomegaly was universal among patients (100 %), and two-thirds presented with massive splenomegaly extending to the umbilicus or left iliac fossa. Ascites, however, was present in less than half the cases (44.4 %), suggesting that PH associated with MPNs may manifest differently from cirrhosis-related PH.

Ultrasound with Doppler revealed predominantly pre-hepatic causes of PH, with portal vein thrombosis (PVT) present in 77.7 % of patients. Intra-hepatic forms accounted for 22.2 % of cases. Notably, none of the patients exhibited Budd–Chiari syndrome, despite its known association with MPN-related thrombosis.

Genetic testing identified the JAK2 V617F mutation in 88.8 % of patients, in line with its recognized prothrombotic potential. Bone marrow biopsy allowed the diagnosis of primary myelofibrosis in 66.6 % of patients and essential thrombocythemia in 33.3 % of cases. No cases of polycythemia vera or chronic myeloid leukemia were detected.

Endoscopic examination revealed high-grade esophageal varices in a majority of patients: grade III varices with red signs in 55.5 %, grade II varices in 11.1 %, and grade I varices with red signs in 22.2 %. One patient had no esophageal varices but presented with hypertensive gastropathy. Gastric varices were found in 33.3 % of patients, and ectopic varices—duodenal and rectal—were observed in 22.2 %. Eight patients underwent endoscopic variceal ligation, with an average of 2.6 sessions (range 1–5), resulting in good clinical improvement.

Treatment combined management of PH (beta-blockers, endoscopic ligation, diuretics) with targeted therapy for the underlying MPN (hydroxyurea or ruxolitinib) and anticoagulation for thrombosis. Cytoreductive therapy produced an overall favorable response, with a reduction in spleen size in 50 % of patients. Nonetheless, PH remained partially persistent, and no patient achieved re-canalization of the portal vein.

Complications during follow-up included two episodes of recurrent gastrointestinal bleeding (22.2 %), a recurrence of ascites in one patient (11.1 %), and one death (11.1 %).

Conclusions Portal hypertension associated with myeloproliferative neoplasms displays a distinctive clinical profile. Presentation often includes inaugural gastrointestinal bleeding and marked splenomegaly, whereas ascites is less common. Endoscopic findings tend to be severe, with a high prevalence of advanced esophageal varices and frequent involvement of gastric or ectopic varices.

Although hematologic therapy does not reverse portal thrombosis, it provides significant stabilization of PH manifestations and contributes to the reduction of splenic enlargement in a substantial proportion of patients.

eP794 EUS-Rendezvous vs Precut for Difficult Biliary Cannulation: An Updated Meta-analysis

Authors Quintini D[1], Chavan R[2], Rancatore G[1, 3], Rizzo GEM[1, 3], Infantino G[1], Ligresti D[1, 3], Devani K[4], Rajput S[5], Da Costa MCP[6], Franco MC[7], Tarantino I[1, 3], Baraldo S[8]

Institutes **1** IRCCS ISMETT, Palermo, Italy; **2** Bharati Vidyapeeth Deemed University Pune, Pune, India; **3** UPMC, Palermo, Italy; **4** Prisma Health-Upstate/University of South Carolina School of Medicine, Greenville, United States of America; **5** Ansh Clinic, Ahmedabad, India; **6** Unimed Sorocaba, Sorocaba, Brazil; **7** UT Health San Antonio, San Antonio, United States of America; **8** Hospital de Amor, Barretos, Brazil

DOI 10.1055/s-0046-1822121

Aims Difficult biliary cannulation (DBC) remains a significant challenge in endoscopic retrograde cholangiopancreatography (ERCP) [1]. When cannulation fails, precut techniques are widely used as rescue techniques. Endoscopic ultrasound-guided rendezvous (EUS-RV) is increasingly used by experts as an alternative to precut for cannulating the bile duct. However, there is limited literature comparing these two techniques. This systematic review and meta-analysis aimed to compare the efficacy and safety of EUS-RV versus precut techniques for biliary access in DBC.

Methods A systematic search was conducted across PubMed, Embase, and Cochrane Library databases up to April 2025. Studies comparing EUS-RV and precut techniques in adult patients with DBC were included. Data were pooled using a random-effects model. Primary outcome was technical success rates; secondary outcome was adverse event rates. A P value < 0.05 was considered statistically significant.

Results Five studies (two randomized controlled trials and three retrospective cohorts) comprising 875 patients were included. Pooled technical success was higher with EUS-RV compared with precut (95.9 % vs. 91.4 %; OR 2.77; 95 % CI, 1.39–5.54; P = 0.004). Adverse event rates were 7.7 % for EUS-RV and 11.2 % for precut, with no statistically significant difference (OR 0.75; 95 % CI, 0.42–1.33; P = 0.321).

Conclusions EUS-RV is associated with higher technical success compared with precut techniques for rescue biliary cannulation after failed standard ERCP, with a comparable safety profile. These findings support EUS-RV may become the preferred rescue strategy, in specific settings, when expertise is available; however, further trials are needed to assess its safety, procedural duration, and learning curve.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP795 Impact of Sedation Method on Pharyngeal Observation and Procedure Efficiency During Esophagogastroduodenoscopy in Trainees: A Real-World Study

Authors Sumi K[1, 2], Sato T[1, 2], Sakurai T[1, 2], Uehara K[3, 2], Ishihara A[2], Inoue H[1]

Institutes **1** Digestive Diseases Center, Showa Medical University Koto Toyosu Hospital, Tokyo, Japan; **2** Hitachi medical center, Hitachi, Japan; **3** Showa Medical University Hospital, Tokyo, Japan

DOI 10.1055/s-0046-1822122

Aims Pharyngeal observation is an essential but technically demanding step in esophagogastroduodenoscopy (EGD), particularly for trainees. This study evaluated the impact of sedation method on pharyngeal observation, procedure efficiency, and safety, with a focus on trainee performance.

Methods We retrospectively analyzed 444 consecutive EGDs performed between April 2024 and March 2025 (trainees, n = 327; attending physicians, n = 117). Patients were classified into a propofol group (n = 199) and a midazolam group (n = 245). Patient characteristics were comparable between groups. Outcomes included pharyngeal observation rate, procedure time, safety (hypotension and oxygen desaturation), patient satisfaction, and discomfort. Factors associated with successful pharyngeal observation were assessed using multivariable analysis.

Results Overall, the pharyngeal observation rate was significantly higher in the propofol group than in the midazolam group (91.5 % vs 83.3 %, p = 0.0110), with a shorter procedure time (6.7 ± 2.4 vs 7.9 ± 3.0 min, p < 0.0001). Safety and patient satisfaction were comparable between groups. Similar results were observed after excluding cases with biopsy.Among trainee-performed EGDs, the pharyngeal observation rate (89.9 % vs 80.3 %, p = 0.0205) and procedure time (7.2 ± 2.6 vs 8.6 ± 3.0 min, p < 0.0001) favored propofol sedation, whereas no significant differences were observed among attending physicians. In the midazolam group, trainees had a significantly lower observation rate than attending physicians (p = 0.0256), while no such difference was seen in the propofol group. Multivariable analysis identified propofol use as an independent predictor of successful pharyngeal observation (OR 2.21, p = 0.0077) and shorter procedure time.

Conclusions In a real-world training setting, propofol sedation improved the pharyngeal observation rate and reduced procedure time during EGD, particularly among trainees. Optimization of the sedation environment may enhance technical acquisition in the early learning phase without compromising safety.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP796 Intraoperative Endoscopic Assistance: A Key Tool for the Safe Resection of a Gastric GIST in a Complex Location

Authors Moreira H[1], Otegui L[1], Pérez S[1], Romo P[1], Farrais S[1]

Institute **1** Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

DOI 10.1055/s-0046-1822123

Introduction Gastrointestinal stromal tumors (GISTs) are mesenchymal neoplasms arising from the gastrointestinal tract, most commonly from the stomach and small intestine. They originate from the interstitial cells of Cajal or related stem-cell precursors and typically express KIT (CD117) or DOG1, which aid in diagnosis. For localized tumors, surgical resection with negative margins remains the treatment of choice. Endoscopy—particularly when combined with endoscopic ultrasound (EUS)—plays a crucial role in establishing an accurate diagnosis, characterizing tumor size and layer of origin, and assessing features associated with malignant potential. Moreover, intraoperative endoscopic guidance can be indispensable when managing lesions that are small, intraluminal, or located in anatomically challenging regions, enhancing the safety and precision of minimally invasive surgery [1–5].

Clinical case We present the case of a 57-year-old man with no relevant medical history who sought medical evaluation due to rectal bleeding, epigastric pain, and unintentional weight loss. A thoracoabdominopelvic CT scan identified a 36-mm mass on the lesser curvature of the stomach, raising suspicion for a GIST. Subsequent upper endoscopy, followed by EUS-guided biopsy, confirmed the diagnosis.

During laparoscopic exploration, external visualization did not allow complete identification of the mass due to its intramural and partially endophytic growth pattern. For this reason, intraoperative endoscopic assistance was employed. Through real-time intraluminal visualization, the endoscopy team was able to

precisely localize the lesion along the lesser curvature and delineate its margins. This guidance facilitated a targeted wedge gastrectomy with adequate oncologic margins, avoiding excessive gastric resection and eliminating the need for adjuvant therapy.

Conclusions Intraoperative endoscopic assistance during laparoscopic GIST surgery constitutes a highly valuable tool, especially in cases where tumor location is complex or when endophytic growth limits visualization from the serosal surface. This combined approach enhances intraoperative tumor identification, improves surgical accuracy, and reduces the risk of complications such as inadvertent perforation, incomplete resection, or tumor rupture—an event associated with worse prognosis.

This case highlights the importance of close collaboration between endoscopists and surgeons in digestive oncologic procedures. The integration of endoscopic expertise into minimally invasive surgery ensures precise localization, optimizes surgical strategy, and contributes to safer and more effective management of submucosal gastric tumors.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822124

Problem to solve Current treatments for defects of the gastrointestinal and respiratory tract, such as fistulae and surgical anastomotic dehiscence, often involve complex surgical interventions and endoscopic procedures with the use of synthetic materials, which may lead to complications, prolonged hospitalization, poor outcomes, low quality of life, and death. For these reasons, we began applying regenerative medicine using mesenchymal stem cells derived from autologous adipose tissue, achieving good results [1–3, 5] in treating these conditions by promoting the growth and repair of damaged tissue. Still, in cases of larger defects, a structural support is required to facilitate better healing and complete closure of the defect. Thus, we aim to create a 3D bioprinted patient-specific scaffold seeded with the mesenchymal stem cells [4].

Innovation Fat tissue harvesting and mechanical emulsification of autologous adipose tissue will yield mesenchymal stem cells, as previously described [1–3]. A 3D bioprinter with dual extruder that allows for simultaneous deposition of materials using cartridges at different temperatures will be used to print component I (mechanically strong material made of PLA/PGA or a combination of these materials) and component II (soft bioink for cell support made of collagen, alginate, or hyaluronic acid or a combination). The composition of components I and II is defined based on mechanical testing outcomes (mechanical resistance and flexibility) and on cell growth enhancement in a 3D environment [6–20].

Results A 74-year-old man developed pneumaturia during chemotherapy + radiotherapy performed after laparoscopic radical prostatectomy with lymphadenectomy + rectal raffia with colonostomy for prostatic adenocarcinoma (cT4). A CT scan confirmed the clinical suspicion of a rectovesical fistula. Two attempts at trans-anal closure of the fistula were performed without success. A further unsuccessful surgical closure attempt was also performed by an open transvesical approach. As a last resort, a permanent urinary catheter was placed. Our rectoscopy showed a 10-mm fistula located on the anterior wall of the rectum, at 2 cm from the internal anal margin. On the rectal side, the mucosa around the fistula borders was massively fibrotic, because of the chronic inflammation due to several surgical closure attempts and radiotherapy. The patient was scheduled for repeated (4 procedures) endoscopic injection of autologous emulsified adipose tissue stromal vascular fraction (tSVFem). Each procedure was performed every 2 months, resulting in a progressive reduction of the fistula diameter to 2 mm, with reduced tissue fibrosis and improved tissue vascularity. Again, complete closure of the fistula was not achieved, and the patient continued to complain of symptoms. Then, we planned to implant a customised 3D-bioprinting-based treatment. The 3D scaffold was a blend of polylactic acid (PLA) and polybutylene adipate-co-terephthalate (PBAT), with a slight curvature and two holes for anchoring to the rectal wall. The scaffold was sutured with Apollo Overstitch, and the tSVFem was injected into the scaffold and the submucosal layer at the fistula borders using a 22-Gauge needle. The post-procedural course was uneventful. The rectoscopy performed 14 days later documented complete healing of the fistula with vascularized mucosal overgrowth and complete degradation of the 3D-printed scaffold. At this stage, the urinary catheter was removed, and no fistula-related symptoms or rectal urinary loss were recorded thereafter. Eight months later, the fistula was still completely closed, and the patient had intestinal recanalisation, without complication or recurrence of the fistula

Conclusions This procedure offers promising advancements in the field of regenerative medicine. It allows tailored, safe, and effective treatments for complex post-surgical defects. Nevertheless, its effectiveness should be confirmed in a larger patient cohort.

eP798 Evaluating the Learning Curve of EUS-Guided Liver Biopsy and Portal Pressure Gradient Measurement: A prospective study

Authors Farah A[1], Geraci O[2], Martel M[2], Chen YI[1], Benmassaoud A[1]
Institutes **1** Division of Gastroenterology and Hepatology, McGill University Health Centre, Montréal, Canada; **2** MUHC Research Institute, Montréal, Canada
DOI 10.1055/s-0046-1822125

Aims Endoscopic ultrasound (EUS)-guided portal pressure gradient (PPG) measurement and liver biopsy have become alternatives to the traditional transjugular methods, providing combined hemodynamic and histological assessment in patients with liver disease in a single session. However, data on the procedural learning curve remain limited. This study evaluates learning curves for combined EUS-guided PPG and LB during a single procedure, focusing on proficiency, milestones, and safety as these techniques are integrated into clinical practice.

Methods A learning curve analysis of a prospectively maintained EUS-guided PPG and LB database was conducted, which involved 29 consecutive outpatients who underwent combined EUS-guided procedures performed by a single operator at a tertiary center. The procedures were performed by an endoscopist with 4 years of independent practice (approximately 2000 EUS procedures and 1000 non-liver fine needle aspirations/biopsies). Before learning curve analysis, the operator had only carried out three EUS-guided PPG measurements and no prior LB. PPG reliability was defined as duplicate or triplicate measurements within 1mmHg of difference, LB adequacy was based on AASLD criteria (≥ 25 mm length and ≥ 11 complete portal tracts), and procedure duration was defined as duration between scope insertion and scope withdrawal. Learning curves were assessed using case-sequence–based logistic regression for binary outcomes (technical success, LB and PPG outcomes) and linear regression for procedure time.

Results Technical success was achieved in 90 % of cases (n = 26), adequate LB were obtained in 93.1 % (n = 27), and reliable PPG measurements were obtained in 82.8 % (n = 24). A learning curve analysis of EUS-guided LB showed no significant improvement in obtaining adequate biopsy specimens over consecutive cases. For the primary endpoint—adequate liver tissue the odds ratio (OR) per case was 0.98 (95 % CI: 0.82–1.61), indicating a slight non-significant 2.3 % decrease in odds of adequacy per additional case. When both adequate LB and reliable PPG were considered, the OR was 1.00 (95 % CI: 0.89–1.12), showing negligible change with experience. For secondary outcomes, technical success increased marginally with experience (OR 1.02, 95 % CI: 0.89–1.18), representing a 2 % improvement per additional case. The mean procedure time for combined EUS-guided LB and PPG was 20.7 ± 4.8 minutes and procedural time showed a non-significant negligible trend toward increase (slope = 0.08 min/case, $p = 0.46$, $R^2 = 0.02$), suggesting time efficiency was achieved early, with case number explaining only 2 % of time variability. There was only 1 (3.4 %) mild adverse event related to the intervention (abdominal pain).

Conclusions In the hands of an endosonographer with 4 years of independent practice, the learning curve for EUS-guided PPG and LB was minimal, with consistent high performance observed across cases with technical success above 90 %, rates of adequate LB above 90 % and 80 % reliable PPG. These findings suggest that combined EUS-guided LB and PPG measurement in the same session can be performed effectively with high success rates and very short learning curve.

eP799 Thirty-day hospital admission following Outpatient ERCP: safety profile, predictive factors and real-world outcomes

Authors Ferro Tomás D[1], Bastos A[1], Teixeira M[1], Ramos Lopes S[1], Cardoso C[1], Mangualde J[1], Freire R[1]
Institute **1** CRI Gastrenterologia, Hospital São Bernardo, ULS da Arrábida, Setúbal, Portugal
DOI 10.1055/s-0046-1822126

Aims Outpatient ERCP is increasingly being adopted and already recommended in selected patients to optimise resource allocation without compromising safety, yet unplanned hospital readmission remains a key concern, particularly when driven by post-procedure complications. This study evaluated 30-day readmission after outpatient ERCP in a medium-volume centre performing 200–300 ERCPs/year, aiming to characterise real-world safety outcomes and identify independent predictors of early unplanned admission [1–4].

Methods A retrospective analysis was conducted of all ERCPs performed between January 2021 and December 2024 (n = 840). Of these, 304 ERCPs were undertaken in the outpatient setting and were included in the primary analysis. The outcome was 30-day unplanned hospital readmission. Variables were grouped into patient, indication, findings, and procedure-related categories. Logistic regression was used for univariate analysis, and variables with $p < 0.15$ were included in a multivariate model (stepwise). A p-value < 0.05 was considered significant. Statistical analysis was done with SPSS v29.0 (▶ **Table 1**).

Results Among 304 outpatient ERCPs, the 30-day readmission rate was 9.5 % (29/304). Readmissions were mainly complication-driven, most frequently due to post-ERCP pancreatitis in 1.6 % (5/304), cholangitis in 3.3 % (10/304), cholecystitis in 2.0 % (6/304), perforation in 0.3 % (1/304), and other complications in 2.3 % (7/304). Overall cannulation success was high, at 289/298 (97.0 %), including 154/161 (95.7 %) in naïve papillae. In univariate analysis, several variables were significantly associated with 30-day readmission. Malignant obstruction as the index indication increased the odds of readmission (OR 3.23, CI 1.15–9.11), as did malignant obstruction confirmed during ERCP (OR 2.76, CI 1.25–6.11). Sphincterotomy was also associated with increased risk (OR 2.29, CI 1.05–4.99). Conversely, a previous ERCP status (with sphincterotomy) reduced the risk of hospital admission (OR 0.35, CI 0.14–0.85), as did suspected choledocholithiasis as the indication (OR 0.45, CI 0.21–0.97). Male sex also showed a near significant protective trend (OR 0.48, CI 0.20–1.12, p = 0.09). The multivariable model retained three variables. Previous sphincterotomy remained independently protective for readmission (OR 0.30, CI 0.11–0.83), suggesting that patients with an already-accessed papilla may have lower procedural complexity and fewer early adverse events. Male sex continued to show a near-significant protective effect (OR 0.43, CI 0.18–1.03, p = 0.06). Malignant obstruction as indication emerged as the strongest independent predictor of early readmission (OR 5.46, CI 2.07–14.42), consistent with more severe underlying disease and greater procedural complexity.

Conclusions In our medium-volume centre, outpatient ERCP was safe, with a low rate of early unplanned hospitalisation and high cannulation success. Malignant obstruction as the indication remained the primary driver of early readmission, highlighting the need for enhanced peri-procedural planning and post-procedural vigilance in this subgroup. Protective factors, including previous sphincterotomy and male sex, may help refine risk stratification. These findings contribute real-world data supporting the safety of ambulatory ERCP and offer practical insight into patient selection and identifying higher-risk patients who may benefit from tailored monitoring strategies and more selective outpatient scheduling.

Endoscopy 2026; 58: S1–S1041

▶ **Table 1**

Variable	Univariate OR (95 % CI)	*p*-value	Multivariate aOR (95 % CI)	*p*-value
Male sex	0.48 (0.20–1.12)	0.09	0.43 (0.18–1.03)	0.06
Previous sphincterotomy	0.39 (0.18–0.86)	0.02	0.30 (0.11–0.83)	0.02
Suspected choledocholithiasis	0.45 (0.21–0.97)	0.04	–	–
Malignant obstruction (indication)	3.23 (1.10–9.48)	0.03	5.46 (2.07–14.42)	0.02
Malignant obstruction confirmed (ERCP finding)	2.76 (1.25–6.11)	0.01	–	–
Sphincterotomy	2.29 (1.05–4.99)	0.03	–	–

eP800 EUS-guided Gastroenterostomy for Malignant Gastric Outlet Obstruction: A Single-Center Retrospective Study of Outcomes and Reintervention Strategies

Authors Troncone E[1], Muzzi E[1], Amendola R[1], De Cristofaro E[1], Moscardelli A[1], Delle Monache M[1], Pietrobelli L[1], Monteleone G[1], Del Vecchio Blanco G[1]

Institute **1** Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy

DOI 10.1055/s-0046-1822127

Aims EUS-guided gastroenterostomy (EUS-GE) has been reported as a safe and effective treatment strategy for patients with malignant gastric outlet obstruction (GOO). The aim of this study was to report the technical/clinical outcomes and the re-intervention rate of EUS-GE in malignant GOO after the introduction of the technique in one center.

Methods This is a retrospective single-center study including patients who underwent EUS-GE for malignant GOO at our institution. All the procedure were performed by one operator using the Wireless Endoscopic Simplified Technique (WEST) after a period of supervised training. Patients with post-surgical anatomy were excluded. Patient characteristics, technical success, clinical success (post-procedure GOO Score ≥ 2), adverse events, and re-interventions were analyzed [1–5].

Results From August 2023 to October 2025, 27 patients underwent EUS-GE for malignant GOO. One patient with post-surgical anatomy was excluded; 26 were included in the analysis (15 females, 57.7 %; median age 71 years, range 42–95). Most patients had pancreatic cancer (20/26; 76.9 %). Overall technical success was 26/26 (100 %). One patient experienced intraprocedural stent misdeployment, which was successfully managed with placement of a new stent. Clinical success was achieved in 24/26 patients (92.3 %). In patients with clinical failure, endoscopic re-intervention (LAMS balloon dilation and placement of a SEMS through the LAMS, respectively) resulted in clinical success. The adverse event rate was 1/27 (3.7 %; fever treated with antibiotics). Median follow-up was 58 days (range 19–311). One patient developed GE dysfunction secondary to food impaction after 249 days, which was successfully treated with endoscopic LAMS cleansing.

Conclusions EUS-GE shows excellent efficacy and safety in patients with malignant GOO. The endoscopic re-intervention rate is low, with high success both in cases of primary clinical failure and in patients with delayed dysfunction.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822128

Aims Same-session endoscopic ultrasound (EUS)-endoscopic retrograde cholangiopancreatography (ERCP) and therapeutic EUS (tEUS) are increasingly adopted for diagnosis and management of pancreaticobiliary diseases. While traditionally performed under deep sedation or general anaesthesia, evidence on moderate sedation strategies remains limited. Moreover, moderate sedoanalgesia may represent an opportunity for non-third-level centres lacking anaesthesiology support for endoscopic procedures. We prospectively evaluated the feasibility, safety, and patient-reported outcomes of performing combined EUS-ERCP and tEUS under moderate sedoanalgesia with intravenous midazolam and meperidine.

Methods The PETI-MIDA study is a prospective observational study conducted in a non-third-level hospital between April and November 2025. All consecutive adults undergoing same-session EUS–ERCP or tEUS under moderate sedoanalgesia with midazolam and meperidine were included. Primary outcomes were procedural completion, safety, and patient-reported experience assessed using a validated tool (PROSAS score). Patients and sedation characteristics, clinical parameters, and adverse events (AEs) were collected in a standardized Case Report Form (CRF). A multivariate logistic regression explored any correlation between clinical characteristics and patient-reported outcomes.

Results In total, 35 patients were enrolled, the median age was 75 years (IQR 63–83), and the median body mass index (BMI) was 26.1 kg/m² (IQR 22.9–30.0). Median Charlson Comorbidity Index was 4 (IQR 2–6), and median ASA score was 2 (IQR 1–3). Indications for endoscopy included choledocholithiasis (65.7 %), malignant biliary obstruction (14.3 %), and indeterminate biliary stricture (20 %). EUS-guided fine-needle biopsy (FNB) was performed in 11 patients (31.4 %), biliary stenting in 10 (28.6 %), and 3 patients (8.6 %) underwent EUS-guided gallbladder drainage (EUS-GBD). Mean midazolam dose administered was 5.6 mg (± 2.1), while meperidine was 64.2 mg (± 13.6). No procedure-related AEs occurred among the cases performed. Most of the patients (88.6 %) were adequately cooperative and no procedures were interrupted due to lack of patients' cooperation. Sedation-related AEs included one (2.9 %) oxygen desaturation, two (5.8 %) tachycardia and one (2.9 %) hypotension, all managed without the need for anaesthesiology support and without leading to an endoscopy interruption. In 29 cases (82.9 %), patients reported satisfaction with the sedation level achieved. On a 0–10 numeric scale administered to assess intraprocedural discomfort (0 indicating no pain and 10 indicating severe pain), the median score was 1 (IQR 0–2). In the multivariate analysis, intraprocedural discomfort level was related to BMI (p-value = 0.03).

Conclusions Moderate sedoanalgesia is an appropriate sedation strategy for same-session EUS–ERCP and tEUS, demonstrating low complication rates and high patient tolerability.

eP802 Predictors of 30-day mortality in upper gastrointestinal bleeding

Authors Kovács BT[1], Kozma MD[1], Vilmos F[1], Morár A[1], Csókay BK[1], Lalák K[1], Papp V[1], Horváth M[1], Hagymási K[1], Müllner K[1], Péter Z[1], Székely H[1], Imecz J[2], Fenyves BG[2], Melicher D[2], Varga C[2], Szijártó A[1], Miheller P[1], Hritz I[1], Patai AV[1]
Institutes 1 Department of Surgery, Transplantation and Gastroenterology, Semmelweis University, Budapest, Hungary; 2 Department of Emergency Medicine, Semmelweis University, Budapest, Hungary
DOI 10.1055/s-0046-1822129

Aims Upper gastrointestinal bleeding (UGIB) is a heterogeneous condition with variceal (V), high-risk non-variceal (HRNV) and low-risk non-variceal (LRNV) subgroups. We aimed to identify clinical and laboratory parameters associated with 30-day mortality in these three subgroups in a tertiary care center.

Methods We retrospectively analyzed all patients undergoing emergency upper endoscopy for UGIB at the Department of Emergency Medicine, Semmelweis University, between 1 January 2022 and 31 December 2023. Within each subgroup we performed univariable tests and univariable and multivariable logistic regression. Associations with 30-day mortality were described using odds ratios (OR) and p-values.

Results The data of 654 patients (V = 126; HRNV = 99; LRNV = 429) were analyzed.

In the variceal group, non-survivors had lower albumin ($p < 0.0001$), higher creatinine and urea levels, lower GFR ($p < 0.0001$) and more frequently had cardiovascular disease ($p = 0.003$). Univariable analyses showed that GFR 30-60 and 15-30 ml/min markedly increased mortality risk (OR = 10.8 and 7.05), as did cardiovascular disease (OR = 5.04) and vasopressor requirement (OR = 3.67), whereas each 1 g/L increase in albumin reduced the odds of death by 22 % (OR = 0.78). In multivariable models, liver disease (OR = 2506), lower albumin (OR = 0.62) and rising urea (OR = 5.6) remained independent predictors.

In the HRNV group, non-survivors presented with lower blood pressure (all components $p \leq 0.006$), older age and more frequent noradrenaline use ($p = 0.026$). Univariable analyses indicated that higher systolic/diastolic blood pressure and MAP were protective (OR = 0.95-0.96 per mmHg), whereas noradrenaline use (OR = 3.75) and elevated INR (OR = 4.5) were risk factors. In multivariable analysis, increasing urea remained an independent predictor (OR = 1.47).

In the LRNV group, non-survivors showed more severe hemodynamic instability ($p < 0.0001$), worse renal function (creatinine $p < 0.0001$), lower albumin ($p = 0.0010$) and more frequent chronic high-dose PPI use ($p = 0.0215$). Univariable analyses demonstrated that lower GFR values (CKD III-V. stages; OR = 5.7-7.2) and rising urea values (OR = 1.17) increased, whereas albumin (OR = 0.90 per g/L) decreased the mortality risk. In multivariable models, albumin (OR = 0.87) and rising urea (OR = 1.15) remained independent predictors.

Conclusions Across all three etiologic subgroups, hemodynamic instability, hypoalbuminaemia and urea dynamics were closely linked to 30-day mortality and may serve as a basis for etiology-specific risk stratification in UGIB.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP803 Diagnostic Performance of Artificial Intelligence Versus Endoscopists in the Detection of Early Gastric Cancer: A Systematic Review and Meta-analysis"

Authors Salvato D[1], De Conte A[2], Schettino P[3], Carrato P[3], Marmo R[3]
Institutes 1 Digestive Endoscopy Unit, Luigi Curto Hospital, Polla, Salerno, Italy; 2 Digestive Endoscopy Unit, Luig Curto Hospital, Polla, Salerno, Italy, salerno, Italy; 3 Digestive Endoscopy Unit, Luig Curto Hospital, Polla, salerno, Italy
DOI 10.1055/s-0046-1822130

Aims Gastric cancer remains a major cause of cancer-related mortality worldwide. Endoscopy is the most reliable modality for detecting early gastric cancer (EGC), yet the identification of subtle early lesions is often challenging. Artificial intelligence (AI) has emerged as a promising tool to support endoscopic diagnosis. This meta-analysis aimed to compare the diagnostic performance of AI systems with that of human endoscopists in detecting EGC

Methods PubMed, Embase, Google Scholar, Cochrane, and Web of Science were searched for articles. Studies were eligible if they allowed extraction of TP, FP, TN, FN. Histopathology was the gold standard. Endoscopists were classified as experts or non-experts. Pooled sensitivity and specificity were estimated using random-effects models; an SROC curve was constructed, and AUC calculated [1–41]

Results Eight studies from Asia were included. A total of 3409 patients were analyzed, comprising 1444 with EGC and 1965 with non-neoplastic conditions. AI achieved a sensitivity of 92 % (95 % CI, 89–94 %) and a specificity of 87 % (95 % CI, 84–90 %). Expert endoscopists reached a sensitivity of 90 % (95 % CI, 86–

93 %) and specificity of 90 % (95 % CI, 80–95 %). Non-expert endoscopists showed sensitivity of 78 % (95 % CI, 72–83 %) and specificity of 78 % (95 % CI, 69–85 %). AI performance was comparable to that of experts and significantly superior to non-experts (sensitivity $p \leq 0.001$; specificity $p \leq 0.01$)

Conclusions AI-assisted endoscopy demonstrates high diagnostic accuracy for early gastric cancer. Its performance closely parallels that of expert endoscopists and substantially exceeds that of non-experts

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP804 Etiological Profile of Benign Esophageal Strictures

Authors bennani B[1], Belabbes F[1], Bennani Y[1], Benjelloun N[1], Delsa H[1], Ben El Barhdadi I[1]
Institute 1 Cheikh Khalifa International University Hospital, Mohammed VI University of Sciences and Health, Casablanca, Morocco
DOI 10.1055/s-0046-1822131

Aims Benign esophageal strictures are defined as a narrowing of the esophageal lumen not directly related to neoplastic or functional pathology. They represent a frequent cause of dysphagia. Upper gastrointestinal endoscopy plays a central role, both diagnostically and therapeutically, through dilation techniques or stent placement. This study aimed to describe the etiological and therapeutic profile of benign esophageal strictures.

Methods This was a retrospective observational study. We reviewed all medical records of patients diagnosed with benign esophageal strictures over a 5-year period, from January 2020 to January 2025.

Results Among 48 patients presenting with dysphagia, 29 had benign esophageal strictures (60.4 %). There was a slight female predominance (51.7 %), with a median age of 49 years (range 5–81). Past medical history included gastroesophageal reflux disease in 55.2 %, esogastric surgery in 34.5 %, anemia in 24.1 %, caustic ingestion in 24.1 %, toxic habits in 24.1 %, and a history of radiotherapy in 20.7 %. Clinically, dysphagia was constant—most often distal (82.8 %)—and was frequently associated with weight loss (58.6 %), odynophagia (48.3 %), and anemia (34.5 %). Upper endoscopy revealed peptic strictures (27.6 %), caustic strictures (24.1 %), postoperative strictures (17.2 %), Plummer–Vinson syndrome (13.8 %), post-radiation strictures (6.9 %), and two cases of epidermolysis bullosa with esophageal involvement and extrinsic compression (3.4 % each). Management relied on balloon dilation (55.2 %), bougie dilation (41.4 %), and metallic stent placement (13.8 %). Clinical evolution showed complete symptom resolution in 69 % of cases. Immediate complications were rare. In the medium term, post-dilation gastroesophageal reflux occurred in 17.2 %, and stricture recurrence in 55.2 %.

