ESGE Days 2026

Date/Venue:
14.–16. May 2026, Milan, Italy

ESGE President:
Cesare Hassan

Welcome message

Tomáš Hucl
ESGE Scientific Committee Chair

Dear colleagues in endoscopy,

On behalf of the ESGE Scientific Committee, it is my pleasure to present the abstracts accepted to **ESGE Days 2026** in this supplemental edition of *Endoscopy*.

We are delighted to see the continued growth of the ESGE Days meeting, reflected not only in the impressive number of abstract submissions received, but also in their outstanding scientific quality. This year we received 2395 abstracts, representing a 21 % increase on last year. The breadth of topics and strong international representation signal the rapid evolution of GI endoscopy and the commitment of our community to advancing research, innovation, and patient care. Original research remains the foundation of our congress, and together we are shaping the future of our field.

We extend our sincere thanks to all authors who submitted their work and I sincerely hope they enjoy the experience of presenting their science at our meeting. Each year we work hard to conceptualize innovative ways to showcase the research on offer. In Milan, abstract authors will showcase their work in oral presentation and pitch your poster sessions. In addition, for 2026 we are introducing ePoster Connect, an in-person forum where delegates with shared special interests can explore and debate the latest science. The six top-ranked abstracts from this year will be presented in the Presidential Session and a dedicated Best Abstracts session. To these researchers we give our heartfelt congratulations and hope that presenting their work under this accolade is a highlight of their endoscopy career. Furthermore, in recognition of the most recent evolution in our field, we are introducing two dedicated Late-Breaking Abstract Sessions, providing a platform for the most up to date and innovative research.

I would also like to acknowledge the dedication of the Scientific Committee, reviewers, and the ESGE Office team, whose efforts have created a high-quality and engaging programme.

At ESGE Days 2026, our mission is to Reimagine Endoscopy: Smarter, together and for the future. We invite you to explore the research presented in this supplement and to join us in Milan to further our mission together.

Your ESGE Scientific Committee Chair
Tomáš Hucl

Aims Strict follow-up after endoscopic resection (ER) is gaining recognition as a valid management strategy for esophageal adenocarcinoma (EAC) invading the submucosa (T1b) [1]. However, the optimal follow-up protocol is still unclear. We present the results of the first prospective international multicenter cohort study (PREFER, NCT03222635) on the safety and efficacy of strict follow-up following R0 ER of T1b EAC, now that all patients have completed at least two years of follow-up.

Methods Patients treated with ER for T1b EAC with tumor free vertical resection margins (R0v) were included at 19 expert centers in Europe and Australia until the sample size of ≥ 141 was reached. Submucosal invasion ≥ 500um, poor differentiation, and lymphovascular invasion were considered risk factors for lymph node metastases (LNM). Lesions were classified low-risk (LR) in case of only superficial submucosal invasion (< 500um), and high-risk (HR) when at least one of the risk factors for LNM was present. All included patients underwent baseline re-staging with gastroscopy, endoscopic ultrasound (EUS) and whole-body CT/PET-CT 6-8 weeks after ER. When no metastases were detected (cT1bN0M0), patients entered strict follow-up with gastroscopy and EUS every 3 months during the first 2 years, every 6 months during years 3 and 4, and once at the end of year 5. CT/PET-CT was repeated 1 year after baseline. Primary outcomes were disease-specific and overall survival; secondary outcomes were rates of LNM, intraluminal recurrence not amenable to endoscopic treatment, and distant metastasis.

Results In total, 157 T1b patients (54 LR, 103 HR) were included between July 2017-July 2023.

In LR-T1b patients (87 % male, median age 70 years), median follow-up was 39 months (IQR 26-57) with 11 endoscopies (IQR 7-13). During follow-up, 3/54 (6 %; annual risk 1.7 %) developed LNM, of whom one patient died of EAC. Intraluminal recurrence not amenable for endoscopic treatment developed in 2/54 (4 %; annual risk 1.1 %), both patients were treated curatively. No distant metastasis were diagnosed.

In patients with HR-T1b (81 % male, median age 71 years), median follow-up was 37 months (IQR 24-51) with a median of 10 endoscopies (IQR 6-12). In total, 10/103 (10 %; annual risk 3.2 %) developed LNM: 7/10 received curative treatment, 3/10 were unfit for curative treatment due to comorbidities. In 8/103 (8 %; annual risk 2.5 %) intraluminal recurrences not amenable for endoscopic treatment developed: all were detected at a curable stage, however, 5/8 refused further treatment or received palliative treatment due to comorbidities, 3/8 died of EAC. Furthermore, 4/103 (4 %; annual risk 1.3 %) developed distant metastases, all without signs of intraluminal recurrence or LNM: 2/4 developed liver metastases, one of whom refused further treatment and died, and the other received immunotherapy but died of hearth failure; 1/4 underwent resection of lung metastasis but developed new pulmonary and liver metastases after 2 years and now receives palliative treatment; 1/4 developed non-regional LNM (i.e. cervical and sacral) with further policy pending. Most distant metastases (3/4) were detected in the third year of follow-up (2/4 detected with CT due to symptoms, 1/4 during regular follow-up EUS), and 1/4 was detected during the per-protocol CT/PET 1 year after baseline. In this cohort, over a median follow-up of 37 months (IQR 25-52), 34/157 (22 %) have successfully completed an event-free 5-year follow-up. Non-EAC mortality (14/157; 9 %) was three times higher than EAC-related mortality (5/157; 3 %).

Conclusions The interim results of this first prospective study on strict follow-up after R0v ER of T1b EAC show that after a median follow-up of 3 years, 34/157 (22 %) have successfully completed event-free 5-year follow-up, non-EAC death (9 %) is 3x higher than EAC death (3 %), and 26/157 (17 %) developed metastasis and/or intraluminal recurrence not amenable to endoscopic treatment, of which the majority (22/26; 85 %) was diagnosed at a curable stage. Our data also show that 3/4 distant metastases were found in the third year of follow-up, not detected by the protocol-mandated CT/PET-CT 1 year after baseline. Given the unknown incidence of distant metastases after year 1 and improved treatment options for distant metastases in recent years, we advise adding annual CT/PET-CT during strict follow-up of these patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820651

Aims Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) has an incidence of approximately 10 %. Both the European and American Society of Gastrointestinal Endoscopy recommend a 100 mg diclofenac or indomethacin suppository just prior to an ERCP procedure as primary prophylaxis against PEP. Furthermore, both societies recommend inserting a plastic stent into the pancreatic duct (PD) following multiple unintentional PD cannulations. However, it remains unclear whether PD stent placement after a single unintentional PD cannulation, combined with non-steroidal anti-inflammatory drugs (NSAIDs), offers additional benefit in preventing PEP.

The aim of the FLUYT-2 trial was to determine whether the combination of NSAIDs and PD stent placement is more effective than NSAIDs alone in preventing PEP in patients with one or more unintentional PD cannulations.

Methods This study was designed as an additional arm of the initial FLUYT trial, a randomized controlled trial that compared the combination of aggressive hyperhydration and rectal NSAIDs with NSAIDs alone in preventing PEP. The initial trial found no significant difference between both groups.

In the FLUYT-2 trial, we prospectively included a new cohort of 275 patients who underwent PD stent placement following even a single unintentional PD wire cannulation. Screening for eligibility occurred with the same exclusion criteria as the initial FLUYT trial. This cohort was compared with a subgroup of 262 patients from the FLUYT trial who did not receive PD stent placement after unintentional PD cannulation. FLUYT-2 was carried out between October 2021 and September 2025 in four academic and 18 community hospitals in The Netherlands.

The inserted prophylactic PD stents were either single pigtail or straight stents without an internal flange, with a recommended size of 5 French and 5 centimeters in length. The primary endpoint was the incidence of PEP, defined according to the Cotton criteria. Secondary endpoints included severity of PEP, ERCP-related complications other than PEP, and the rate of spontaneous PD stent migration.

Results A total of 275 patients were included, with 217 successfully placed straight or single-pigtail PD stents that remained in place during the procedure. The primary indication for ERCP was choledocholithiasis (63.6 %). The incidence of PEP was 19.8 % in the group without PD stent placement vs. 12.4 % in the group with PD stent placement (p = 0.03). In the subgroup of patients with a dislocated stent during the procedure (n = 19), the incidence of PEP was 15.8 %. The severity of PEP did not differ significantly between both groups, and there was no significant difference in duration of hospital admission (1 night [IQR 1-4] in the no-PD stent group vs. 1 night [IQR 1-3] in the PD stent group). The incidence of other ERCP-related complications was comparable between both groups. Pigtail stents had a lower PEP incidence compared with straight stents (10.8 vs. 13.5 %) and were more likely to dislocate spontaneously within the two weeks after ERCP (76.7 % vs. 64.6 %). A total of 53 PD stents had to be removed by gastroscopy after abdominal X-ray was made. None of these patients developed pancreatitis after stent removal.