Conclusions In our cohort, benign esophageal strictures were predominantly peptic and caustic, accounting for more than 51.7 % of cases. Upper endoscopy remains essential for both etiological diagnosis and treatment through dilation or stenting. However, the high recurrence rate highlights the need for close and prolonged follow-up.

eP805V Diving Deep – Making It Safer: Underwater ESD for Large Duodenal LST Polyp

Authors Barić Z[1], Skrlec I[1], Omae M[2], Grubelic Ravić K[1]
Institutes 1 University Hospital Centre Zagreb, Zagreb, Croatia; 2 Karolinska University Hospital Huddinge, Stockholm, Sweden
DOI 10.1055/s-0046-1822132

Abstract Text

A 61-year-old patient with a large duodenal laterally spreading tumor (LST-G 6.5 × 4 cm) below the papilla of Vater. Literature reports superficial non-ampullary duodenal tumor (SNADT) prevalence at 1.0–1.5 % in retrospective series and 4.6 % prospectively, with adenomas at 0.03–0.4 %.In collaboration with a visiting expert, enbloc underwater endoscopic submucosal dissection (ESD) was accomplished without complications.Histopathology confirmed R0 resection of a tubular adenoma with low-grade dysplasia and focally high-grade dysplasia.The water immersion technique enhanced visualization, endoscope stability, and mucosal-submucosal separation, reducing risk of perforation in this delicate area.Our center's treatment alternative,Whipple surgery,highlights ESD as a safe,minimally invasive option for selected large duodenal polyps by skilled expert [1, 2].

eP806V Over-the-wire EUS-directed Transduodenal ERCP in a Patient with Duodenal Stenosis and Hilar Cholangiocarcinoma: A Video Case

Authors Troncone E[1], Moscardelli A[1], Pietrobelli L[1], Muzzi E[1], Delle Monache M[1], De Cristofaro E[1], Monteleone G[1], Del Vecchio Blanco G[1]
Institute 1 Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy
DOI 10.1055/s-0046-1822133

Abstract Text

A 59-year-old female with hilar cholangiocarcinoma and indwelling biliary stents was admitted for cholangitis and gastric outlet obstruction. ERCP failed due to neoplastic duodenal stenosis. The patient underwent EUS-gastroenterostomy (GE) with a 20 mm LAMS, and EUS-directed transduodenal ERCP (EDDE) was attempted. However, access to the papillary region was not possible due to unfavorable angulation of the GE. A guidewire was passed through the duodenal stenosis in an antegrade manner toward the LAMS and then into the stomach through the LAMS. Using a rendezvous (RV) technique, the gastroscope was reintroduced alongside the guidewire, which was retrieved through the working channel. This maneuver allowed the gastroscope to advance efficiently through the LAMS up to the papillary region using double traction. ERCP was then successfully completed with placement of a new biliary stent [1–2]

eP807 Bowel preparation with split-dose vs single-dose polyethylene glycol: Preliminary results of a prospective study

Authors Basri Z[1], Delsa H[1], Nadi A[1], Bahlaoui O[1], Alaoui Mdaghri R[1], Harouchi A[1], Belabbes F[1], Bennani Y[1], Benjelloun N[1], Khannoussi W[1], Ben El Barhdadi I[1]
Institute 1 Cheikh Khalifa International University Hospital, Mohammed VI University of Sciences and Health, Casablanca, Morocco
DOI 10.1055/s-0046-1822134

Aims Bowel preparation is essential for achieving high-quality colonoscopy outcomes. Common preparatory protocols include the conventional single-dose polyethylene glycol (PEG) regimen and the increasingly utilized split-dose regimen. Our study aims to compare the quality of colonoscopies obtained using different protocols, based on the Boston Bowel Preparation Scale (BBPS).

Methods This was a prospective, single-center study conducted in an endoscopy unit. All patients referred for diagnostic, screening, follow-up, or therapeutic colonoscopy were included.

All patients underwent bowel preparation along with a low-residue diet for one to three days. Participants were divided into two groups: Group 1(standard single-dose preparation of 4L the day before colonoscopy) and Group 2 (split-dose preparation, with 3 subgroups: A = 3L the day before and 1L the morning of the examination, B = 2L the night before + 2L in the morning of the examination and C = 4L the day before and 2L the morning of the examination). Several parameters were studied: Tolerance of the preparation, adherence to the low-residue diet, BBPS, polyp detection rate (PDR), adenoma detection rate (ADR), mean number of polyps (MNP), and mean number of adenomas (MNA). Comparative statistical analysis of the different groups was performed using JAMOVI software.

Results 248 patients were included in the study, with a median age of 57 years and a male-to-female ratio of 113/135. The indications for colonoscopies were: 77 % diagnostic, 7.3 % screening, 13.3 % follow-up or surveillance, and 2.4 % therapeutic.

Comparison of groups 1 and 2 with respect to bowel preparation quality and the detection rate of polyps and adenomas did not reveal any statistically significant difference. However, within group 2, subgroup b (2L the evening before + 2L the morning of) showed a significant superiority compared to the other subgroups and group 1, with a significant p-value of 0.011.

Multivariate analysis using binomial regression confirmed the absence of a significant influence of age, sex, or indication on bowel preparation quality.

The split-dose protocol, particularly subgroup b was better tolerated than the standard preparation, with a significant reduction in side effects (nausea, vomiting), and a p-value < 0.001.

Conclusions The split-dose preparation proved more effective than the standard preparation in achieving good bowel preparation quality, as it was better tolerated. Among the different split-dose protocols, the subgroup 2b regimen offered the best compromise between efficacy and tolerability. Conversely, the 6L dose did not demonstrate superiority and proved more burdensome for patients.

DOI 10.1055/s-0046-1822135

Aims Liver transplant (LT) recipients frequently require biliary interventions to manage post-transplant complications and remain at increased risk for infectious adverse events. This study aimed [1] to evaluate the prevalence of infectious complications following biliary drainage in LT recipients and to identify associated clinical and intraprocedural risk factors, and [2] to describe the biliary and intestinal microbiological profile, including bile culture results and rectal colonization patterns.

Methods We conducted a retrospective single-centre study including all adult patients who underwent LT at our institution between January 2017 and December 2022. Among these, we selected those who underwent Endoscopic Retrograde Cholangiopancreatography (ERCP), Double-Balloon Enteroscope–assisted ERCP (DBE-ERCP), or Percutaneous Transhepatic Cholangiography (PTC) within 24 months from transplantation. We collected clinical, microbiological and interventional data, including indication for biliary drainage, procedure type, endoscopic interventions (sphincterotomy, balloon dilation, stent placement or removal, endoscopic device configuration), bile culture and rectal swab results, and antimicrobial exposure. Clinically significant infectious events occurring within 30 days after the procedure including cholangitis, primary bloodstream infection, intra-abdominal infection, surgical site infection, liver abscess, and acute bacterial skin and skin structure infection, were recorded. Continuous variables were summarised as mean (SD) or median (IQR), and categorical variables as counts and percentages. Associations with infectious events were assessed by univariable logistic regression, reporting unadjusted odds ratios (OR) with 95 % confidence intervals, while group comparisons used chi-square or Fisher's exact tests as appropriate. A p-value < 0.05 was considered statistically significant. Analyses were performed using R (version 4.5.1).

Results Seventy-one LT recipients (mean age 55.5 ± 9.9 years, 74.6 % males) underwent 238 biliary procedures (81.5 % ERCP, 17.6 % PTC, 0.8 % DBE-ERCP). Indications included anastomotic strictures (58.8 %), stent removal (18.9 %), bile leakage (8.8 %), biliary fistula (6.3 %), bile duct stones (5.9 %), and procedures performed to treat active biliary infection (26.9 %). Bile cultures were obtained in 110 procedures (46.2 %) and showed a high diagnostic yield, with 81.8 % positivity. Enterobacterales accounted for the majority of isolates (85.6 %), followed by *Enterococcus faecium* (14.4 %). Multidrug-resistant organisms were identified in 22.2 % of positive cultures. Rectal swabs performed within 90 days before the procedure were available for 147 procedures (61.8 %) and were positive in 41.5 % of cases. Infections following biliary procedures were found in 44 out of 238 procedures (18.5 %), accounting for a total of 49 infectious episodes, as some patients developed more than one event during the follow-up period. Infectious events were significantly associated with LT for primary or secondary sclerosing cholangitis (OR 5.97, 95 %CI 1.72–21.7; p = 0.0046), with early biliary complications after LT such as leaks or strictures (OR 2.03, 95 %CI 1.05–3.96; p = 0.036), and with younger age at LT, assessed as a per-year decrease in age (OR 0.96, 95 %CI 0.93–0.99; p = 0.0347). On the contrary, a significantly lower risk of infectious was observed in case of biliary re-intervention leading to stent removal (OR 0.27; 95 %CI 0.06–0.77; p = 0.0329;) and when ERCP was conduct using duodenoscope equipped with a single-use tip (OR 0.35, 95 %CI 0.18–0.64, p = 0.002). The rate of infectious complications following biliary drainage was not affect by sphincterotomy or stent placement, as well by antibiotic exposure, either prophylactic or therapeutic [3, 4].

Conclusions In LT recipients undergoing biliary procedures, primary or secondary sclerosing cholangitis at LT and early post-LT biliary complications are linked to a higher risk of clinically relevant infections after drainage. The protective effect of single-use duodenoscope tips and the high diagnostic yield of bile cultures for multidrug-resistant pathogens highlight the role of procedural optimization in preventing infections. These results support an integrated approach in which microbiological sampling and endoscopic or radiologic interventions guide personalized management. Prospective studies are needed to define optimal antimicrobial and biliary drainage strategies in high-risk patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP809 Safety of Precut Versus Standard Sphincterotomy in Outpatient ERCP for Naïve Papillae: A Comparative Analysis

Authors Ferro Tomás D[1], Bastos A[1], Teixeira M[1], Ramos Lopes S[1], Cardoso C[1], Mangualde J[1], Freire R[1]
Institute 1 CRI Gastrenterologia, Hospital São Bernardo, ULS da Arrábida, Setúbal, Portugal
DOI 10.1055/s-0046-1822136

Aims Precut techniques remain a subject of debate in ERCP, traditionally viewed as higher-risk approaches for biliary access, particularly in naïve papillae. While contemporary evidence suggests that early precut may be safe when performed by experienced endoscopists, data from the outpatient setting are scarce, and few studies provide detailed statistical comparisons of complication rates, time-to-event outcomes, and readmissions. This study aimed to evaluate the safety of precut versus standard sphincterotomy in outpatient ERCP among patients with naïve papillae, with specific attention to statistically robust comparison of post-procedural complications and hospital admissions [1, 2].

Methods A retrospective cohort analysis was conducted using a prospectively maintained database of consecutive outpatient ERCPs. Only naïve papillae were included. Patients were stratified into a standard sphincterotomy group and a precut group. Primary endpoints were post-procedural complications: pancreatitis, cholangitis, perforation, cholecystitis and other clinically relevant events. Secondary endpoints included 30-day unplanned admission (all-cause and ERCP-related). Fisher's exact test was used for group comparisons, with significance defined as $p < 0.05$. Statistical analysis was made with SPSS v29.0 (▶ **Table 1**).

Results A total of 166 outpatient ERCPs performed in naïve papillae were included, comprising 121 standard sphincterotomy cases and 45 precut cases. Cannulation success was achieved in all standard sphincterotomy procedures (121/121, 100 %) and in 84.4 % of precut procedures (38/45). Overall post-procedural complication rates were low and comparable between groups ($p = 1.00$). No significant differences were observed across specific complication types: pancreatitis occurred in 3.3 % vs 2.2 % ($p = 1.00$), cholangitis in 3.3 % vs 4.4 % ($p = 0.663$), perforation in 0.8 % vs 0 % ($p = 1.00$), and cholecystitis in 5.0 % vs 0 % ($p = 0.192$) for standard versus precut, respectively. Thirty-day all-cause admission rates were nearly identical between standard sphincterotomy and precut groups (14.0 % vs 13.3 %, $p = 1.00$), and ERCP-related readmission rates showed no significant difference (9.1 % vs 6.7 %, $p = 1.00$).

Conclusions In this real-world outpatient cohort restricted to naïve papillae, precut techniques displayed a safety profile statistically indistinguishable from standard sphincterotomy, with no increase in post-procedural complications, delayed complication timing, or 30-day hospital readmission. These findings support the selective, expert-driven use of precut for biliary access in outpatient ERCP, demonstrating that precut is not an independent risk factor for adverse outcomes in this setting.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP810V EUS guided management of "Carpeting" Gastric Varices

Author Mukewar S[1]
Institute 1 Midas Hospital, Nagpur, Nagpur, India
DOI 10.1055/s-0046-1822137

Abstract Text
"Carpeting" of gastric varices is uncommon finding seen in patients of portal hypertension with dilated tortuous venous channels widespread across the gastric lumen. Typically, endoscopic management is not considered feasible for these patients due to multiple columns of varices.
Case # 1: 37-year-old male with chronic pancreatitis with left-sided portal hypertension with multiple episodes of melena secondary to multiple gastric varices carpeting the body and fundus. Case # 2: 38 year-old-male with extra-hepatic portal venous obstruction with hematemesis and melena with fundal varices and multiple columns of "carpeting" varices. Both patients underwent EUS-guided coil and glue injection successfully, with obliteration. Both had no adverse events and bleeding on 3-month follow-up evaluation. EUS guided management of carpeiting gastric varices is a viable option.

eP811 The yield of fine needle biopsy during endoscopic ultrasound in the diagnosis of lymph nodes

Authors Benjelloun Abidi B[1], Salihoun M[1], Acharki M[2], Kabbaj N[2]
Institutes 1 Rabat, Morocco; 2 Ibn Sina University Hospital, Rabat, Morocco
DOI 10.1055/s-0046-1822138

Aims The aim of our study was to evaluate the contribution of fine-needle biopsy (FNB) coupled with ultrasound endoscopy for the exploration and diagnosis of mediastinal and abdominal lymph nodes.
Methods This was a descriptive retrospective study over a period of 3 years from July 2021 to March 2024 within a hepatogastroenterology department at Ibn Sina University Hospital in Rabat, including all patients who underwent fine-needle biopsy (FNB) of lymphadenopathy under endoscopic ultrasound. Exclusion criteria included patients already diagnosed with granulomatosis, or with metastatic digestive cancer, and those with lymph nodes that are difficult to access to fine-needle biopsy under endoscopic ultrasound or less than one centimeter in size.
Results A total of 22 patients were included during the study period out of a total of 274 patients that underwent ultra sound endoscopy. Patients were 10 males and 12 females with a mean age of 53 years (range: 20-82).
The circumstances of discovery were as follows: in 45 % of cases (n = 10), there was cholestatic jaundice, associated with epigastric pain in 9 % of cases. Four patients presented with weight loss, three cases were incidentally discovered during exploration of a pancreatic mass, one case presented with hemorrhagic syndrome, one case with dyspnea and hemoptysis, and one case with algic syndrome.
Imaging was performed in all patients. Abdominal-pelvic CT scans were conducted in 85 % of patients, and MRCP in 20 % of patients. Imaging revealed in 41 % of cases a cluster of mediastinal lymphadenopathies, associated or not with abdominal lymphadenopathies, in 32 % of cases, the presence of a pancreatic lesion with lymph node involvement; and in 18 % of cases, thickening of the main bile duct. Two cases of gastric thickening were noted.
The site of fine-needle biopsy was abdominal in 64 % of cases (n = 14), abdominal and mediastinal in 14 % (n = 3), and mediastinal in 23 % (n = 5). For abdominal lymph nodes, 50 % were located at the hepatic hilum, 36 % at the celiac level, and 21 % at the perigastric level. For mediastinal lymph nodes, fine-needle biopsy was performed at station 7 in 85 % of cases and at station 9 in 15 % of cases.
The average size of lymph nodes was 23mm [range: 10-45]. The needle gauge used was 20G in 55 % of cases and 22G in 45 % of cases. The number of passages ranged from 1 to 3 per biopsy with fanning technique.
The diagnosis was malignant in 36 % of cases: 5 cases of pancreatic adenocarcinoma, 1 case of lymphoma, 1 case of neuroendocrine carcinoma, and 1 case of undifferentiated carcinoma. In 18 % of cases, biopsy results favored granulomatosis in 4 patients: 2 cases of sarcoidosis and 2 cases of tuberculosis. Finally, reactive adenitis was found in 41 % of cases, and hemorrhagic content was observed in 5 % of cases.
It is noteworthy that no complications related to FNB during EUS were observed.
Conclusions Endoscopic ultrasound coupled with FNB is at the forefront for diagnosing deep lymph nodes, whether they are mediastinal or abdominal. In our study, the diagnostic yield was 95 % after initial histopathological analysis. This technique remains minimally invasive and effective. It allows not only to exclude metastatic lymph nodes but also the initiation of specific treatment once the pathology is documented.

eP812 From Cholangitis to Hemorrhage: Complex Post-ERCP and Post-Surgical Complications in the Management of Malignant Pancreatic Tumors

Authors Obreja DA[1], Sandru V[2, 3], Constantinescu G[3, 4]
Institutes 1 Spitalul Clinic de Urgență București, București, Romania; 2 Department of Gastroenterology, Clinical Emergency Hospital of Bucharest, Bucharest, Romania; 3 Carol Davila University of Medicine and Pharmacy, 020021, Bucharest, Romania; 4 Clinical Emergency Hospital of Bucharest, Bucharest, Romania
DOI 10.1055/s-0046-1822139

Introduction Upper gastrointestinal (UGI) bleeding in the setting of locally advanced pancreatic adenocarcinoma is a challenging clinical problem, often exacerbated by tumor invasion, altered postoperative anatomy, and friable mucosa. When standard endoscopic strategies are insufficient, a multimodal approach may be required to achieve durable hemostasis. This case-report describes the complex management of recurrent UGI hemorrhage arising after ERCP and palliative Roux-en-Y gastrojejunostomy in a patient with pancreatic cancer, highlighting the role of sequential endoscopic interventions and covered self-expandable metal stents (SEMS) [1, 2].
Case Presentation A 78 year-old patient with locally advanced pancreatic adenocarcinoma presented with acute cholangitis characterized by fever, jaundice, and elevated cholestatic markers. ERCP was performed promptly, achieving biliary decompression through successful cannulation and stent placement. Given symptoms of gastric outlet obstruction due to the tumor's mass effect, the patient subsequently underwent a palliative Roux-en-Y gastrojejunostomy. During the postoperative period, the patient developed melena accompanied by a significant hemoglobin drop. Urgent endoscopy revealed a bleeding ulcer at the gastro-enteral anastomosis. Hemostasis was initially achieved with norepinephrine injection, followed by thermal coagulation using a Coagrasper device, resulting in short-term stabilization.Over the following weeks, the patient experienced multiple hospital readmissions for recurrent UGI bleeding. Each episode required repeated endoscopic evaluations, but the distorted postoperative anatomy and presence of friable ulcerated tissue limited the effectiveness of conventional techniques.
Given persistent and recurrent hemorrhage, the multidisciplinary team opted for advanced endoscopic intervention. A fully covered SEMS was positioned across the gastro-enteral anastomosis to tamponade the ulcerated bleeding site. The patient initially improved, but another episode of bleeding occurred, prompting a second endoscopic procedure. A second covered SEMS was deployed to reinforce the area and extend the zone of mechanical hemostasis. Following this intervention, the bleeding resolved definitively.

Discussion and Conclusions This case illustrates the difficulty of managing recurrent anastomotic ulcer bleeding in patients with pancreatic malignancy and surgically altered anatomy. Multidisciplinary coordination is essential for successful outcomes in such complex postoperative bleeding scenarios. Standard endoscopic hemostatic techniques often fail when bleeding arises from unstable, tumor-influenced tissue. The use of covered SEMS, while more commonly applied for malignant obstruction, proved crucial in achieving sustained hemostasis by exerting tamponade on the ulcerated region and stabilizing the anastomotic site.

eP813 Pancreatic, hepatic and small bowel toxicity due to Immune Checkpoint Inhibitors: a case report

DOI 10.1055/s-0046-1822140

Abstract Text

Immune-checkpoint inhibitors (ICIs) are an essential therapeutic option for many types of cancers; their mechanism of action involves the activation of cytotoxic T cells through targeting PD-1, PD-L1 and CTLA4. Gastrointestinal adverse events due to ICI toxicity can occur, ranging from mild diarrhoea to severe colitis mimicking inflammatory bowel disease [1, 2]; pancreas, liver and small bowel involvement, although possible, are less frequent [1, 3]. We present the case of a ICI-related acute pancreatitis, asymptomatic hepatitis and a steroid-refractory small bowel ulcerative and atrophic enteropathy.

A 57 years-old woman with history of triple-negative breast cancer treated with 6 months of neoadjuvant paclitaxel, carboplatin, doxorubicin, cyclophosphamide and pembrolizumab, followed by mastectomy and adjuvant pembrolizumab was referred to our department for chronic severe diarrhoea and weight loss in the last 4 months. She suffered from ICI-related mild acute oedematous pancreatitis 3 months before, which led to pembrolizumab discontinuation.

Laboratory test showed normocytic anaemia (Hb 11.7 g/dL), asymptomatic elevation of liver enzymes (GGT 1085 U/L, total bilirubin 2.1 mg/dL, direct bilirubin 1.45 mg/dL) and high levels of faecal calprotectin (403 mg/kg) with negativity of coeliac serology, C. difficile serology, stool culture and stool parasites.

Colonoscopy revealed a mosaic pattern in the ileum and normal findings in all the colon, with histological evidence of focal criptitis in the descending colon only. Gastroscopy showed a severe ulcerative duodenitis, with severe villous atrophy at the histopathological examination. Capsule endoscopy revealed multiple duodenal ulcerations and severe duodenal and ileal villous atrophy with only mild villous blunting in the jejunum.

Prednisone 1 mg/kg/day for 3 weeks was started, but without any improvement in symptoms or laboratory findings. Capsule endoscopy was repeated, showing healing of the duodenal ulcers but persistence of villous atrophy in the duodenum and ileum. Budesonide 9 mg daily and cholestyramine 4 g twice daily were added, but without any significant clinical improvement. The patient was therefore referred to a tertiary centre.

This case emphasises the necessity for clinicians to perform an exhaustive evaluation in patients undergoing ICIs therapy with clinical or endoscopic suspicion of gastrointestinal toxicity, in order to reduce diagnostic delay and the consequent risk of steroid inefficacy and related complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP815 Amoebic Colitis- a rare diagnosis from a Bowel Cancer Screening Colonoscopy

Authors Rassam T[1], Chudasama A[1], Stevens S[1], Hoare J[1], Sebepos-Rogers G[1], Soubieres A[1], Sikafi R[1], Radhakrishnan S[1], Patel N[1], Direkze N[1]

DOI 10.1055/s-0046-1822142

Abstract Text

A 50-year-old female was referred for colonoscopy via the UK Bowel Cancer Screening Programme. Six months earlier, after travel to India, she developed lethargy, nausea, and severe bloody diarrhoea. Symptoms began two weeks after returning to the UK. She denied abdominal pain, weight loss or red-flag features. Past history included unilateral nephrectomy, no regular medications and no family history of IBD or GI malignancy [1–4].

Initial investigations included stool PCR, Clostridioides difficile testing, ova/cysts/parasites examination and blood cultures. She tested positive for Giardia lamblia and completed a 7-day course of metronidazole. Her systemic symptoms improved, but loose stools and rectal bleeding persisted. During this period, she completed the home FIT test, which was positive, prompting BCSP referral.

Colonoscopy revealed marked ulceration localised to the caecum. Biopsies were taken for histology and mycobacterial culture. Histopathology demonstrated trophozoites of Entamoeba histolytica, confirming amoebic colitis.The patient was treated with a 1-week course of paromomycin for luminal eradication, resulting in complete symptom resolution.

Amoebic colitis is uncommon in the UK but remains a significant differential diagnosis in patients with persistent gastrointestinal symptoms following travel to endemic regions. Surveillance data indicates approximately 100 laboratory-reported cases in the UK annually, the vast majority occurring in returning travellers from endemic regions[1]. E. histolytica often mimics IBD or colorectal cancer, both clinically and endoscopically, with caecal involvement being most typical[2,3]. Delayed or missed diagnosis is well documented, especially when co-infection with other parasites, such as Giardia, creates diagnostic anchoring bias.

Literature also emphasises that FIT positivity is not specific for neoplasia and can occur in a range of inflammatory and infectious conditions, including amoebiasis [4]. E. histolytica associated ulceration can produce bleeding significant enough to trigger FIT positivity, leading to endoscopic identification.

Inadequate treatment is a recognised pitfall: while nitroimidazoles, such as Metronidazole, treat invasive disease, luminal agents such as paromomycin are required to prevent relapse or chronic carriage. Partial treatment, or treatment directed only at co-infecting organisms, can result in persistent symptoms and late diagnosis.

Clinicians should consider amoebic colitis in returning travellers with ongoing gastrointestinal symptoms, even when an initial pathogen has been identified. It also demonstrates how FIT-based screening may reveal non-neoplastic but clinically significant pathology. Awareness of travel-related infectious mimics is essential to avoid misdiagnosis, ensure appropriate therapy and prevent complications.

eP816 Endoscopic Suturing as a Rescue Tool for the Closure of Postoperative Gastric Dehiscence in Multivisceral Transplantation: Case Report

Authors Ramírez Alcázar P[1], Delgado Lobo M[1], Franchez Martincorena B[1], Meizoso Montesinos C[1], Olmedo C[1], Del Pozo-Garcia AJ[1]

Institute **1** 12 de Octubre University Hospital, Madrid, Spain

DOI 10.1055/s-0046-1822143

Case Report: A 58-year-old woman underwent multivisceral transplantation (liver, pancreas, intestine, and stomach with gastro-gastric reconstruction) for ultrashort bowel syndrome due to intestinal ischemia following complications from resection of a symptomatic duodenal cyst, which led to multiple subsequent electrolyte and nutritional complications. Eight days after surgery, the patient developed fistulization of the gastric suture documented on CT, initially managed conservatively with complete bowel rest and percutaneous drainage. After 10 days without improvement and with radiologic confirmation of an approximately 5 cm gastro-gastric anastomotic dehiscence, endoscopic vacuum therapy with sponge placement (EVT) was initiated. Over 50 days, 13 sponge exchanges were performed, with an incomplete response and persistence of a fistulous tract up to 25 mm in maximal diameter. Given the patient's instability and severe post-transplant complications, surgical reintervention was deemed unfeasible. Therefore, endoscopic suturing was attempted to close the defect, first refreshing the fistulous edges with argon plasma coagulation (60 W, 1.2 L/min) to promote healing. The entire discontinuity was closed using a single 2-0 polypropylene suture in a continuous Z-pattern, supplemented by 2 hemostatic clips placed at one margin. Subsequent radiologic and endoscopic follow-up demonstrated complete closure of the dehiscence without complications, despite being closed two months after its onset — a factor typically associated with reduced efficacy.

Discussion: Anastomotic dehiscence is a common postoperative complication in gastro-gastric anastomoses. EVT is currently considered the first-line management for dehiscence at this level. However, failure rates of up to 20 % have been reported when used as monotherapy, requiring access to alternative therapeutic options. Full-thickness endoscopic suturing systems enable the placement of transmural sutures that provide robust tissue approximation without requiring surgical intervention [1]. These systems are currently approved for bariatric procedures, as well as for postoperative defects closure, with early diagnosis being a key factor in improving clinical success [2]. Our case highlights the role of these systems as a rescue therapy even in chronic defects, particularly in poor surgical candidates. Limited number of targeted studies and requirement for specialized training remain barriers to their broader implementation in high-volume centers.

Conclusions: Endoscopic suturing shows promising outcomes for the closure of mural defects such as gastro-gastric anastomotic dehiscence and may be particularly useful in high volume units of complex surgical cases. Comparative studies against EVT, as well as specialized training programs, are needed to expand the reach and clinical adoption of this technique.

DOI 10.1055/s-0046-1822144

Aims This study assesses the effectiveness of large language models (LLMs) in generating lay summaries for patient education on the management of precancerous lesions and early neoplasia in the stomach.

Methods In this pilot study, we used a two-period, crossover, blinded design to compare two summary versions: a ChatGPT-4o summary and a summary from Digestive Cancers Europe (DiCE). Two panels participated in the ratings: an expert physician panel and a patient panel composed of members of the DiCE Patient Advisory Committee (PAC). Experts rated accuracy (6-point), completeness (5-point), comprehensibility (5-point), and satisfaction (5-point) across five sections of the summary. Patients rated overall summary completeness, comprehensibility, and satisfaction. The paired design allowed all raters to serve as their own control. Results are reported as medians with ranges and interquartile ranges (IQRs), and p values for the comparison between the two summaries were derived from the mixed-effects estimates. Objective readability score was calculated with Flesch–Kincaid Grade Level (FKGL) and SMOG Index.

Results Median expert ratings were similar between materials across metrics: For the overall summary, median (range; IQR) scores were: accuracy 5 (4–6; 0.75) for ChatGPT-4o vs 5 (3–6; 1) for DiCE with p = 0.102; completeness 4 (3–5; 1) vs 4 (2–5; 1) with p = 0.272; comprehensibility 4 (3–5; 1) vs 4 (2–5; 1), with p = 0.329; and satisfaction 4 (2–5; 1) vs 3 (1–5; 2) with p = 0.329. Patient ratings mirrored experts, with very similar results on completeness, comprehensibility, or satisfaction. Readability failed to meet guideline recommenda-

tions for both summaries with both FKGL and SMOG score; DiCE read lower than ChatGPT-4o (FKGL: 11.16 vs 12.92; SMOG: 12.96 vs 14.84).

Conclusions ChatGPT-4o produced patient materials comparable to DiCE, but both require readability optimization; a human-in-the-loop workflow and future tests across prompts and models are warranted.

DOI 10.1055/s-0046-1822145

Abstract Text

A 52-year-old male with prior right hemicolectomy for colorectal cancer underwent endoscopic resection of a large duodenal adenoma involving 95% of the luminal circumference in the third duodenal part. Circumferential (360°) resection of the lesion was followed by partial closure of mucosal defect using Mantis and TTS clips. Focal capillary bleeding was controlled with a hemostatic coagrasper and adjunctive hemostatic powder. A post procedural CT scan revealed a small volume of peri-duodenal air and fluid, which resolved spontaneously without the need for intervention. Scheduled surveillance endoscopies at 20, 30 and 40 days after resection were performed and included circumferential submucosal triamcinolone injection to prevent post-procedural stenosis. This was well tolerated and effectively prevented lumen narrowing, with maintained patency on follow-up.

eP819 Beyond the Short Term: Three-Year Outcomes of EUS-Guided Gallbladder Drainage in a Large Patient Cohort

Authors Cominardi A[1], Comparato G[1], Cattaneo G[2], Aragona G[1]

Institutes 1 Gastroenterology and Digestive Endoscopy Unit, Guglielmo da Saliceto Hospital, Piacenza, Italy; 2 Ospedale "Guglielmo da Saliceto", Piacenza, Italy

DOI 10.1055/s-0046-1822146

Aims Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) using lumen-apposing metal stents (LAMS) provides excellent technical and short-term clinical success. However, being a relatively recent technique, limited evidence is available regarding its long-term performance. The aim of this study was to evaluate long-term clinical outcomes and adverse events (AEs) following EUS-GBD with LAMS.

Methods All EUS-GBD procedures performed in our Digestive Endoscopy Unit between January 2022 and November 2025 were retrospectively reviewed. Patients who underwent LAMS placement and had at least 30 days of follow-up were included. Technical outcomes, long-term clinical outcomes (>30 days), and long-term AEs (>30 days) were collected and analysed.

Results A total of 99 patients were included (44.9% male; median age 84 years, range 64–97).

EUS-GBD was performed for acute cholecystitis (AC) in non-surgical candidates in 90.9% of cases and for failed ERCP in 9%. LAMS was deployed from the stomach in 38.4% of patients and from duodenal bulb in 61.6%. Technical success was achieved in 96/99 procedures (97%), and initial clinical success in 95/99 (96%).

Median follow-up was 922 days (range 30-1416). Long term clinical success was observed in 90.9% of patients. AEs occurred in 9 of 99 patients (9%); only one AE occurred within 30 days, while 88.8% occurred during long-term follow-up.

Late LAMS migration was reported in 3 patients (33.3% of long-term AEs). In all 3 cases the LAMS migrated in the gastrointestinal lumen and patients remained asymptomatic. Migration was incidentally detected during surveillance ultrasound and confirmed by CT imaging. The median time to migration was 474 days (range 358–523) fromEUS-GBD.

Recurrent AC occurred in 6 patients (66.7% of long-term AEs). AC was caused by LAMS occlusion by food impaction in 5/6 cases and in all cases LAMS was deployed form the stomach. All LAMS occlusions were successfully treated endoscopically and the median hospitalisation for recurrent AC was 5 days.

Multivariate analysis showed no association between long-term outcomes and patient age, LAMS size or type, or EUS-GBD indication (AC vs. ERCP failure). However, transgastric LAMS placement was significantly associated with long-term AEs ($p<0.005$).

LAMS removal was performed in 12 patients (12.1%). There was no statistical difference in long term AEs between patients with or without stent removal.

During follow-up, overall mortality was 47.5%, with no deaths attributable to EUS-GBD or related AEs. Median time to death was 347 days post-procedure.

Conclusions EUS-GBD with LAMS is a safe and effective procedure not only in the short term but also over extended follow-up. Long-term clinical efficacy remained high, and the incidence of late AEs was low, supporting the durability and safety of this intervention for patients unfit for surgery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP820 Central reading reveals high inter-rater variability in Boston Bowel Preparation Scale scoring: results from a prospective randomised trial

Authors Sinonquel P[1, 2], Demedts I[1, 2], Camps C[3], Luypaerts A[3], Willekens H[3], Roelandt P[2, 1], Bisschops R[1, 2]

Institutes 1 Department of Translational Research in Gastrointestinal Diseases (TARGID), KU Leuven, Leuven, Belgium; 2 Department of Gastroenterology and Hepatology, University Hospitals Leuven, Leuven, Belgium; 3 UZ Leuven, Leuven, Belgium

DOI 10.1055/s-0046-1822147

Aims The Boston Bowel Preparation Scale (BBPS) is a widely used, validated tool to assess bowel cleanliness, but its reliability is limited by inter-observer variability among endoscopists. Central reading can reduce variability and improve the consistency in clinical trials.

Methods We prospectively included 494 patients scheduled for colonoscopy in UZ Leuven (Leuven, Belgium), to assess the impact of a low-fiber dinner the evening prior to colonoscopy. Participants were randomized (1:1) to either a standard regimen or a more lenient regime allowing a low-fiber dinner up to 2 hours before start of the bowel preparation procedure. In this analysis, we aim to compare the assessment of adequate (>6) and optimal BBPS (8-9) by the endoscopist and an independent central reader who was not involved in the procedure. Comparison of BBPS scoring performance using Fisher's exact test, inter-observer agreement was calculated using weighted Cohen's k-statistics.

Endoscopy 2026; 58: S1–S1041

Results By endoscopists scoring, adequate BBPS scoring was achieved in 99.0 % (489/494) and optimal bowel preparation was achieved in 98.0 % (484/494) of the cases.

After central reading, both scorings for adequate and optimal bowel preparation decreased significantly to 86.4.0 % (427/494) and 64.6 % (319/494), respectively ($p < 0.00001$).

On the 494 BBPS scorings, 217 (43.9 %) were agreed upon after central reading ($k = 0.154$, 95 %CI 0.044-0.244). Based on endoscopist scoring 4 patients had right-sided BBPS 0-1 (1 control and 3 in the interventional group), but only 2 were equally scored after central reading (1 was total BBPS 2 and 1 total BBPS 3). Overall, central readers scored 6 patients with a right-sided BBPS 0-1 (1.2 %), whereas by endoscopist's scoring only 2 were similarly scored (0.04 %).

Conclusions Validated bowel preparation scoring systems like BBPS are well-integrated though prone to high-interrater disagreement, up to 56.1 % in this study, potentially affecting clinical trial outcomes and quality assessment. Objective and continuous quantification by artificial intelligence may overcome this weakness and improve future practice and research.

eP821V Lost in the Tunnel – Guided by the Emerald Green

Authors Kanani Y[1], Bhagwat S[1], Chandrashekar A[1], Khatri P[1], Pujari R[1], Bapaye A[1]

Institute 1 Deenanath Mangeshkar Hospital and Research Center, Pune, India

DOI 10.1055/s-0046-1822148

Problem to solve Submucosal tunneling endoscopic resection (STER) is effective for resecting gastric subepithelial lesions (SELs) but requires precise tunnel orientation. Misdirected tunneling is a common challenge, particularly for small lesions, in large or roomy organs such as the stomach, and in procedures performed by trainees. Loss of direction can significantly prolong procedure time and lead to complications including bleeding and / or mucosal breach, making safe closure difficult. Rescue techniques for regaining orientation in such situations have not been adequately described. We report the innovative use of indocyanine green (ICG) which appears emerald green under white-light endoscopy to localize a missed lesion and redirect a tunnel during STER.

Innovation A small proximal gastric body SEL on posterior wall was planned for STER. A mucosal incision was made below the gastroesophageal junction (GEJ) and tunneling was commenced. The tunnel deviated from the intended plane, resulting in loss of lesion orientation and a small mucosal breach, complicating closure. As a rescue strategy, 1.25 mg/mL ICG was injected around the lesion using a direct transluminal approach and retroflexion. STER was continued using white light endoscopy, relying on ICG's distinctive green color under white light.

Results On re-entering the tunnel, the emerald green ICG staining clearly delineated the correct trajectory, enabling precise redirection toward the SEL. The SEL was thus identified and resected enbloc. Mucosal closure was completed successfully, and the patient had an uneventful recovery.

Conclusions White-light ICG marking is a safe, easily available, non-allergenic adjunct for real-time localization during challenging STER cases. ICG dissipates naturally without leaving foreign material, and unlike India ink, it does not trigger inflammatory reactions, abscesses, or adhesions if minor leakage occurs into the peritoneum. Methylene blue has already stained the submucosa blue – ICG offers a different color which stands out over and above the blue. This technique therefore offers an effective rescue method to manage misdirected tunneling, reduce complications, procedure time and enhance procedural success representing a meaningful innovation in third-space endoscopy.

eP822 Evaluation of a Large Language Model for Decision Support in Colorectal Polyp Characterization and Resection Planning. A retrospective study

Authors Pikoulas A[1], Zormpas P[1], Spinou M[1], Nakou E[1], Leontidis N[1], Papathanasis A[1], Dimitriadis D[1], Dimopoulou K[1], Voudoukis E[1], Tribonias G[1]

Institute 1 Gastroenterology Department, Korgialeneio-Benakeio Hellenic Red Cross Hospital, Athens, Greece

DOI 10.1055/s-0046-1822149

Aims Early identification of malignant potential and appropriate endoscopic resection technique are essential to optimize curative resection and minimize complications in colorectal neoplasia. Although artificial intelligence (AI) systems have demonstrated high accuracy in real-time optical diagnosis, large language models (LLMs) have not been systematically assessed for their ability to integrate morphology, optical classifications and ability to predict histology and recommend resection strategy. This study evaluates the diagnostic performance of a widely used, commercially available LLM for predicting polyp histology and recommending an optimal resection strategy, aiming to determine whether it can function as a decision-support tool in advanced endoscopic resections such as ESD (▶ **Table 1**).

Methods Early identification of malignant potential and appropriate endoscopic resection technique are essential to optimize curative resection and minimize complications in colorectal neoplasia. Although artificial intelligence (AI) systems have demonstrated high accuracy in real-time optical diagnosis, large language models (LLMs) have not been systematically assessed for their ability to integrate morphology, optical classifications and ability to predict histology and recommend resection strategy. This study evaluates the diagnostic performance of a widely used, commercially available LLM for predicting polyp histology and recommending an optimal resection strategy, aiming to determine whether it can function as a decision-support tool in advanced endoscopic resections such as ESD.

Results The study included 62 colorectal lesions from 58 patients; 45 % were females and ages ranged from 18-89 years (mean 66 years). Lesions were most commonly located in the sigmoid colon (29.03 %), rectum (22.5 %) and ascending colon (20.96 %). Clinical information provided to the AI software in the informed condition included age, sex, relevant medical history (prior CRC, adjuvant therapy, surgery), lesion size and location and optical classifications (Paris/JNET/Kudo). For resection strategy selection, the LLM showed 70.96 % agreement with expert's decisions in the photos only conditions ($\kappa = 0.59$), which increased to 90.32 % in the informed condition ($\kappa = 0.751$). Direct comparison between outputs in the two conditions demonstrated that 12 cases improved to match the expert's recommendation when clinical and optical classification data were added ($\kappa = 0.415$, $p < 0.001$). For histology prediction, accuracy compared with final pathology was 72.72 % in the photos only condition ($\kappa = 0.408$) and increased to 87.03 % in the informed condition ($\kappa = 0.758$).

Comparison of the two conditions identified 7 lesions for which histology categorization improved with additional clinical and optical data ($\kappa = 0.624$, $p < 0.001$). Response time for each case remained under 45 seconds to support feasibility for real-time use.

Conclusions This study provides the first evaluation of a widely used LLM as a decision-support tool for colorectal lesion characterization, histology prediction and resection strategy selection especially in lesions requiring advanced resection techniques as ESD. Our data has shown that performance improved markedly when clinical and endoscopic information supplemented photos, highlighting the importance of multi-modal input. These findings suggest that general-purpose LLMs could complement existing AI systems and offer practical decision support in settings where advanced resection expertise is limited.

eP823 Organ-Preserving Endoscopic enbloc Resection for Large GISTs in Difficult Anatomical Locations After Neoadjuvant Imatinib

Authors Kanani Y[1], Bhagwat S[1], Chandrashekar A[1], Khatri P[1], Oswal C[1], Kumbhar C[1], Pujari R[1], Bapaye A[1]

Institute 1 Deenanath Mangeshkar Hospital and Research Center, Pune, India

DOI 10.1055/s-0046-1822150

Aims Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors of the GI tract. While surgical resection remains standard for localized disease, the low risk of lymph node spread makes organ-preserving endoscopic resection a viable alternative. Neoadjuvant imatinib further enhances this approach by shrinking tumors, reducing bleeding risk, and enabling safe en-bloc endoscopic removal in anatomically challenging locations

Methods Retrospective analysis of prospectively maintained database of 5 patients with large GISTs undergoing neoadjuvant imatinib followed by endoscopic resection. Assessed for demographics, tumor characteristics, imatinib response, resection/closure techniques; outcomes including histology with chemotherapy related changes and residual viable tumor, margins, complications, length of stay and follow-up.

Results 5 patients with anatomically difficult location – 2 rectal (involving internal anal sphincter and abutting the external anal sphincter), 2 duodenal (1- D3, 1- D1-D2 junction), 1 – exophytic gastric lesion. Mean baseline tumor size (mm) – 38 [SD 9.30]. Layer of origin on EUS – all arising from muscularis propria (MP) and 1 involving the gastric serosa. Clinical presentation – G.I bleed – 3 (ulcerated lesions), abdominal pain – 1 and dyspepsia – 1. Tumor grade 4 – low grade (Mitotic index < 2/50 hpf), 1 – high grade (> 5/50 hpf).

Neoadjuvant imatinib (400-800 mg OD) for 13 -24 weeks. 3 patients tolerated Imatinib well. 2- diarrhoea – managed symptomatically. None of the ulcerated lesions had bleeding episodes while on imatinib and achieved a mean size reduction- 54 % i.e 20.6 mm(SD-4.66) on CECT.

Resection modalities EFTR-3, STER-1, ETSSD-1 (endoscopic tunneling and subserosal dissection). Primary closure techniques used: 2 – endoscopic suturing, 2 – endoclips and 1 – endoclips + intraluminal EVT.

Mean total procedure time – 191 min [SD30.33]. Enbloc resection achieved in all, no complications, with mean length of hospital stay 7 days. R0 resection with treatment related changes on HPE. Adjuvant Imatinib continued in all.

Follow up PET scan at most recent follow up- negative for recurrence/metastasis. Rectal lesions resected – no stool incontinence on follow-up. Median follow up 22 months and maximum 38 months.

Conclusions Neoadjuvant imatinib substantially downsizes large non-metastatic GISTs and enhances tissue planes, enabling safe, effective, organ-preserving en-bloc endoscopic resection even in anatomically challenging locations where surgery would otherwise require morbid surgeries. This strategy achieves high R0 rates, preventing morbidity, suggesting that neoadjuvant imatinib may serve as a viable alternative to radical surgery for selected large localised GISTs amenable to endoscopic resection. Prospective studies are needed to validate and expand its use beyond expert centers.

eP824 Learning Curve in Endoscopic Submucosal Dissection Training Using an Ex-Vivo Animal Model: Impact of a One-Week Intensive Course Within a Dedicated ESD Program

Authors Finci L[1], Lepillez V[2, 1], Jacques J[3], Bichard P[1], Frossard JL[1]

Institutes 1 Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland; 2 Jean Mermoz Private Hospital – Ramsay Health, Lyon, France; 3 CHU Dupuytren 1, Limoges, France

DOI 10.1055/s-0046-1822151

Aims Endoscopic submucosal dissection (ESD) is a technically demanding procedure with a steep learning curve. The European Society of Gastrointestinal Endoscopy (ESGE), as most international societies, recommends training on animal models prior to performing ESD in humans, and guidelines emphasize the importance of structured programs to achieve competency.

In this context, we evaluated the feasibility of ex-vivo animal model training through unsupervised procedures, in addition to participation in such dedicated curriculum (SFED program, including both in-vivo and ex-vivo training).

Methods Performance was assessed over 14 unsupervised ex-vivo procedures before and 14 procedures after a one-week supervised intensive training course in a specialized facility, with the aim of determining whether there was a measurable improvement in outcomes.

Results The mean area of resected ex-vivo specimens prior to the course was 261 mm^2 (range 33–777), compared with 240 mm^2 (range 80–667) after the course, with no statistically significant difference between groups. The mean duration of the procedures was significantly reduced, from 31 minutes pre-course (range 17–54; SD 10.8) to 16.5 minutes post-course (range 12–24; SD 3.2). Six perforations occurred before the course, representing 43 % of procedures (2 complete and 4 incomplete perforations), whereas no perforations were observed after the course. Two initial procedures were excluded from the analysis due to extensive perforations that made completion of the dissection impossible.

When dissection characteristics of the ex-vivo specimens were analyzed, the mean dissection speed increased from 8.7 mm^2/min (range 1.3–15.3; SD 5.2) before the course to 14.2 mm^2/min (range 3.9–44.5; SD 11.2) after the course, corresponding to a 62.6 % improvement in speed. This improvement in efficiency was achieved without compromising specimen size and was associated with a marked reduction in perforation rate.

Conclusions A one-week intensive supervised training program significantly increased dissection speed on an ex-vivo animal model and markedly reduced the perforation rate during unsupervised ESD procedures. These findings support the value of structured, short-term intensive training within dedicated curricula to enhance both efficiency and safety in the early phase of ESD skill acquisition.

eP825V Undersaline endoscopic submucosal dissection in high-risk colitis associated neoplasias

Authors Gubbiotti A[1], Wilde LG[2], Baglione E[3], Rosa-Rizzotto E[1]

Institutes 1 Gastroenterology and Digestive Endoscopy Unit, Sant'Antonio Hospital, Padua, Italy; 2 Padova University Hospital, Padova, Italy; 3 Gastrointestinal endoscopy unit, Padua university hospital, Padua, Italy., Padua, Italy

DOI 10.1055/s-0046-1822152

Abstract Text

Patients with inflammatory bowel disease (IBD) carries an increased risk of colorectal cancer. High-risk colitis-associated neoplasia (HR-CAN) is a recently validated definition, which encompasses all non polipoid lesion > 20 mm or polipoid lesion with submucosal invasion stigmata independently from diameter, arising in an inflammed or mucosal healing segment.

These lesions are thought to carry higher neoplastic risk, so that they should be resected en bloc, preferably with endoscopic submucosal dissection (ESD), even though this approach is often markedly challenging, as a consequence of severe fibrosis [1].

We present a case where undersaline pocket method strategy allowed safe, quick and efficient en bloc resection of a descendent colon HR-CAN.

eP826 Mantle Cell Lymphoma with Extensive Gastrointestinal Infiltration: Diagnosis by Endoscopy and Capsule Endoscopy

Authors Pérez S[1], Moreira H[1], Romo P[1], Ortega A[1], Caballero JC[1], Sanchez-Fayos P[1], Farrais S[1], Mata S[1]

Institute 1 Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

DOI 10.1055/s-0046-1822153

Introduction An 82-year-old woman who had been evaluated for iron-deficiency anemia and a positive fecal occult blood test. Gastroscopy and colonoscopy showed no abnormalities. She was lost to follow-up until 3 years later, when Primary Care requested a new colonoscopy due to altered bowel habits.

Endoscopy Colonoscopy revealed flat polyps (Paris 0-IIa) smaller than 5 mm in the rectum, which were biopsied, demonstrating infiltration by mantle cell lymphoma, classic variant. As part of the staging work-up, an upper endoscopy was performed, showing erythematous areas with loss of glandular pattern and irregular vessels in the gastric fundus; in addition, 3–5 mm eroded nodular lesions were seen in the duodenal bulb. Both sites were biopsied, with results consistent with infiltration by the same lymphoma.

A PET-CT scan demonstrated uptake in the gastric fundus, supra- and infradiaphragmatic lymph nodes, and intestinal involvement. Capsule endoscopy revealed multiple nodular lesions (3–5 mm) in the duodenal bulb, some of them eroded, compatible with mantle cell lymphoma. In the distal ileum, millimetric nodular lesions (2–3 mm), some eroded, were identified, highly suggestive of infiltration at this level.

Comments/Conclusions Gastrointestinal mantle cell lymphoma is uncommon, with the small intestine being its most typical site of involvement. Endoscopic diagnosis requires a high degree of clinical suspicion and targeted biopsies. This case illustrates multifocal involvement of the gastrointestinal tract, from the colon to the ileum, highlighting the key role of endoscopy and capsule endoscopy in diagnosis and staging. The patient is currently under Hematology follow-up and has initiated treatment with bendamustine and rituximab.

eP827 Predictive factors of complications of endoscopic retrograde cholangiopancreatography in the treatment of biliary lithiasis

Authors Mouslim I[1], Oualaalou S[2], Jioua C[3], Abdelfattah T[3], Fouad N[1], Berrag S[3], Adioui T[3], Tamzaourte M[3]

Institutes 1 Mohamed V Military training hospital, Rabat, Morocco; 2 Military Hospital Mohammed V, Rabat, Morocco; 3 Mohammed V Military Training hospital, Rabat, Morocco

DOI 10.1055/s-0046-1822154

Aims Endoscopic retrograde cholangiopancreatography (ERCP) remains a key procedure in the therapeutic management of biliary and pancreatic diseases, particularly lithiasis. Its complications are mainly dominated by acute pancreatitis.The aim of our study is to assess the frequency and predictive factors of ERCP-related complications.

Methods We retrospectively included all patients who underwent ERCP between September 2024 and September 2025 for lithiasic disease.Statistical analysis was performed using the Jamovi software. The associated factors studied were: age, sex, history of ERCP, use of NSAIDs before the procedure, cannulation of the pancreatic duct and the number of passages into the Wirsung duct, performance of a precut, and the total duration of the procedure.

Results A total of 31 patients were included. The mean age was 58.4 ± 15.3 years, with a sex ratio of 0.47. Four patients (12.9 %) had a history of ERCP. Twenty-four patients (80 %) received NSAIDs prior to the procedure. Sphincterotomy was performed in 30 patients (96.8 %), and a precut was required in 2 patients (6.7 %). Accidental cannulation of the Wirsung duct occurred in 13 patients. The stone extraction success rate was 80.6 %.

Regarding complications, 3 patients developed acute pancreatitis, and 1 patient experienced bleeding, which was controlled by pneumatic compression of the margins.

In univariate analysis, factors associated with the occurrence of complications were: the number of passages into the Wirsung duct, procedure duration, and NSAID use before the procedure.In multivariate analysis, only the number of passages into the Wirsung duct appeared to be associated with the occurrence of complications ($p = 0.04$; OR = 1.7; 95 % CI [0.9–2.3]).

Conclusions Only the number of passages into the Wirsung duct appears to be a predictive factor for the occurrence of complications.

eP828 Three-Way Comparison of Stenting + Naso-Cavitary Drainage, EsoSponge EVT, and VACStent for Upper-GI Postsurgical Leaks

Authors Dioscoridi L[1], Forti E[2], Gallo C[3], Palermo A[2], Bonato G[4], Cintolo M[2], Stegagnini M[1], La Mantia A[2], Pugliese F[2], Mutignani M[5]

Institutes 1 ASST Great Metropolitan Niguarda, Milano, Italy; 2 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy; 3 ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy; 4 ASST Great Metropolitan Hospital Niguarda, Milano, Italy; 5 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy., Milan, Italy

DOI 10.1055/s-0046-1822155

Aims Upper-GI postsurgical leaks are a major complication after esophagectomy, gastrectomy or bariatric surgery. Endoscopic techniques for leak management have evolved — from simple stent-based sealing toward strategies combining luminal coverage with cavity drainage and negative-pressure therapy. Among these, three widely adopted methods are: (1) fully covered self-expanding metal stents (FCSEMS) combined with naso-cavitary drainage (NTCD), (2) endoscopic vacuum therapy (EVT) using sponge devices (e.g., EsoSponge), and (3) hybrid systems combining stent and vacuum therapy such as VACStent. A missing datum in the available literature is to establish a correct rationale in terms of selected ideal indications to understand their real efficacy and limitations [1, 2].

Methods A retrospective study to evaluate the efficacy related to predecided indications was performed and data on technical and clinical successes of our cohorts were compared to the ones available in the international literature. The pre-established indication were based on the morphology of the leak: FCSEMS + naso-cavitary drainage was used to treat dehiescence associated with not-drained cavity with or without fistolous tract, EsoSponge EVT was used in case of wide paraluminal cavity, and VACStent was used for early detected leaks without paraluminal collections or well-drained paraluminal collections. Data on the three groups were compared in terms of clinical success and timing to complete closure of the leak.

Results A total of 110 patients were included in the present study, 53 with gastric leaks and 57 with esophageal leaks, from 2018 to november 2025

97 patients were treated with FCSEMS + NTCD, 5 with gastric leak and 92 with esophageal leak. This technique provides leak coverage while allowing drainage of the external collection. In 89 patients, an intrastent naso-luminal tube in continuos suction was placed. Reported clinical success (leak closure) rates range between 60–80 %. Our technical success was 100 % while clinical success was 90 %. Mean time for closure was 21 days.

10 patients were treated by EVT, 2 with gastric leak, 8 with esophageal leaks. EVT exerts continuous negative-pressure therapy that promotes collapse of the leak cavity, granulation tissue formation, and closure. Several series report closure rates of 75–95 %. Our technical success was 100 % and clinical success was 100 % in our case series. Mean time for closure was 32 days.

Remaning 3 patients were treated by VACStent. Two patients had esophageal leaks, 1 patient had gastric leak post-bariatric surgery. By combining a fully covered stent with an external vacuum sponge, VACStent offers internal drainage plus maintenance of luminal patency. Early clinical reports indicate closure rates around 80–90 %. Our technical success was 100 % but clinical success was 67 % with significant lower time to closure than standard stenting (7 days vs 21 days).

From comparison of the three technqiues, technical success was not different while clinical success was not statistically different between FCSEMS + NTCD ($p = 0,8$). However, clinical success of VAC stent was statistically lower than the other tecniques ($p < 0,01$). This finding can be limited by small case series both in EVT and VACStent group.

On the other hand, the VACStent when successful, has the most rapid time to closure ($p < 0,05$). The other two techniques showed no statistically different time to closure ($p = 0,09$).

Conclusions Tailored endoscopic management of upper-GI postsurgical leaks can be effectively improved by the study of leak morphology, size of leak cavity, and patient condition. FCSEMS + NTCD remains an option for leaks with not well-drained collections; EVT is preferred when rapid cavity collapse and granulation of parluminal cavities are required; and VACStent appears as a promising hybrid in case of early detected leaks. Prospective multicentric larger comparative studies are warranted to define standardized treatment algorithms and identify predictors of success and failure for each modality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Endoscopic submucosal dissection (ESD) of the ileocecal valve (ICV) is technically demanding. We report a case of a laterally spreading tumor involving both lips of the ICV and extending 1 cm into the terminal ileum. After performing a circumferential underwater dissection with a colonoscope fitted with a conic hood, we adopted several strategies to prevent adverse events. These included intraprocedural coagulation of visible vessels and eversion of the ileal margin, which was then clipped to the distal colon to achieve a 180 ° closure. On the contralateral side, we applied a self-assembling peptide matrix. This approach avoided the creation of a circumferential defect and promoted optimal healing. No adverse events occurred, and at 1-year follow-up the ileocecal valve remained widely patent, with no evidence of stenosis.

eP830 Ileal Pseudomelanosis: A Rare Endoscopic Finding with Clinical and Pathological Relevance

Authors Pérez S[1], Moreira H[1], Romo P[1], Otegui L[1], Alvarez M[1], Farrais S[1], Silva A[1]

Institute **1** Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

DOI 10.1055/s-0046-1822157

Introduction Intestinal pseudomelanosis is an uncommon condition, more frequently observed in the colon, with a prevalence of 10–15 % in patients receiving iron supplementation, activated charcoal, or with chronic metabolic diseases. It is characterized by the accumulation of iron- and lipofuscin-derived pigments within macrophages of the lamina propria. Although benign, its diagnosis is important to differentiate it from serious pigmented pathologies. It has been associated with comorbidities such as hypertension, chronic kidney disease, or iron supplementation. Histological confirmation is key to avoid inappropriate management.

Endoscopy A 78-year-old man with hypertension was referred from Primary Care for colorectal cancer screening due to a family history of polyposis. His last colonoscopy revealed a spastic colon and dolichocolon. Complete colonoscopy with cecal intubation and distal ileum visualization was performed, showing areas of edematous mucosa with patchy dark pigmentation and villous atrophy. Ileal biopsies were taken. Histopathology confirmed ileal pseudomelanosis. Melanosis coli was also observed throughout the explored colon.

Comments/Conclusions Ileal pseudomelanosis is very rare, and its endoscopic recognition may raise diagnostic doubts, especially due to its pigmented appearance, which can mimic serious conditions such as metastatic melanoma. Histology is essential for confirmation. Its association with melanosis coli and a history of chronic treatments supports its benign nature. No formal follow-up guidelines exist, but accurate identification allows avoidance of unnecessary tests or treatments, optimizing clinical management.

eP831 Development of a synthetic AI-enhanced microwave-based colonoscopy training model

Authors Fernández-Esparrach MG[1, 2], Neira LM[3], Yago A[3], Garrido A[3], Cantú-Germano E[2, 1], Nuñez J[1], Escuin T[3], Guardiola M[3]
Institutes **1** Hospital Clinic de Barcelona, Barcelona, Spain; **2** Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; **3** MiWendo Solutions, Barcelona, Spain
DOI 10.1055/s-0046-1822158

Problem to solve Up to 22 % of polyps are missed during colonoscopy and current solutions relay on improving the endoscopic image or using AI.

Innovation Microwave-based colonoscopy (MWC) is a disruptive new solution that has proved to be safe and feasible in a human pilot study. MWC can differentiate polyps from normal tissue based on their different dielectric properties and consists on three elements: the acquisitor (an add-on ring-shaped device provided with microwave antennas), the analyzer (external unit) and the software (embedded in the analyzer). The software analyses the signals received and provides with an output (sound). Unfortunately, there are no available microwave signal databases for colorectal polyps that can be used for training the algorithm and we need more representative examples to improve the performance. For this reason, we designed a dedicated phantom using an ex-vivo porcine colon that included six synthetic polyps selected from a set of models with different morphologies, including flat polyps 2 mm in height and 25, 10 or 7 mm in diameter, as well as polyps 10 mm in diameter and 5 or 10 mm in height. Performance metrics were evaluated after the explorations. We used the optical colonoscopy video as ground truth. The optical video from colonoscopy was examined and temporally segmented into sets of consecutive and homogeneous frames [1].

Results We performed a total of 24 colonoscopies with a total of 144 polyps and 32,441 frames. A convolutional neural network (CNN) was trained on these data, and each detection was labelled as TP, TN, FP and FN. The CNN was then validated using six new trajectories that included 36 flat polyps. The sensitivity and specificity for polyp detection were globally 80.5 % and 75.0 %. respectively. Sensitivity increased up to 93.3 % for flat polyps.

Conclusions MWC has the potential for detecting colon flat polyps and can be trained in dedicated synthetic phantoms.

Conflicts of Interest G.F.-E. and M.G. are shareholders of MiWendo Solutions

Abstract Text

Eosinophilic gastroenteritis(EGE) is a rare immune-mediated disorder marked by gastrointestinal mucosal dysfunction and eosinophil inflammation. We evaluated mucosal dysfunction and intestinal permeability in two patients using endoscopy, histology, and probe-based confocal laser endomicroscopy (pCLE) at diagnosis and after five weeks of corticosteroid therapy. Baseline histology confirmed marked eosinophilic infiltration, while pCLE revealed interstitial leakage and increased epithelial permeability even in endoscopically and histologically normal mucosa. Treatment induced clinical, endoscopic and histologic remission but pCLE continued to detect subtle, persistent barrier defects in regions with normalized endoscopy and histology, suggesting residual subclinical disease. These findings suggest that achieving "functional healing" of the gut barrier may represent a critical, new therapeutic frontier [1, 2].

eP833 Efficacy and Safety of Endoscopic Ultrasound-Guided Radiofrequency Ablation in Small Pancreatic Neuroendocrine Tumors: A Single-Center Study

Authors Kozlowska K[1], Hsino-Sito N[2], Kozlowska K[3], Jedruszek S[3], Springer M[3], Pawlak K[2], Wiechowska-Kozłowska A[2]
Institutes **1** Department of Translational Medicine, Pomeranian Medical University, Szczecin, Poland; **2** Hospital of the Ministry of Interior and Administration, Endoscopy Unit, Szczecin, Poland; **3** Pomeranian Medical University, Szczecin, Poland
DOI 10.1055/s-0046-1822160

Aims Endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) is an emerging and minimally invasive modality that may offer a therapeuthic alternative to surgery in selected patients with pancreatic neuroendocrine tumors (pNETs). This study reports a single-center experience with EUS-RFA for pNETs ≤ 2 cm, with emphasis on its safety and efficacy.

Methods A total of 62 patients with 65 histologically proven G1 pNETs underwent EUS-RFA and were included in this retrospective analysis. Surveillane was perfomed using EUS and/or contrast enhanced computed tomography (CT). Adverse events were classified according to the AGREE criteria.

Results Sixty two patients (25 males; mean age 53 years) with 65 lesions (mean lesion size 12.1mm; range 7-25) were treated with EUS-RFA (mean total ablation time for lesion 39.9 ± 33s; range 5-168s; mean session number 1.52; range 1-5). The cohort comprised 57 non-functioning pNETs (88 %) and 8 insulinomas (12 %). All patients with insulinomas remained asymptomatic during follow-up. Overall, 78 % of patients achieved complete regression, defined as no contrast enhancement in CT or/and EUS, while 22 % demonstrated partial response (mean follow-up 18.7 ± 15.3 months; range 3-56 months). Regarding safety, most patients (88 %) presented no adverse events. Three patients (5 %) developed Grade I AEs, four (6 %) Grade II AEs and one (1.5 %) Grade IIIA AE.

Conclusions EUS-RFA appears to be an effective and safe treatment option for small pNETs. Prospective studies with longer follow-up are warranted to better define long-term outcomes and recurrence rates.

eP834 ChatGPT 5 vs Expert Endoscopists: A Comparative Evaluation of Adherence to the ESGE STAR Project

Authors Ait Errami A[1], Zouaki I[2], Nacir O[3], Fatima Ezzahra L[1], Krati K[1]
Institutes **1** CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco; **2** UHC MED VI, Marrakesh, Morocco; **3** MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1822161

Aims The ESGE STAR Project provides a 55-item standardized framework for upper GI endoscopy reporting, based on expert consensus due to the absence of high-quality evidence. The ability of artificial intelligence (AI) systems to apply these structured criteria remains unknown. This study compares the adherence of ChatGPT-Audio, using voice-dictation input, to that of expert endoscopists when both are instructed to follow the STAR recommendations.

Methods A total of 104 EGD reports were analyzed: 52 generated by ChatGPT 5.1 and 52 written by expert endoscopists, all under explicit instruction to follow the 55-item ESGE STAR checklist. Two blinded senior reviewers independently evaluated each report for item-level compliance across pre-, intra- and post-procedural domains. Primary outcome: overall compliance rate. Secondary outcomes: domain-specific compliance, number of missing items, inter-rater reliability (κ), and ROC analysis.

Results Overall compliance was 87.6 % ± 4.8 for ChatGPT-Audio and 93.1 % ± 3.5 for experts (p = 0.002). ChatGPT-Audio missed 6.8 ± 3.2 items per report compared with 3.7 ± 2.1 for experts. Domain-specific compliance was: • Pre-procedural: 81 % vs 94 % • Intra-procedural: 92 % vs 95 % • Classification usage (LA, Prague, Forrest, Paris): 89 % vs 94 % • Post-procedural: 76 % vs 90 %Inter-rater agreement was excellent (κ = 0.84). ROC analysis identified a threshold of ≥ 90 % compliance (AUC = 0.86).

Conclusions When explicitly instructed to apply the ESGE STAR criteria, ChatGPT-Audio produced highly structured and guideline-conformant EGD reports, approaching expert performance. Human endoscopists nonetheless demonstrated superior compliance, particularly regarding pre- and post-procedural elements. This study provides the first controlled assessment of an AI voice-dictation system's ability to apply the ESGE STAR reporting standard and supports its potential role in advancing standardized endoscopy documentation.

eP835 Clinical Impact of Red Dichromatic Imaging on Bleeding Visibility and Hemostasis Performance: A Meta-analysis

Authors Dağcı G[1], Yağlı MA[1], Gurbanov A[1], Telli P[1], Ağargün BF[1], Mammadov S[1], Çavuş B[1], Selman FB[1], Kadir D[1], Akyüz F[1], Kaymakoğlu S[1]
Institute **1** Istanbul University Faculty of Medicine, Istanbul, Türkiye
DOI 10.1055/s-0046-1822162

Aims Red Dichromatic Imaging (RDI) is a novel image-enhancement modality designed to highlight bleeding points more clearly during endoscopic procedures. Although early studies suggest improved visualization, its overall clinical impact across different bleeding scenarios has not been quantified. This study aimed to evaluate the effect of RDI compared with White Light Imaging (WLI) on bleeding visibility and hemostasis performance.

Methods Comparative studies assessing RDI versus WLI during active gastrointestinal bleeding or bleeding-related interventions were systematically reviewed.Random-effects meta-analyses were performed for visibility scores (standardized mean difference, SMD) and for hemostasis or treatment time (mean difference, MD). Three studies reported visibility outcomes (n = 175 observations) and two studies provided procedural time data (n = 2,064 hemostatic actions).

Results RDI significantly improved blee
ding visibility compared with WLI (SMD 0.79; 95 % CI 0.56–1.02; p < 0.00001; I^2 = 7 %). Overall hemostasis/treatment time was not significantly different between modalities (MD − 0.13 min; 95 % CI − 10.55 to 10.30; p = 0.98; I^2 = 83 %). However, in variceal EIS/EISL procedures RDI markedly shortened treatment time (MD − 4.67 min), while ESD-related hemostasis times were comparable.

Conclusions RDI provides a consistent and clinically meaningful improvement in bleeding visibility. Although overall hemostasis time was not reduced, RDI substantially accelerates variceal therapy. These findings support RDI as an emerging tool for enhancing real-time endoscopic bleeding management.

eP836 Severe Delayed Post-POEM Hemorrhage: When Less Is More

Authors Inês S[1], Bruno R[1], Lima PA[1], Cristina C[1], Barreiro P[1, 2]
Institutes **1** Hospital Egas Moniz, Lisboa, Portugal; **2** Lusíadas Hospital, Advanced Endoscopy Center of Lisbon, Lisbon, Portugal
DOI 10.1055/s-0046-1822163

Abstract Text

A 62-year-old man, with no comorbidities or regular medication, underwent POEM for symptomatic type I achalasia (Eckardt score 7). The procedure was uneventful, using an anterior approach with partial full-thickness myotomy, and mucosal integrity was confirmed at the end of the procedure [1–3].

Twelve hours later, he developed shock with hypotension and prostration, associated with a hemoglobin drop to 8 g/dL. CT imaging showed the stomach filled with blood and a small esophagogastric wall hematoma (3 × 5 cm), without signs of active bleeding. Endoscopy revealed an intact mucosotomy closure and a small bulge compatible with an intramural hematoma extending from the distal esophagus to the gastric body. The stomach contained abundant fresh and clotted blood. After aspiration and repositioning, a 10-mm mucosal laceration was identified in the proximal gastric body with adherent clots, consistent with the rupture point on the gastric side of the tunnel. As there was no active bleeding or significant intra-tunnel hematoma, a conservative approach with close monitoring was chosen.

The patient remained hospitalized for five days under pantoprazole and antibiotics, requiring two units of packed red blood cells. He progressed favorably without recurrent bleeding and remained asymptomatic at one-year follow-up. This case highlights a rare but clinically significant delayed post-POEM hemorrhage. Although many reports advocate re-entry into the tunnel for clot evacuation and hemostasis, this case demonstrates that conservative management may be appropriate in selected patients, depending on the specific characteristics of the lesion and clinical stability. Iconography and video are provided.