Conclusions Insertion of a plastic stent in the pancreatic duct following unintentional PD cannulation in combination with rectal NSAIDs is superior to NSAIDs alone in preventing PEP. We recommend the placement of a single pigtail 5cm 5Fr PD stent after common bile duct intervention in patients with even a single unintentional PD cannulation.

Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong; 3 Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong; 4 Medical Data Analytic Centre, The Chinese University of Hong Kong, Hong Kong, Hong Kong; 5 Department of Surgery, The Chinese University of Hong Kong, Hong Kong, China
DOI 10.1055/s-0046-1820652

Aims Direct oral anticoagulants (DOAC) increase the risk of post-polypectomy bleeding (PPB). We aim to evaluate the effectiveness of prophylactic clipping among these high-risk patients.

Methods We performed an industry-independent, double-blinded, parallel-group, superiority randomized trial in Hong Kong. Subjects who received DOAC and underwent colonoscopies were recruited. They withheld DOAC for 48 hours pre-procedure and resumed on the next day unless contraindicated. Endoscopic resection was standardized (cold polypectomy for < 10mm and non- pedunculated polyps, hot resection for large or pedunculated polyps). When polypectomy was performed, subjects were randomized 1:1 to receive prophylactic clipping (intervention) or without (control) by an independent research staff. In intervention arm, endoclips were used to close all polypectomy sites. In control arm, no endoclip was applied to any polypectomy site, except in case of uncontrolled immediate PPB. Randomization was blinded to non-endoscopist physicians in-charge, patients and data analysts. The primary endpoint was 30-day complicated delayed PPB, associated with i) unstable hemodynamics despite resuscitation; ii) decrease in hemoglobin ≥ 2 g/dL; iii) blood transfusion; iv) hemostatic interventions by endoscopy, angiographic embolization or surgery; v) prolonged hospitalization or vi) death. Secondary endpoints were overall PPB and cardiovascular events. All endpoints were adjudicated by an independent physician [1–3].

Results Between December 2021 and April 2025, 440 subjects were screened with 148 subjects excluded due to absence of polyp, withdrawal of consent or unfit for procedures. 145 and 147 subjects were randomized to intervention and control arms respectively. Baseline characteristics were comparable including demographics, medications, endoscopic factors, polyp characteristics (size, location) and resection techniques. (▶ **Table 1**) The 30-day complicated delayed PPB rates were 3.4 % (5/145) in intervention and 3.4 % (5/147) in control arms respectively, with no significant difference between the two arms (hazard ratio (HR) 1.01, 95 %CI 0.29-3.48, p = 0.991). The overall PPB rates were 9.7 % (14/145) in intervention and 8.8 % (13/147) in control arms respectively, without significant difference between arms (HR 1.07, 95 %CI 0.50-2.28, p = 0.856). Only one cardiovascular event (ischemic stroke) occurred in the control arm.

▶ **Table 1**

	Intervention arm (n = 145)	Control arm (n = 147)
Age (mean, SD)	70.9 (7.4)	71.9 (6.0)
HAS-BLED score	2.32 (0.97)	2.39 (1.05)
Apixaban (%)	81 (55.9)	74 (50.3)
Dabigatran (%)	28 (19.3)	30 (20.4)
Other anti-Xa (%)	36 (24.8)	43 (29.3)
Standard dose (%)	96 (66.2)	101 (68.7)
Aspirin/clopidogrel (%)	75 / 27 (51.7 / 18.6)	74 / 21 (50.3 / 14.3)
Polyp number (mean, SD)	3.7 (2.9)	4.1 (3.9)
< 10mm (n, %)	143 (98.6)	146 (99.3)
10-19mm (n, %)	24 (16.6)	26 (17.7)
≥ 20mm (n, %)	9 (6.2)	10 (6.8)

▶ **Table 1**

	Intervention arm (n = 145)	Control arm (n = 147)
Right colon (n, %)	109 (75.2)	119 (81.0)
Left colon (n, %)	106 (73.1)	109 (74.1)
Cold biopsy (n, %)	23 (15.9)	27 (18.4)
Cold snare (n, %)	138 (95.2)	141 (95.9)
Hot snare (n, %)	18 (12.4)	21 (14.3)
EMR (n, %)	6 (4.1)	9 (6.1)
ESD (n, %)	1 (0.7)	1 (0.7)

Conclusions In this randomized trial, prophylactic clipping was not superior to standard care in preventing delayed PPB and associated complications among DOAC users. The cost-effectiveness of this widely-adopted practice should be reconsidered. (ClinicalTrial.gov: NCT05169242)

Conflicts of Interest Authors do not have any conflict of interest to disclose.

BA004 EUS-guided versus percutaneous ultrasound-guided biopsy for parenchymal liver disease: A randomized controlled, non-inferiority trial

Authors Johri I[1], Bhatia V[1], Mukund A[1], Rastogi A[1], Bihari C[1], Singh S[1], Rajan V[1], Chand P[1]

Institute 1 Institute of Liver and Biliary Sciences, New Delhi, India
DOI 10.1055/s-0046-1820653

Aims Endoscopic ultrasound-guided liver biopsy (EUS-LB) is being increasingly used to acquire liver biopsies. However, the current accepted standard of EUS-LB using 19G Franseen needle has never been compared with the current gold standard of percutaneous ultrasound-guided liver biopsy (PC-LB) using a full-core 16G or 18G cutting needle.

Methods We conducted a parallel-group, randomized controlled trial at the Institute of Liver and Biliary Sciences (ILBS), New Delhi. Patients were randomized via the ILBS Interactive Web Response System (IWRS; block size 10). EUS-LB was done by a single experienced endosonographer (VB) using a 19G Franseen (Acquire™, Boston Scientific) needle, under total intravenous anesthesia (TIVA) by an anaesthesiologist. PC-LB was done by multiple interventional radiologists using an 18G BioPince full core (Argon medical devices) needle under local anesthesia.

For EUS-LB, a modified wet-heparin suction technique was used; the number of passes and needle actuations (for EUS-LB) were not restricted. Either the left or right lobe (or both) was accessed as per the operator's judgement. To avoid confounding by differences in the number of passes, we submitted the biopsy material from each pass separately for analysis of the adequacy parameters after slide digitization (MorphoLens 6). The pathologist reporting the liver bi-

opsy specimens was not blinded to the allocation sequence. The primary endpoint was specimen adequacy (defined as total specimen length [TSL] ≥ 15 mm and ≥ 8 complete portal tracts [CPTs]). Secondary endpoints were the number of fragments, number of fragments > 9mm, number of CPTs, biopsy area, collagen proportionate area, fibrosis staging, diagnostic yield, width of specimen, pain scores, satisfaction, and adverse events. For calculating the sample size, we assumed the success rate of procurement of adequate liver biopsies (defined above) to be 90 % in the PC group and 85 % with EUS-LB, based on existing literature. With an α of 10 %, a power of 80 %, and a non-inferiority margin of 10 %, we required 44 patients per arm (total sample size of 88); to account for technical limitations, we planned to enroll 90 patients. The trial was registered online (CTRI Number: CTRI/2023/10/058529; Clinical Trials.gov ID: NCT06047327)

Results EUS-LB yielded 6.9 cm of total specimen length per patient compared with 2.0 cm for PC/TUS, and achieved a markedly larger total biopsy area (39.75 mm^2 vs 10.42 mm^2, $p < 0.01$). Even on a per-pass basis, EUS-LB produced substantially greater tissue area (19.5 mm^2 vs 10.65 mm^2, $p < 0.001$). EUS-LB also generated many more tissue fragments (13 vs 1 per patient, $p < 0.01$), with correspondingly higher complete portal tract (CPT) counts (42 vs 9 per patient, $p < 0.01$), and this advantage persisted on a per-pass comparison (21 vs 9 CPTs, $p < 0.001$), indicating markedly superior architectural representation. Although EUS cores were slightly narrower in width (667.2 µm vs 747.8 µm, $p < 0.01$), they provided more fragments > 9 mm (2 vs 1 per patient) and greater cumulative length, with collagen proportionate area remaining comparable between groups (11.0 % vs 8.1 %, $p = 0.78$). Across all major adequacy standards—including the study primary definition (≥ 15 mm and ≥ 8 CPT), AASLD, EASL, APASL, and BGS criteria—EUS-LB consistently outperformed PC/TUS-LB. Adequacy rates with EUS-LB ranged from 95.6 % to 97.8 % per patient, compared with 28.9 % to 64.4 % for PC/TUS (all $p < 0.001$ except EASL $p = 0.01$). On a per-pass basis, adequacy with EUS-LB ranged from 81.8 % to 93.2 %, compared with 25.5 % to 63.8 % for PC/TUS (all $p < 0.001$ except EASL $p = 0.03$), confirming the consistently superior histologic yield of EUS-guided biopsy. The risk difference in adequacy (primary endpoint) between a single pass of EUS-LB and PC-LB was 0.26 (95 % CI 0.11 to 0.41).