The authors present a rare but potentially severe delayed complication of POEM, occurring in 0.2 to 0.7 % of procedures. Due to its rarity, optimal management is not well established, with many reports describing re-entry into the tunnel, clot clearance and identification and coagulation of visible vessels. This case illustrates successful conservative management of severe post-POEM hemorrhage, guided by specific patient characteristics. Iconography is provided.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP837V Bouveret syndrome (BS): a rare cause of gallstone ileus, resolved endoscopically by electrohydraulic (EHL), laser and mechanical lithotripsy

Authors Escribano de la Torre V[1], Martinez-Ortega A[2], Caballero-Hernandez M[2], Andreo-Vidal BE[2], Aranda-Olaizola G[2], Garcia-Redero M[2], Jimenez-Hernandez B[2], Gomez-Hidalgo R[2], Tejerizo-García L[2], Segarra Ortega JX[1], Velasco-Guardado AJ[3], Geijo-Martinez F[2], Alvarez-Delgado A[2]

Institutes 1 Salamanca University Hospital, Salamanca, Spain; 2 Complejo Asistencial Universitario de Salamanca, Salamanca, Spain; 3 Digestive Diseases Unit, Salamanca University Hospital., Salamanca, Spain

DOI 10.1055/s-0046-1822164

Introduction Bouveret syndrome is a rare form of gallstone ileus in which a stone passes through a fistula and becomes impacted in the duodenum. Although surgery is the standard treatment, we present a case resolved endoscopically.

Clinical Case An 87-year-old woman referred to our centre due to obstruction from a 4 cm stone impacted in the duodenum after passing through a cholecystoduodenal fistula. Surgery was dismissed, so endoscopic therapy was used in three sessions. Initial EHL and polypectomy-snare attempts failed. Holmium laser lithotripsy (HLS) enabled partial fragmentation, and further fragmentation was achieved with a loop-shaped guidewire. Total fragmentation required HLS and EHL. The fragments were moved to the stomach, mechanically broken, and removed.

Discussion Endoscopic management can be effective in BS when surgery is contraindicated.

DOI 10.1055/s-0046-1822165

Aims The use of simulator training offers new avenues for high-quality education in endoscopy. Nevertheless, even with the availability of various simulators, their validation and impact on training remain marginalized. Therefore, we evaluated the novel "Endonix" simulator, a 3D-printed simulator comprising an endoscope handle connected to a computer that does not require cumbersome technical setup ("plug-and-play"), allowing easy training access. The aim of this study was to prospectively evaluate the simulator's validity, feasibility and usability in novices, beginners and experienced endoscopists as well as to assess participants' perception of the simulator and simulation training in general.

Methods Delegates at two international conferences (DGVS and ENDOCLUB-NORD, both 2024 in Germany) were invited to participate in this study. Study participants were asked to complete a pre-testing questionnaire requesting their perception of endoscopy simulation training. Afterwards, two exercises were performed, covering line markings and ESD markings in a virtual environment. Following the simulation, participants were asked to complete the System usability scale (SUS) and NASA Task Load Index as well as a questionnaire evaluating the simulator.

Results A total of 310 participants completed the study (n = 146 DGVS, n = 164 EndoClub), comprising 114 novices, 49 beginners, and 147 experts. The majority reported no access to simulation training at their institution (83.9 %), and only a minority had structured curricula available (21 %). The majority of participants supported endoscopy simulation training (83.1 %) and the requirement of simulation training before first patient encounters (61.9 %). The majority of all three groups (novices: 74.4 %, beginners: 62.2 %, and experts: 63.1 %) supported the introduction of the simulator at their institution, revealing rather good face validity. However, while the majority of novices (57.3 %) found the simulator realistic, compared to a minority of beginners (34.9 %) and experts (37.2 %), revealing merely sufficient content validity. In contrast, construct validity was also favorable as experienced endoscopists completed both modules faster than novices or beginners. Criterion validity was assessed using the correlation of training time and experience level, which showed significant correlation for both exercises. The SUS yielded 75 out of 100 points (corresponding to good usability) with no discernible difference between novices, beginners and experienced endoscopists. The NASA-TLX, ranging from 0 to 600 points, reflecting level of exhaustion, exhibited a higher score in novices and beginners than experienced endoscopists (285 vs. 210 vs. 225 points, respectively, $P < 0.001$).

Conclusions The first validation of a novel virtual simulator demonstrated its feasibility and usability, with mostly sufficient validity. Many participants favored its implementation in endoscopy training, particularly for novice and beginner endoscopists, who were identified as the most suitable target learners. The availability of simulation training is currently not meeting the needs of trainees and trainers, demonstrating potential for inclusion in endoscopy training.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP839 Infected WON – does an upfront necrosectomy improve the outcome?

Authors Seulean E[1, 2], Orzan RI[2], Dragomir I[2, 1], Rednic NV[1, 2], Cristina P[1, 3], Seicean S[1], Mercea V[1, 2], Molnar G[4], Al Hajjar N[4], Seicean A[1, 2]

Institutes 1 Regional Institute of Gastroenterology and Hepatology Prof. Dr. O. Fodor, Cluj-Napoca, Romania; 2 Iuliu Haţieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; 3 Babes-Bolyai University, Faculty of Psychology and Educational Sciences, Cluj-Napoca, Romania; 4 Third Department of Surgery, Iuliu Hatieganu Univeristy of Medicine and Pharmacy, Cluj-Napoca, Romania

DOI 10.1055/s-0046-1822166

Aims The use of upfront direct endoscopic necrosectomy (DEN) at the index drainage of pancreatic walled-off necrosis (WON) remains controversial when compared with on-demand necrosectomy, particularly in patients presenting with severe sepsis. Moreover, the exact role of SOFA score in selecting candidates for upfront DEN has not been established yet. The aim of our study was to assess the upfront endoscopic necrosectomy for infected WON based on SOFA score > 2 in choosing upfront DEN [1–3].

Methods A retrospective analysis of a prospectively collected database was conducted on patients who underwent endoscopic drainage and necrosectomy for symptomatic pancreatic WON at one tertiary referral center between September 2023 and September 2025. Patients were divided into: Group 1 included patients with upfront DEN and infection with SOFA score > 2 and group 2 with step-up therapy with infections and SOFA score < 2 or no infection. QNI classification was used for initial characterization of WON. The choice of LAMS or plastic stent was performed by the endoscopist according to the WON features. Infection resolution was defined by clinical improvement (absence of fever and septic signs) and biochemical response (reduction of CRP < 2 mg/dl or normalization of procalcitonin). Radiological improvement was recorded when available, but was not required for defining infection clearance. Clinical success was based on radiological WON resolution < 30 mm at the 3-month imaging follow-up.

Results The distribution of patients into group 1 (n = 11) and group 2 (n = 49) was similar for age, sex, and size of WON (120.45 ± 36.95 mm vs 103 ± 40 mm), ≥ 3 quadrants involvement (54.5 % vs 30.6 %, p = 0.169) or necrosis ≥ 30 % (81.8 % vs 49 %, p = 0.091). Infected WON were significantly more common in the group 1 compared with the group 2 (100 % vs 16.3 %, p < 0.001).

LAMS were used similarly in the two groups (6/11, 55 % in Group 1 vs 26/49, 53 % in Group 2, p = 1.00). The mean number of DEN sessions (2.64 ± 1.57 vs 2.04 ± 1.51, p = 0.270), the need for > 3 DEN (36.4 % vs 22.4 %, p = 0.563) or additional percutaneous, surgical, or ERCP procedures did not differ significantly (3/11 vs 10/49, p = 0.690).

Clinical success was 100 % and 81,6 % (p = 0,15), while time to infection resolution was 13.9 days in Group 1 and 10.9 days in Group 2 (p = 0,054). Complication rates (18.2 % vs 16.32 %, p = 0.847) and overall mortality at 3 months (0 % vs 8.2 %, p = 1.00) were similar between groups.

Conclusions Selection based on high SOFA score for upfront DEN in WON assures similar outcome to lower SOFA scores patients, without influencing the outcome, the number of DEN or additional procedures, complications or mortality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP840 Evaluating ChatGPT-5 for the Classification of Colorectal Polyp Images: A Comparative Analysis with Two Expert Endoscopists

Authors Ait Errami A[1], Zouaki I[2], Fatima Ezzahra L[1], Nacir O[3], Krati K[1]

Institutes **1** CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco; **2** UHC MED VI, Marrakesh, Morocco; **3** MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco

DOI 10.1055/s-0046-1822167

Aims Accurate characterization of colorectal polyps is essential for estimating neoplastic risk and guiding appropriate therapeutic management. However, endoscopic interpretation varies among clinicians, particularly in the classification of polyp morphology and surface patterns. Artificial intelligence (AI) systems may assist clinicians by improving diagnostic consistency.

Methods This single-center, retrospective observational study evaluated the agreement between ChatGPT-5 and two expert endoscopists in interpreting colonoscopic images of colorectal polyps. A total of 45 images were analyzed. ChatGPT-5 was prompted to assign Paris and NICE classifications and to predict neoplasia. The primary outcome was the level of agreement between ChatGPT-5 and experts across classification systems. Secondary outcomes included diagnostic accuracy for neoplasia prediction.

Results ChatGPT-5 demonstrated moderate agreement with endoscopists for neoplasia prediction (κ = 0.42), but lower agreement for Paris (κ = 0.31) and NICE classification (κ = 0.39). Diagnostic performance showed an overall accuracy of 71.1 %, sensitivity 76.0 %, specificity 66.7 %, PPV 72.0 %, NPV 71.0 %, and an AUC of 0.74. Notably, ChatGPT-5 struggled with flat lesions and subtle vascular patterns, leading to discrepancies in classification compared with experts.

Conclusions ChatGPT-5 demonstrates moderate accuracy in the visual interpretation of colorectal polyp images but remains inferior to expert assessment, particularly for detailed morphological classifications. While its performance indicates potential as an adjunctive support tool, significant limitations persist, and further refinement is required before integration into routine colonoscopic decision-making.

eP841V Cold- Endoscopic Submucosal Dissection: Time to Go Further?

Authors Fraile-Lopez M[1], Terán Á[1], Cagigal ML[2], Adolfo PB[3]

Institutes **1** Gastroenterology and Hepatology Department, Marqués de Valdecilla University Hospital, Santander, Spain; **2** Pathology Department, Marqués de Valdecilla University Hospital, Santander, Spain; **3** Nottingham City Hospital Campus, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

DOI 10.1055/s-0046-1822168

Abstract Text

Colonic ESD is increasingly popular in Western countries. However, it still not fully implemented due to its long learning curve and associated risks. A 68-year-old woman presented a 30-mm flat serrated lesion in the transverse colon with a 12-mm dysplastic area (JNET 2B, Kudo IIIL) proposing for en-bloc resection. Cold-ESD, minimizes electrocautery to reduce thermal injury and perforation risk. After submucosal injection, a stepwise mucosal incision was created using biopsy forceps, followed by early clip-band traction. Submucosal dissection proceeded with rotatable scissor-type knives (Clutch-Cutter/Coag Dissector), enabling blunt dissection and vessel coagulation. Histology confirmed HGD with clear margins. Cold-ESD appears to enhance safety for colonic ESD. Further development of dedicated instruments may facilitate broader adoption [1–10].

eP842 A systematic review of video game interventions in technical skills training

Authors Shanahan W[1], Doherty G[2], Egan L[1], Slattery E[1]

Institutes **1** University Hospital Galway, Galway, Ireland; **2** St. Vincent's University Hospital, Dublin, Ireland

DOI 10.1055/s-0046-1822169

Aims Endoscopy, laparoscopy, and robotic surgery share similar training difficulties; new hand movements and interpretation of real-life three-dimensional environments on two-dimensional screens. Such adjustments overlap with video gaming which may offer repeated, low-stakes opportunities to develop the common psychomotor, visuo-spatial, and perceptual speed abilities. Whether this skill transferability may be harnessed as a training adjunct for procedural novices is the subject of multiple studies to date. This systematic review aims to summarise and analyse the evidence for the use of video game interventions in training clinical technical skills.

Methods A systematic search of PUBMED, EMBASE, CINAHL, and SCOPUS was performed using a combination of MeSH/Emtree/CINAHL/free terms. The searches were formulated using the Population (novice proceduralists), Intervention (video gaming), Comparator (any), Outcome (procedural performance) (PICO) framework. Peer review of the electronic search strategy was performed prior to search performance on October 1st, 2025. Citation searching was also performed. Inclusion criteria were full published English language texts, of prospective nature, including videogame intervention(s), aimed at procedural competency, involving healthcare professionals in training or service. Texts were excluded if no procedural assessment was performed, or medical content focused serious games were used in the intervention. Risk of bias in studies was assessed using Cochrane's ROB2 and ROBINS-I V2 tools for randomised and non-randomised studies respectively. Studies determined to be at high or serious/critical risk of bias were excluded. The systematic review was performed in accordance with PRISMA guidelines. The review was registered on PROSPERO (CRD420251159486).

Results 1418 records were identified. Following the removal of duplicates (451), abstract screening (886), eligibility evaluation (55), and bias assessment (9), seventeen records were included in the review. Two included studies pertain to endoscopy. The remainder relate to laparoscopy (9), microsurgery (3), bronchoscopy (1), suturing (1), and ultrasound (1). Narrative synthesis was performed owing to the heterogeneity of study designs and outcome measures. Two study approaches were identified; the use of video games for task warm-up, and the use of video games as non-procedural training. Of five studies using videogames for task warm-up, four demonstrated positive result elements. Positive results have been demonstrated in the contexts of both task naivety and prior exposure. Eight of twelve studies using video games as non-procedural training demonstrated positive result elements. Of all included studies, only one study included patient-based assessment. Seven studies tested clinicians, with the remainder involving students only. The Nintendo Wii was the most utilised console, used in six of seventeen studies.

Conclusions By comparison to surgical skills, there is a dearth of quality literature on the use of video games to aid the performance of novice endoscopists. Videogames have been repeatedly demonstrated to benefit technical skills performance, in the context of procedural warm-up and training. More high-quality studies are needed in endoscopy to determine if videogames may lead to improved performance. Additionally, studies are required on the transferability of skills to patient based clinical performance.

DOI 10.1055/s-0046-1822170

Aims To evaluate efficacy and safety of Argon Plasma Coagulation (APC) in the treatment of various gastrointestinal lesions

Methods This is a retrospective, descriptive, and monocentric study conducted at the gastroenterology department of the Bab El Oued university hospital, including all patients who underwent APC for various indications between January 2022 and October 2025. Data on patient demographics, indications, technical success, complications, and follow-up were collected and analyzed.

Results We collected data from 114 patients with a mean age of 67.69 years and a sex ratio of 1.92. The indications for APC were gastrointestinal bleeding related to: angiodysplasias in 45.61 % of cases (80.76 % colonic, 15.38 % gastric, and 3.86 % duodenal), radiation proctitis in 35.08 % of cases (32 cases of prostate cancer and 8 cases of cervical cancer) , severe hypertensive gastropathy in 14.03 % of cases, and solitary rectal ulcer in 5.28 % of cases. Most patients required multiple APC sessions, and technical success was achieved in 111 patients (97.37 %). No complications were observed in this series.

Conclusions APC is a reliable and well-tolerated treatment option for patients with gastro-intestinal bleeding and other lesions, offering a high technical success rate and minimal risk of complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP844 EUS-guided gastrogejunostomy (EUS-GJ) vs. gastric partitioning gastrojejunostomy (GPGJ) in malignant gastric outlet obstruction (MGOO) in patients with higher survival (>5 months): a comparative analytical study

Aims The development of EUS-GJ has largely replaced GPGJ, the traditional surgical approach, for patients with MGOO. However, in patients with higher survival, there are doubts as to whether this approach offers better results, due to the lower recurrence rate it has classically been associated with.

The main objective of the study was to compare the recurrence rate of MGOO symptoms between EUS-GJ and GPGJ in patients with longer survival. The secondary objectives were to compare the baseline characteristics, survival rates, technical aspects and adverse events between EUS-GJ and GPGJ in patients with MGOO and longer survival.

Methods We designed a retrospective, single-centre, observational study. Patients with MGOO and >5 months post-procedure survival were considered.

A search in the clinical history of these patients was conducted, including suitable patients until October 2025. We defined clinical success as the recovery of oral tolerance (GOOS ≥ 2) after the procedure and recurrence as a loss of oral tolerance (GOOSS = 0) at any point after the procedure.

Results In total, 36 patients were included (26 EUS-GJ vs. 10 GPGJ). The only statistically significant differences we found in their baseline characteristics were in tumoral etiology (the GPGJ group only included gastric and duodenal tumors, while the EUS-GJ group included other etiologies, p = 0.043) and stricture location (the GPGJ group mostly included pyloric stricture, while the EUS-GJ group included strictures at other locations, p = 0.081).

There were no statistically significant differences in clinical success (100 % for both groups) or immediate adverse events (11.54 % EUS-GJ vs. 0 % GPGJ, p = 0.262). All the adverse events were managed during the index endoscopic procedure itself (AGREE IIIa). There were also no significant differences in the days of admission between both groups (13.3 EUS-GJ vs. 19.1 GPGJ, p = 0.1211).

After a median survival time of 286 days, we observed 3 recurrences in the GPGJ group, compared to 1 in the EUS-GJ group. The cumulative incidence of recurrence at 6 and 12 months was 20 % and 30 % (GPGJ) vs. 3.84 % and 3.84 % (EUS-GJ). The log-rank test showed a significant difference in recurrence-free survival between both groups (p = 0.016). The recurrences in the GPGJ group were all managed conservatively, while the recurrence in the EUS-GJ group could be treated with the placement of a new stent.

No statistically significant differences were found between the survival rates of both groups (p = 0.8682).

Conclusions We found EUS-GJ is an effective approach for the treatment of MGOO in patients with longer survival. In comparison with GPJG, EUS-GJ is less invasive, and in our study, it even presents a lower rate of recurrence. Therefore, EUS-GJ could be considered as a first-line therapy for these patients. However, these results need to be confirmed with prospective intervention studies.

eP845 Endoscopic Management of Biliary Complications Post-Liver Transplant: A 5-year national experience from Bulgaria

Authors Hinkova G[1], Katzarov A[1], Katzarov K[1], Konaktchieva M[1]
Institute 1 Military Medical Academy, Sofia, Bulgaria
DOI 10.1055/s-0046-1822172

Aims Investigate the rate and types of biliary complications post-liver transplant and the management via endoscopic treatment in Bulgaria.

Methods A retrospective observational study was conducted on 37 patients who underwent orthotopic liver transplantation (OLT) from a deceased donor over five years (from May 2021 until Sept 2025). Biliary complications were assessed through patient history, lab tests, and imaging (computed tomography (CT)/magnetic resonance cholangiopancreatography (MRCP). Endoscopic treatment was performed via endoscopic retrograde cholangiopancreatography (ERCP). We utilized frequency distribution to analyze the occurrence of various biliary complications and descriptive statistics to assess the proportion of patients who achieved successful endoscopic treatment.

Results Fourteen patients (approximately 37.8 %) experienced biliary complications – had signs of cholangitis, jaundice or pruritus, presented with elevated liver enzymes with or without high bilirubin levels, had CT/MRCP showing biliary changes. Early complications (within 6 months) were noted in 11 patients; late complications (after 6 months) in 3. Main complication was stenosis of the biliary anastomosis (10 patients), the remaining 4 patients experienced the following complications: 2 had necrosis at the biliary anastomosis site, 1 presented with a leakage, and 1 had both leakage and stenosis at the biliary anastomosis. Nine patients were treated endoscopically, 4 surgically, and 1 conservatively. Eight of these 9 patients had stenosis of the anastomosis.

The endoscopic group showed a resolution rate of 66.7 % (6 out of 9), 2 other patients are still undergoing treatment, and 1 patient unfortunately passed away due to complications related to thrombosis of the arterial anastomosis and sepsis. Six patients were treated with multiple plastic stents, and 3 patients received self-expandable metal stents (SEMS). For the group treated with plastic stents, an average of 5 ERCP procedures and 3 or 4 stents were required for successful treatment. In the SEMS group, 2 patients achieved resolution of the stenosis after a single ERCP session for stent insertion, with the SEMS removed after 10 months. The use of single-operator cholangioscopy (SOC) aided complex cases (3 patients).

Conclusions The incidence of biliary complications has decreased in recent years (from 42.8 % in previous years (2007-2019, no OLT were performed in 2020) to 37.8 % in the study period). The predominant issue identified was stenosis of the biliary anastomosis, which occurred in the majority of cases. Endoscopic treatment emerged as a key approach. Notably, the use of SEMS proved effective, with successful outcomes achieved after fewer ERCP sessions compared to plastic stents which leads to lower risk of infections in this immunocompromised cohort of patients and also lower costs. However, the small sample size limits definitive conclusions. The implementation of single-operator cholangioscopy (SOC) also showed promise in addressing complex cases. Further studies with larger cohorts are warranted to refine treatment protocols and improve patient outcomes in this challenging area of post-transplant care.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP846 A rare case of upper gastrointestinal bleeding: A diagnosis hidden in the dark

Authors Allo G[1], Chon SH[2], Neumann-Haefelin C[1], Kasper P[1]
Institutes 1 Klinik und Poliklinik für Gastroenterologie und Hepatologie der Uniklinik Köln, Cologne, Germany; 2 Klinik und Poliklinik für Allgemein-, Viszeral- und Tumorchirurgie, Köln, Germany
DOI 10.1055/s-0046-1822173

Abstract Text

A 74-year-old woman presented to the emergency department with a three-day history of nausea, vomiting and melena. Her medical history included chronic obstructive pulmonary disease and a curative resection of pancreatic adenocarcinoma with duodenojejunostomy performed three months ago. Her regular medication included torasemide, pantoprazole, pravastatin, duloxetine and olanzapine, while recent intake of other substances was denied. On admission she was hypotensive, hypothermic and she had a heartrate of 93 bpm. The further clinical physical examination was unremarkable. Laboratory testing revealed markedly elevated inflammation parameters while hemoglobin and lactate levels were normal.

Emergency esophagogastroduodenoscopy (EGD) was performed for suspected gastrointestinal bleeding and revealed a circumferential black discoloration of the lower two thirds of the esophagus with a sharp demarcation at the gastroesophageal junction and no involvement of the stomach. Beyond the stomach, the small intestine also exhibited blackened friable mucosa. No active bleeding was detected. (Panel A)

Based on the clinical, laboratory and endoscopic findings, what is the diagnosis? - Acute esophageal necrosis (AEN) accompanied by concurrent small bowel necrosis was established.

AEN, also known as “black esophagus”, is associated with high mortality rates of about 30 % [1, 2]. AEN is commonly associated with cardiovascular disease, malignancy, hyperglycemia, malnutrition, cocaine use and sepsis. [3, 4].

Patients commonly present with signs of gastrointestinal bleeding, with the diagnosis typically made via endoscopy. While some cases of AEN have been reported previously, simultaneous small bowel involvement is very rare [2].

Endoscopy 2026; 58: S1–S1041

The pathogenesis of this phenomenon is incompletely understood and probably results from synergistic effects of ischemic insult and impaired mucosal defense against gastric acid, particularly in the hypoperfused regions supplied by the celiac axis. Further management includes the exclusion of complications such as esophageal perforation, supportive pharmacotherapy with proton pump inhibitors and treatment of comorbidities.

Subsequent contrast-enhanced tomography showed no signs of perforation or vascular abnormality. The patient was treated with high-dose proton pump inhibitors and broad spectrum antibiotics. A follow-up EGD on day three revealed substantial mucosal healing (Panel B). Enteral nutrition was gradually reintroduced and tolerated well. Inflammatory parameters normalized and the patient was referred to a local hospital for further rehabilitation after 14 days.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP847 Recurrent periampullary bleeding in a transplant recipient: Navigating a complex clinical scenario

Authors Erasmus HP[1], Friedrich-Rust M[1], Martin S[1], Mihm U[1], Dultz G[1], Welsch C[1], Heise M[1], Michael F[1]

DOI 10.1055/s-0046-1822174

Abstract Text

A 76-year-old male liver-transplant recipient (HBV-associated cirrhosis with prior HCC) initially presented for routine check-up without complaints. Shortly afterwards, he developed a superficial leg vein thrombosis and was started on rivaroxaban by his GP. Three weeks later, he returned with weakness and melaena to our hospital. Laboratory tests revealed severe anaemia (haemoglobin 6.5 g/dL) with otherwise stable liver and renal parameters. Emergency gastroscopy showed active periampullary bleeding with clot and a suspected subepithelial mass. A side-view examination was attempted but adequate visualization was impossible due to persistent bleeding. CT angiography demonstrated active extravasation from the gastroduodenal artery and a 2.9-cm duodenal mass. Selective angiography confirmed bleeding from the pancreaticoduodenal arcade, which was temporarily controlled by embolization.

Subsequent ERCP excluded papillary bleeding but revealed an infiltrative periampullary lesion. Histology confirmed moderately differentiated duodenal adenocarcinoma. Staging showed no metastases, and surgery was planned. In March, exploratory laparoscopy demonstrated tumour infiltration of the mesenteric root, rendering resection unfeasible. Palliative treatment was initiated. Following surgery, galliferous wound drainage and cholangitis developed, accompanied by multiple enterocutaneous fistulas requiring continuous wound-bag management. Progressive distal bile duct obstruction prompted repeated ERCPs with metal-stent placement and extensive lavage. Due to pronounced intra- and extrahepatic cholestasis with severe cholangitis, an emergency CT-guided PTCD was placed but could not be internalized into the small intestine. Via subsequent ERCP a covered self-expandable metall stent was placed to allow for internal drainage.

The patient's condition deteriorated with abdominal pain, weakness, and malnutrition. Planned palliative chemotherapy was cancelled owing to reduced performance status. He was transferred to the palliative care unit 2 months later with ECOG 3–4 status, persistent fistulas, post-prandial pain, and general decline. Supportive care included nutritional support, analgesic optimization, antibiotics for recurrent cholangitis, wound and stoma care, physiotherapy, and psycho-oncology. Gradual stabilization allowed discharge to a hospice care 1 month later, where he passed shortly thereafter.

This case underscores the complexity of managing periampullary malignancy in transplant recipients, requiring tightly coordinated multimodal and palliative care.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP848 Upper esophageal sphincter (UES) alterations in achalasia before and after per-oral endoscopic myotomy (POEM): a prospective observational study protocol and evidence-based rationale

Authors Dioscoridi L[1], Pugliese F[2], Bonato G[3], Gallo C[4], Stegagnini M[1], Cintolo M[2], Palermo A[2], La Mantia A[2], Forti E[2], Mutignani M[5]

Institutes 1 ASST Great Metropolitan Niguarda, Milano, Italy; 2 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy; 3 ASST Great Metropolitan Hospital Niguarda, Milano, Italy; 4 ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy; 5 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy., Milan, Italy

DOI 10.1055/s-0046-1822175

Aims Alterations of the upper esophageal sphincter (UES) are frequently reported in patients with esophageal achalasia and appear to relate to the degree of esophageal pressurization and impaired bolus transit. Several retrospective and short-term series suggest that POEM, while targeted to the lower esophageal sphincter (LES), may also change proximal esophageal motility and reduce UES resting and residual pressures with symptom improvement.

The aim of the study was to prospectively quantify UES structural/functional abnormalities in treatment-naïve achalasia patients, and to determine the long-term effects of POEM on UES metrics, proximal esophageal motility, and relevant clinical outcomes (dysphagia, regurgitation, cough, aspiration risk) [1].

Methods Study design: single-center prospective observational cohort.

Population: consecutive adult patients with manometrically confirmed achalasia (Chicago Classification v4.0) scheduled for primary POEM.

Assessments and timing: High-resolution manometry (HRM) with standardized UES protocol (resting pressure, residual pressure during wet swallows), at baseline and 12 months post-POEM.

Symptom scores: Eckardt score at baseline and 12 months after POEM

Primary endpoint: change in UES basal and residual pressure (pre- to 12 month post-POEM) 1) evaluation of changes in UES pressures before and after POEM; 2) correlation between Eckradt score and changes in UES pressures.

Secondary endpoints: try to obtain a cut-off value of UES change and symptom improvement (Eckardt score) after POEM; define risk factors to residual UES dysfunction.

Results Out of 179 patients from 2019 to 2024, 27 were selected for the present study. 152 have missing data needed to obtain primary and secondary outcomes or were affected by other esophageal motility disorders. Three patients had achalasia type I with mean UES basal pressure 51,5 mmHg with mean residual pressure 9,3 mmHg. After POEM, these patients had mean UES basal pressure 86,7 mmHg and UES residual pressure 10,7 mmHg.

Eckardt score generally decreased in these patients with a mean 7 before and a mean 2 after POEM.

22 patients had type II achalasia with mean UES basal pressure 75,1 mmHg and residual pressure 17,7 mmHg. After POEM, mean UES basal pressure became 66,9 mmHg and residual pressure 9,5 mmHg. Eckardt score generally decreased also in this group with a mean value of 8 before and a mean value of 1 after POEM.

The remaining two patients had type III achalasia with a mean UES basal pressure 45,8 mmHg and residual pressure 6,4 mmHg. After POEM, mean UES basal pressure and residual pressure were reported respectively 52,6 mmHg and 2,8 mmHg.

Eckardt score decreased in both cases from a mean of 8,5 to a mean of 1 after POEM.

Although in type I and III significant correlations cannot be found due to the small number of patients, in type II patients > 65 years tend to have lesser post-POEM UES pressures decrease (mean pre-POEM UES basal 45,5 mmHg residual 15,3 mmHg vs post-POEM UES basal 42,2 mmHg residual 10,3 mmHg). Furthermore, higher post-POEM UES residual pressure > 12 mmHg was related to higher Eckardt score that points to a role of UES pressure on dysphagic symptoms (mean post-POEM Eckardt score 3 vs mean post-POEM Eckardt score 1,2).

Conclusions Our prospective, standardized evaluation of UES metrics before and after POEM evidenced the prevalence and mechanisms of proximal sphincter dysfunction in achalasia, define the UES recovery after LES myotomy especially in achalasia type II, and identify older age and post-POEM UES residual pressure > 12mmHg as risks for persistent symptoms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822176

Aims A biliary stricture is a narrowing of the bile ducts with upstream dilatation. Since most cases are malignant, histological diagnosis is essential. ESGE guidelines recommend an integrated diagnostic approach that combines multiple techniques to improve diagnostic accuracy. In this setting, Endoscopic ultrasound (EUS) tissue acquisition (TA) has demonstrated good sensitivity (83 %) being the preferred diagnostic modality for both imaging and TA, even in absence of abnormal laboratory test. The introduction of ancillary techniques as DFI (Detective Flow Imaging), which enables the detection of low-velocity blood flow without the use of contrast media, represents a potential useful addition in the diagnostic algorithm. The aim of this study is to assess the feasibility of performing the novel DFI-EUS technique in the setting of biliary stricture and its capability to evaluate the presence and type of stricture microvascularization [1–3].

Methods Single-centre retrospective study on the role of EUS-DFI in characterizing unexplained biliary strictures and CBD dilatation. We included consecutive patients with unexplained biliary strictures/CBD dilatation who underwent biliopancreatic EUS between January 2024 and October 2025 at the Digestive Diseases Unit of Sant'Andrea University Hospital, Rome. A convex echoendoscope (EG-740UT; Fujifilm) and an ultrasound system (ARIETTA 850; FUJIFILM Medical Co., Ltd., Tokyo, Japan) were used. During EUS for biliary stricture evaluation (lesions or thickening of CBD wall), DFI was performed and if microvascularization was observed, vascular pattern was classified as regular or irregular. Results were compared with the final diagnosis, defined by histopathology obtained with EUS-TA or ERCP-based sampling and/or ≥ 6 months clinical follow-up as gold standard. TA was performed with EUS-FNB (fine needle biopsy) and/or ERCP (Endoscopic Retrograde Cholangiopancreatography) intraductal biopsies/brushing (▶ **Table 1**).

▶ **Table 1**

Type of CBD Stricture(n = 19)	Hypovascularization (n = 2)	Microvascularization (n = 17)	Regular pattern (n = 3)	Irregular pattern (n = 14)
Fibroinflammatory (n = 4)		3/3	2	1
PDAC (n = 4)	1/4	3/4		3
Cholangiocarcinoma (n = 8)		8/8		8
Dysplasia (n = 3)	1/3	2/3		2

Results Nineteen patients included (12(63 %) male; median age 75). All underwent MRI/ Contrast-Enhanced CT as first line imaging: 4(21.1 %) had a perihilar stricture, 14 (73.7 %) a medio-distal, 1(5.3 %) had "in toto" CBD thickening. Among all, EUS identified 16 (84 %) lesions (mean diameter 17 mm) and 3 (15.8 %) CBD wall thickening. Eighteen (94 %) strictures were hypoechoic, 1 (6 %) isoechoic. EUS-TA was performed in all patients, revealing 12(63 %) malignancies (8 cholangiocarcinomas, 4 PDAC), 3 (16 %) dysplasias, 4 (21 %) fibroinflammatory strictures. In 6 cases (31.6 %) a second look TA < 6 months was needed to obtain the final diagnosis. In all pts DFI-EUS was feasible. Microvascularization was detected in 17 cases (89 %), with an irregular pattern observed in 14(73.7 %) patients. Among these, 8(57 %) cholangiocarcinoma, 3(14.3 %) PDAC, 2(14.3 %) dysplasia, 1(7.1 %) inflammatory disease. A regular pattern was detected in 3 (15.8 %; all benign strictures). Hypovascularization was shown in 2(10.5 %) cases (1 PDAC; 1 dysplasia).

Conclusions In a small cohort of patients with indeterminate biliary strictures, the novel DFI-EUS technique proved to be feasible for assessing microvascularization in CBD stenosis and revealed characteristic irregular patterns or hypovascularization in malignant lesions and dysplasia. Further prospective studies with larger population are needed to confirm these preliminary findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP850 Performance of TOP100 Software in Detecting Key Small Bowel Findings at Capsule Endoscopy

Authors Devanand A[1], Moore M[1], Tai FWD[1], Hale M[1], Bentley C[1], Thurston V[1], Healy A[1], McAlindon M[1], Nandi N[1], Sidhu R[2, 1]
Institutes **1** Academic Unit of Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK, United Kingdom; **2** Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom
DOI 10.1055/s-0046-1822177

Aims Capsule endoscopy (CE) is a non-invasive diagnostic modality that has become a valuable tool for evaluating small bowel (SB) pathology. Despite its clinical value, it is limited by the time required for complete video interpretation and the associated reader fatigue. Studies have shown that accuracy drops even in the hand of experts after just one video. Artificial intelligence software has been developed to assist the reporting process. TOP100 is an integrated software that selects 100 images most likely to contain abnormalities (1). The aim of this study was to assess the overall diagnostic performance of TOP100 for specific SB findings in real-life clinical practice, by comparison with the standard reader together with its performance across different clinical indications [1].

Methods A retrospective single-centre cohort study was conducted at our tertiary referral centre. We included all consecutive patients who underwent CE using the PillCam SB3 system between January 2024 to August 2025. Data collected included: baseline demographics, comorbidities, previous endoscopy and laboratory findings, indications for CE, adequacy of bowel preparation. CE findings were compared between the standard reader (SR) and a second reader using the TOP100 images, who was blinded to the original report. All CE readers had read > 500 CE in their lifetime.

The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NVP) of TOP100 were compared to the SR (gold standard) for each type of CE finding (inflammatory, bleeding etc). A sub-analysis of diagnostic accuracy was also performed based on the CE indication.

Results A total of 812 patients were included, however 5 were excluded from the analysis, with 3 unable to swallow the capsule and 2 lacking available Top100 readings. The final analysis comprised of 807 patients (57 % female, median age 53 years, IQR 34–65). The most common indications were suspected or known inflammatory bowel disease (IBD) (50 %), and iron-deficiency anaemia (24 %). In 88 % of patients the bowel prep was adequate and 90 % had a complete examination. Median SB transit time was 3h51mins (2h46 – 4h50m).

The diagnostic yield of findings at CE was significantly higher by SR compared to TOP100 (40 % vs 29 %, $p < 0.01$). For any indication, the sensitivity and specificity of TOP100 for active bleeding was 58 % (54 %-61 %) and 97 % (95 %-98 %), and for angiodysplasias was 58 % (54 %-61 %) and 97 % (95 %-98 %), respectively. In patients with overt bleeding, TOP100 identified 80 % of the total angiodysplasias and 71 % of active bleeding reported by SR, with a sensitivity and specificity for P2 lesions of 65 % (59 %-77 %) and 100 % (100 %-100 %), respectively. The overall sensitivity and specificity of TOP100 for ulcers was 53 % (49 %-56 %) and 96 % (94 %-97 %), and for erosions was 40 % (40 %-44 %) and 90 % (88 %-92 %). In patients with suspected or known IBD, the diagnostic performance of TOP100 for ulcers was similar, while sensitivity improved for erosions by almost 12 %.

Conclusions SR remains the reference standard for reading and reporting CE, however TOP100 can be a useful tool for quick preview of the video to assist in capsule reading and identifying cases that needs to be prioritized – especially in high volume centres. The diagnostic performance is also dependent on the indication of CE with improved performance noted in bleeding and IBD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP851V Complex Hepatico-jejunostomy Stricture (HJS): Single-session Drainage using EUS-guided Hepatico-jejunostomy via LAMS to salvage failed EUS-Directed trans-Enteric ERCP (EDEE)

Authors Martinez-Cuevas C[1], Sanjose A[1], Cobreros del Caz M[1], Sánchez-Ocaña R[1], De La Serna Higuera C[1], Perez-Miranda M[2]
Institutes **1** Rio Hortega University Hospital, Valladolid, Spain; **2** Hospital Universitario Rio Hortega, Valladolid, Spain
DOI 10.1055/s-0046-1822178

Abstract Text

EDEE failed despite successful through-the-LAMS limb access in a post-Whipple patient with relapsing cholangitis and a complex benign HJS without intrahepatic dilatation. Direct jejunal EUS-guided needle puncture from the efferent jejunum allowed target distention and freehand 20-mm LAMS placement into the afferent limb. After jejuno-jejunal LAMS-balloon dilation a gastroscope was advanced to the HJS. The surgical anastomosis could not be found. A linear EUS scope was then carefully passed through the LAMS. The left hepatic duct was imaged and punctured under combined EUS & fluoroscopy. Cholangiography confirmed bilateral HJS stricture with sclerosing cholangitis. A plastic stent was placed into the LHD from the afferent jejunum. Post-procedure bleeding was managed endoscopically and biliary drainage re-established.

DOI 10.1055/s-0046-1822179

Aims Bowel obstruction is a common clinical manifestation in colorectal cancer, occurring in up to 29 % of cases, and the prognosis for these patients is significantly worse at the same stage. Self-expanding metal colonic stents represent a therapeutic alternative to surgery for the urgent relief of acute colonic obstruction prior to curative surgery or for palliative treatment in inoperable patients. The aim of this study is to evaluate the effectiveness of self-expanding metal colonic stents and to define their role in the management of tumor-related colonic obstruction.

Methods This is a retrospective study conducted in our department over a 4-year period between September 2021 and September 2025. Twenty-five patients with tumor-related colonic obstruction who were treated with colonic stents were included.

Results The mean age of our patients was 53 years, with a sex ratio of 2.57. Most patients presented clinically with a bowel obstruction syndrome, including cessation of stool and gas passage. Abdominal X-rays showed air-fluid levels in all patients, and CT scans revealed a stenosing colonic tumor with upstream bowel dilation in 19 patients.

The indication for colonic stent placement was palliative in 20 cases and preoperative in 5 cases. All patients underwent stent placement via colonoscopy under general anesthesia.

Subsequent treatments following stent placement included chemotherapy in 11 cases, curative surgical resection in 5 cases, and a stoma in 2 cases, while the remaining 7 patients received no further treatment.

The technical success rate, defined by proper placement and deployment of the colonic stent, was 95 %. Clinical success, defined as relief of colonic obstruction within 48 hours without the need for re-intervention, was achieved in 90 % of cases.

Immediate outcomes were favorable in all patients. No immediate complications were reported, and the mean hospital stay was three days. Stent migration occurred in one patient after 8 months.

Conclusions Colonic stents represent an effective alternative to surgical treatment for symptomatic tumor-related colonic strictures, either to allow preparation for elective curative surgery or for palliative purposes before initiating potential chemotherapy.

eP853 Endoscopic Treatment Rationale of Gastric Antral Vascular Ectasia (GAVE): a type-based efficient approach

Authors Dioscoridi L[1], Corradi M[2], Tontini GE[3], Mutignani M[4]

Institutes **1** ASST Great Metropolitan Niguarda, Milano, Italy; **2** ASST MELEGNANO MARTESANA, Milano, Italy; **3** Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Gastroenterology and Endoscopy, Milan, Italy; **4** Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy., Milan, Italy

DOI 10.1055/s-0046-1822180

Aims Gastric antral vascular ectasia (GAVE) is an uncommon but clinically significant cause of chronic gastrointestinal bleeding and iron-deficiency anemia. Endoscopic therapy is the mainstay of treatment, particularly when medical management is insufficient. Multiple modalities have been evaluated, with differences in depth of injury, technical complexity, durability, and recurrence rates. Missing data on therapy related to morphology of GAVE are still awaiting [1].

The aim of the present study was to start to fill the literature gap to define an endoscopic rationale for treatment of GAVE

Methods A retrospective analysis on endoscopic treatment of GAVE was conducted in our tertiary referral center. The patients were divided in two groups depending on the morphology of GAVE: diffuse or nodular type. Primary endpoint was clinical success based on absence of Hb decrease and no need for blood transfusion at 6 months. Statistical analysis was accordingly performed.

Results 277 patients were included in the present study, 195 affected by diffuse type and 82 by nodular type. All patients with diffuse type were treated by thermal ablation (APC or dual emission laser ablation) showing 80 % of clinical success as defined in Methods. No patients with clinical insuccess were treated by EBL in this group.

Patients with nodular type were generally treated by APC as first line treatment (80 patients) and in two cases directly by EBL. APC treatment showed in this setting 60 % of clinical success (significantly lower than in the diffuse type). Furthermore, only 20 patients out of 80 were treated by EBL as secondary approach. These patients showed a cumulative clinical success of 87,5 %.

Statistical analysis confirmed a significant difference of clinical success in nodular type group between APC treatment and EBL (p = 0,01).

Conclusions Our study preliminarly demonstrate that thermal ablation is effective in diffuse type of GAVE while nodular type is better treated by EBL.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP854 Real-World Performance and Diagnostic Yield of Dual-Camera MiroCam Small Bowel Capsule Endoscopy in the United Arab Emirates: Analysis of 463 Consecutive Procedures

Authors Bukhari M[1], Borrow DM[2], Omar M[3]

Institutes **1** Dr Sulaiman Al Habib Medical Group, Dubai, United Arab Emirates; **2** St guys, London, United Kingdom; **3** New Mowasat hospital, Salmiya, Kuwait

DOI 10.1055/s-0046-1822181

Aims Small bowel capsule endoscopy (SBCE) is a key modality for evaluating obscure gastrointestinal bleeding, iron-deficiency anemia, and suspected small bowel disease. The dual-camera MiroCam capsule, increasingly used in the United Arab Emirates (UAE), provides enhanced mucosal visualization. Real-world dataOK from the region remain limited. This study evaluates the performance and diagnostic patterns of SBCE using the dual-camera MiroCam system in routine clinical practice.

Methods A retrospective review of **463 consecutive SBCE examinations** performed in a UAE tertiary center was conducted. Variables collected included demographics, completion rate, visualization quality, capsule retention, and predefined diagnostic categories (normal, inflammatory, ulcerative, vascular, structural). Descriptive statistics were generated.

Results A total of **463 patients** were included (mean age **48.7 years**, 55 % female).Technical performance was high:

- **Completion rate: 92 %**
- **Good/fair visualization: 96 %**
- **Capsule retention: 2.6 %**Diagnostic patterns (n = 463):
- **Normal studies:** 32.4 % (150/463)
- **Inflammatory lesions (mild–severe):** 36.1 % (167/463)
- **Vascular lesions:** 16.8 % (78/463)
- **Ulcerative lesions:** 11.2 % (52/463)
- **Structural abnormalities:** 1.9 % (9/463)

Inflammatory and vascular findings accounted for the majority of abnormal examinations. The dual-camera system provided high-quality visualization throughout the small bowel, supporting detection of both subtle and extensive lesions.

Conclusions In this real-world UAE cohort, dual-camera MiroCam SBCE demonstrated excellent completion and visualization rates with a low retention rate. Clinically relevant abnormalities were identified in over two-thirds of abnormal studies. These findings support the routine clinical use of dual-camera MiroCam SBCE for comprehensive small bowel evaluation in the UAE.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP855 Elevated eosinophil count at diagnosis is associated with the need for second-line treatment in patients with eosinophilic esophagitis (EoE)

Authors Ioannou A[1], Axiaris G[2], Pardalis P[1], Perlepe N[3], Delidis T[1], Dimitriadis K[1], Bakogiannis K[1], Leonidakis G[1], Vassilieva L[1], Zampeli E[1], Frangou E[3], Michopoulos S[1]

Institutes **1** Gastroenterology Department, "Alexandra" General Hospital of Athens, Athens, Greece; **2** Theageneio Anticancer Hospital of Thessaloniki, Thessaloniki, Greece; **3** Nicosia General Hospital, Strovolos, Cyprus

DOI 10.1055/s-0046-1822182

Aims Evaluation of prognostic factors associated with proton pump inhibitors (PPIs) treatment failure and the need for second-line therapy in patients with EoE.

Methods Retrospective study of patients with EoE treated with PPIs, during the decade 9/2013-9/2023. Data were collected prospectively. Demographic, clinical, endoscopic [Endoscopic Reference Score – EREFS] and histological characteristics were analyzed at diagnosis, at 24 weeks and then annually. Non-response was defined as a decrease of < 50 % in the Dysphagia Symptom Questionnaire (DSQ) score and/or > 15 eosinophils/hpf at histology at week 24,

while loss of response was defined as a relapse of the same parameters at the week 52 after an initial response.

Results Thirty-five patients (26Males/9Females), with a median age of 37 years [IQR (31-56)] and a median follow-up of 45 months [IQR (19-116)], were included. All patients received initial treatment with PPIs. Six (17.1 %) patients required second-line treatment, five (14.3 %) due to lack of initial treatment response and one (2.8 %) due to loss of response to PPIs within 20.5 months, [IQR (14.2-61). The number of eosinophils at histology at diagnosis [44.5 IQR (41.5 -66.3)] was higher than in PPIs responders [35, IQR (26-42)] (p = 0.009). These patients were also younger (median age 31.0 vs 30.5) and had a higher DSQ at diagnosis (mean 4.33 ± 0.76 vs 4.10 ± 0.24) though without statistically significant differences. In the ROC curve (AUC = 0.845, p = 0.009), the eosinophil count ≥ 41 predicted the need for second-line therapy with a sensitivity of 83.3 % and specificity of 71.4 % (PPV = 37.4 %, NPV = 95 %).

Conclusions 1) An increased number of eosinophils histologically at diagnosis is strongly correlated with failure of first-line treatment with PPIs in patients with Eosinophilic Esophagitis. 2) It may help predict PPI failure and indicate the need for earlier aggressive treatment.

eP856 A Gut Feeling? The role of faecal calprotectin in endoscopy

Author Tawfik A

DOI 10.1055/s-0046-1822183

Aims This retrospective study of 8264 patients in the Western Trust aims to establish the threshold at which faecal calprotectin levels are correlated with colonoscopy findings.

Methods The following retrospective observational study included a total of 8,264 patients who underwent colonoscopy at the Western Trust between 2022 and 2024. NIECR was used to view endoscopy reports. This allowed for a comparison of referral reasons and findings on colonoscopy, and subsequent correlation with FC levels, if included in the referral. Referral reasons included: raised faecal calprotectin over 50 µg/g, altered bowel habit, PR bleeding, IBD screening, IDA workup, and polyp/cancer screening. Findings on colonoscopy included polyps, Diverticulosis, haemorrhoids, known IBD, non-specific inflammation, tumours, new IBD, and normal findings.

Results Referral indications were: polyp/cancer screening (3,060), altered bowel habit (2,058), PR bleeding (1,627), iron deficiency anaemia (IDA) workup (446), raised FC (413), and IBD assessment (660). The Colonoscopy findings included polyps (2,959), Diverticulosis (1,736), haemorrhoids (941), known IBD (453), non-specific inflammation (248), tumours (161), new IBD (63; CD 10, UC 53), and normal findings (1,689).

Among the 413 patients referred for raised FC, 25 (6 %) were only diagnosed with new IBD (Female 10; Male 15; average age 46). The referral indications of the remaining 38 newly diagnosed IBD patients were PR bleeding (12), IBD screening (8), altered bowel habit (9), polyp/cancer screening (5), and IDA workup (4).

The vast majority of new IBD cases (70 %) had FC levels > 300 µg/g. Interestingly, the scope findings in the remaining 350 patients referred with raised FC were, Haemorrhoids (43), 25 % had FC levels > 300 µg/g, Diverticulosis (98) 25 % had FC levels > 300 µg/g, Polyps (62) 29 % had FC levels > 300 µg/g, indeterminate colitis and radiation proctitis (24) 37 % had FC levels > 300 µg/g, Tumour (7) 42 had FC levels > 300 µg/g, Normal (116), 22 % had FC levels > 300 µg/g.

Conclusions The study results affirm that although FC is as useful as a screening tool for IBD — particularly at levels greater than 300 µg/g — its value remains limited. One should be mindful of this when considering isolated rises in FC. Such results should be interpreted in the context of clinical presentation. Establishing a local threshold for FC-guided referral is thus essential to ensure appropriate use of endoscopy services for patients with gastrointestinal symptoms.

eP857 Conscious sedation failure in diagnostic endoscopic ultrasound: a single-centre study

Authors Prateek P[1], Malik J[1], Mylonas I[1], Zhang D[1], Wadsworth C[1], Simon D[1], Ahmed W[1]

Institute **1** Imperial College Healthcare NHS Trust, London, United Kingdom

DOI 10.1055/s-0046-1822184

Aims Conscious sedation (CS) failure in diagnostic endoscopic ultrasound (dEUS) remains poorly characterised. Understanding the demographic and clinical characteristics of patients who experience sedation failure with CS during dEUS is useful for risk stratification and the development of pre-procedural screening tools.

This study aims to characterise patients experiencing CS failure during dEUS procedures at a tertiary referral centre.

Methods A retrospective analysis was conducted on all patients undergoing dEUS, between October 2024 and September 2025. CS failure was defined as an incomplete procedure attributed to inadequate patient tolerance of sedation (agitation, paradoxical reaction, or intolerance to standard sedation regimens). Demographic data, comorbidities, sedation dosages, and clinical outcomes were extracted and described.

Results Thirteen patients (1.7 % of 765 procedures) experienced CS failure. The cohort was predominantly female (61.5 %, n = 8) with median age 60 ± 13.9 years (range 33–78). 23.1 % were current smokers (n = 3) and 15.4 % ex-smokers (n = 2). 23.1 % reported active alcohol use (n = 3). Complex comorbidities were prevalent, including chronic obstructive pulmonary disease (n = 2), chronic kidney disease/end-stage renal disease (n = 2), type 2 diabetes mellitus (n = 2), and psychiatric conditions including depression and prior intravenous drug use (n = 2). Despite high sedation doses – mean fentanyl 104.2 ± 30.3 mcg and mean midazolam 5.8 ± 1.7 mg – these patients failed to achieve adequate sedation. Procedural indications were predominantly pancreatic (n = 8) and biliary pathology (n = 2). Nine of these patients went on to have an EUS under general anaesthesia (GA). Of the remaining patients, one was referred for CT guided biopsy while the others were managed with non-invasive surveillance after multidisciplinary team discussion. There were no post-procedure adverse events at 30-day follow-up.

Conclusions In general, CS appears to be effective and well-tolerated for dEUS. Patients experiencing CS failure demonstrate a distinct clinical phenotype characterised by female predominance, and alcohol and smoking use history. Pre-procedural identification of these "hard-to-sedate" characteristics may enable risk-stratified sedation planning, with consideration for alternative approaches including deep sedation or general anaesthesia to improve procedural success and patient safety.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP858 Gastric pH Changes after Sleeve Gastrectomy and Roux-en-Y Gastric Bypass: preliminary results of a tertiary referral center

Authors Dioscoridi L[1], Girardi V[2], Salerno A[3], Mutignani M[4]

Institutes **1** ASST Great Metropolitan Niguarda, Milano, Italy; **2** Niguarda, Milan, Italy; **3** Istituto Nazionale per la Cura dell'Obesità, Clinica Galeazzi, GSD, Milan, Milan, Italy; **4** Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy., Milan, Italy

DOI 10.1055/s-0046-1822185

Aims Alterations in esophageal acid exposure are an important physiologic consequence of bariatric procedures and are closely linked to gastro-oesophageal reflux disease (GERD) symptoms and mucosal injury. Sleeve gastrectomy (SG) has been associated with new or worsened acid exposure in many series,

while Roux-en-Y gastric bypass (RYGB) is generally reported to reduce esophageal acid exposure and improve reflux [1].
The aim of the study is to evaluate if any alteration exists in gastric pH before and after bariatric surgery due to anatomical alterations.

Methods A prospective study was designed to determine gastric pH during EGDS before and after bariatric surgery. Gastric pH was mesured by aspiration of gastric pool during endoscopy. Comparison between patients who underwent SG and RYGB was performed to assess differences using chi-squared test. As secondary aim, esophagitis was considered as GERD index in both categories.

Results Till present date, 36 patients were studied. The complete trial will comprehend 100 patients.
Preliminary analysis shows a general decrease of gastric pH after bariatric surgery (mean preop value = 1.6 vs mean post-op value = 3.9, p value = 0,01) both in SG (mean post-op value = 3.7) and RYGB (mean post-op value = 4.1) without significant difference (p value = 0,1). Esophagitis was reported preoperatively in 8 patients (grade A in 4, grade B in 3, grade C in 1) and all these patients underwent gastric bypass. After bariatric surgery, esofagitis was seen in 8/22 patients (36,3 %) after SG and 0/14 after RYGB.

Conclusions Bariatric surgery shows a significant reduction of gastric pH in both SG and RYGB. This datum shows that GERD after SG is mainly related to increased pressure of the gastric remnant and underline the potential role of hypochloridia in post-bariatric malasorbption.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822186

Aims Saline-immersion therapeutic endoscopy (SITE) enhances visualization andhemostasis, but it alters electrosurgical behavior due to the high conductivity of saline, whichreduces tissue impedance and voltage stability. These effects may vary depending on the knifesize, as electrode diameter influences current density.

Methods An ex-vivo porcine gastric mucosa model was used to compare three electrosurgicalknives with different sizes, namely one with a thick electrode (HybridKnife T-Type, 1.5 mm), andtwo with thin electrodes (HYBRIDKnife flex I-Type, 0.5 mm; DualKnife J-Type, 0.4 mm). This wasperformed in air and under saline across seven electrosurgical modes (2 cutting, 3 coagulation and2 dissection modes). Electrical parameters (impedance, peak voltage, power output), cuttingsuccess, and lateral thermal spread, were measured during 252 standardized incisions. Statisticalanalysis was performed using both univariate and multivariate methods.

Results The average decrease in impedance when passing from air to saline immersion washigher for thick as compared with thin knives (92 % vs. 55 %, p<0.001) across multiple modes.Corresponding increase in power was also higher for thick (up to 19-fold) than for thin (up to 5-fold,p<0.001) knives, while peak voltage decreased by 30 % for thick knives and increased by 2 % forthin knives (p<0.001). Cutting success decreased from 57 % (CO 2) to 43 % (SITE) with the thickknife (p = 0.28), but it remained ≥ 71 % for thin knives. Lateral thermal spread increased from <1 mmin CO 2 to 1.35 mm (256 %) in saline for the thick knife, while it was ≤ 0.8 mm (71 %) for thin knives(p<0.001, between thin and thick knives), irrespective of the setting. Electrode diameter and salineimmersion were the strongest independent predictors of lateral spread (β = 0.469 and 0.353,respectively; both p < 0.001).

Conclusions The effect of saline immersion on impedance and voltage is dramatically higher whenusing thicker compared to thinner knives. This explains the differing tissue effects observed withvarying electrode sizes in third-space endoscopy.

eP860 EUS-guided Gastrojejunostomy: A UK Tertiary Centre Experience

Authors Kainth S[1], Dusserre Cordonnier C[1], Malik J[2], Prateek P[2], Zhang D[2], Yousaf A[2], Mylonas I[2], Wadsworth C[2], Ahmed W[2], Simon D[2]

Institutes **1** Imperial College London, South Kensington Campus, London, United Kingdom; **2** Imperial College Healthcare NHS Trust, London, United Kingdom

DOI 10.1055/s-0046-1822187

Aims Malignant gastric outlet obstruction (MGOO) is a significant complication of advanced malignancy, traditionally managed through surgical bypass or duodenal stenting. Endoscopic ultrasound-guided gastrojejunostomy (EUS-GJ) with lumen-apposing metal stents (LAMS) represents a minimally invasive alternative offering durable symptom palliation with lower morbidity than surgical approaches. Previous cohort studies have reported high technical and clinical success rates for EUS-GJ, but UK real-world data remain limited.
We aimed to evaluate the feasibility, safety, and clinical efficacy of EUS-GJ with LAMS in a UK tertiary centre cohort, with particular focus on length of stay, time to oral intake, and objective dietary progression using the Gastric Outlet Obstruction Score (GOOS).

Methods A retrospective service evaluation was undertaken of 13 consecutive patients undergoing EUS-GJ for MGOO between January 2024 and September 2025. All procedures used a 20mm LAMS. Primary outcomes were technical success (successful stent deployment) and clinical success (improvement in GOOS). Secondary outcomes included post-procedure length of hospital stay, time to oral intake, and longitudinal GOOS-based assessment of diet (pre-procedure, 1 week, 1 month, and where available 3, 6, and 12 months).

Results The cohort comprised of 13 patients (median age 65 years, range 53–89 years; 10 males, 3 females). Underlying diagnoses were pancreatic cancer (10/13, 76.9 %), distal cholangiocarcinoma (1/13, 7.7 %), small bowel adenocarcinoma (1/13, 7.7 %), and a single undiagnosed case. Most obstructions were in D2 (8/13) or the D1/D2 junction (2/13).
Technical success was achieved in 12 of 13 cases (92.3 %), with one case of stent maldeployment managed endoscopically and rescheduled for successful placement one week later. No patients required intervention for stent obstruction or malfunction after successful deployment.
Post-procedural complications occurred in 1 of 13 patients (7.7 %): this involved a major post-procedural haemorrhage which was managed successfully – requiring ITU admission and blood transfusion only. No delayed complications requiring readmission were observed.
Clinical success was high, with marked and sustained GOOS improvement. Baseline GOOS was G0-G1 (liquid or no oral intake). By 1-week post-procedure,

8/13 patients (61.5 %) had reached G3 (tolerance of normal diet), and by one month, all 13 patients (100 %) had achieved G3. There was rapid in-hospital progression from liquids to soft diet within a few days. Among patients with extended follow-up, 2 patients maintained G3 by 12 months, a further 2 maintained G3 at 6 months, and 3 maintained G3 at 3 months. There were no documented permanent regressions in GOOS scores.

Length of post-procedural hospital stay varied with a median 7 days (IQR 12 days, range 0–39 days). Most patients (8/13) were discharged within one week of their procedure, with three patients requiring extended stays (>2 weeks) due to concurrent medical complications unrelated to stent placement.

Conclusions EUS-GJ with LAMS in a UK tertiary centre is feasible, safe, and highly effective in the palliative management of malignant gastric outlet obstruction. The technique demonstrates high technical success, rapid resumption of oral intake (liquids within 24 hours), and excellent clinical outcomes, with all patients achieving sustained G3 GOOS (normal diet) by one month. The complication profile is acceptable and manageable, and post-procedure length of stay is compatible with complex oncological care. EUS-GJ should be considered a key minimally invasive alternative to surgical bypass or duodenal stenting, and larger multicentre UK studies are warranted to further validate these findings.

DOI 10.1055/s-0046-1822188

Problem to solve High resolution anoscopy (HRA) is the gold standard for anal cancer screening, yet its interpretation is limited by suboptimal accuracy and marked interobserver variability. Artificial intelligence (AI) has the potential to improve diagnostic yield, but existing studies have focused on differentiating low-grade and high-grade squamous intraepithelial lesions (LSIL and HSIL) in still images. To date, no real-time clinical application has been reported.

Innovation We describe the first real-time deep learning application implemented during HRA. The system was evaluated in three patients undergoing anal cancer screening at a high-volume American center. To enable real-time lesion recognition, a YOLO-based object detection model was integrated into the live video stream, allowing continuous frame analysis. When a region displayed visual characteristics suggestive of HSIL, the algorithm generated an on-screen bounding box to highlight the suspected lesion in real time [1–3].

Results Three patients undergoing HRA were evaluated with concurrent real-time AI analysis. Case 1: A 53-year-old HIV-negative male with prior LSIL had three lesions identified on HRA: two acetowhite, lugol-positive LSIL-type lesions and one acetowhite, lugol-negative flat lesion with a mosaic pattern suggestive of HSIL. The AI model generated a bounding box exclusively for the HSIL-suspected anterior lesion, which histopathology confirmed, while the remaining lesions proved LSIL. Case 2: A 38-year-old HIV-negative male with incidentally detected LSIL presented with two LSIL-compatible lesions. The AI system generated no HSIL predictions, and biopsies confirmed LSIL. Case 3: A 40-year-old HIV-positive male with previous HSIL showed no suspicious lesions on HRA, and the AI system generated no HSIL predictions. Across all procedures, the model detected only histologically confirmed HSIL and showed no activation when no lesions or only LSIL were present.

Conclusions This first demonstration of real time AI enhanced HRA shows that deep learning algorithms can deliver accurate predictions and perform consistently during live procedures, expanding their value far beyond still image analysis. This technology can reduce interobserver variability, accelerate skill acquisition, and support broader adoption among clinicians with varying experience, while strengthening diagnostic performance in expert settings. These advances signal a meaningful step toward improving anal cancer screening by enabling earlier detection and more timely intervention. Larger multicenter studies are now essential to validate these findings and confirm their generalizability.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP862 Primary Pancreatic Squamous Cell Carcinoma: Not even the EUS Fellow saw this coming

Authors Ferro Tomás D[1], Bastos A[1], Teixeira M[1], Ramos Lopes S[1], Pereira M[1], Cardoso C[1], Mangualde J[1], Freire R[1]

Institute **1** CRI Gastrenterologia, Hospital São Bernardo, ULS da Arrábida, Setúbal, Portugal

DOI 10.1055/s-0046-1822189

Introduction: Primary squamous cell carcinoma (SCC) of the pancreas is an exceptionally rare entity, as the pancreas lacks native squamous epithelium. According to SEER database, the incidence of SCCP is low, accounting for 0.5–5 % of exocrine pancreatic tumors. Its pathogenesis remains unclear, and diagnosis requires meticulous exclusion of metastatic SCC from more common primary sites. We present a case of primary pancreatic SC, illustrating the difficulties in establishing diagnosis and determining therapeutic strategy [1].

Case Presentation: A 66-year-old woman, non-smoker, with previous osteoarthritis and depression, presented with long-standing lumbar pain attributed to known spinal disease. Over the preceding three months, she developed progressively worsening left upper quadrant pain radiating posteriorly, with characteristics distinct from her baseline pain. She denied jaundice, pruritus, gastrointestinal symptoms, weight loss, or constitutional complaints. Laboratory studies showed leukocytosis (13,300/µL) and mild hyponatraemia (131 mmol/L), with normal liver function, pancreatic enzymes, bilirubin, and inflammatory markers. An initial non-contrast CT revealed focal thickening at the pancreatic body–tail junction, suspicious for neoplasia. A contrast-enhanced CT performed subsequently demonstrated a heterogeneous mass in the distal body/tail. suspicious for pancreatic adenocarcinoma. Tumor markers CEA 22 ng/ml and CA 19.9 3262 U/ml supported the hypothesis. Endoscopic ultrasound identified a 63 × 52 mm predominantly hypoechoic, heterogeneous lesion involving the distal pancreatic body and tail, with invasion of the splenic artery and vein and the porto-spleno-mesaraic confluence. Multiple suspicious celiac and perilesional lymph nodes were observed. No ascites was detected. Fine-needle biopsy (22G) yielded cohesive epithelial cells with dense cytoplasm and marked nuclear atypia. Immunohistochemistry showed positivity for AE1/

AE3, CK7, and p40, supporting the diagnosis of primary squamous cell carcinoma of the pancreas. Surprisingly, no adenocarcinoma component was identified. A comprehensive staging workup excluded extrapancreatic origin. The case was discussed at the multidisciplinary tumour board, which classified the tumour as borderline resectable, due to involvement of the splenic vessels, thus recommended neoadjuvant chemotherapy with the intention of achieving potential resectability.

Conclusion: This case highlights the rarity and aggressive behaviour of primary pancreatic SCC and the essential role of multidisciplinary evaluation to tackle the poor prognosis. Different therapeutic approaches including surgery, chemotherapy, radiotherapy, anti-angiogenic therapies, and immune checkpoint inhibitors have been explored with mixed results. Except for surgery, which offers the most significant survival benefit, available treatments have demonstrated limited efficacy in managing SCC of the pancreas.

Abstract Text

An 82-year-old woman was referred for endoscopic submucosal dissection (ESD) of a circumferential granular-mixed laterally spreading tumor in the ascending colon. Markedly redundant colon and sharp angulations due to adhesions of the descending colon were observed. After reaching the transverse colon with double-balloon endoluminal intervention platform (an accessory designed to maintain endoscope position and creation of a therapeutic zone), blood was observed inside the overtube. At the descending colon, a full-thickness colonic perforation was identified, with spleen visible intraluminally. Laceration was closed successfully with through-the-scope clips, without requiring pneumoperitoneum decompression (procedure under CO_2). The patient was treated with broad-spectrum intravenous antibiotics and had an uneventful recovery (discharged on postoperative day 4) [1–3].

eP864 Post Hoc Counterfactual Analysis of AI-assisted EUS: A Multitask Ensemble to Reduce Uncertainty in Pancreatic Disease

Authors Almeida MJ[1], Mascarenhas M[1], Martins Pinto da Costa A[2], Perez Gonzalez A[2], Agudo B[2], Martins M[1], Mendes F[1], Mota J[1], Frias J[1], Araújo C[1], Carvalho M[3], Lera Dos Santos ME[4], Moris M[5], Hourneaux de Moura EG[6], Widmer J[7], González-Haba Ruiz M[8], Macedo G[1]

DOI 10.1055/s-0046-1822191

Problem to solve Despite substantial progress in endoscopic ultrasound and fine needle techniques, critical diagnostic uncertainties persist in the evaluation of pancreatic cysts, solid lesions, and lymph nodes. Misclassification continues to drive overtreatment or delayed therapy, particularly in indeterminate cysts, low-grade IPMNs, and lymph node staging. Real-world evidence on how artificial intelligence could reshape decision making across diverse EUS scenarios remains limited. Addressing this gap is essential to advance precision, reduce unnecessary interventions, and strengthen the accuracy of pancreatic and nodal assessment.

Innovation This multicenter retrospective study applied a validated AI-CNN ensemble to real EUS images from three distinct patients, in a *post hoc,* counterfactual fashion. The models — previously trained and tested on separate multicenter datasets — included pancreatic cystic model (mucinous vs. non-mucinous cyst), pancreatic solid lesions model (PDAC vs. PNET), and lymph nodes model (benign vs. malignant LN). All predictions were made blinded to histopathology and outcomes. The aim was to evaluate whether AI predictions could have informed different more accurate clinical actions.

Results

Case 1: A 71-year-old woman with a stable 3.5 cm pancreatic cyst underwent multiple EUS-guided FNAs over two years, all of which were non-diagnostic. The AI system classified the lesion as non-mucinous with over 90 % confidence. In retrospect, this high-certainty prediction could have supported a decision to reduce the intensity of follow-up, avoiding repeat procedures and minimizing long-term patient anxiety associated with presumed risk of malignancy.

Case 2: A 48-year-old man with a 7.1 cm mixed-type IPMN and several worrisome features underwent duodenopancreatectomy. Final histopathology revealed only low-grade dysplasia. Retrospectively, the AI model classified the lesion as low-grade with consistent confidence levels above 80 %. Had the tool been available in real time, this result might have supported a more conservative management approach, potentially sparing the patient from an extensive surgery with significant morbidity.

Case 3: A 59-year-old man with obstructive jaundice underwent two EUS-guided FNAs targeting a pancreatic mass and hilar lymph nodes. Pancreatic adenocarcinoma was confirmed only after the second attempt, while lymph node cytology remained negative. Retrospectively, the AI model identified the mass as PDAC with 98 % probability. Furthermore, the AI model highlighted one accessible lymph node—previously unbiopsied—with fluctuating malignancy probabilities between 57 % and 71 %. Targeting this node might have altered staging, supporting the early initiation of neoadjuvant chemotherapy. The patient ultimately underwent surgery, which confirmed pancreatic ductal ad-

Endoscopy 2026; 58: S1–S1041

enocarcinoma with N2 nodal status, underscoring the potential of AI to inform more accurate staging and improve the likelihood of achieving an R0 resection—an important prognostic factor in pancreatic cancer.