Conclusions EUS-LB using a 19G Franseen-tip needle was non-inferior and superior compared to PC-LB using 18G full-core, cutting needle. EUS-LB yields higher TSL, CPT number, and biopsy area, albeit with more fragmentation and less biopsy width. A single pass of EUS-LB yields an adequate specimen about 26 % more often than PC-LB (absolute increase in adequacy rate). Adverse effects with EUS-LB were significantly higher, but minor.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

BA005 Post-colonoscopy colorectal cancer in SCREESCO (Screening of Swedish colons): comparison low- versus high-rate detectors of adenomas and proximal serrated polyps

Authors Westerberg M[1], Sekiguchi M[2], Andreasson A[3], Forsberg AM[4]

DOI 10.1055/s-0046-1820654

Aims We aim to assess risk factors for post-colonoscopy colorectal cancers (PCCRC) in a national Swedish randomized controlled colorectal cancer screening trial, SCREESCO. The focus is on quality indicators of the endoscopists and impact on the occurrence of PCCRC.

Methods In SCREESCO, 278,051 individuals aged 60 were randomly assigned to once-only primary colonoscopy vs control, or two rounds of two-stool fecal immunochemical testing (FIT) two years apart with cut-off 10 µg hemoglobin/g feces vs control. Intervention was completed in 2020.

A PCCRC in this study was defined as a CRC following a negative colonoscopy either in the primary colonoscopy arm (PCOL) or in the FIT arm after a work-up examination after a positive test. CRCs detected after > 6 months up to 10 years after the index colonoscopy were considered as a PCCRC. Endoscopist's ADR and proximal sessile lesion detection rates (PSPDR) were divided into either low- or high detection rates with a cutoff of 25 % in the PCOL arm and 40 % in the FIT arm for ADR, and 10 % in both arms for PSPDR. Endoscopists with at least 20 colonoscopies in the FIT arm and 20 colonoscopies in the primary colonoscopy arm performed in SCREESCO were included. In the FIT arm separate analyses were performed for the first and the second round [1].

The cumulative incidence proportion of CRC from 6 months up to 10 years after the index colonoscopy was computed with 95 % confidence interval (CI) considering death from any cause as a competing risk.

Results In the PCOL arm 10,620 colonoscopies were included and in the FIT arm there were 3,259 colonoscopies in round 1 and 3,886 in round 2. There were 22 PCCRCs in the PCOL arm, 16 in FIT round 1 and 2 in round 2. Of these 3, 4 and 1 were detected within 3 years respectively. Of the total of 42 PCCRCs 18 (42 %) were diagnosed in men. Stage I-II was seen in 23 (55 %), Stage III-IV in 15 (36 %) and for 4 (9 %) of the cases.

A total of 141 endoscopists were included; 51 were defined as high-detectors of adenomas and 36 of PSP. There were 31 defined as low-detectors of adenomas and 46 of PSP. Data was missing in 58 of the endoscopists.

Within 6-36 months after the index colonoscopy the risk of PCCRC was 0.03 % (95 % C I: 0.02-0.03 %) in low ADR detectors in the PCOL arm, 0.24 % (95 % C I: 0.20-0.29 %) in FIT round 1, and 0 % in FIT round 2. In high ADR detectors the corresponding risks was 0.03 % (95 % C I:0.03-0.04 %) in PCOL, 0.05 % (95 % C I: 0.04-0.07 %) in FIT round 1 and 0.06 % (95 % C I: 0.05-0.08 %) in FIT round 2. In low PSP detectors the risks were 0.02 % in PCOL, 0.22 % in FIT round 1, and 0.07 % in FIT round 2. In high PSP detectors the risks were 0.05 % in PCOL, 0 % in FIT round 1 and 2. The risks became increased somewhat between 4 to 7 years after the index colonoscopy, more pronounced among the low detectors.

Conclusions ADR and PSPDR of endoscopists seem to be associated with the occurrence of PCCRC.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820655

Aims Optical diagnosis involves real time characterization of polyps during colonoscopy to characterise the nature of polyp to decide the best management strategy for the polyp. Trained Endoscopists can use enhanced imaging (EI) or use newly developed AI based CADx to make an optical diagnosis to implement resect & discard strategy. The aim of our study is to compare the outcome of EI based optical diagnosis performed by experts with newly developed AI based CADx in a RCT.

Methods This was a prospective, randomized controlled trial (RCT) conducted across multiple tertiary centres in UK. Patients were randomized (1:1) to either

the control arm (AI off) or the intervention arm (AI on). The CAD-x device used for this study was WISE VISION (NEC Japan). This was a superiority trial, powered on NPV, to demonstrate an improvement from 75 % (endoscopist) to 90 % (CADx), with an 80 % power and an alpha of 0.05. In the control arm, endoscopist made an optical diagnosis by using EI and that was recorded and compared with the final histology. In the AI arm, CADx diagnosis on WLI and EI was prospectively recorded and compared with the histology. Data on sensitivity, specificity, accuracy and NPV was collected for each arm for all polyps and for polyps < 5mm in size.

Results A total of 653 patients were randomised across 3 centres in the UK. 328 to the control arm where experts made EI based OD and 324 to the intervention arm with CADx based OD. The mean age was 60.34 ± 12.28 and 60.44 ± 13.11 (p = 0.92), in the control and intervention group and a significantly lower rate of male (49.39 % vs 57.72 %, p = 0.04) was observed for control.
For the control group, the endoscopist performance was evaluated on 628 polyps (414 diminutive). For all polyps, sensitivity, specificity and negative predictive value were 0.93, 0.63 and 0.87 on white light and 0.92, 0.62 and 0.85 on EI. For diminutive polyps sensitivity, specificity and negative predictive were 0.90, 0.63 and 0.84 on white light and 0.90, 0.62, 0.82 on EI.
For the intervention group, CADx performance was evaluated on 699 polyps (494 diminutive). For all size polyps sensitivity, specificity and negative predictive value were 0.72, 0.62, 0.61 on white light and 0.77, 0.56 and 0.63 on EI. For diminutive polyps sensitivity, specificity and negative predictive value were 0.70, 0.64 and 0.59 on white light and 0.77, 0.56 and 0.63 on EI.
The performance of the composite diagnosis of endoscopist plus CAD-x were measured on 658 polyps (522 diminutive). For all size polyps sensitivity, specificity and negative predictive value were 0.89, 0.59 and 0.79 on white light and 0.88, 0.58 and 0.78 on EI. For diminutive polyps sensitivity, specificity and negative predictive value were 0.88, 0.57 and 0.77 on white light and 0.89, 0.56 and 0.78 on EI.
Finally, the threshold of NPV > 0.90 for diminutive polyps was not met by the experts using EI and neither was it met by CAD-X. However, PIVI-2 threshold of > 90 % concordance of follow up was met (agreement 97.4 %) by CADx based OD

Conclusions Our study demonstrates that current version of CAD-X is suboptimal and cannot be used on its own or in combination with Endoscopist based diagnosis. We found that CADx cannot improve the performance of expert endoscopists and if anything, it can negatively influence it.

Aims Recommended colonoscopy surveillance intervals for patients after polyp removal are arbitrary because randomized trials comparing surveillance intervals are lacking.

Methods We randomized 10,799 patients with high-risk adenomas in 8 European countries 1:1 to currently recommended 3-year colonoscopy or to colonoscopy after 5 years. To avoid lead time bias, the 3-year am also received colonoscopy after 5 years. A parallel single-arm trial enrolled patients with removed serrated polyps to 5-year surveillance colonoscopy. The primary endpoint was non-inferiority of colorectal cancer risk at 5 years.

Results We randomized 5,398 patients to less frequent (first after 5 years) and 5,401 to more frequent (first after 3 years) surveillance. The 5-year risk of CRC was 0.47 % with less frequent surveillance as compared to 0.48 % with more-frequent surveillance (absolute risk difference adjusted for competing risk of death -0.003 %; upper bound of 99.12 % confidence interval: 0.381 %). The 5-year CRC risk was 0.46 % (95 %CI 0.112 to 0.911 %) among 1,861 patients with serrated polyps. The distribution of CRC stage at diagnosis was similar between study arms. Five patients died of CRC; three in the less frequent surveillance arm (0.06 %) and two in the more frequent surveillance arm (0.04 %). No patients with only serrated polyps died of CRC. The cumulative yield of advanced adenomas was 10.82 % in patients with advanced adenomas with more frequent and 10.66 % with less frequent surveillance (p = 0.83), and 7.45 % in patients with serrated polyps.