Conclusions In this post hoc counterfactual analysis, the AI models demonstrated strong concordance with final histology and exposed pivotal decision moments where real-time guidance could have meaningfully altered management. The findings point to clear opportunities to reduce unnecessary procedures, prevent overtreatment, and accelerate timely systemic therapy. Despite its retrospective design, this innovative framework positions AI as a compelling second-opinion tool and calls for prospective studies to integrate AI-guided EUS into routine clinical workflows, aiming to elevate the precision and impact of pancreatic care.

eP865 Minor Papilla Sphincterotomy in Pancreas Divisum: Technical Success and Clinical Effectiveness

Authors Saichi S[1], Ahmed S[2]
Institutes **1** CHU Lamine Debaghine Bab El Oued, Algiers, Algeria; **2** Fatema el Azhar clinic, Dely Brahim, Algiers, Algiers, Algeria
DOI 10.1055/s-0046-1822192

Aims Pancreas divisum (PD) is the most common congenital pancreatic duct anomaly. Only a minority of patients become symptomatic, and the role of minor papilla sphincterotomy remains debated. We report outcomes of endoscopic therapy in symptomatic PD.

Methods A retrospective, descriptive, single-center study including **21 patients with PD**, of whom **16 were symptomatic** and underwent therapeutic ERCP between 2018 and 2025.Collected data included clinical presentation, anatomical type, pancreatic duct stones, endoscopic interventions, complications, and clinical outcomes. Median follow-up was 29 months [1–4].

Technical success: successful minor papilla sphincterotomy with adequate ductal drainage and/or stent placement.

Clinical success: complete or significant improvement of symptoms (abdominal pain, recurrent pancreatitis) without the need for surgery.

Results Among the 21 patients with PD, **16** were symptomatic:
acute pancreatitis: n = 5
recurrent acute pancreatitis: n = 7
chronic pancreatitis: n = 4
The remaining 5 patients had an incidental diagnosis of PD during MRI workup for CBD stones and were not included in the therapeutic analysis.
The sex ratio among symptomatic patients was 0.77 (7 men, 9 women), with a mean age of 28.6 years (range 11–63).
Among the 16 symptomatic patients:10 (62.5 %) had complete PD, and 6 (37.5 %) had incomplete PD
Minor papilla sphincterotomy with stent placement was performed in 15 of the 16 symptomatic patients.There was one technical failure due to a tight stenosis, requiring surgical bypass (Wirsungo-jejunostomy).No procedure-related mortality or complications occurred.
All 15 successfully treated patients improved clinically:

- 12 after a single procedure
- 3 after three procedures
- 1 after four procedures

Conclusions Minor papilla sphincterotomy with stent placement is technically feasible and clinically effective for symptomatic pancreas divisum. All successfully treated patients showed symptom improvement, with no procedure-related complications in our series

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP866 Marital status, fertility and miscarriage rate in gastrointestinal polyposis syndromes

Authors Pompecki T[1], Koschny R[2], Eckstein Y[1], Wehling C[2]
Institutes **1** Department of Gastroenterology, University Hospital Heidelberg, Heidelberg, Germany; **2** University Hospital, Department of Gastroenterology, Endoscopy Unit, Heidelberg, Germany
DOI 10.1055/s-0046-1822193

Aims Gastrointestinal polyposis syndromes represent a group of genetic disorders characterized by numerous adenomas in the colon and small intestine. In familial adenomatous polyposis (FAP), the most frequent syndrome, patients have an almost 100 % lifetime risk of colorectal cancer. Prophylactic proctocolectomy is typically performed during the phase of relationship formation and family planning. This study examined whether polyposis syndromes and proctocolectomy affect relationship status, family formation, fertility, and reproductive outcomes compared with the general population.

Methods Patients from a tertiary polyposis outpatient clinic (FAPHD cohort) completed an anonymous standardized questionnaire assessing relationship status, number of children, fertility treatment, miscarriages, and colectomy status. Data were compared with the „Family Research and Demographic Analysis“ (FReDA) cohort, a nationwide dataset of German adults, with focus on marital and partnership situations during the family formation phase. Student's t-test and Pearson's chi-square-test with Yates' continuity correction were used to assess group differences. Negative binomial regression was applied to evaluate age-adjusted differences in fertility, and results were verified by age-grouped analysis.

Results 155 FAPHD patients (87 women, median age 50 years, range 18–85) and 21,265 FReDA participants (11,939 women, median age 37 years, range 18–55) provided complete data. Relationship status did not differ significantly between cohorts (79.4 % FAPHD vs. 76.6 % FReDA; p = 0.48).
Among women, 58.6 % in FAPHD had children compared with 51.8 % in FReDA (p = 0.24). Crude fertility rates were similar (1.06 vs. 0.96 children per person in FAPHD and FReDA, respectively; p = 0.24). However, subgroup analysis of 53 female FAPHD patients aged 18-55 showed a decreased fertility rate (0.66; p = 0.01). Age-adjusted analyses confirmed a lower annual fertility increase in FAPHD (3.47 % vs. 7.1 %; p = 0.001), resulting in a lower predicted fertility rate above age 27.7. Age-grouped analyses showed significantly lower estimated fertility rates in FAPHD women aged 40-45, 45-50, and 50-55 years (-0.64, -1.08, and -0.96; all p < 0.03).
In the FAPHD cohort, 124 of 155 patients had undergone proctocolectomy. Post-proctocolectomy patients were more likely to be in a relationship (83.1 %; p = 0.042), while parenthood rates did not differ. Use of fertility treatment did not differ significantly among women (18.4 % FAPHD vs. 14.5 % FReDA; p = 0.38). Lifetime miscarriage was reported by 21.8 % of FAPHD women vs. 4.7 % in FReDA. However, the FReDA questionnaire captured only miscarriages occurring within the 14-year survey period.

Conclusions Polyposis syndromes and proctocolectomy do not appear to impede relationship status. In patients with polyposis, those who had undergone proctocolectomy were even more frequently in a relationship, likely because surgery is usually performed at younger ages, when long-term relationships typically form. However, age-specific analyses revealed a reduced fertility increase in FAPHD, especially beyond 40 years. Despite this, the use of fertility treatment was comparable to that in the general population.

eP867V Endoscopic management of an unusual clinical presentation of cholecystocolonic fistula

Authors Salvador I[1], Loras C[2], Fernàndez-Herrera S[1], Osorio-Ramos AL[3], Güell M[3]
Institutes 1 Hospital Universitari MútuaTerrassa, Terrassa, Spain; 2 Endoscopy Unit, Digestive Diseases Department, Hospital Universitari Mútua Terrassa, Terrassa, Spain; 3 Hospital Sant Joan de Déu de Manresa – Fundació Althaia, Manresa, Spain
DOI 10.1055/s-0046-1822194

Abstract Text

Cholecystocolonic fistula (CCF) is a rare biliary–enteric communication that often presents with nonspecific symptoms. We report the case of an 82-year-old woman who initially presented with large bowel obstruction caused by a 40-mm calcified intraluminal mass requiring sigmoid resection and colostomy. During her hospital stay, she developed acute cholecystitis with pneumobilia, and imaging studies suspected a CCF. Endoscopic ultrasound showed gallbladder wall thickening with intraluminal air and clear communication to the colon, confirming CCF. ERCP with biliary sphincterotomy was also performed. Colonoscopy revealed a 15-mm fistulous opening, which was treated with margin ablation using argon plasma coagulation and was closed with an over-the-scope clip. This case highlights the diagnostic challenges of CCF and supports endoscopic management as an effective alternative in high-surgical-risk patients [1, 2].

Abstract Text

Correct identification of the Treitz flexure during EUS-guided gastroenterostomy (EUS-GE) is essential. Three anatomical variants have been described, with Type III (an inverted alpha-loop) being prone to misinterpretation between duodenal and jejunal limbs. We reviewed 238 EUS-GE procedures from a prospective multicenter registry (GESICA, NCT-05128604) performed with oro-enteral catheter assistance. Only cases in supine position were analyzed to optimize angle assessment. Type III anatomy was found in 18 % of procedures.These cases were examined, and an educational video integrating fluoroscopy and EUS images was developed to illustrate key recognition features. Awareness of Type III configuration may help anticipate technical challenges, prevent misidentification of the duodenojejunal flexure, and avoid unexpected difficulties in patients who may later require surgery [1].

eP869 EUS-guided pancreaticogastrostomy in the treatment of complicated pancreatitis

Authors Bella E[1], Pawlak K[2], Kaczor P[1], Piątkowski J[1], Jackowski M[1], Jagielski M[1]
Institutes 1 Wojewódzki Szpital Zespolony im. L. Rydygiera w Toruniu, Toruń, Poland; 2 Hospial of the Ministry of Interior and Administration in Szczecin, Szczecin, Poland
DOI 10.1055/s-0046-1822196

Aims To assess the effectiveness and safety of EUS-guided endoscopic anastomosis between the main pancreatic duct and the stomach (pancreaticogastrostomy) in patients in whom transpapillary access to the main pancreatic duct could not be achieved during ERCP.

Methods A retrospective analysis of treatment outcomes of all pancreatitis patients who underwent EUS-guided pancreaticogastrostomy between 2018 and 2025 at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum, Nicolaus Copernicus University in Toruń.

Results EUS-guided pancreaticogastrostomy was performed in 13 patients with chrinic pancreatitis (11 men, 2 women; mean age 49.26 [36–66] years) due to lack of transpapillary access during ERCP. Main pancreatic duct strictures in the pancreatic head due to chronic pancreatitis were diagnosed in 7/13 (53.85 %) patients. Disconnected pancreatic duct syndrome was identified in 4/13 (30.77 %) patients. Postprocedural stricture of pancreaticogastrostomy anasotmosis were diagnosed in 2/13 (15.38 %) patients. Technical success was achieved in 12/13 (92.31 %) patients. Complications occurred in 3/13 (23.08 %) patients. Clinical success was achieved in 12/13 (92.31 %) patients. Mean follow-up was 1055 (148–1732) days. Long-term success was achieved in 11/13 (84.61 %) patients.

Conclusions EUS-guided endoscopic pancreaticogastrostomy seems an effective and safe treatment method when transpapillary access to the main pancreatic duct is not possible.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP870 Is Cold the New Standard? Modified Underwater Submucosal Injection Cold Lesion Excision (MUSCLE) vs. Hot EMR for Dysplastic Sessile Serrated Lesions

Authors Massimi D[1, 2], de Sire R[3], Minini F[1], Vadalà V[1], Capogreco A[1], Alfarone L[1], De Deo D[1], Maselli R[3, 2], Hassan C[1, 2], Repici A[2, 1]
Institutes **1** IRCCS Humanitas Research Hospital, Digestive Endoscopy Unit, Rozzano, Italy; **2** Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy; **3** Humanitas San Pio X, Milano, Italy
DOI 10.1055/s-0046-1822197

Aims Current ESGE guidelines recommend hot snare polypectomy for Sessile Serrated Lesions with Dysplasia (SSLD) based on theoretical benefits regarding malignant potential and resection depth. However, no randomized trials have specifically compared resection techniques for SSLD > 10 mm. While recent meta-analyses demonstrate significant safety advantages of cold Endoscopic Mucosal Resection (EMR) for non-dysplastic serrated lesions, these studies excluded dysplastic lesions, leaving the applicability of cold techniques to SSLD undetermined. This study represents the first comparative analysis evaluating a novel Modified Underwater Submucosal Injection Cold Lesion Excision (MUSCLE) technique versus conventional hot EMR exclusively in patients with SSLD ≥ 10 mm [1–5].

Methods We retrospectively identified consecutive patients with SSLD > 10 mm treated at two Italian tertiary centers. Lesions removed by conventional hot EMR or by the MUSCLE technique, which combines underwater cold snare resection with prior submucosal lifting, were propensity score matched 1:1. Matching variables included lesion size (> 2 cm vs. ≤ 2 cm), location (left vs. right colon), anatomical access difficulty, operator expertise (expert vs. non-expert), and Paris morphology (flat vs. sessile). The primary outcome was the recurrence rate at ≥ 1-year surveillance colonoscopy. Secondary outcomes included technical success and adverse events, specifically immediate/delayed bleeding, perforation, and post-polypectomy electrocoagulation syndrome (PECS) (▶ **Table 1**).

Results From 190 pre-propensity lesions with ≥ 1-year follow-up, 172 eligible lesions remained after excluding 18 ESD cases. Propensity score matching yielded 102 analyzed lesions (51 matched pairs) with balanced characteristics (61 % ≤ 2cm, 32 % expert operators, 94 % flat morphology, 86 % right colon, 80 % good access). Technical success was 100 % in both groups. Recurrence occurred in 1/51 lesions (1.96 %) in both groups at ≥ 1-year follow-up, with no significant difference (p = ns; 95 % CI: -5.4 % to 5.4 %). The composite outcome of any adverse event showed a trend favoring MUSCLE (0 % vs 9.80 %, p = 0.063).

Conclusions The MUSCLE technique represents a novel hybrid approach integrating the safety advantages of non-thermal cold snare resection with the technical benefits of underwater mucosal buoyancy and enhanced snare capture, while preserving adequate resection depth through submucosal injection. In this first propensity score-matched analysis targeting SSLD > 10 mm, MUSCLE achieved equivalent technical success and comparable one-year recurrence rates to conventional hot EMR, with a favorable trend toward improved safety. These findings provide the first specific clinical evidence challenging current ESGE guidelines that mandate thermal resection for this high-risk subtype, suggesting cold resection techniques may be a viable, safer alternative. Larger multicenter prospective trials are warranted to confirm these results.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims To evaluate the effectiveness and safety of extra-anatomical endoscopic access to the bile ducts in the treatment of patients with benign and malignant biliary strictures.

Methods A prospective analysis of treatment outcomes of all patients with obstructive jaundice due to biliary strictures who underwent endoscopic treatment between 2016 and 2023 at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum, Nicolaus Copernicus University in Toruń. The study group consisted of patients in whom transpapillary access to the bile ducts could not be obtained during ERCP, and in whom EUS-guided transmural access was therefore used during endotherapy.

Results In 343 patients in whom transpapillary access during ERCP was unsuccessful, transmural EUS-guided techniques were employed. Endoscopic transpapillary biliary stenting using EUS-guided transmural access was performed in 56/343 (16.32 %) patients. In the remaining 287/343 (83.67 %) patients, extra-anatomical EUS-guided transmural biliary–enteric anastomosis was created. Technical success was achieved in 330/343 (96.21 %) patients, and clinical success in 302/343 (88.05 %) patients. Complications occurred in 46/343 (13.41 %) patients, including fatal complications in 9/343 (2.62 %).

Conclusions Endoscopic techniques utilizing EUS-guided transmural access are effective and safe in the endotherapy of patients with biliary strictures and constitute an alternative to surgical techniques in cases where transpapillary drainage during ERCP is unsuccessful.

eP872 EUS-guided transmural drainage of perianal abscesses

Authors Kaczor P, Pawlak K[1], Bella E[1], Piątkowski J[1], Jackowski M[1], Jagielski M[1]
Institute **1** Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum NCU, Toruń, Poland
DOI 10.1055/s-0046-1822199

Aims To assess the efficacy and safety of transmural (through the rectal wall) drainage of perianal abscesses under the EUS guidance.

Methods Prospective analysis of treatment outcomes for patients with perianal abscesses who underwent EUS-guided transmural drainage between 2019 and 2025 at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum Nicolaus Copernicus University in Toruń, Poland. In all patients, during the initial endoscopic procedure, endoluminal puncture of the abscess through the rectal wall was performed under endoscopic ultrasound guidance. Subsequently, a *Lumen-Apposing Metal Stent* (LAMS) was inserted through the puncture site after dilation, through which a drain was introduced into the abscess cavity for postoperative salvage. Subsequent endoscopic procedures included irrigation of the abscess and ultimately removal of the LAMS when complete collapse of the collection was observed.

Results In 6 patients (6 men; mean age 39.57 [28-72] years) with perianal abscesses, transmural endoscopic drainage was performed. In 5/6 (83.33 %) patients, perianal abscesses were caused by complicated diverticulitis; in 1/6 (16.67 %) patients, the abscess was a consequence of ulcerative colitis. The mean abscess size was 78 (46-132) mm. The mean number of endoscopic procedures (endoscopic revision of abscess cavity with irrigation) was 2.8 (2-6). The mean time of treatment was 6 (4-12) days. Successful endoscopic treatment of perianal abscesses, which was defined as the resolution of clinical symptoms and complete regression of the abscess, was achieved in all 6 patients. No complications related to EUS-guided treatment were observed. The patients were followed subsequently in CT scan during mean period of 981 (224-1516) days, where no abscess recurrence was observed in all patients.

Conclusions EUS-guided transmural drainage of perianal abscesses seems safe and effective and potentially might be alternative for more invasive treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP873 Outcomes and surveillance following incidental colorectal cancer detection in endoscopic submucosal dissection histopathology specimens from a tertiary UK centre

Authors Maristany Bosch E[1], Kalopitas G[1], Dell'Unto E[1], Rimondi A[2], Cossa L[1], Athanasiadou E[3], Murino A[4, 1], Despott E[1]

DOI 10.1055/s-0046-1822200

Aims Endoscopic submucosal dissection (ESD) is a well-established technique for en bloc resection of large premalignant colorectal lesions, providing high R0 resection rates and low recurrence [1]. Its use has expanded to include early-stage colorectal cancer (CRC) [2–5]. However, the increasing adoption of ESD has led to finding of incidental high-risk histopathological features, for which post-ESD management, whether conservative or surgical, remains less clearly defined with variance among guidelines. The American Gastroenterological Association and the European Society of Gastrointestinal Endoscopy recommend ESD for lesions with high suspicion of limited submucosal invasion [1, 6]. For non-curative ESD, surgery is generally advised unless surgical risk is prohibitive, in which case close endoscopic and radiologic surveillance is an alternative. Positive vertical margin and lymphovascular invasion are particularly associated with residual tumor and nodal involvement [2, 7]. The aim of this study was to present our data on incidental CRC findings after ESD and to evaluate subsequent surveillance outcomes.

Methods We conducted a retrospective, single-centre study including consecutive patients who underwent ESD for suspected premalignant colorectal lesions with unexpected diagnosis of colorectal cancer (CRC) on final histopathology. Between 2018 and 2025, a total of 241 colorectal lesions were resected en bloc with ESD. Clinical, endoscopic, histopathological, and follow-up data were collected and analysed, focusing on curative resection status, subsequent management, and oncological outcomes.

Results Of the 241 lesions, 11 (4.5 %) were diagnosed as submucosal invasive carcinoma (SMIC). Lesions were located within the rectum (3/11, 27.3 %) and colon (8/11, 72.7 %). R0 curative resection was achieved in 1 case (9.1 %), R0 non-curative in 2 (18.2 %), and R1 resection with positive vertical margins in 8 cases (72.7 %). Among the non-curative R0 resections, one patient underwent radical surgery with no residual malignancy identified; none of the R0 cases

showed local recurrence or distant disease during follow-up (median follow-up time was 39 months (IQR 27-42.5, range 15-46)).

Of the 8 R1 resections, 6 (75 %) underwent surgery and 2 (25 %) were managed conservatively. Four (66.7 %) of the surgical cases showed deeply invasive (≥ 1000 µm) submucosal carcinoma, while 2 (33.3 %) had no residual malignancy. Overall, 50 % of R1 resections had no recurrence at median follow-up of 13 months (IQR 9.5-15, range 5-17).

Among the 11 patients with high-risk features, 7 (63.6 %) achieved curative resection with ESD alone, showing no residual disease or recurrence at follow-up despite 8 having had R1 resection. **Total median follow-up time was 15 months (IQR 10–17, range 5–46).**

All 4 cases with residual cancer after surgery (36.4 %) showed surface features JNET 2B, variably located in the sigmoid (25 %), transverse (25 %), ascending colon (25 %), and rectum (25 %). These included 2 Paris 0-Is (50 %), 1 LST-G-M (25 %), and 1 LST-NG-FE (25 %); all were R1 resections, and all presented with muscle-retraction during ESD. Biopsies pre-ESD were only available in two out of four patients: only low-grade dysplasia in one and focal high-grade dysplasia the other.

Conclusions Incidental colorectal cancer diagnosed after ESD is infrequent but clinically relevant. Most cases, including some with R1 resection, required no additional treatment, highlighting that selected patients with limited submucosal invasion and favourable histology may potentially be safely managed conservatively, especially if elderly or comorbid. Nevertheless, achieving R0 resection remains essential to minimise the risk of residual disease or recurrence. Radical surgery offered a curative option in patients with high risk findings after ESD. Future prospective studies are needed to validate these findings and establish evidence-based recommendations for post-ESD management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP874 Endoscopic management of post-inflammatory pancreatic fistulas

Authors Bella E[1], Pawlak K[2], Kaczor P[1], Piątkowski J[1], Jackowski M[1], Jagielski M[1]

Institutes **1** Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum NCU, Toruń, Poland; **2** Hospial of the Ministry of Interior and Administration in Szczecin, Szczecin, Poland

DOI 10.1055/s-0046-1822201

Aims To assess the effectiveness of various endoscopic techniques in the treatment of patients with post-inflammatory pancreatic fistulas.

Methods A prospective analysis of endoscopic treatment outcomes of all patients with pancreatic fistulas secondary to inflammatory pancreatic diseases between 2018 and 2025 at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum, Nicolaus Copernicus University in Toruń.

Results Post-inflammatory pancreatic fistulas were diagnosed in 56 patients (51 with internal pancreatic fistulas, and 5 with external, i.e. pancreatico-cutaneous fistulas). Among internal fistulas, the most common abnormal connection was between the pancreatic ducts and the pleural cavity—pancreaticopleural fistulas were diagnosed in 33 patients, followed by pancreaticoperitoneal fistulas in 14 patients, pancreaticointestinal fistulas in 2 patients, and pancreatico-biliary fistulas in 2 patients. Chronic pancreatitis was identified in 33/56 (58.93 %) patients. Endoscopic retrograde pancreatography with endoscopic sphincterotomy and main pancreatic duct stenting was performed in 47/56 (83.93 %) patients. In 9/56 (16.07 %) patients, due to lack of anatomical transpapillary access to the main pancreatic duct, transmural drainage of the fistula tract under EUS guidance was performed. Clinical success was achieved in 51/56 (91.07 %) patients. The total duration of endotherapy averaged 513 (91–1399) days. Long-term success of endoscopic treatment was achieved in 48/56 (85.71 %) patients.

Conclusions Endoscopic treatment seems an effective therapeutic method for post-inflammatory pancreatic fistulas. Passive transpapillary drainage (main pancreatic duct stenting) remains the preferred treatment method. When anatomical transpapillary drainage is not feasible, EUS-guided transmural drainage of the fistula tract remains the alternative. In patients with pancreatic fluid collections complicated by the presence of a pancreatic fistula, decompression of the collection via endoscopic drainage leads to fistula closure.

eP875 TOP100: Is it enough to top the human reader?

Authors Nandi N[1], Devanand A[1], Tai FWD[1], Sidhu R[2, 1]

Institutes **1** Academic Unit of Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK, United Kingdom; **2** Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom

DOI 10.1055/s-0046-1822202

Aims Capsule endoscopy (CE) is an accepted modality to investigate the small bowel (SB). Reading and reporting of CE however can be time consuming. Previous studies have showed that even in the hands of experts, reader attention span drops after just one study. Artificial intelligence has exploded in the field of medicine including within CE. The TOP100 is a feature on the CE software which identifies the 100 most significant images from the entire video which may help to reduce physician reporting time. Previous studies [1–3] have shown good diagnostic performance, especially for active bleeding and inflammatory lesions, and good agreement between standard human reading (SR) and TOP100. The aim of this study is to evaluate the agreement in findings and patient management between the same reader and different readers with SR and TOP100.

Methods A retrospective analysis was conducted to compare SR of an entire video with TOP100 images identified by the software. The two experienced physician experts and senior trainee had all read > 500 lifetime of CE videos. The 2 experts who reported the original video were asked to review TOP100 images which was in a short video format in a blinded fashion. The senior trainee was asked to read TOP100 which was subsequently compared to the expert standard read. Comparisons were made on significant findings and main diagnosis and subsequent suggested management. Secondary outcomes were a comparison of reading time between standard read and TOP100 reads and interobserver variability of CE readers between the standard human versus TOP100 reads. A comparison was also made between TOP100 by the trainee compared to the physician read.

Results A total of 50 CE videos were reviewed by each expert with TOP100. Findings were recorded and patient management was suggested based on TOP100 findings and the CE indication. Each expert reviewed 25 videos of suspected SB bleeding and 25 videos of known or suspected inflammatory bowel disease (IBD). Both expert readers had a substantial intra-observer agreement (K 0.61-0.80) between SR and TOP100 for ulcers and active bleeding. One reader had only a fair (K 0.37, $p < 0.01$) intra-observer agreement for angiodysplasias while the other reader had a moderate agreement (K 0.68, $p < 0.01$) for the same category. Agreement on patient management based on TOP100 readings was similar for the two experts (75 % and 78 %). The inter-observer agreement between the senior trainee and the expert readers when using TOP100 was substantial for ulcers (K 0.90, $p < 0.01$), angiodysplasias (K 0.61, $p < 0.01$) and with an overall diagnostic yield (K 0.69, $p < 0.01$). Agreement was moderate for active bleeding (K 0.54, $p < 0.01$) and erosions (K 0.58, $p < 0.01$). The mean reading time per CE video with TOP100 was 1m48s vs 40min for SR.

Conclusions The TOP 100 has shown moderate intra-observer agreement compared to standard reading for the final CE diagnosis and subsequent change in management of the two expert readers. On comparison between the TOP100 read of the senior trainee and the expert read- there was a moderate to substantial agreement, suggesting that the TOP100 could be an adjunct to trainees in reporting of CE. Further studies with a larger pool of differing experience of trainees would help substantiate our study findings.

DOI 10.1055/s-0046-1822203

Problem to solve Endoscopic full-thickness resection (EFTR) by using non-exposed full-thickness resection device (FTRD) is a safe procedure often adopted for non-lifting colorectal lesions. As showed by recent literature, one of the technical challenges may be reaching the lesion after mounting the FTRD device on the colonoscope, particularly in case of difficult colonoscopy due to loop formation or laxity. This issue may lead to procedural failure as well as damage and exposure to complications [1–3].

Innovation We combined the FTRD with the use of Endorail System, an accessory for colonoscopy that uses a magnetic balloon to solve colon loops and improve the manoeuvrability of the endoscope. It consists of a balloon catheter introduced through the endoscope's channel, filled with a ferromagnetic fluid, and then magnetically anchored to a handpiece placed on the patient's abdomen. This allows the endoscopist to pull the colonoscope and straighten loops, making the procedure faster and complete. We entered an Endorail-assisted EFTR for a single case of appendiceal adenoma.

Results We evaluated a 74-year-old woman with a 20 mm sessile adenoma of the appendiceal orifice and history of incomplete colonoscopies due to laxity, loop formation and the concomitant need for prolonged sedation.

We performed a complete traditional colonoscopy. After reaching the ceacum and marking the lesion, we released the Endorail balloon in the ascending colon to stabilize the position and it was left in situ as a guide. Through the transcutaneous magnetic anchoring system, the balloon remained stationary in position and was therefore used as a guide alongside the endoscope for performing colonoscopy with FTRD. Reaching the caecum by following this guide was extremely easy and took 4 minutes less time, without any loops forming or difficulties in proceeding in the lumen. After reaching and removing the magnetic balloon, the full-thickness resection procedure was successfully completed, with no immediate or late adverse events. In particular, there was no damage to the remaining colon and no acute appendicitis occurred in the following days. Histological examination confirmed curative and ful-thickness resection of tubular adenoma with low-and high-grade dysplasia.

Conclusions Our experience shows how combining two devices can help overcome difficulties challenges, reduce potential adverse events and lead to safer technical success in less time.

eP877 EUS-guided treatment of postoperative intra-abdominal abscesses

Authors Kaczor P[1], Pawlak K[1], Bella E[1], Bereziak L[1], Piątkowski J[1], Jackowski M[1], Jagielski M[1]
Institute **1** Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum NCU, Toruń, Poland
DOI 10.1055/s-0046-1822204

Aims To assess the effectiveness of EUS-guided transmural drainage in the treatment of postoperative intra-abdominal abscesses.

Methods Retrospective evaluation of endoscopic treatment results in all patients with intra-abdominal abscesses following abdominal surgery between 2018 and 2023 at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum, Nicolaus Copernicus University in Toruń, Poland. Patients were divided into two groups based on the time between surgery and the initiation of endoscopic treatment. The first group consisted of patients in whom EUS-guided transmural drainage of intra-abdominal abscesses was performed within 14 days of surgery. The second group consisted of patients in whom endoscopic treatment was initiated 14 days after surgery.

Results All 37 patients with intra-abdominal abscesses underwent active transmural (transgastric) EUS-guided drainage via a single approach. The first group included 21/37 (56.76 %) and the second group included 16/37 (43.24 %) patients with intra-abdominal abscesses. In both groups, intra-abdominal abscesses were a complication following urgent laparotomy for purulent or fecal peritonitis caused by colonic pathology. Active endoscopic drainage was performed for 6 (4-12) days in the first group and for 14 (7-22) days in the second group ($p < 0.05$). Complications of endoscopic treatment were noted in 3/21 (14.29 %) patients in the first group and in 2/16 (12.5 %) in the second group (p = NS). Clinical success (resolution of clinical symptoms and complete regression of the abscess) was achieved in 20/21 (95.24 %) patients in group 1 and 13/16 (81.25 %) patients in group 2 ($p < 0.05$). Long-term treatment success (no abscess recurrence in subsequent CT scans) was achieved in 19/21 (90.48 %) patients in group 1 and 12/16 (75 %) patients in group 2 ($p < 0.05$).

Conclusions EUS-guided transmural drainage seems effective treatment for postoperative intra-abdominal abscesses. Early endoscopic drainage is associated with better endoscopic outcomes in this group of patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP878 Evaluation of the ESGE Endoscopic Submucosal Dissection (ESD) training curriculum in a Western tertiary centre: Outcomes of first-year-fellows in-training

Authors Maristany Bosch E[1], Kalopitas G[1], Dell'Unto E[1], Rimondi A[2], Athanasiadou E[3], Cossa L[1], Murino A[4, 1], Despott E[1]
Institutes **1** The Royal Free Hospital and University College London Institute for Liver and Digestive Health, London, United Kingdom; **2** Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; **3** The Royal Free Hospital and University College London Institute for Liver and Digestive Health, Lond, United Kingdom; **4** Cleveland Clinic London Hospital, London, United Kingdom
DOI 10.1055/s-0046-1822205

Aims The ESGE curriculum outlines structured competency standards for endoscopic submucosal dissection (ESD) training, including minimum case volumes, supervised learning, and defined performance benchmarks [1]. This study evaluated the first-year outcomes from two post-CCST advanced endoscopy fellows in a Western tertiary centre.

Methods All consecutive ESD procedures performed by two fellows under expert supervision between October 2024 to October 2025 were prospectively recorded. All ESD procedures were performed using the saline-immersion/irrigation technique (SITE), due to its advantages, including improved visualisation through optical clarity and magnification, natural buoyancy, enhanced conductivity through saline (with optimal vessel pre-coagulation and management), and patient comfort. Descriptive analysis was performed for demographics, lesion characteristics, technical performance, and histopathological and safety outcomes. Training milestones were mapped against ESGE curriculum standards.

Results A total of 54 ESD procedures were performed in 42 patients, distributed as 29 and 25 procedures per trainee, respectively, either totally (15, 37.5 %) or partially assisted by an expert supervisor (27, 64.3 %). Median proportion of the procedure performed by fellows was 60 % (IQR 30-100). Mean patient age was 66.9 ± 14.4 years; 64.3 % were men. Median ASA was 1 (IQR 1–2). Lesions were located in the colon (61.9 %), rectum (31 %), and stomach (7.1 %). Median lesion diameter was 50mm (IQR 40–65).

Macroscopic morphology included 57.2 % LST-G, 26.2 % LST-NG, 4.8 % sessile lesions, 4.8 % semi-pedunculated and 2.4 % pedunculated and submucosal. A degree of submucosal fibrosis was present in 54.7 % (F1–F2).

En bloc R0 and curative resection was achieved in 92.9 %. One case (2.4 %) was abandoned due to suspected deep submucosal invasion and referred for surgery which confirmed invasive adenocarcinoma. Median procedure time was 135 minutes (IQR 90–177). Overall median resection speed was 13.1 mm^2/min (IQR 7.6–18.7). When analysed quarterly, resection speed progressively increased: Q1: 9.58 mm^2/min, Q2: 13.46 mm^2/min and Q3: 18.30 mm^2/min, demonstrating steady procedural efficiency improvement during training. Also percentage of procedure performed by trainee was analysed quarterly increasing from a median of 65 % (IQR 8.75-95) to 100 % (IQR 50-100) from Q1 to Q3.

Adverse events included 3 intraprocedural perforations (7.1 %), one (2.4 %) in the rectum and 2 (4.8 %) in the ascending colon; all were managed successfully endoscopically with through-the-scope clip-closure without hindering the procedure outcome or patient safety. Operator-delivered conscious-sedation was used in 92.9 %, including all colorectal cases. General anaesthesia was only used for gastric lesions.

Training was conducted under full supervision, following ex-vivo and model-based practice, observation of > 50 expert cases, and participation in > 3 hands-on courses.

Conclusions After one year of structured ESD training, which included completion of recommended preparatory steps such as ex-vivo courses, animal models, theoretical instruction, and acquisition of independent advanced endoscopic skills, both trainees achieved performance standards outlined in the ESGE curriculum. However, in our series, most lesions were located within the colon rather than the rectum, reflecting the real-world case availability within our centre. If training had been restricted exclusively to rectal lesions, the recommended case volumes could not have been met.