Conclusions First surveillance colonoscopy after five years is non-inferior to currently recommended 3-year colonoscopy for patients with high-risk adenomas. NCT02319928.

Customizing POEM for Optimal Patient Outcomes

14/05/2026, 08:30–09:30 Sky 1

OP001 Contractility patterns on functional lumen imaging probe (FLIP) prior to peroral endoscopic myotomy predict outcomes in achalasia

Authors Perananthan V[1], Chhoda A[1], Ospina Velasquez LE[1], Wong Kee Song LM[1], Law R[1], Codipilly D[1], Snyder D[1], Leggett C[1], Alexander J[1], Ravi K[1]

Institute 1 Mayo Clinic, Rochester, United States of America

DOI 10.1055/s-0046-1820656

Aims While functional lumen imaging probe (FLIP) is well-established for identifying esophagogastric junction outflow disorders, its role in patients with confirmed achalasia before per-oral endoscopic myotomy (POEM) are unclear. This study aimed to evaluate whether FLIP provides additional diagnostic value before POEM.

Methods This retrospective study of prospectively collected data included patients with primary achalasia confirmed on high-resolution esophageal manometry who underwent FLIP at a tertiary center from March 2020 to June 2024. Reduced EGJ opening (REO) on FLIP was defined as a distensibility index < 2 mm²/mmHg at 60 mL balloon volume and diameter < 12 mm at 70 mL. Contractile response (CR) was categorized using published criteria. Outcome measures comprised of clinical success (Eckardt score ≤ 3) and significant barium retention on timed barium esophagram (TBE), defined as a column height > 5 cm at 5 minutes and/or retention of a 13-mm barium tablet.

Results Among 166 patients (44.6 % female; median age 60.0, IQR 44.5–73.0), 18 (10.8 %) had type I, 123 (74.1 %) type II, and 25 (15.1 %) had type III achalasia. All patients demonstrated REO on FLIP; 126 (75.9 %) had absent CR and 40 (24.1 %) had some contractility (▶ **Table 1**). Significant barium retention on TBE was observed in 48 patients (28.9 %). Absent CR was associated with increased barium retention (RR 1.3, 95 % CI 1.1-1.5, p = 0.005) and greater mean column height at 5 minutes (2.0 cm vs. 0.8 cm, p = 0.048) post POEM procedure.

▶ **Table 1**

	Total cohort	No contractility	Contractility present	p-value
N	166	126 (75.9 %)	40 (24.1 %)	
Age years (median + IQR)	60.0 (44.5 – 73.0)	61.5 (44.8 – 73.0)	55.0 (44.0 – 73.0)	0.636
Female (n, %)	74 (44.6 %)	60 (47.2 %)	14 (35.9 %)	0.270
BMI (median + IQR)	27.6 (23.6 – 33.0)	26.8 (23.1 – 32.5)	29.9 (26.2 – 34.3)	0.039 *
Type 1 (n, %)	18 (10.8 %)	14 (11.0 %)	4 (10.3 %)	0.999
Type 2 (n, %)	123 (74.1 %)	98 (77.2 %)	25 (64.1 %)	0.142
Type 3 (n, %)	25 (15.1 %)	15 (11.8 %)	10 (25.6 %)	0.043 *
Pre-POEM Eckardt score (median + IQR)	7.0 (5.0 – 8.0)	7.0 (5.0 – 8.0)	6.0 (4.0 – 9.0)	0.636
Esophageal Myotomy length (cm)	6.0 (6.0 – 8.0)	6.0 (6.0 – 8.0)	8.0 (6.0 – 10.5)	0.114
FLIP Distensibility (mm²/mmHg) at 60mL Pre-POEM (median + IQR)	1.2 (0.8 – 2.3)	1.2 (0.8 – 2.2)	1.2 (0.6 – 2.5)	0.571
FLIP Diameter (mm) at 70mL Pre-POEM (median + IQR)	8.2 (6.2 – 11.5)	8.2 (6.4 – 12.0)	8.7 (5.8 – 10.8)	0.448

Conclusions Absent CR on FLIP prior to POEM predicts significant barium retention on TBE following POEM, supporting an additive role for FLIP to predict outcomes.

OP002 Long term efficacy of pneumatic dilation in type I and II achalasia

Authors Scala P[1], Zagari RM[2], Montagnani M[1], Ioannou A[3], Mandolesi D[1], Vestito A[1], Bombaci F[1], Mussomeli E[1], Torresan F[1]

Institutes 1 Gastroenterology Unit, Department of Medical and Surgical Sciences, S. Orsola-Malpighi Hospital, Bologna, Metropolitan City of Bologna, Italy; 2 Gastro-esophageal organic diseases unit. IRCCS azienda Opedaliero Univaersitaria di Bologna, Bologna, Italy; 3 Gastroenterology Department, "Alexandra" General Hospital of Athens, Athens, Greece

DOI 10.1055/s-0046-1820657

Aims Achalasia is a chronic degenerative disease affecting the esophageal motility. The treatment of achalasia is mainly symptomatic, aimed at symptom relief by reducing the LES pressure. The main treatments for achalasia are pneumatic dilation (PD), Heller laparoscopic myotomy (LHM), and endoscopic peroral myotomy (POEM), each with specific risks and benefits. The effectiveness of treatments tends to decline over time, and studies comparing the three therapeutic options have provided conflicting results in the long-term. Over the last two decades, the introduction of High-resolution manometry (HRM) enabled the identification of 3 types of achalasia, allowing a more precise and individualized treatment approach. The latest ESGE 2020 and the ACG 2020 guidelines recommended graded pneumatic dilation as first line treatment for type I and type II achalasia. This study aims to evaluate the efficacy and safety of graded pneumatic dilation in the treatment of type I and type II achalasia in our center, over a 10-year follow-up.

Methods This is a single-center, retrospective, observational study designed designed and realized in our tertiary referral Gastroenterology Unit. From January 2009 to December 2019, we enrolled a total of 73 patients, 23 with type I achalasia and 50 with type II achalasia. The enrolled patients underwent a graded dilation protocol. The treatment was based on up to three incremental dilations as needed (30–35–40 mm caliber). Fifty-seven patients completed a 5-year follow-up, and 23 patients completed a 10-year follow-up. The primary outcome was clinical remission, defined as an Eckardt score ≤ 3 during an annual clinical follow-up. The secondary outcome was the rate of postprocedural complications and subgroup analysis to evaluate the factors associated with treatment failure. A Kaplan-Meier curve was constructed for the time to treatment failure. The subgroup analysis on the time to treatment failure was performed using univariate Cox regressions.

Endoscopy 2026; 58: S1–S1041

Results The cumulative success rate of pneumatic dilation was 94.4 % at 2 years (95 %CI: 85.9 %-97.9 %), 91.5 % at 5 years (95 %CI:82.0 %-96.1 % CI), and 81.9 % at 10 years (95 %CI 68.1 %-90.1 % CI). In the subgroup analysis, the need for multiple dilations was associated with treatment failure. Treatment failure was not associated with age, gender, type of achalasia, or clinical severity as assessed by the Eckardt score before dilation. The major complication rate was 1.3 %: a single contained perforation that was managed conservatively.

Conclusions This retrospective, observational, single-center study demonstrates that graded pneumatic dilation is a safe and effective long-term treatment for patients with type I and type II achalasia. Our findings indicate the reliability of pneumatic dilation with a graded on-demand approach as a highly effective treatment option for achalasia. These results warrant the graded PD technique as a viable first-line treatment in type I and type II achalasia patients, as an alternative to Heller myotomy or POEM.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP003 Full-thickness or circular myotomy alone in Peroral Endoscopic Myotomy (POEM) in patients with newly diagnosed achalasia. Results of a double-blind, randomized clinical trial

Authors Sediqi E[1], Reuterwall Hansson M[2, 3], Lundell L[2], Thorell A[3, 2], Håkanson B[3, 2]

Institutes **1** Department of Surgery, Institute of Clinical Sciences, Sahlgrenska Academy, Gothenburg, Sweden; **2** Institution for Clinical Sciences, Danderyds Hospital, Karolinska Institutet, Stockholm, Sweden; **3** Karolinska Institutet and Department of Surgery and Anaesthesiology, Ersta Hospital, Stockholm, Sweden

DOI 10.1055/s-0046-1820658

Aims Achalasia is defined as a functional obstruction of the esophagus due to impaired relaxation of the lower esophageal sphincter (LES) with absent or spastic contractions of the tubular esophagus. Modern treatment is dominated by Peroral Endoscopic Myotomy (POEM) which traditionally involves a transmural myotomy extending down to the upper part of the gastric sling fibers. A significant side effect of this procedure is, however, gastroesophageal reflux.

Question: Does myotomy of only the LES circular muscle component provide comparable clinical symptom control as does full-thickness myotomy, but better control of the gastroesophageal reflux?

Methods 55 patients (29 males and 26 females with a median age of 44 years) with newly diagnosed achalasia were randomized at the start of the endoscopic myotomy to either full-thickness (n = 28) or circular LES myotomy alone (n = 27). The groups were comparable with respect to relevant clinical and disease-specific variables. In all patients, swallowing-related symptoms, reflux symptoms (GSRS) and quality of life (SF 36) were recorded before treatment and at defined time points postoperatively

Results Preoperatively, a median Eckard score of 7 was recorded in both groups (range; 3 – 11) and a median value of 2 and 1.5 (1 – 5), respectively was recorded regarding the reflux dimension within the GSRS instrument.The treatments could be carried out with limited morbidity (Clavien Dindo > 3a) without any difference between the treatment groups. All procedures were carried out on an outpatient basis. 12 months postoperatively, a median Echardt score of 2 was reported in both groups (range; 0 – 3 vs 0 – 5) and the reflux dimension in the GSRS also gave similar values in both groups (median 1.5; range 1 – 4). The mental and physical dimensions in the SF 36 were reported equitpose in both treatment groups

Conclusions One-year follow-up after full-thickness or circular LES endoscopic myotomy, performed in patients with newly diagnosed achalasia, shows identical outcomes regarding both reflux symptoms and Eckhardt score. These results suggest that circular myotomy alone is preferable in POEM, but more detailed analysis and longer follow-up are required to allow more firm conclusions

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP004 Impact of gastric length of myotomy during POEM on the incidence of gastroesophageal reflux: A randomized controlled trial

Authors Nabi Z[1], Inavolu P[1], Rughwani H[1], Pratap Singh A[1], Reddy DN[2]

Institutes **1** AIG Hospitals, Hyderabad, India; **2** Asian Institute of Gastroenterology (AIG Hospitals), Department of Medical Gastroenterology, Hyderabad, India

DOI 10.1055/s-0046-1820659

Aims Peroral endoscopic myotomy (POEM) is an effective treatment for achalasia cardia, but gastroesophageal reflux disease (GERD) remains a significant concern. The length of gastric myotomy may influence reflux outcomes, but high-quality data are lacking. This randomized controlled trial compared the incidence of GERD after short versus long gastric myotomy (SGM vs LGM) during POEM [1–5].

Methods In this randomized trial, we compared SGM (gastric myotomy < 3 cm) with LGM (gastric myotomy > 3 cm) during POEM in cases with type I or II achalasia. The primary endpoint was significant reflux esophagitis defined as Los Angeles grade B or higher esophagitis at 6 months follow-up. Secondary endpoints included esophageal acid exposure (≥ 6 % total acid exposure time [AET]) on 24-hour pH monitoring, reflux symptoms, proton pump inhibitor (PPI) use, Eckardt score, esophageal emptying, and high-resolution manometry parameters.

Results A total of 100 patients were randomly assigned to undergo either POEM with SGM (50 patients) or LGM (50 patients). Baseline characteristics were similar between groups. At 6 months, significant reflux esophagitis occurred in 24 % (12/50) of SGM patients versus 42 % (22/50) of LGM patients (p = 0.035; odds ratio, 2.45; 95 % CI, 1.04–5.79). Upright acid exposure was significantly lower in the SGM group (median 0.75 % vs 3.2 %; p = 0.036). No differences were observed in reflux symptoms, PPI use, total AET, or clinical efficacy between groups (▶ **Table 1**).

▶ **Table 1**

LA ≥ Grade B esophagitis, (%)	Long Gastric Myotomy	Short Gastric Myotomy	P	Odds ratio (95 % CI)	Relative risk (95 % CI)	Unadjusted absolute difference, % (95 % CI)
Intention to treat (ITT)	22/50 (44)	12/50 (24)	0.035	2.45 (1.04-5.79)	1.83 (1.02-3.30)	20 (1.8-38.2)
Per-protocol (PP)	22/47 (46.8)	12/48 (25)	0.027	2.49 (1.05-5.91)	1.84 (1.03-3.29)	21.8 (3-40.6)

Conclusions SGM significantly reduces the risk of clinically relevant reflux esophagitis after POEM without compromising efficacy. SGM should be considered a simple technical modification to reduce post-POEM GERD. (ClinicalTrials.gov number, NCT05500196)

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Peroral endoscopic myotomy (POEM) is effective for the treatment of esophageal motility disorders (EMD) but is associated with a high rate of gastroesophageal reflux disease (GERD). Impedance planimetry (IP) may help reduce this risk. The aim of our study was to evaluate the association between distensibility and diameter of the esophagogastric junction measured by IP and post-POEM GERD [1–15].

Methods Prospective, international, multicenter cohort study including consecutive naïve patients diagnosed according to Chicago IV with achalasia or esophagogastric junction outflow obstruction (EGJOO). All patients had baseline Eckardt scores and high-resolution manometry (HRM). IP was performed before and after POEM, and clinical, endoscopic, manometric, and pH monitoring without proton pump inhibitor (PPI) follow-up was carried out at 3–5 months. Clinical success was defined as a post-POEM Eckardt ≤ 3, and GERD according to Lyon 2.0 criteria. Different acidification patterns were considered. Fermentation was defined as a slow fall in pH below 4, with a drop rate < 1 pH unit per minute and lasting more than 5 minutes. Stasis was defined as a fall in pH below 4 during meals that persisted more than 5 minutes after finishing.

Results Eighteen patients were included (mean age 50.7 years [SD 16.9]; 7 [38.9 %] males). The indication for POEM was type I achalasia in 3 patients (16.7 %) and type II in 15 (83.3 %).Technical and clinical success reached 100 %, with Eckardt score decreasing from 7 (IQR: 6–9) to 1 (IQR: 0–1) ($p < 0.001$). Distensibility at 50 ml increased from 1.1 mmHg (SD 0.5) to 3.2 mmHg (SD 1) ($p < 0.001$), and diameter from 10.2 mm (SD 2.4) to 15.8 mm (SD 2.3) ($p < 0.001$).The GERD rate at 3 months was 61.1 %. In 11.1 % of patients it was considered borderline. pH-metric reflux was found in 44.4 % and endoscopic reflux in 33.3 %. Three patients (16.6 %) presented grade B esophagitis, two grade C (11.1 %), and one grade D (5.6 %).No statistically significant differences were found between GERD and non-GERD groups, except for GERD-Q ($p = 0.012$) and post-POEM upright IRP ($p = 0.003$). No significant association was found between IP and post-POEM GERD nor between IP and fermentation and stasis.

Conclusions Our study did not demonstrate a statistically significant association between impedance planimetry values and the risk of post-POEM GERD. These are preliminary results from an ongoing prospective study currently in the recruitment phase.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Sump formation — a redundant, dilated segment with food stasis — may develop in the neo-esophagus after esophagectomy or in end-stage achalasia with sigmoid megaesophagus, leading to refractory emptying impairment. The POPE (Per-oral Plication of the Esophagus) technique offers an endoscopic suturing approach for remodeling the lumen to improve esophageal emptying. Our aim was to describe the feasibility, technical performance, and short-term clinical outcomes of per-oral plication of the esophagus (POPE) for refractory esophageal sump formation in patients with end-stage achalasia or delayed emptying of a gastric conduit after esophagectomy.

Methods We conducted a multicenter retrospective analysis of all consecutive POPE procedures performed between September 2024 and November 2025 at three university hospitals in Spain. All patients were discussed within a multidisciplinary team and met one of two indications: (1)end-stage achalasia or blown-out myotomy (BOM) after previous myotomy for achalasia, (2) Delayed emptying of gastric conduit after esophagectomy. Demographic, clinical, and procedural variables were collected. All procedures were performed with the patient under general anesthesia, in the supine position, with single-dose of antibiotic prophylaxis and at least 1 night of admission postprocedure. Luminal remodeling was performed in the dilated segment (the sump area identified pre- and intraprocedurally) using a suturing device without an overtube, grasping tissue with either a tissue helix or a grasper. Adjunctive mucosal denudation techniques such as argon plasma coagulation (APC) or endoscopic mucosal resection (EMR) were applied at the discretion of the endoscopist, as were the suturing pattern, number of sutures, and number of stitches.

Clinical response was defined as any symptomatic improvement including a decrease in the Eckardt score. Technical success was defined as successful luminal remodeling according to the treating endoscopist at the end of the procedure [1–3].