These findings suggest that while the ESGE curriculum is practical, safe, and feasible when implemented under direct expert supervision, some flexibility regarding the recommended lesion location may be necessary to allow trainees to reach adequate numbers within Western training environments. Allowing supervised exposure to colonic lesions earlier in training may support broader applicability of the curriculum without compromising safety or outcomes. The consistent performance and safety outcomes observed with SITE-ESD suggest that this technique may also be particularly advantageous for facilitating safer early training for colonic ESD.

eP879 Management of ERCP-related perforations: A 20-year experience from a tertiary referral center

Authors Velegraki M[1], Psaroudakis I[1], Skouloudi C[1], Arna D[1], Fragkiadakis I[1], Fragaki M[1], Koukoutsi K[1], Theodoropoulou A[1], Vardas E[1], Paspatis G[1]
Institute 1 Department of Gastroenterology, Venizeleion General Hospital, Heraklion, Crete, Greece
DOI 10.1055/s-0046-1822206

Aims Perforation is an uncommon but potentially serious adverse event of endoscopic retrograde cholangiopancreatography (ERCP). Although its incidence is low, associated morbidity can be significant, particularly when diagnosis or intervention is delayed. Mechanisms of injury vary and are classified using the Stapfer system, which serves as a useful tool in determining appropriate management. Recent advancements in endoscopic closure techniques have broadened treatment options and may reduce the need for surgery. The aim of this study was to evaluate the clinical characteristics, mechanisms of injury, management strategies, and outcomes of ERCP-related perforations treated at a high-volume referral center over a 20-year period.

Methods We retrospectively examined all ERCP procedures performed at Venizeleion General Hospital between March 2005 and June 2025. Perforation was diagnosed by: (i) direct endoscopic visualization of a mucosal defect, (ii) fluoroscopic evidence of contrast extravasation or retroperitoneal air, or (iii) post-procedural CT findings in symptomatic patients such as retroperitoneal air, fluid collections or leakage of orally administered contrast. Perforations were classified according to the Stapfer classification (Types I–IV). Data recorded included demographics, ERCP indication, perforation characteristics, therapeutic approach (conservative, endoscopic, surgical), AGREE (Adverse events in Gastrointestinal Endoscopy) grading, hospitalization duration and mortality.

Results Among 6719 ERCPs, 19 perforations were identified (0.28 %). Mean age of the patients was 69.4 years, and 58 % were female. Choledocholithiasis was the most common indication (78.9 %), followed by malignancy (15.8 %). Stapfer type II perforations were the most common (63.2 %, 12/19), followed by type I (26.3 %, 5/19) and type III (10.5 %, 2/19). Mechanisms of type II injury included large balloon dilation (6/12), standard sphincterotomy (3/12), transpancreatic sphincterotomy (2/12), and needle-knife precut sphincterotomy (1/12). Type III perforations resulted from guidewire manipulation, while type I injuries occurred in patients with altered or difficult anatomy.

Management strategies were individualized. Among type II cases, 6 patients (50 %) were treated conservatively, 4 (33.3 %) underwent endoscopic therapy with plastic or fully covered self-expandable metal stents, and 2 (16.7 %) required surgery, with one postoperative death. Regarding type I perforations, one patient was treated conservatively, 2 underwent endoscopic closure with an over-the scope clip (OTSC), and 2 required surgery in the pre-OTSC era. One of these patients died postoperatively. Both type III cases were managed conservatively. According to the AGREE classification, perforations were graded as Grade II in 47.4 %, Grade III in 42.1 %, and Grade V in 10.5 % (fatal cases). Overall mortality among all ERCPs was 0.03 %, with both deaths occurring after surgical treatment. The mean length of hospitalization was 12.6 days.

Conclusions Prompt recognition of ERCP-related perforation is essential for optimizing outcomes. With the development of advanced endoscopic closure devices, particularly OTSC, non-operative management has become a feasible and effective first-line strategy in selected cases. Multidisciplinary collaboration remains critical to achieving favorable outcomes.

eP880 Predicting Lethal Outcomes Using Laboratory and Clinical Parameters in Acute Pancreatitis

Authors Ravlić L[1], Ljubičić N[2], Tkalec K[1], Budimir I[2]
Institutes 1 School of Medicine, University of Zagreb, Zagreb, Croatia; 2 Sisters of Charity Hospital, Zagreb, Croatia
DOI 10.1055/s-0046-1822207

Aims Acute pancreatitis (AP) is an inflammatory condition with highly variable clinical outcomes. In this study, we aimed to present data on patients diagnosed with acute pancreatitis and to identify laboratory and clinical parameters, along with established scoring systems for AP, that may help predict clinical outcomes of this condition.

Methods In this retrospective observational cohort study, we analyzed 95 patients treated at our tertiary care center throughout 2024. Data was collected from electronic medical records. Variables included medical history (medication use, history of AP, alcohol consumption, etc.), vital parameters on admission, laboratory and imaging findings, as well as scoring systems for acute pancreatitis (SIRS score, BISAP score, CT severity score, Ranson and modified Ranson criteria). The primary clinical outcome was 30-day mortality. Secondary outcomes included sepsis, multi-organ failure and length of treatment. A p-value of under 0,05 was considered statistically significant. Fisher's exact test was used for categorical variables, while Mann-Whitney U test was applied in comparison of continuous variables.

Results Patients were divided based on 30-day mortality outcomes. 86 patients had successfully recovered, while 9 had a lethal outcome. Using Fisher's exact test, significant correlations were discovered between 30-day mortality and the following events: pancreatic infection (11.6 % vs 66.7 %, $p < 0.001$), sepsis (5.8 % vs 66.7 %, $p < 0.001$), bleeding (1.2 % vs 22.2 %, $p = 0.023$), multi-organ failure (1.2 % vs 77.8 %, $p < 0.001$), loss of consciousness (0.0 % vs 22.2 %, $p = 0.022$), kidney damage (2.3 % vs 44.4 %, $p < 0.001$), shock (2.3 % vs 55.6 %, $p < 0.001$) and pancreatic necrosis (35.3 % vs 83.3 %, $p = 0.049$). Lethal outcomes were additionally associated with lower mean arterial pressure (99.83 ± 12.79 vs 83.59 ± 16.53 mmHg, $p = 0.008$), elevated blood urea levels 48 hours after admission (4.97 ± 2.46 vs 9.83 ± 5.96 mmol/L, $p = 0.0039$) and higher leukocyte count (12.02 ± 4.24 vs 15.64 ± 5.97 $[10^9]$/L, $p = 0.037$). Based on calculated odds ratio (OR) with 95 % confidence intervals (95 % CI), the strongest predictors of 30-day mortality were multi-organ failure (OR 77.829, 95 % CI 3.379 – 1792.804) and BISAP score (OR 2.471, 95 % CI 1.123 – 5.435).

Conclusions Several clinical and laboratory parameters correlated with lethal outcomes in acute pancreatitis, with multi-organ failure emerging as the strongest predictor and BISAP showing the highest scoring accuracy. While further studies with larger samples are needed, these findings highlight the potential of clinical variables in early identification and timely management of high-risk patients.

eP881 Impact of drainage-tube use on the outcomes of Saline-Immersion/irrigation TEchnique endoscopic submucosal dissection of colonic lesions: a comparative cohort analysis

Authors Maristany Bosch E[1], Kalopitas G[1], Dell'Unto E[1], Rimondi A[2], Athanasiadou E[3], Cossa L[1], Murino A[4, 1], Despott E[1]
Institutes 1 The Royal Free Hospital and University College London Institute for Liver and Digestive Health, London, United Kingdom; 2 Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; 3 The Royal Free Hospital and University College London Institute for Liver and Digestive Health, Lond, United Kingdom; 4 Cleveland Clinic London Hospital, London, United Kingdom
DOI 10.1055/s-0046-1822208

Aims the saline-Immersion/irrigation Technique (SITE) endoscopic submucosal dissection (ESD) has been reported for improving the feasibility and safety of ESD [1–5]. In 2023, drainage-tubes were introduced to reduce bowel overdistension and facilitate dissection during SITE-ESD, [6–8]. In our practice, we now employ a drainage-tube for all colonic SITE-ESD, by using a slim 8Fr fenestrated nasal-jejunal feeding tube wrapped around the scope and secured with vinyl-tape to enhance the advantaged of SITE-ESD. This tube, which we named the 'Asclepius tube', given its similarity to the medical symbol of the snake around the rod of Asclepius, has the objective of draining redundant fluid from continuous saline-irrigation and diathermy-generated gas, obviating the need for scope aspiration. This approach aims to enhance dissection efficiency, visual clarity and patient comfort. A retrospective study by Kagaya et al. demonstrated that drainage improved ESD efficiency in the rectum [9].

We aimed to compare procedural and clinical outcomes between colonic SITE-ESD performed with and without drainage tube placement.

Methods We retrospectively analyzed 137 colonic SITE-ESDs (50 without drainage, 87 with drainage) performed between May 2018 and October 2025 at a tertiary endoscopy unit. Baseline demographic, procedural, and histopathological parameters were compared. Primary outcomes included resection speed, total procedure duration, R0 resection rate, and adverse events. Statistical analysis was performed using IBM SPSS v30.0.

Results Groups were comparable in age, gender, ASA score, lesion diameter, and location (all $p > 0.05$). While median procedure duration was similar (120 min vs 120 min; $p = 0.97$), our resection speed was significantly higher with drainage (11.4 mm^2/min vs 6.9 mm^2/min; $p = 0.006$). R0 resection rates (88.5 % vs 92 %; $p = 0.78$) and delayed adverse events (4.6 % vs 4 %; $p = 0.86$) did not differ significantly.

Conclusions Drainage-assisted colonic SITE-ESD significantly increased resection speed while maintaining similar safety and histological outcomes. Its use may enhance procedural performance and stability in complex colonic resections. Further prospective comparative studies are merited.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A 92-year-old patient with surgically altered anatomy (total gastrectomy with Roux-en-Y for gastric cancer) presented with recurrent biliary obstruction. Imaging revealed gallbladder and common bile duct (CBD) lithiasis. The patient was unfit for surgery, prompting an endoscopic approach. i) First, EUS-guided transjejunal gallbladder drainage was performed using a 10 × 10-mm LAMS with coaxial pigtail plastic stent. ii) Four weeks later, antegrade trans-LAMS access to the CBD was unsuccessful. A second EUS-guided biliary drainage (choledochojejunostomy) was created with a 6 × 8-mm LAMS, followed by transpapillary dilation and double-pigtail stent placement (10 Fr × 7 cm). This case demonstrates the feasibility of sequential EUS-guided biliary drainage for complex biliopancreatic disease in altered anatomy [1–3].

eP883 Effectiveness and safety of EUS-guided drainage of liver abscesses

Authors Kaczor P[1], Pawlak K[1], Bella E[1], Piątkowski J[1], Jackowski M[1], Jagielski M[1]

Institute **1** Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum NCU, Toruń, Poland

DOI 10.1055/s-0046-1822210

Aims To assess the effectiveness and safety of EUS-guided drainage of liver abscesses.

Methods Retrospective analysis of treatment results of all patients with liver abscesses who underwent endoscopic treatment at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum Nicolaus Copernicus University in Toruń, Poland in the years 2018–2025.

Results Endoscopic drainage was performed in 13 patients (9 men, 4 women; mean age 66.52 [42-78] years) with liver abscesses. 11/13 (84.62 %) patients had a single abscess of the left liver lobe; the remaining 2/13 (15.38 %) patients had a single abscess of the right liver lobe. The mean size of the liver abscess was 85 (52-132) mm. Each patient underwent ERCP with attempted transpapillary drainage of the abscess if the abscess communicated with the bile ducts. In 3/13 (23.08 %) patients in whom contrast leakage from the bile ducts into the abscess cavity was detected during ERCP, active transpapillary drainage of the liver abscess was performed; in 1 patient, additional percutaneous drainage of the liver abscess was performed during transpapillary drainage of the liver abscess. The remaining 10/13 (76.92 %) patients with left hepatic abscesses were qualified for transmural abscess drainage – active transgastric drainage of the abscess was performed under EUS guidance. The mean duration of active drainage of liver abscesses was 7 (5-16) days. Clinical success of endoscopic drainage of liver abscesses was achieved in 11/13 (84.62 %) patients. The mean duration of endotherapy was 224 (67-459) days. The mean follow-up period was 882 (226-1446) days. Long-term success of endoscopic treatment of liver abscesses was achieved in 9/13 (69.23 %) patients during the follow-up period.

Conclusions Endoscopic drainage of liver abscesses seems an effective and safe treatment method. The preferred approach is anatomical transpapillary drainage of the abscess during ERCP. If transpapillary access to the abscess cavity is impossible, extraanatomic transmural drainage of the liver abscess is an effective treatment option, which is only possible for left lobe abscesses.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP884 Endoscopic ablation of focal pancreatic lesions

Authors Bella E[1], Pawlak K[2], Kaczor P[1], Piątkowski J[1], Jackowski M[1], Jagielski M[1]

Institutes **1** Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum NCU, Toruń, Poland; **2** Hospial of the Ministry of Interior and Administration in Szczecin, Szczecin, Poland

DOI 10.1055/s-0046-1822211

Aims To assess the effectiveness and safety of EUS-guided endoscopic ablation of focal pancreatic lesions.

Methods A prospective assessment of treatment outcomes of all patients in whom EUS-guided ablation of a focal pancreatic lesion was performed between 2019 and 2025 at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum, Nicolaus Copernicus University in Toruń.

Results Endoscopic ablation of 26 focal pancreatic lesions was performed in 21 patients (14 women, 7 men; mean age 39.77 [21–75] years). Seventeen patients had solitary lesions, and four had multifocal lesions. Eight lesions were located in the pancreatic head, 12 in the body, and 6 in the tail. Histopathology revealed G1 neuroendocrine tumors in 14 patients, while in the remaining 7 patients metastatic renal cell carcinoma or breast cancer lesions were identified. The mean size of the focal lesions was 11 (7–20) mm. In 9 patients, EUS-guided radiofrequency ablation (EUS-RFA) of 12 pancreatic lesions was performed. In 12 patients, ablation of 14 lesions using 98 % ethanol was carried out. Technical success was achieved in 23/26 (88.46 %) lesions in 19/21 (90.48 %) patients. Complications occurred in 4/21 (19.05 %) patients. The mean follow-up was 864 (88–1464) days. Long-term success was achieved in 17/21 (80.95 %) patients.

Conclusions EUS-guided endoscopic ablation of focal pancreatic lesions is an effective and safe treatment option in selected patients and represents an alternative to surgical management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP885 Comparison of minimally invasive techniques in the treatment of high gastrointestinal obstruction

Authors Kaczor P[1], Pawlak K[1], Bella E[1], Piątkowski J[1], Jackowski M[1], Jagielski M[1]

Institute **1** Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum NCU, Toruń, Poland

DOI 10.1055/s-0046-1822212

Aims To determine the safety and effectiveness of gastroenterostomy performed using minimally invasive techniques.

Methods Retrospective analysis of treatment results of all patients with symptoms of high gastrointestinal obstruction who underwent laparoscopic or endoscopic (EUS-guided) gastrointestinal anastomosis in the years 2020–2025 at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum Nicolaus Copernicus University in Toruń, Poland.

Results In 64 patients (51 men, 13 women; mean age 61.72 [39-91] years) with symptoms of high gastrointestinal obstruction, gastrointestinal anastomosis using minimally invasive techniques was performed. Laparoscopic surgery was performed in 34/64 (53.13 %) patients, and endoscopic surgery in the remaining 30/64 (46.87 %) patients. Gastrointestinal malignancy was the cause of obstruction in 57/64 (89.06 %) patients. Technical success was achieved in 59/64 (92.19 %) patients. Complications of surgical treatment were observed in 14/64 (21.88 %) patients. Clinical success of gastrointestinal anastomosis using minimally invasive techniques was achieved in 55/64 (85.94 %) patients. During a mean follow-up period of 412 (155-1211) days, 2/64 (3.13 %) patients required endoscopic re-intervention due to gastrointestinal anastomosis stricture.

Conclusions Gastroenterostomy using minimally invasive techniques is a safe and effective treatment method for patients with high gastrointestinal obstruction

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP886 The role of endotherapy in colonic obstruction

Authors Kaczor P[1], Pawlak K[1], Bella E[1], Piątkowski J[1], Jackowski M[1], Jagielski M[1]

Institute **1** Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum NCU, Toruń, Poland

DOI 10.1055/s-0046-1822213

Aims To assess the treatment outcomes of patients with gastrointestinal obstruction due to colorectal cancer who underwent endoscopic treatment with the insertion of a self-expanding metal stent (SEMS).

Methods Retrospective analysis of treatment outcomes in patients with gastrointestinal obstruction due to colorectal cancer who underwent an endoscopic treatment with the insertion of SEMS in the years 2018–2025 at the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum Nicolaus Copernicus University in Toruń, Poland.

Results In 128 patients with gastrointestinal obstruction due to colorectal cancer, endoscopic treatment with the insertion of SEMS was performed. In 56/128 (43.75 %) patients, the procedure was palliative. In the remaining 72/128 (56.25 %) patients, the endoscopic procedure served as a bridge to surgery. Technical success of the endoscopic procedure was achieved in 119/128 (92.97 %) patients. Early complications, such as gastrointestinal perforation, were observed in 8/128 (6.25 %) patients who required surgery. Clinical success was achieved in 104/128 (81.25 %) patients. 11/128 (8.59 %) patients required surgery due to persistent symptoms of gastrointestinal obstruction.

Conclusions The use of SEMS for gastrointestinal obstruction associated with colon cancer reduces the frequency of urgent surgical procedures involving stoma formation. Furthermore, stenting of colonic obstruction provides a bridge to laparoscopic oncological treatment in some patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP887 Comfort and Success: Real-World Evaluation of Transnasal Endoscopy in the UK

Authors Gongaki S[1], Mukherjee S[1], Coda S[1], Mbiandji H[1], Gupta A[2], Tribich S[3], Banerjee S[1]

Institutes **1** Barking, Havering And Redbridge University Hospitals Nhs Trust, London, United Kingdom; **2** Digestive Diseases Centre (DDC), London, United Kingdom; **3** UCLH, london, United Kingdom

DOI 10.1055/s-0046-1822214

Aims Transnasal endoscopy (TNE) has emerged as a comfortable, sedation-sparing and resource-efficient alternative to the conventional oesophagogastroduodenoscopy (OGD). We aimed to evaluate feasibility, completion rates, safety, tolerance and indications for diagnostic TNE, predominantly in the outpatient setting across three sites of Barking Havering & Redbridge University Hospitals NHS Trust (BHRUT).

Methods A retrospective observational study included all consecutive TNE procedures performed between 01/05/2025 and 31/10/2025 at BHRUT. Procedures were performed using two ultrathin endoscope models: the Olympus GIF-H190N and the Pentax EG17-J10. Data collected included demographics, indication, use of nasal anaesthesia, sedation use, comfort score (0–4), completion to second part of the duodenum (D2), conversion to oral gastroscopy, and adverse events. Descriptive statistics were used to summarise outcomes. The majority of procedures were undertaken in the outpatient and ambulatory setting, aligned with the new Trust's transition of diagnostic OGD to TNE within Community Diagnostic Centres (CDC) and one-stop Faster Diagnostic Service (FDS) pathways.

Results A total of 138 procedures were included. The mean age was 60,8 years (range 17-89) and 70 patients (51 %) were female. Most procedures were performed in the outpatient and ambulatory setting (n = 80, 58 %). Nasal anaesthesia was almost universally used (n = 135, 98 %), while sedation was infrequently required (n = 28, 20 %).Patient tolerance was high, as 126 patients (92 %) reported a comfort score of 0 (no discomfort) or 1 (minimal discomfort). No patient reported the highest discomfort score of 4.Completion to D2 was achieved in 134 cases (97 %), comparable to conventional OGD. Conversion to oral gastroscopy occurred in 8 cases (6 %), mainly due to narrow nasal cavity (n = 4, 3 %) or patient intolerance (n = 3, 2 %). No adverse events were recorded. TNE was performed for a wide range of clinical indications, mirroring those of standard OGD. The most common was dysphagia, accounting for 42.8 % of all referrals. Other frequent indications included dyspepsia (25.4 %), unintentional weight loss (18.8 %), abdominal pain (13.8 %), heartburn (11.6 %), nausea (9.4 %), and anaemia (7.2 %). Less frequent indications included vomiting, bloating, oesophagitis and Barrett's surveillance. This demonstrates the broad applicability of TNE across both diagnostic and surveillance pathways.

Conclusions In this real-world UK cohort, transnasal endoscopy demonstrated excellent safety, high patient tolerance, and strong technical performance, comparable to conventional OGD, while offering clear operational advantages. The high completion rate, low conversion rate, minimal sedation use, excellent comfort scores and absence of adverse events highlight its suitability as a first-line diagnostic modality within ambulatory and Faster Diagnostic Service pathways. Particularly in our case, the introduction of ambulatory TNE within the CDC has freed capacity in core endoscopy rooms, enabling expansion of OGD services and supporting additional Trust-wide initiatives. These findings support broader adoption of TNE to improve patient experience, streamline diagnostic pathways and enhance system-wide efficiency. Further prospective work should assess cost-effectiveness and long-term patient-reported outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP888 Endoscopic Removal of Gastric GISTs Using a Novel Combined Approach – Endoscopic Submucosal Dissection, Full Thickness Resection, the Clip-Line Technique and a New Mucosal Flap Closure Technique – a Report of Two Cases

Authors Diaconu IG[1], Hazzouri N[1], Kreiner M[1], Kreysel C[1], Melchior I[1], Kreysel N[1], Layka H[1], Chaouachi R[1], Kösters K[1], Hünerlitürkoglu AN[1], Wullstein C[1], Gerges C[1]

Institute **1** Helios HMU Clinic Krefeld, Krefeld, Germany

DOI 10.1055/s-0046-1822215

Abstract Text

Gastrointestinal stromal tumours (GIST) are the most common type of subepithelial lesions (SEL). Current guidelines recommend surgery as the standard treatment for potential resectable tumours. However, with the advancement of third-space endoscopy, growing evidence supports endoscopic removal of gastric GIST as both effective and safe.

We report two cases of gastric GISTs removed endoscopically with a novel approach which integrates endoscopic submucosal dissection (ESD), full thickness resection (FTR), the clip-line technique and a new mucosal flap closure technique.

The first case involved a 62-year-old man with persistent abdominal pain. The second case concerned a 77-year-old woman transferred to our unit after multiple admissions in another hospital for recurrent upper gastrointestinal bleeding, requiring repeated transfusions. Both patients were diagnosed by gastroscopy and endoscopic ultrasound with fine-needle biopsy. Computed tomography was performed to exclude metastasis. The therapeutic options were thoroughly discussed. Endoscopic removal was chosen in both cases—by patient preference in the first case and due to significant cardiopulmonary comorbidities and high surgical risk in the second one. In the first case, endoscopy revealed a 20 mm SEL on the lesser curvature, approximately 1 cm distal to the gastroesophageal junction. In the second case, an approximately 50 mm SEL with an eroded surface was observed at the corpus-fundus junction [1–6]. Both therapeutic procedures were performed under general anaesthesia with orotracheal intubation. In both cases, marking and incision were performed with an ESD hybrid knife, followed by application of the clip-line technique to lift the submucosa. Layer-by-layer dissection was performed and coagulation with bipolar forceps due to marked vascularization had to be used. Because both lesions were adherent to the muscularis propria, FTR was carried out. Following these steps, complete en bloc removal of the lesions was achieved. A new mucosal flap closure technique – adjustment and repositioning of the mucosal flap and the subsequent placement of multiple clips – was then used to close the defects. Macroscopically, in sano resection was achieved in both cases. However, due to enucleation, R0 status could not be definitively assessed in the first case, whereas histology of the second confirmed tumour-free circumferential margins. In both cases, second-look gastroscopies confirmed intact resection sites with clips in situ. Prophylactic antibiotics were administered and the post-interventional course was uneventful.

In conclusion, these two cases show that gastric GISTs, including larger lesions, can be safely and effectively treated using this novel endoscopic approach combining ESD, the clip-line technique with FTR and mucosal flap closure.

DOI 10.1055/s-0046-1822216

Aims To assess and compare the diagnostic yield and histologic quality of samples obtained with EchoTip ClearCore and Acquire needles during EUS-guided biopsy of solid pancreatic lesions.

Methods A retrospective descriptive–correlational study including 19 patients who met the inclusion criteria and had no exclusion criteria, between June and November 2025. Tumor location, MOSE (visible core), number of passes, histologic quality, complications, and the need for repeat biopsy were evaluated. Differences between groups were assessed using the two-tailed Fisher's exact test (▶ **Table 1**).

Results The most frequent lesion location was the head/uncinate process (13/19; 68.4 %). An adequate visible core (MOSE ≥ 4 mm) was obtained in all cases. Most procedures required more than one pass (14/19; 73.7 %). No post-procedural complications were recorded. High-quality histology (score ≥ 7) was achieved in 91.7 % of samples obtained with the EchoTip ClearCore needle, compared with 71.4 % with the Acquire needle; this difference did not reach statistical significance (p = 0.5232), although the OR favored ClearCore (OR = 4.40). The mean number of passes was similar between devices (ClearCore 2.58 vs Acquire 2.14; p = 1.00). Diagnostic yield was high in both groups: 83.3 % for EchoTip ClearCore and 100 % for Acquire, with no significant differences (p = 0.5088). No complications were observed in either group.

Conclusions Both needles demonstrated safety and satisfactory diagnostic performance. No statistically significant association was found between needle type and either histologic sample quality or diagnostic yield. A limitation of the study was the small sample size.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP890 Longitudinal follow-up of double duct dilatation: What happens without EUS?

Authors Nyirenda TJ[1], Diamond J[1], Corallo C[1], On W[1]
Institute 1 St James's University Hospital, Leeds, United Kingdom
DOI 10.1055/s-0046-1822217

Aims Double duct dilatation (DDD) without an associated mass found on cross-sectional imaging warrants further investigations to exclude an occult periampullary tumour, although benign findings are common. Endoscopic ultrasound (EUS) can be performed in these patients. We aim to investigate the difference in longitudinal outcomes of patients who underwent EUS versus those who did not, and whether there were predictive factors for findings of pancreaticobiliary malignancies in these patients.

▶ **Table 1**

		EchoTip ClearCore	Acquire	p	OR
Tumor location	Head/Uncinate process	10 (83.3 %)	3 (42.9 %)		
	Body/Tail	2 (16.7 %)	4 (57.1 %)	0.1287	6.67
MOSE (Visible core)	Adequate (≥ 4 mm)	12 (100 %)	7 (100 %)		
	Inadequate (< 4 mm)	0 (0 %)	0 (0 %)	1.00	
Number of needle passes	0 (1 pass)	3 (25 %)	2 (28.6 %)		
	1 (> 1 pass)	9 (75 %)	5 (71.4 %)	1.00	0.8333
Histological quality	High (≥ 7)	11 (91.7 %)	5 (71.4 %)		
	Low (< 7)	1 (8.3 %)	2 (28.6 %)	0.5232	4.4
Histological diagnosis	Diagnostic	10 (83.3 %)	7 (100 %)		
	Non-diagnostic	2 (16.7 %)	0 (0 %)	0.5088	
Post-procedural complications	No	12 (100 %)	7 (100 %)

	Yes	1 (8.3 %)	1 (14.3 %)	1.00	1.8333
Surgical confirmation	No	12 (100 %)	6 (85.7 %)		
	Yes	0 (0 %)	1 (14.3 %)	0.3684	

Endoscopy 2026; 58: S1–S1041

Methods Patients with DDD between January 2015 to December 2023 were identified from radiology electronic patient records within a tertiary centre based in the United Kingdom. A dedicated radiologist re-reviewed the index scans to confirm the presence of DDD. DDD was defined as a common bile duct of greater than 7mm and a pancreatic duct of greater than 3mm at the pancreatic head. A retrospective analysis using clinical data from electronic patient records was performed. Follow-up of each case was defined as the point of review of their medical records, date of development of a malignant pancreaticobiliary condition or the date of death. Data was analysed using chi-squared, mann-whitney u test and fisher exact test depending on the type of data.

Results Initial search of the hospital medical imaging system resulted in 470 scans. The list was subsequently cut down to 153 individual cases by exclusion criteria including no DDD or associated mass found on imaging. 56 % had EUS (G1) performed following their scans, whilst 44 % had no EUS (G2). The median age of G1 was lower than G2 [median 68 years (58-75) vs 77 (69-85.5), p < 0.00001]. G1 had 53 % females and G2 had a higher proportion of 71 % (p = 0.03).

Baseline characteristics revealed G1 had significantly more patients with chronic pancreatitis (19 % vs 6 %, p = 0.03). Frequency of previous cholecystectomy (12 % vs 10 %, p = 0.77), opioid use (35 % vs 34 %, p = 0.85) and previous endoscopic retrograde cholangiopancreatography (4 % vs 1 %, p = 0.63) were similar in both groups. Biliary pain and jaundice followed a similar pattern of increased frequency in G1 but with no significant differences (39 % vs 28 %, p = 0.16) and (25 % vs 18 %, p = 0.29) respectively. Also, there was no difference with regards to weight loss (25 % vs 26 %, p = 0.8).

Abnormal LFTs were similar in both groups (56 % vs 60 %, p = 0.76). However, ALT was found to be significantly different [median 44 (17.5-154) vs 32 (12-85), p = 0.03]. Bilirubin [median 10 (6-29.5) vs 9 (6-18), p = 0.42], ALP [median 161 (95.5-485.5) vs 155 (91-390), p = 0.58] and Ca19-9 [median 28 (10-60) vs 19 (8.5-50), p = 0.42] had no significant differences. Proportions of computed tomography (52 % vs 60 %, p = 0.29) and magnetic resonance imaging (48 % vs 40 %, p = 0.29) scans were similar between both groups. Common bile duct [median 13 (11-17) vs 13 (11-18), p = 0.51] and pancreatic duct [median 6 (5.5-7) vs 7 (6-7.5), p = 0.12] sizes were also similar.

Lastly, median follow-up was significantly different with a longer time frame in G1 [40.6 months (26.5-65.9) vs 34.4 (13.4-56.1), p = 0.01]. The incidence of malignancy, however, was similar (5 % vs 13 %, p = 0.08). Patients diagnosed with malignancy during index EUS (n = 14) had predictive factors of jaundice (n = 11), weight loss (n = 6) and biliary pain (n = 6). The same factors were frequent in patients diagnosed during follow-up too (n = 13) with jaundice (n = 10), weight loss (n = 3) and biliary pain (n = 3).

Conclusions Our study has demonstrated in cases where no cause of DDD is seen on cross-sectional imaging or EUS, there are low rates of malignancy in the follow-up period. Though not statistically significant, patients who did not have EUS had an increased occurrence of malignancy. In the absence of jaundice, weight loss and biliary pain, the likelihood of malignant pathology is low. Given the risks associated with pancreaticobiliary endoscopy, especially in an aging population, this study stresses the importance of careful case selection and allowing time to counsel patients for invasive investigations, if deemed appropriate.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP891 EUS Training Across Five Continents: A Global Snapshot of Skills, Challenges, and Training Needs

Authors Delsa H[1], El Amrani K[1], Nadi A[1], Bahlaoui O[1], Belabbes F[1], Alaoui Mdaghri R[1], Harouchi A[1], Bennani Y[1], Benjelloun N[1], Khannoussi W[1], Ben El Barhdadi I[1]

Institute **1** Cheikh Khalifa International University Hospital, Mohammed VI University of Sciences and Health, Casablanca, Morocco

DOI 10.1055/s-0046-1822218

Aims The objective of this study is to assess endoscopists' training needs in Endoscopic Ultrasound (EUS) via an anonymous survey and to identify the key challenges faced to develop appropriate training programs.

Methods This prospective cross-sectional study used an anonymous online survey completed by over one hundred endoscopists involved in EUS practice or training. The needs assessment was conducted using the FGP grid (frequency, gravity, and problems) across seven items. Each item was evaluated based on its frequency (0, 1, 2), severity (0, 1, 2), and the difficulties related to knowledge, skills, and attitudes (0, 2, 4). Data processing and statistical analysis were performed using Jamovi version 2.4.

Results A total of 85 responses were collected from 30 countries spanning five continents. Of the respondents, 60 % were male (male-to-female ratio: 1.5). Half of the participants were aged between 30 and 40 (48.2 %), followed by those aged between 40 and 50 (30 %). One in three participants was a teacher. Endoscopy had been practised by 49.4 % of participants for more than 10 years, while EUS had been performed by 62.4 % for less than 5 years. Although 83.6 % of training centres had EUS equipment, only 55.3 % of participants had received EUS training.

Several EUS training methods were reported, including hands-on training with patients (63.5 %), a university or inter-university diploma (47.1 %), webinars or distance learning (35.3 %), hands-on training with models or animals (30.6 %), and certification programmes (25.9 %). The majority of participants preferred hands-on training with patients (84.7 %) or models (42.4 %), followed by a university diploma (42.4 %).

55,3 % of the participants felt that the training they had received was inadequate. According to the FGP grid, the main difficulties encountered were related to knowledge, followed by skills.

81.2 % of participants reported theoretical difficulties in interpreting EUS and understanding interventional EUS techniques. The availability of equipment was challenging for 3 out of 4 participants (75,3 %).

From a practical perspective, interventional EUS and EUS interpretation were the most problematic issues for 3 out of 4 participants (75.3 %, 77.6 %).

When comparing the training methods, the group with hands-on training with patients reported fewer difficulties in performing EUS (p = 0.003) and professional skills (p = 0.019). The statistical analysis comparing the group of participants working in centers performing 10 to 20 EUS procedures per week and those working in expert centers (more than 20 EUS procedures per week) showed a significant difference regarding practical difficulties in performing and interpreting EUS (p = 0.001).

Conclusions EUS is a fundamental modality for both diagnosing and treating digestive and biliopancreatic disease. Findings from our international multicenter survey indicate significant training needs, especially in EUS interpretation and interventional practice. We observed that theoretical and technical challenges were fewer for endoscopists working in expert centers with high volumes of procedures, and that hands-on training with patients provided a clear performance advantage, reinforcing its importance in EUS education.

DOI 10.1055/s-0046-1822219

Aims Large Traditional Serrated Adenomas (TSA ≥ 20mm) are an important subgroup of colorectal neoplasms. There is limited data about large TSAs and most information on these lesions has been derived from the analysis of smaller lesions. We sought to analyse the clinicopathological features of large TSAs in comparison to large Tubulovillous Adenomas (TVAs) in a multicenter prospective cohort (▶ **Table 1**).