Results A total of 11 patients were treated (median age 54 years, IQR 69.5-45; 7 women). Eight cases involved end-stage achalasia with megaesophagus or BOM, and three cases involved delayed emptying of a gastric conduit after esophagectomy. All achalasia patients had undergone previous myotomy (Heller and POEM in 5, only Heller in 2, only POEM in 1). POPE was technically successful in all cases. A zig-zag plication pattern was used in most procedures, with a median of 3 sutures per patient (mean 6 stitches per suture). Combining techniques included EMR in 5 cases, and APC in 4 cases (EMR + APC in 2 cases). Median procedure time was 70 minutes (IQR 87.5-57.5). Initial clinical improvement was observed in 10/11 patients (90.9 %), with a reduction of median Eckardt score from 6 (11/11) to 2 (available in 9/11). One patient with end-stage achalasia and pronounced sigmoid angulation of the distal and proximal esophagus did not show any clinical improvement, with only minimal changes on esophagogram. One patient with post-esophagectomy conduit torsion that presented initial clinical, endoscopic and radiological improvement required subsequent surgical correction (crurotomy) due to persistent dysphagia, with correct improvement after surgery. Complications were mild and included chest pain in 2 patients that achieved clinical response, delayed bleeding managed endoscopically (1 case with an ulcer and dehiscence of a suture at the ulcer level). No severe adverse events occurred. Median hospital stay was 2 days (IQR 2-1.25). Median follow-up was 48 days (IQR 87-20.5).

Conclusions POPE is a feasible and safe endoscopic option for patients with refractory sump formation due to advanced achalasia or dysfunctional gastric conduits. Most patients experienced early clinical improvement with low complication rates. Larger prospective studies with long-term follow-up are needed to assess the durability of the remodeling and define optimal patient selection.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820662

Aims EUS-guided gastroenterostomy (EUS-GE) is the preferred treatment for gastric outlet obstruction (GOO) [1]. However, EUS-GE dysfunction can lead to symptomatic recurrence and reduced quality of life. Data regarding the management of this adverse event are scarce. [2] We aimed to define the incidence and chronology of EUS-GE dysfunction, identifying risk factors, and assessing the efficacy of potential dysfunction salvage strategies.

Methods We conducted a retrospective study including 663 patients from six centres with GOO who underwent EUS-GE between May 2018 and December 2024.Inclusion criteria: technically successful EUS-GE with primary or secondary dysfunction. Clinical, technical, and follow-up variables were collected.

Results EUS-GE dysfunction occurred in 41/663 patients (6.2 %) (52.4 % male; mean age 71 ± 10.3 years). Baseline variables: median pre/post-EUS-GE GOOSS: 0/2; native anatomy in 90 %; malignant aetiology in 77 %. Technical variables:

80.5 % of the EUS-GE were performed using the 20x10mm Axios, and 95.1 % were performed by the direct anterograde method using a nasobiliary catheter. Dysfunction features: median time to occurrence 32 days (IQR 7–240). The most common cause of dysfunction was ingrowth (30.95 %). Endoscopic reintervention was performed in 90.5 % of cases, most commonly by coaxial metal stent placement (18 % LAMS; 45 % others). EUS-GE dysfunction resolved after endoscopic reintervention in 31 patients (75.6 %), after surgery or combined treatments in 2 patients each (4.9 %), while 14.6 % remained unresolved. Success rates by treatment type were: 86.5 % endoscopic (32/37), 100 % surgical (3/3), and 0 % pharmacological (0/7). There was a significant association ($p < 0.05$) between dysfunction resolution and treatment type (endoscopic/surgical vs pharmacological). EUS-GE dysfunction was not associated with mortality ($p = 0.35$). No anatomical or technical risk factors were associated with EUS-GE dysfunction.

Conclusions This study reports a 6 % incidence of EUS-GE dysfunction, most commonly occurring 32 days post-procedure due to tissue ingrowth. The most common cause was ingrowth, which responded to coaxial stent placement in over 76 % of cases. Endoscopic salvage is highly effective (86.5 % success rate) and should be considered the first-line management strategy.

DOI 10.1055/s-0046-1820663

Aims With reported technical and clinical success rates of approximately 94.0 % and 89.9 %, respectively, EUS-guided gastroenterostomy (EUS-GE) has emerged as a major therapeutic option for gastric outlet obstruction (GOO) [1]. However, nearly all existing studies originate from expert centers, and population-based real-world data are virtually nonexistent. Consequently, ESGE guidelines currently recommend restricting the procedure to expert centers [2]. The aim of this study was to evaluate, in real-life conditions and across an entire defined population, the technical success, clinical success, and complication rates of EUS-GE.

Methods This was a multicenter, real-world, population-based retrospective observational study conducted across two large regions (18 administrative divisions, 8.4 million inhabitants). All patients undergoing EUS-GE for GOO (defined as inability to tolerate oral intake or liquid-only intake) were included. Technical success was defined as optimal placement of the lumen-apposing metal stent (LAMS) between the stomach and the duodeno-jejunum. Clinical success was defined as resumption of at least a soft/blended diet (GOOS ≥ 2). Complications were classified according to the AGREE classification.

Results A total of 247 patients (mean age 70.0 years; 45.7 % women) underwent EUS-GE between January 2020 and August 2025: 72.9 % in 5 university hospitals, 23.1 % in 3 general hospitals, and 4.0 % in 2 private clinics. Procedures were performed by 27 operators (range 1–37 procedures per operator). Etiologies of GOO were pancreatic adenocarcinoma (61.3 %), other malignancies (33.0 %), and benign disease (5.7 %). Mean follow-up was 129 days. Technical and clinical success rates were 93.1 % and 85.6 %, respectively. In university hospitals these rates were 92.2 % and 86.1 %, versus 95.5 % and 84.4 % outside university hospitals. Technical success outside university hospitals was not inferior to that observed in university hospitals (difference 3.3 %, 90 % CI: − 2.0 % to + 8.6 %). Complications occurred in 29.4 % of patients (12.6 % AGREE 2 and 16.8 % AGREE ≥ 3). Misdeployed stents occurred in 7.8 % of cases and was managed as follows: repeat EUS-GE (44.5 %), placement of a duodenal stent after removal of the LAMS (27.8 %), simple LAMS removal (22.2 %), surgical gastroenterostomy (5.6 %), and early death without further intervention (5.6 %). Mean postoperative hospital stay was 10.6 days (median 7 days). A total of 4.9 % of patients required ICU. One-month mortality was 21.3 %, with 2.2 % directly attributable to the procedure. Secondary failure occurred in 10.8 % of cases after a mean of 123 days and was managed by repeat EUS-GE (21.7 %), duodenal stent placement (4.3 %), medical therapy alone (13.0 %), or no intervention due to end-of-life status (60.9 %). On multivariate analysis: ascites was significantly associated with lower clinical success (OR 0.34; $p = 0.015$) and increased risk of secondary failure (OR 3.9; $p = 0.024$). · Peritoneal carcinomatosis was associated with higher secondary clinical failure (OR 3.09; $p = 0.046$). · Direct puncture technique was associated with lower technical success (OR 0.12; $p = 0.015$), higher overall complications (OR 5.36; $p = 0.018$), and higher severe complication rates (OR 4.47; $p = 0.040$). A biliary obstruction was present in 57.8 % of patients, prior (56.9 %), synchronous (36.5 %), or subsequent (6.6 %) to EUS-GE, and managed by ERCP (43.4 %), EUS-guided choledochoduodenostomy (EUS-CDS) (22.1 %), EUS-guided cholecystoduodenostomy (EUS-GBD) (3.7 %), EUS-guided hepaticogastrostomy (EUS-HGS) (16.2 %), percutaneous radiologic drainage (14.0 %), or surgery (0.7 %). Secondary biliary failure occurred in 41.4 % of cases (52.6 % after ERCP, 55.0 % after EUS-CDS, 20.0 % after EUS-GBD, 13.6 % after EUS-HGS, and 26.3 % after percutaneous drainage). These failures were managed by ERCP (25 %), EUS-CDS (12.5 %), EUS-GBD (7.1 %), EUS-HGS (28.6 %), percutaneous drainage (16.1 %), or no treatment in end-of-life patients (10.7 %).

Conclusions Initially considered as a complex procedure, EUS-GE proves to be relatively accessible for endoscopists trained in therapeutic EUS and ERCP. Real-life, population-based outcomes and safety profiles appear comparable to those reported in the literature. EUS-GE should become the reference treatment for gastric outlet obstruction and be accessible to all eligible patients

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820664

Aims Endoscopic ultrasound-directed transgastric ERCP (EDGE) has emerged as an important modality for biliary access in patients with altered upper gas-

trointestinal anatomy, but data from real-world multicentre practice remains limited. This study reports outcomes of EDGE performed in three tertiary centres in the UK.

Methods A retrospective analysis was conducted of consecutive EDGE procedures performed over 2024 – 2025. Data collected included demographics, indication, anesthesia type, stent characteristics, anastomosis type, single or multiple stage, use of stent fixation, completion of the intended therapeutic outcome, subsequent fistula management and adverse events. Analysis was performed around outcomes comparing single vs multiple stage.

Results Thirty-one patients (mean age 59.7 years; 23 female, 8 male) were included. The main indication was common bile duct stones (23 cases), with additional indications including EUS with biopsy (2), papillary fibrosis (2), bile leak, biliary biopsy, and gallbladder drainage. Eighteen procedures were performed under general anesthesia and 13 under conscious sedation. AXIOS stents sized 15 × 10 mm and 20 × 10 mm were used in 3 and 28 procedures respectively. Anastomoses were gastrogastrostomy (24) and enterogastrostomy (7). Thirteen procedures were completed as single-stage procedures (all under general anaesthesia), while 18 were two-stage with a mean interval of 16.3 days between the stages. 5 of the multiple stage procedures were performed under general anaesthesia. Stent fixation clips were used in 16 procedures (including 3 two-stage cases), whereas 15 procedures were performed without clip fixation, all in the two-stage setting. Overall, the intended therapeutic outcome was achieved in 29 of 31 (93.5 %) procedures. 4/31 (12.9 %) had an adverse event related to the first stage, all of which were stent dislodgement and 3/4 were managed endoscopically. 2/31(6.5 %) had an adverse event in the second stage (1 migration and 1 displacement) and 1 patient developed post ERCP pancreatitis (3.2 %). There was no significant difference in adverse event rate comparing single vs. multiple stage (3/13 vs. 2/18, p = 0.95) or GA vs. sedation (4/18 vs. 2/13, p = 0.64). Fistula follow up showed 8 closed spontaneously, 13 required no closure, 2 were closed at surgery, 1 was closed endoscopically and 7 are awaiting further imaging.

Conclusions In this multicentre series, EDGE demonstrated a high rate of technical and clinical success with acceptable adverse event rates. Most adverse events can be managed endoscopically and no difference was seen comparing number of stages or use of sedation/anaesthesia. The findings support EDGE as an effective modality for biliary and related interventions in patients with altered anatomy. Larger evaluations are being conducted to improve the statistical power of the comparisons.

DOI 10.1055/s-0046-1820665

Aims Endoscopic ultrasound-guided gastroenterostomy (EUS-GE) using lumen-aposing metal stent (LAMS) has emerged as a promising technique for the palliation of malignant gastric outlet obstruction (mGOO), offering more durable symptom relief compared with enteral stenting (ES). ES, however, remains widely used because of its rapid deployment and technical simplicity, particularly in patients with limited life expectancy [1].

Methods All patients with mGOO treated with EUS-GE or ES between March 2022 and September 2025 in a tertiary referral center in Romania were prospectively included. A propensity score-matching analysis was performed, in order to reduce selection bias, resulting in a 1:1 matched cohort. Clinical and procedural data were collected, and patients were followed for 3 months after the end of the study period or until death. Primary outcomes assessed were technical success (defined as correct deployment of LAMS or ES), clinical success – defined as Gastric Outlet Obstruction Scoring System (GOOSS) ≥ 2 and reintervention rates. Secondary outcomes included survival and complication rates.

Results Propensity score matching yielded 40 patients in total, 20 in each group. Technical success was achieved in all ES procedures and in 95 % of EUS-GE procedures. Clinical success was 100 % in the EUS-GE group and 80 % in the ES group (p = 0.20). Stent occlusion occurred in 5 ES patients and in none of the EUS-GE patients (p < 0.04). Reintervention was required in 5 ES patients (25 %)—due to tumor ingrowth or food impaction—and in 1 EUS-GE patient (5 %) due to misdeployment of distal flange which was resolved endoscopically (p = 0.18). Median survival was 223 ± 147 days in the EUS-GE group and 181 ± 124 days in the ES group (p = 0.10). Median hospitalization duration was 10 ± 4 days for EUS-GE and 9 ± 3.7 days for ES (p = 0.30). Two minor complications occurred in each group, consisting of pneumoperitoneum in EUS-GE group and self limited bleeding in ES group. No major complications (AGREE ≥ II) were reported.

Conclusions EUS-GE demonstrated a trend toward superior and more durable clinical efficacy compared with ES, with lower reintervention rates and significantly fewer cases of stent occlusion. Safety profiles between the two techniques were comparable.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820666

Problem to solve Current standards for EUS-guided gastrojejunostomy (EUS-GE) generally rely on Lumen-Apposing Metal Stents (LAMS). However, LAMS are associated with potential long-term complications and the burden of subsequent re-interventions for exchange or removal, a limitation that is especially critical in the setting of benign disease. While magnetic compression anastomosis creates a permanent fistula without a permanent stent, endoscopic placement of magnets remains critically limiting, with no standardized delivery method.

Innovation We describe a novel technique and specialized delivery system designed to convert an existing LAMS-based EUS-GJ into a magnetic compression anastomosis. The innovation lies in the delivery catheter, which utilizes a torque-release mechanism and a triple traction-based approach. The procedure involves a multistep strategy: downsizing the initial fistula, utilizing a double traction guidewire and traction suture for precise distal magnet placement, and achieving controlled magnetic apposition to form a permanent compression anastomosis, effectively replacing the LAMS.

Results The procedure was executed in sequential stages:
Preparatory Endoscopy: Removal of the LAMS with the goal of downsizing the previous fistula. Insertion of a duodenal stent for temporary enteral feeding.
Index Endoscopy:

Removal of the duodenal stent and passage of a guidewire through the remnant gastrojejunal fistula, followed by retrieval of the distal end through the pylorus using forceps.

Passage of a traction suture attached to the distal magnet parallel to the guidewire. Using double traction, insertion of the distal magnet attached to the delivery catheter. Removal of the proximal end of the guidewire and simultaneous traction of the suture to maintain the magnet in position.

Insertion of the proximal magnet attached to the proximal end of the delivery system until magnet apposition is achieved. Disconnection of the proximal portion of the delivery catheter using a torque mechanism.

Technical success was achieved in 7 out of 8 patients. Follow-up at + 7 days showed no severecomplications.Revision

Endoscopy (+ 10 days): Removal of the magnets and visualization of a wide and patent magnetic anastomosis.

Conclusions Converting a LAMS-GE to a magnetic anastomosis is a feasible technique with an acceptable initial safety profile. This approach offers a potential solution for creating permanent fistulas that avoids the long-term disadvantages of LAMS. However, further refinement andoptimization of the delivery system are essential to simplify the technical complexity of the procedure before it can be widely adopted as a standard alternative [1–3].

OP012 Stent Patency and Clinical Outcomes of EUS-GJ versus Enteral Stenting in Malignant Gastroduodenal Obstruction

Authors Zanini A[1], Pigò F[1], Lupo M[1], Grande G[1], Cocca S[1], Marocchi M[1], Marsico M[1], Boarino V[1], Riccardo C[1], Conigliaro R[1], Bertani H[1]

DOI 10.1055/s-0046-1820667

Aims Malignant gastroduodenal obstruction (mGOO) is a serious complication that compromises quality of life. Traditionally, options to restore luminal patency in patients with mGOO were surgical gastrojejunostomy (SGJ) and enteral stenting (ES). Recently, EUS-guided Gastro-Jejunostomy (EUS-GJ) has gained popularity in tertiary care centers. This retrospective study compares the efficacy and safety of EUS-GJ versus ES. The primary objective was to compare stent failure-free survival (patency time) between EUS-GJ and ES in patients with unresectable mGOO. Secondary objectives included comparing technical success, clinical success (defined as an improvement of at least two points in the Gastric Outlet Obstruction Scoring System [GOOSS] score), need for re-intervention, length of hospital stay, incidence of adverse events (AEs), and overall survival (OS).

Methods A single-center retrospective analysis (Azienda Ospedaliero Universitaria Policlinico di Modena) was conducted on all consecutive patients with confirmed symptomatic mGOO who were not candidates for curative surgical resection and underwent EUS-GJ or ES between January 2019 and August 2025. Demographic data, mGOO etiology, procedural data, and clinical follow-up were collected and analyzed. EUS-GJ procedures were performed using the wire-endoscopic simplified technique (WEST). Cumulative patency and overall survival were analyzed using the Kaplan-Meier method and compared using the log-rank test [1–7].

Results A total of 109 patients were analyzed: 62 treated with ES and 47 with EUS-GJ. Baseline characteristics were comparable, although pancreatic etiology was more frequent in the EUS-GJ group ($p = 0.004$) and gastric etiology in the ES group ($p = 0.012$). Median stent failure-free survival was significantly longer in the EUS-GJ group (135 days) compared to the ES group (59 days; $p = 0.00068$). Technical success was comparable and high in both groups (EUS-GJ 97.9 % vs. ES 100 %; $p = 0.43$). However, clinical success was significantly higher in the EUS-GJ group (95.5 % vs. 72.3 %; $p = 0.004$). The need for re-intervention was significantly lower in the EUS-GJ group (4.3 %) compared to the ES group (22.6 %; $p = 0.012$). The overall rate of adverse events was similar (EUS-GJ 21.3 % vs. ES 24.2 %; $p = 0.82$), although tumor ingrowth (the main cause of ES failure) was significantly more frequent in the ES group ($p = 0.028$). Median overall survival was significantly longer in the EUS-GJ group (135 days vs. 71.5 days; $p = 0.017$).