▶ Table 1

				EMR			ESD			En bloc			Piecemeal		
	TSA (n = 107)	TVA (n = 1989)	P value	TSA (n = 82)	TVA (n = 1817)	P value	TSA (n = 25)	TVA (n = 172)	P value	TSA (n = 30)	TVA (n = 309)	P value	TSA (n = 77)	TVA (n = 1679)	P value
Cancer	11/107 (10.2 %)	176/1989 (8.8 %)	0.613	8/82 (9.8 %)	144/1817 (7.9 %)	0.717	3/25 (12 %)	32/172 (18.6 %)	0.420	3/30 (10 %)	46/309 (14.9 %)	0.467	8/77 (10.39 %)	130/1679 (7.7 %)	0.399
Recurrence	10/72 (13.9 %)	165/1645 (10.0 %)	0.289	10/59 (16.9 %)	161/1506 (10.7 %)	0.131	0/13 (0 %)	4/139 (2.9 %)	0.535	0/17 (0 %)	6/309 (1.9 %)	0.562	10/55 (18 %)	159/1336 (11.9 %)	0.162

Significant deep mural injury	8/107 (7.5 %)	90/1989 (4.5 %)	0.157	5/82 (6 %)	76/1817 (4.2 %)	0.401	3/25 (12 %)	14/172 (8.1 %)	0.521	5/30 (16.7 %)	23/309 (7.4 %)	0.08	3/77 (3.9 %)	67/1679 (4.0 %)	0.967

Methods We analysed the Australian Colonic Endoscopic Resection cohort, a multicenter, observational study of consecutively referred patients with large non-pedunculated colonic polyps (LNPCP). Participants were enrolled at 1 of 7 sites between July 2008 to February 2025. The clinicopathological data of large TSAs were compared with large TVAs.We analysed the Australian Colonic Endoscopic Resection cohort, a multicenter, observational study of consecutively referred patients with large non-pedunculated colonic polyps (LNPCP). Participants were enrolled at 1 of 7 sites between July 2008 to February 2025. The clinicopathological data of large TSAs were compared with large TVAs.

Results Among 4665 LNPCPs, there were 114 large TSAs (2.4 %) and 2411 TVAs (51.6 %). TSAs were more often left sided (70 % vs 40 %, p < 0.01) and occurred more frequently in women (61 % vs 45 %, p = 0.004). Lesion size and morphology were comparable. SMIC rates were equivalent (10.2 % vs 8.8 %, p = 0.77). Recurrence at first surveillance was similar (13.9 % vs 10 %, p = 0.29). Synchronous LNPCPs occurred in 11.4 % vs 8.7 % respectively (p = 0.53). Post procedural bleeding (6.5 % vs 9.1 %, p = 0.37) and significant deep mural injury (7.5 % vs 4.5 %, p = 0.16) were comparable between the two groups.

Conclusions We present novel data indicating that large TSAs are clinically significant lesions with an SMIC risk of 10.2 %. They parallel TVAs in morphology and resection outcomes. Their management warrants the same meticulous approach applied to advanced adenomatous lesions, encompassing technical precision and vigilance during index and surveillance endoscopy for synchronous neoplasia.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP893 Outcomes and determinants of delayed ERCP in acute cholangitis: a retrospective cohort study

Authors Inês S[1], Figueiredo P[1], Barreiro P[1], Bana E Costa T[1], Cristina C[1]
Institute 1 Hospital Egas Moniz, Lisboa, Portugal
DOI 10.1055/s-0046-1822220

Aims The cornerstone of acute cholangitis treatment is antibiotic therapy combined with biliary drainage. The Tokyo Guidelines 2018 provide severity grading criteria that help predict prognosis and identify patients requiring early biliary drainage. While mild cholangitis can often be managed initially with antibiotics alone, moderate and severe cases typically require early and emergent drainage, respectively. Our aim is to explore factors influencing the timing of ERCP in acute cholangitis and its impact on clinical outcomes.

Methods This retrospective single-center cohort study included patients diagnosed with acute cholangitis who underwent ERCP between March 2022 and December 2024 in a tertiary hospital with ERCP. Diagnosis and severity grading were based on the Tokyo Guidelines 2018. Descriptive and statistical analyses were performed to evaluate patient characteristics, severity classification, timing to ERCP and related clinical outcomes.

Results A total of 145 patients underwent ERCP for acute cholangitis; 79 were female (54 %) and the median age was 79 years. Based on the Tokyo 2018 criteria, 41 patients (28.3 %) had grade III cholangitis, 60 (41.4 %) grade II and 44 (30.3 %) grade I. Regarding etiology, lithiasis was the predominant cause of cholangitis, with 99 patients showing choledocholithiasis on ERCP. Malignant biliary strictures accounted for 12 cases (8.2 %), and among these, 50 %presented with a previously placed biliary stent. Only 12 patients (8.3 %) underwent ERCP within 24 hours of admission – 4 with grade III, 4 with grade II and 4 with grade I. Within 72 hours, 56 patients (38.6 %) had undergone ERCP – 21 with grade III, 20 with grade II and 15 with grade I. Notably, 49 % of grade III cases were submitted to ERCP more than 72 hours after admission, with a median of 2 days of antibiotics before drainage. There was no statistically significant association between ERCP timing and patient age, cholangitis severity, intensive/intermediate care admission or anticoagulant/antiplatelet use. Among organ dysfunction criteria, only neurological dysfunction showed a statistically significant association with earlier ERCP (p = 0.032). Admission on Friday to Sunday strongly predicted delayed intervention (p < 0.001), 84 % of these patients underwent ERCP more than 72 hours after admission, compared with 45 % for weekday admissions. Cholangitis severity was significantly correlated with length of hospital stay (grade I: 7.6 ± 3 days, grade II: 7.7 ± 4 days, grade III: 12.3 ± 4 days; p < 0.001). The 30-day mortality rate was 3.4 %, with no significant association with ERCP timing or cholangitis severity. The median age of patients who died was 88 years (range 86–97). Only one death was directly attributed to severe acute cholangitis, in which ERCP was performed past the guideline recommended timing.

Conclusions In this real-world cohort, ERCP was frequently delayed beyond the recommended window, even in severe acute cholangitis. Weekend admission was a significant contributor to this delay. However, no association was found between ERCP timing and 30-day mortality, likely due to small sample size. These findings highlight the need for optimized access to biliary drainage, particularly during weekends, to better meet guideline recommendations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP894 Evaluating Prophylactic Measures in Piecemeal Resection: The Role of Endoscopist Expertise

Authors Inês S[1], Rui M[1], Cristina C[1]
Institute **1** Hospital Egas Moniz, Lisboa, Portugal
DOI 10.1055/s-0046-1822221

Aims Piecemeal endoscopic mucosal resection (p-EMR) remains widely used for large non-pedunculated colonic polyps when en-bloc excision is not feasible. However, piecemeal resection is associated with a substantial risk of residual or recurrent adenoma due to fragmentation and incomplete resection. The 2024 ESGE guideline on colorectal polypectomy and EMR recommends that after hot-snare piecemeal EMR of large non-pedunculated colorectal polyps (LNPCPs), resection margins should undergo thermal ablation using snare-tip soft coagulation to decrease adenoma recurrence. In real-world practice, recurrence after EMR without margin ablation has been reported to reach 15–20 %. Accordingly, reduction of recurrence – and the role of endoscopist expertise – remains critical for optimisation of patient outcomes. This study aimed to evaluate adenoma recurrence after piecemeal hot-snare resection in our center, and to assess the impact of prophylactic interventions (margin ablation and/or cold-snare margin resection) as well as endoscopist expertise.

Methods We conducted a retrospective, single-center cohort study of all patients undergoing piecemeal hot-snare polypectomy or mucosectomy between January 2022 and December 2023 in a tertiary-care hospital. Lesions were classified based on the Paris Classification. We defined "experienced endoscopist" as one performing > 50 EMRs annually and/or having expertise in endoscopic submucosal dissection (ESD). We recorded whether prophylactic measures were applied after resection: margin thermal ablation and/or cold-snare margin resection. Descriptive statistics and appropriate comparative analyses were employed to explore associations between recurrence rates, the use of prophylactic measures, and endoscopist experience.

Results We resected 102 lesions in 102 patients. The median lesion size was 25 mm (range 10–50 mm); most lesions were located in the ascending colon (37.3 %) or cecum (22.5 %). The majority were Paris 0-IIa morphology (71.6 %), including 45 granular and 8 non-granular LSTs. Prophylactic measures were applied in 66 cases (64.7 %) – margin thermal ablation in 43, cold-snare margin resection in 9, and both in 14. Histopathology revealed 88 adenomas, 13 serrated lesions without dysplasia, and one with dysplasia. Of the 88 adenoma cases, 57 (64.8 %) underwent surveillance colonoscopy at a mean of 8.7 months post-resection. Overall adenoma recurrence was observed in 19.3 % of patients. With prophylactic measures, recurrence was 14 %; notably, none of the patients in whom both techniques were used had recurrence, compared with 28 % recurrence in the no-prophylaxis group — though this difference did not reach statistical significance. Recurrence was not associated with lesion size, location, or morphology. In contrast, procedures performed by an experienced endoscopist had a significantly lower recurrence rate (4 % vs. 31.3 %, $p = 0.016$). Within the prophylaxis subgroup, recurrence remained lower in the experienced endoscopist group, although the difference did not achieve statistical significance — likely due to limited sample size.

Conclusions In our series, nearly one in five patients had adenoma recurrence after piecemeal resection, despite surveillance. Use of prophylactic measures (margin ablation and/or cold-snare margin resection) was associated with a lower recurrence rate, particularly when both techniques were applied. However, statistical significance was not reached, due to limited sample size and follow-up. Importantly, endoscopist expertise emerged as the most significant factor associated with decreased recurrence, underscoring the critical role of operator experience. These findings suggest that concentration of EMR in experienced hands may improve outcomes. Larger, adequately powered prospective studies are warranted to better define optimal prophylactic strategies, operator competency thresholds, and follow-up protocols.

DOI 10.1055/s-0046-1822222

Aims We tested whethera 3D-printed cap delivers non-inferior efficiency with superior handling versus a standard commercial cap in the multicenter ENDOPRINT trial (ex vivo porcine models) which took place in Prague and Olomouc (Czech Republic) and Boston (USA).

Methods Across three centers, 99 ESDs (33/site) were randomized 1:1 to a 3D-printed or commercial cap (Olomouc 20/13; Prague 15/18; Boston 16/17). The primary endpoint was procedure time.The secondary endpoints were lesion size, en-bloc resection rate, ergonomics, scope withdrawal for cleaning/exchange, and adverse events. The 3D-printed cap was createdon Form 3B using BioMed Flex 80A.

Results Procedure time was the same for both caps (median 17.3 min; $p = 0.952$); technical and en-bloc resection rates were the same (100 %). Ergonomic parameters favored the 3D-printed cap (visibility 4 vs 3; manipulation 4 vs 3; retraction 5 vs 3; all $p < 0.001$) and were replicated at each center. Adverse events were rare and similar (tears 4 vs 3; perforation 0 vs 1). Lesion size correlated with time ($\rho = 0.44$; $p = 0.001$), center effects, not cap type, explained time variability.

Conclusions Custom 3D-printed distal attachment caps are non-inferior for speed and safety; however, 3D caps provide superior visibility and traction. These data support rapid, design-tailored, cost-efficient accessories for ESD and training. Clinical in vivo validation and economic analyses are warranted.

DOI 10.1055/s-0046-1822223

Aims identify the clinical, lesion characteristics and endoscopic factors that led tosurgical management of colorectal tumors potentially amenable to endoscopic resection(ER). Secondary aims included assessing the accuracy of optical characterization, theimpact of reassessment in an expert center, as the outcomes of non-curative ER of pT1adenocarcinoma (ADC).

Methods retrospective analysis of all patients submitted to surgery between 2020-2024with surgical specimen showing dysplasia, pT1 ADC, or no dysplasia/ADC after ER.Patients with polyposis syndromes, inflammatory bowel disease and neoadjuvantchemoradiotherapy were excluded. Data on index colonoscopy, reassessment atreferral center, ER attempt, surgical indication, final histopathology and post-resectionoutcomes were collected.

Results Results:113 patients with 113 lesions were included (61 % male; 71 ± 8 years-old). Indexcolonoscopy was performed mainly in private clinics (55 %); 24 % were reassessed at areferral center. Median lesion size was 35 mm (IQR 20), most frequently located in theleft colon (28 %), ascending colon (24 %), or caecum (22 %).53 % were described as neoplastic, and 28 % underwent virtual chromoendoscopyevaluation. When enhanced imaging was used, there was a correlation between opticaldiagnosis and the surgical specimen histopathology: NICE/JNET 3 showed 64 % of ADC(p = 0.050). Describing a lesion as "neoplastic" on white-light endoscopy showed noassociation with final ADC (p = 0.177).ER was attempted in 23 % of cases. Piecemeal mucosectomy (42 %), polypectomy(35 %) and en-bloc mucosectomy (8 %) were the most common techniques. Amongpatients operated for non-curative ER (12 %) – defined as positive margins,lymphovascular invasion, poor differentiation or deep invasion – 77 % had no dysplasia/ADC on the surgical specimen.Indications for surgery were suspicion of deep invasion (61 %), non-curative ER (12 %)and ER failure (11 %). Predictors of "advanced lesion suggestive of deep invasion" were:description as neoplastic (OR 19.4, p<0.001), NICE/JNET 3 (OR 11.7, p = 0.005), andbiopsy suggesting ADC (OR 2.56, p = 0.062). Reassessment at a referral center wasprotective (OR 0.17, p = 0.005). Lesion size did not reach significance (p = 0.081).Final histology revealed 41 % HGD and 48 % ADC. Submucosal invasion was quantifiedin 13.5 % of the ADC specimens. Excluding deep submucosal invasion as a risk factor,7 % presented any high-risk criteria for lymph-node metastasis (LNM) (50 % was deepsubmucosal invasion), with one confirmed LNM. Postoperative morbidity occurred in27 %, 55 % with dysplasia. The median length of hospital stay was 6 days (IQR 3).

Conclusions surgical management of colorectal dysplasia and T1 cancer was largelydriven by initial endoscopic impression on index colonoscopy, rather than by structuredand comprehensive lesion characterization. Limited use of virtual chromoendoscopy,low rates of expert reassessment, and underutilization of ER contributed to escalationtoward surgery, often without high-risk histological features. These findings highlightsubstantial overtreatment potential and underscore the need to strengthen opticaldiagnosis, standardized referral pathways, and reassessment in expert centers.

eP897 First-in-human study of proximal intestinal mucosal ablation (PIMA) for the treatment of inadequately controlled type 2 diabetes

Authors Norton B[1,2], Telese A[2,1], Marin P[3], Hoebel P[3], Vignolo P[3,4], Johnson G[5,2], Rodriguez Grunert L[3], Shaheen N[6], Haidry R[2]

Institutes **1** University College London, London, United Kingdom; **2** Cleveland Clinic London, London, United Kingdom; **3** Clínica Colonial, Santiago, Chile; **4** Clinica Alemana, Santiago, Chile; **5** University College Hospital, London, United Kingdom; **6** University of North Carolina at Chapel Hill, Chapel Hill, United States of America

DOI 10.1055/s-0046-1822224

Aims Proximal intestinal mucosal ablation (PIMA) is a metabolic endoscopic procedure that aims to replicate the glycaemic benefits of gastric bypass surgery in patients with type 2 diabetes (T2D). This is achieved by endoscopically ablating up to 60 cm of the abnormal, hypertrophied intestinal mucosa. PIMA is completed with the through-the-scope, radiofrequency vapor ablation (RFVA) mesh-tip catheter. In our first in-human study, we investigated RFVA as a modality of duodenal mucosal ablation for the treatment of T2D, which is limited to 15 cm of treated duodenum. We hypothesised that a longer ablation length could lead to an improved and more durable glycemic response without compromising safety. Accordingly, we report the first-in-human evaluation of PIMA, which aimed to assess its safety, tolerability, feasibility, and early efficacy.

Methods A prospective, single-centre first-in-human study evaluating PIMA using RFVA for the treatment of uncontrolled T2D (glycated haemoglobin [HbA1c] 7.5-10.0 %) despite ≥ 1 oral glucose-lowering agent (GLA) within Clinica Colonial, Santiago (NCT05887635). After screening, patients underwent a 4-week run-in period to ensure stable glycaemic control before undergoing PIMA between September 2024 and May 2025, alongside standard lifestyle advice for T2D and no change in GLAs. PIMA was performed via an adult colonoscope (Olympus HQ190L) with the circumferential through-the-scope mesh-tip RFVA catheter under general anaesthesia. RFVA was delivered at a dose of 250-275J with double application (2X) to the post-ampullary intestinal mucosa. Patients were discharged within 24 hours on a modified day for 14 days. Technical success was defined as ≥ 20 cm of ablated post-ampullary mucosa. The primary outcomes were safety (serious adverse events), tolerability (visual analogue score [VAS] for pain post-procedure), feasibility (procedure time and ablation length), and reduction in HbA1c at 3- and 6-months. Secondary exploratory outcomes included change in body mass index (BMI) and Homeostatic Model Assessment of Insulin Resistance (HOMA-IR).

Results In total, 13 patients (38.5 % female) with an average age of 52 years (IQR 45-61) underwent PIMA. The average T2D disease duration was 6 years (IQR 5-9), the baseline HbA1c was 9.3 % (SD 0.7), BMI was 31.4 kg/m2 (SD 2.5), and the average number of GLAs was 1 (IQR 1-2). PIMA was successful in all patients with an average treatment length of 54 cm (IQR 44-60) and 40.8 (SD 10.7) ablations. Six patients were treated with a 250 J dose, and seven patients with 275 J. The average procedure time was 62.2 minutes (SD 14.4) and catheter time 51.3 minutes (SD 19.2). PIMA was well-tolerated with a maximum median VAS score of 1 (IQR 0-2) on day 2. All patients reached six months follow-up, and there were no adverse events related to the procedure or episodes of hypoglycaemia. Follow-up enteroscopy with biopsy was normal in all patients. The median reduction in HbA1c at 3- and 6-months was 2.5 % (IQR 1.4-2.9; p < 0.0001) and 2.2 % (IQR 1.0-2.5; p = 0.0001), respectively. Over the same period, we observed a non-significant reduction in BMI by 0.6 kg/m2 (SD 1.3; p = 0.13) and 1.0 kg/m2 (SD 1.9; p = 0.08), as well as reductions in HOMA-IR by -2.7 (SD 3.3; p < 0.05) and -2.0 (SD 3.3; p = 0.05), respectively.

Conclusions PIMA appears to be a safe, feasible, and well-tolerated metabolic endoscopic procedure that leads to major reductions in glycated haemoglobin comparable to modern injectable pharmacotherapies.

Aims This study aims to evaluate the efficacy and safety of Speedboat Submucosal Dissection (SSD) for large colorectal pedunculated polyps compared with conventional Hot Snare Polypectomy (HSP)

Methods This retrospective, multicenter study was conducted at three tertiary hospitals in Thailand. The study period spanned from October 2022 to October 2025. We included patients diagnosed with large colorectal pedunculated polyps (Size ≥ 2cm) who underwent endoscopic resection using either Speedboat Submucosal Dissection (SSD) or Hot Snare Polypectomy (HSP). Clinical data, including patient demographics, procedural details, and adverse events, were retrospectively collected from medical records. Statistical analysis was performed to compare the efficacy and safety outcomes between the two groups (▶ **Table 1**).

Results A total of 55 patients were included in the study, comprising 25 patients in the Speedboat Submucosal Dissection (SSD) group and 30 patients in the Hot Snare Polypectomy (HSP) group. The mean polyp size was 2.72 cm in the SSD group and 2.46 cm in the HSP group.

In terms of efficacy, the complete resection rate was 100 % (25/25) in the SSD group compared with 93.3 % (28/30) in the HSP group; however, this difference was not statistically significant (p = 0.495). Histopathological analysis revealed adenocarcinoma in 12 % (3/25) of the SSD group and 13.3 % (4/30) of the HSP group. Notably, the mean procedure time was significantly longer in the SSD group compared with the HSP group (94.28 min vs. 53.70 min, p = 0.020).

Regarding safety outcomes, there were no significant differences in adverse events between the two groups. Delayed bleeding was not observed in the SSD group (0 %) but occurred in one patient (3.3 %) in the HSP group (p = 1.000). No perforation occurred in either group.

Conclusions Our study demonstrates that Speedboat Submucosal Dissection (SSD) is a safe and feasible technique for the management of large pedunculated colorectal polyps when compared with conventional Hot Snare Polypectomy (HSP). A key finding of this study was the 100 % complete resection rate achieved in the SSD group. Although this did not reach statistical significance compared to the HSP group, likely due to the limited sample size, the absolute success rate suggests that SSD offers high efficacy without compromising safety.

In terms of safety, SSD showed a comparable profile to HSP with no occurrences of serious complications, such as perforation or uncontrolled bleeding. However, it is important to note that the procedure time for SSD was significantly longer than that for HSP. This difference reflects the technical complexity of the SSD procedure, which involves precise submucosal dissection, compared to the more rapid snare technique.

Abstract Text

We present a 73-year-old patient with multiple cardiovascular comorbidities, unfitfor surgery, diagnosed with Barrett's esophagus (C3M6) with visible lesions (ParisIIa, IIc, Is) and high-grade dysplasia (HGD). The patient underwent endoscopic submucosal dissection (ESD) for suspected submucosal invasion. Histopathology revealed G2 adenocarcinoma (pT1b sm2) with intestinalmetaplasia and extensive HGD, but no lymphovascular invasion, with clear margins(R0). Post-procedure, esophageal stricture required multiple dilations. Surveillance gastroscopy identified a new adenocarcinoma (pT2Nx, R0), managed by full-thickness resection and stenting. Nine months post-treatment, the patient remains recurrence-free. This case underscores advanced endoscopic techniques asorgan-sparing solutions for high-risk patients.

eP900 Evaluating Proximal Intestinal Mucosal Ablation as a Repeat Endoscopic Therapy for Type 2 Diabetes

Authors Norton B[1, 2], Telese A[2, 1], Marin P[3], Hoebel P[3], Vignolo P[3, 4], Johnson G[5, 2], Rodriguez Grunert L[3], Shaheen N[6], Haidry R[2]

DOI 10.1055/s-0046-1822227

Problem to solve Endoscopic small intestinal ablation is an investigational therapy for patients with type 2 diabetes (T2D) designed to replicate the metabolic benefits of gastric bypass surgery. To date, ablation has been limited to 10-15 cm of the post-ampullary duodenum due to limitations with currently available devices. In our first-in-human study (NCT05887635), we demonstrated that radiofrequency vapor ablation (RFVA) with a novel through-the-scope catheter was feasible for duodenal mucosal ablation (DMA), though glycaemic responses were heterogeneous. Major unanswered questions in the field are whether endoscopic small intestinal ablation is durable and whether the procedure can be safely repeated to maximise metabolic benefit over time. To address these limitations, we developed proximal intestinal mucosal ablation (PIMA), which is an extended ablation approach targeting up to 60 cm of proximal small bowel. Through PIMA, we hypothesised that (1) small intestinal ablation with RFVA could be safely repeated, and (2) extending the ablation length would elicit improved glycaemic control even in patients with an inadequate response to prior DMA.

Innovation This prospective, single-centre study (NCT06724822) evaluated PIMA, a newly developed small intestinal ablation technique using the second-generation circumferential RFVA catheter. This catheter was specifically designed to safely enable a longer ablation (up to 60 cm) with its mesh-tip and ability to pass through-the-scope. Patients with an inadequate glycaemic response to initial DMA (defined as < 0.5 % glycated haemoglobin [HbA1c] reduction or HbA1c > 7.5 % at the end of 6-months follow-up from our initial DMA cohort) were enrolled. All suitable participants underwent PIMA between Sep-2024 and May-2025. Continuous glucose monitoring (CGM) was initiated at baseline, and PIMA was performed via an adult colonoscope (Olympus HQ190L) under general anaesthesia. RFVA was delivered at a dose of 275J with double application to the post-ampullary intestinal mucosa. Post-procedure, patients followed a 14-day modified diet, continued oral glucose-lowering agents (GLA), and received standard lifestyle advice for T2D. Primary innovation endpoints included (1) Procedural feasibility, (2) Safety and tolerability of repeat RFVA, and (3) Early metabolic efficacy captured by HbA1c and CGM parameters over six months.

Results Nine patients were screened and six (mean age 52.5 years [IQR 48–58], 83.3 % female) underwent PIMA at an average of 13.9 months after DMA. During initial DMA, mean HbA1c reductions from screening to 3-, 6-, and 12-months were 0.8 % (SD 0.9), 0.4 % (SD 0.7), and –0.3 % (SD 0.9). At re-treatment, mean baseline HbA1c was 9.0 % (SD 0.9), body mass index (BMI) 30.3 kg/m² (SD 4.0), and patients were on a median of one GLA. PIMA was successful in all patients with an average length of treated bowel of 57.5 cm (IQR 51-63) and 51.0 (SD 11.8) ablations. Average procedure time was 74.5 minutes (SD 20.1) and catheter time 62.3 minutes (SD 19.8). PIMA was well tolerated, with a maximum median visual analogue score for pain of 1 (IQR 0–2) on day 3. Follow-up enteroscopy with biopsies was normal in all patients. Five patients have completed 6-month follow-up with no serious adverse events and one related adverse event (abdominal pain). Median HbA1c reduction was 1.9 % (IQR 1.2–2.5; p = 0.002) at 3-months and 1.8 % (IQR 1.7–2.3; p = 0.0006) at 6-months. BMI decreased by 1.3 kg/m² (SD 1.0; p = 0.03) and 1.0 kg/m² (SD 1.8; p = 0.35), respectively, while time-in-range (3.9-10.0 mmol/L) at these time points was 87 % (IQR 75–91) and 74 % (IQR 73–81).

Conclusions PIMA with RFVA appears safe and feasible as a repeat endoscopic therapy for T2D. The greater HbA1c reduction observed with PIMA suggests that ablation length may be a key determinant of metabolic efficacy.

Conflicts of Interest RH, LARG, PM, PBH, PV, BCN, and NS disclose receipt of research funding from Aqua Medical Inc. to support research infrastructure

eP901 From Routine to Optimized: The Real-World Impact of Water-Assisted Colonoscopy

Authors Lekakis V[1], Karageorgou M[2], Daskalaki E[2], Karaoulanis V[2], Sfyri F[2], Vlachogiannakos I[2]

Institutes **1** General Hospital of Athens, G.Gennimatas UoA, Athens, Greece; **2** Evgenidion Hospital, UoA, Athens, Greece

DOI 10.1055/s-0046-1822228

Aims Water-assisted colonoscopy (WAC) has gained attention over the past decade as a technique that may enhance patient comfort, reduce sedation needs, and potentially improve mucosal visualization compared with conventional gas insufflation. Despite its advantages, widespread adoption in daily practice remains limited. The aim of this study was to evaluate the real-world performance, safety and feasibility of implementing WAC as the default method for routine colonoscopy in a high-volume endoscopy unit.

Methods This prospective observational study included all consecutive colonoscopies performed with the water-assisted technique over a 12-month period. A total of 487 examinations were analyzed. Data collected included cecal intubation rate (CIR), total procedure time, propofol dose, adenoma detection rate (ADR), patient-reported tolerance and adverse events. The feasibility and safety of underwater polypectomy during WAC were also assessed.

Results Cecal intubation was achieved in all examinations (100 %), demonstrating the technical reliability of the method even in a mixed screening and diagnostic population. The mean total procedure time was 12.6 ± 3.5 minutes, clearly shorter than commonly reported times for standard air or CO_2 insufflation techniques. Sedation requirements were remarkably low, with a mean propofol dose of 35 ± 10 mg. Nearly one quarter of patients (23.8 %) required only minimal sedation (< 20 mg). These findings highlight one of the most practical advantages of WAC in real-world settings: significantly reduced medication use and faster post-procedural recovery. The overall ADR was 45.8 %, a performance level consistent with high-quality colonoscopy practice and comparable to or superior to previously published WAC data. The clear water-filled lumen and buoyancy-induced stabilization of mucosal folds appeared to assist in the visualization of flat or subtle lesions. Underwater polypectomy was performed in 67 polyps, mainly flat or sessile lesions up to 25 mm. In approximately 75 % of these cases, no submucosal injection was required due to the lifting effect created by the water column, which facilitated safe and controlled resection. Safety outcomes were excellent. No perforations or delayed bleeding events occurred, and overall complications were negligible. Mild, transient post-procedural abdominal discomfort was reported in only 2.4 % of patients. Patient satisfaction was high, with 96 % rating the experience as “excellent” or “very good,” largely attributed to minimal discomfort, reduced cramping and decreased need for sedation.

Conclusions In conclusion, water-assisted colonoscopy can be successfully incorporated into the daily workflow of a modern endoscopy unit, offering significant advantages over conventional colonoscopy. The technique was associated with shorter examination times, minimal propofol requirements, high adenoma detection rates, excellent patient tolerance and an extremely low complication profile. These real-world findings support the broader adoption of WAC as an efficient, patient-friendly and high-quality method for routine colonoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822229

Aims Irritable Bowel Syndrome (IBS) affects 5–10 % of the population and remains a diagnosis of exclusion, based on Rome IV symptom-based criteria, rather than analytical, endoscopic or histological biomarkers. Given clinical similarities with inflammatory bowel disease many patients with IBS-like symptoms—such as diarrhea, constipation or abdominal pain—undergo colonoscopy, that has no macroscopic or histological abnormalities, contributing to diagnostic delay and healthcare burden. The absence of identifiable endoscopic features differentiating Rome IV-confirmed IBS from nonspecific symptom presentations highlights a major unmet clinical need. Deep learning models may detect subtle mucosal patterns beyond human perception, potentially redefining the diagnostic role of endoscopy in functional bowel disorders. In this context, the authors aimed to develop an artificial intelligence model capable of identifying endoscopic features suggestive of IBS during colonoscopy.
Methods A total of 183,543 frames from 242 colonoscopy exams performed in Portugal, Spain and Brazil, using five different colonoscopy systems, were included for model development. Only exams with good bowel preparation (Boston Bowel Preparation Scale ≥ 6) and no evidence of inflammatory bowel disease were considered. Among these, 129 patients had IBS confirmed according to Rome IV criteria. Images were divided into training, validation and testing sets (70 % / 20 % / 10 %). The model was evaluated using accuracy, precision, recall and F1-score.
Results In the testing dataset, frames from IBS-confirmed patients were identified with 97.1 % accuracy, 91.7 % precision, 70.6 % recall, and an F1-score of 79.5 %. Frames from non-IBS patients were classified with 91.7 % accuracy, 94.3 % precision, 91.2 % recall, and an F1-score of 92.6 %.
Conclusions This proof-of-concept study is the first to demonstrate that deep learning can identify endoscopic patterns associated with IBS, even when colonoscopy appears macroscopically normal. These findings suggest the existence of subtle visual signatures of IBS that may be detectable by AI but remain invisible to the human eye, potentially transforming the diagnostic pathway from a purely symptom-based approach to an image-assisted functional assessment during standard colonoscopy.

eP903 Procedural Learning Curve For Proximal Intestinal Mucosal Ablation (PIMA) Using A Novel Through-The-Scope Radiofrequency Vapor Ablation Catheter

Authors Norton B[1, 2], Telese A[2, 1], Marin P[3], Hoebel P[3], Vignolo P[3, 4], Johnson G[5, 2], Rodriguez Grunert L[3], Shaheen N[6], Haidry R[2]

DOI 10.1055/s-0046-1822230

Problem to solve Metabolic endoscopy is increasingly recognised as a potential adjunct to conventional treatment for patients with type 2 diabetes (T2D). Current ablation modalities are limited by technical intricacies because of their over-the-guidewire design, which could limit real-world scalability. These systems used for duodenal mucosal ablation have been associated with prolonged procedure times relative to the length of tissue treated. An advancement of current ablation methods is proximal intestinal mucosal ablation (PIMA), an investigational endoscopic procedure for the treatment of T2D. The procedure aims to reversibly destroy up to 60 cm of the abnormal, hypertrophied proximal intestines with a through-the-scope Radiofrequency Vapor Ablation (RFVA) catheter. While ablating a longer segment of bowel may enhance glycaemic effect and durability, procedure skill acquisition is unclear. Therefore, we aimed to evaluate the feasibility and scalability of PIMA through a procedural learning curve.
Innovation We evaluated procedure times among 39 patients undergoing PIMA for the treatment of T2D in a series of first-in-human studies (NCT06655740, NCT06724822, NCT05887635). All procedures were performed between Sep-2024 and May-2025 in Santiago, Chile, by two therapeutic endoscopists in five discrete treatment windows. Patients underwent PIMA via an adult colonoscope (Olympus HQ190L) with the through-the-scope RFVA catheter. Sequential ablations were delivered with double application to the post-ampullary intestinal mucosa with minimal overlap. Total procedure time was defined as the duration (minutes) from endoscope insertion to final removal. Catheter time was defined as the duration from RFVA catheter insertion to final removal. Time per ablation was calculated as total catheter time divided by the number of ablations delivered. Learning curves were modelled using non-linear regression of the form time = a + b/case number. Predicted values and 95 % confidence intervals were generated to visualise the model fit. The first derivative of the fitted curve was used to identify the procedural plateau, defined as a reduction of < 0.5 minutes per additional case (< 0.05 minutes for time per ablation), beyond which further experience did not meaningfully reduce procedure time. Mean procedure duration at this plateau was considered the stabilised procedural time (procedural efficiency). Linear regression evaluated temporal changes in ablation number.
Results Across the cohort, average age was 50.2 years (SD 7.9) and 56.4 % were female. The mean procedure time was 62 minutes (SD 16.2), catheter time was 53 minutes (SD 14.2), and time per ablation was 1.14 minutes. The median ablated length was 60 cm (IQR 50-65). The learning curve for catheter time showed a plateau after approximately five cases, with a stabilised mean duration of 53.1 minutes. However, the non-linear learning-curve explained little of the variation in catheter time ($R^2 = 0.01$; $p = 0.535$), which indicates no measurable reduction in catheter duration with increasing operator experience. A similar pattern was observed for total procedure time ($R^2 = 0.01$; $p = 0.483$). The paradoxical initial increase in catheter and procedure times on the learning curve is driven by the increasing number of total ablations delivered, which was confirmed on linear regression ($\beta = 0.40$; $R^2 = 0.21$; $p = 0.004$). When assessing true procedural efficiency, measured using time required to deliver each ablation, we observed a stabilised performance at 1.13 minutes per ablation after only five cases, with no further evidence of learning beyond this point.
Conclusions PIMA is associated with a minimal ongoing learning effect, with stable time per ablation after five cases. Case-to-case variability appears driven by the complexity of enteroscopy with increasing treatment lengths rather than by catheter manipulation.