Conclusions EUS-GJ demonstrated significantly longer stent failure-free survival compared to enteral stenting. In addition to comparable technical success and overall safety profiles, EUS-GJ provided higher clinical success, markedly longer anastomosis patency, and a significant reduction in the need for re-interventions. These benefits are primarily attributable to overcoming tumor ingrowth, which remains the main limitation of ES. The results suggest that EUS-GJ should be considered the first-line palliative procedure for mGOO patients in high-volume centers with adequate expertise.

OP013 Randomized Controlled Trial Comparing Endoscopic Balloon Dilation Versus Endoscopic Stricturotomy For Short Strictures (< 3 Cm) Related To Crohn's Disease (The BEST-CD Trial) (NCT05521867)

Authors Pal P[1], Pooja K[2], Naaz SM[2], Gupta R[2], Tandan M[2], Reddy DN[2]
Institutes 1 AIG Hospitals, Banjara Hills, Hyderabad, India; 2 Asian Institute of Gastroenterology, Hyderabad, India
DOI 10.1055/s-0046-1820668

Aims Endoscopic balloon dilation (BD) is widely practiced for Crohn's disease (CD)–related strictures but is limited by frequent recurrence and need for surgery. Endoscopic stricturotomy(ES) has shown encouraging results in retrospective studies, especially for anastomotic strictures, but prospective randomized evidence is lacking. The BEST-CD trial was designed to directly compare EBD and ES for short CD strictures and to evaluate predictors of recurrence, reintervention, and surgery.

Methods This single-centre, open-label, randomized controlled trial was conducted between August 2022 and March 2025 at the Asian Institute of Gastroenterology, Hyderabad, India. Eligible patients were adults 18–65 years with CD with symptomatic, strictures (< 3 cm, de novo/ anastomotic, accessible by standard endoscopy). Patients with > 2 strictures, strictures beyond endoscopic reach, or prior ES were excluded. Participants were randomized to undergo either EBD or ES using insulated tip knife. The primary outcome was clinical recurrence at 1 year. Secondary outcomes included reintervention, stricture-related surgery, emergency visits, hospitalization, technical and clinical success, adverse events, and time-to-event outcomes. Cox multivariable regression was done to assess independent predictors [1–3].

Results Of 157 patients screened, 101 were randomized (50 EBD, 51 ES). Baseline demographics, disease extent, and prior therapies were comparable between groups. Technical success was achieved in 88 % of both groups, and clinical success was 92 % in the EBD arm and 96 % in the ES arm. Median procedure time was longer for ES than EBD (35 vs 30 minutes, p = 0.007). At a median follow-up of 12 months (range 3–36), ES significantly reduced clinical recurrence (24.5 % vs 54.3 %, p = 0.003), need for reintervention (23.5 % vs 52 %, p = 0.004), stricture-related emergency visits (17.6 % vs 54 %, p < 0.001), and hospitalizations (15.7 % vs 38 %, p = 0.01) compared with EBD. Stricture-related surgery was numerically lower after ES (3.9 % vs 16 %, p = 0.051) but did not reach statistical significance. Cox regression showed ES was associated with significantly longer time to recurrence (hazard ratio [HR] 0.35, p = 0.004), reintervention (HR 0.36, p = 0.006), and first emergency visit (HR 0.28, p < 0.001), with a trend towards longer time to hospitalization (HR 0.42, p = 0.02). Time to surgery was not significantly different between groups (p = 0.4). Adverse events occurred in 22 % of EBD and 13.7 % of ES patients (p = 0.31), mostly minor bleeding or post-procedure pain, with one perforation in each arm. On multivariable analysis, treatment with ES (Hazard ratio [HR] 0.315, 95 % CI 0.136–0.728, p = 0.007), greater stricture length (OR 3.59, 95 % CI 1.62–7.95, p = 0.002) and upper GI location (▶ **Table 1**) independently predicted reintervention and clinicel recurrence while surgery was predicted by longer stricture length rather than treatment modality.

▶ **Table 1**

Variable	Reinterevention – p, OR (95 % CI)	Clinical recurrence – p, OR (95 % CI)	Surgery – p, OR (95 % CI)
Length of strictures	0.002, 3.587 (1.619-7.949)		0.086, 5.139 (0.792-33.336)
Ileocecal vs UGI	0.017, 0.15 (0.032-0.708)	0.005, 0.093 (0.018- 0.497)	
Ileal vs upper GI	0.003, 0.106(0.024-0.461)	0.004, 0.107 (0.023- 0.494)	
ES vs EBD	0.007, 0.315 (0.136-0.728)	0.001, 4.886 (1.964-12.154)	

Conclusions In this first randomized controlled trial of endoscopic therapy for CD strictures, ES demonstrated superior efficacy over EBD with a comparable safety profile. EBD and longer stricture length independently predicted adverse outcomes, whereas surgery was determined by stricture length rather than treatment allocation. These findings suggest ES may be a safer and more effective first-line therapy than EBD for short CD strictures. Larger multicentre studies with longer follow-up are warranted to confirm these results and to refine patient selection.

DOI 10.1055/s-0046-1820669

Aims Accurate assessment of endoscopic disease activity is essential for the management of Ulcerative colitis (UC). Virtual chromoendoscopy (VCE) enhances mucosal and vascular detail, yet interpretation remains challenging and subject to substantial interobserver variability. Recent AI-models can detect and convert VCE modalities, providing a multimodal and objective evaluation [1]. However, existing AI systems predominantly analyse isolated frames, lacking spatial context and overlooking patchy inflammation. Frame-based approaches are prone to artefacts and misclassification because they cannot follow mucosal changes across the entire colon. To address these limitations, we developed and externally validated a multiple-instance learning (MIL) model that integrates spatial attention to capture patchy inflammation and mucosal granularity, together with temporal tracking of inflammatory changes across full-length endoscopic videos.

▶ Table 1

	Accuracy % (95 % CI)	Sensitivity % (95 % CI)	Specificity % (95 % CI)	PPV % (95 % CI)	NPV % (95 % CI)	F1 score % (95 % CI)	AUC %
LIMUC	92.4	93.6	90.4	95.5	90.6	94.0	97.8
5-fold cross validation	(92.3-94.9)	(92.7- 95.9)	(89.7- 94.5)	(94.0- 96.7)	(87.9- 92.7)	(92.0-95.6)	
PICaSSO	94.6	84.0	96.8	80.8	96.7	84.0	95.7
External validation	(88.8- 97.2)	(63.9-95.5)	(90.8-98.7)	(63.6- 90)	(92.3-98.6)	(70-92)	
Birmigham	86.0	88.0	84.0	82.6	87.5	86.3	91.4
External validation	(73.3- 94.2)	(68.8- 97.5)	(63.9- 95.5)	(68.9-93.2)	(70.5-95.4)	(73.5-95.4)	

Methods Endoscopic videos from high-definition white-light endoscopy (HD-WLE), iScan2, iScan3, and narrow-band imaging (NBI) modalities from UC patients in the LIMUC [2], PICaSSO [3], and Birmingham (BHM) [4] cohorts (1,391, 302, and 54 patients, respectively) were used to develop SpatioMIL. This MIL framework integrates spatial and temporal attention to aggregate frame-level information for robust video-level inflammation detection **(Figure 1).** Videos were labelled as active inflammation or remission according to Mayo Endoscopic Score. Overall, 784 colonoscopy videos (7,840 frames) from LIMUC dataset were used for model training. External validation was performed on 148 full-length PICaSSO (30,000 frames) and 51 BHM videos (8,000 frames). Model performance in predicting endoscopic remission was evaluated.

Results ▶ **Table 1** details the performance metrics of SpatioMIL across the three cohorts**.** In the LIMUC cohort, the model achieved a sensitivity, specificity and accuracy of 93.6 %, 90.4 % and 92.4 %, respectively. External validation demonstrated robust generalizability, with excellent performance in predicting endoscopic remission in both PICaSSO and BHM cohorts (sensitivity: 84.0 % and 88.0 %, specificity: 96.8 % and 84.0 %, accuracy: 94.6 % and 86.9 %). Interestingly, SpatioMIL outperformed all state-of-the-art MIL approaches, with 94.6 and 86 % accuracy in the PICaSSO and BHM cohort, respectively.

Conclusions Our novel SpatioMIL model integrates spatial and temporal attention for UC assessment, enabling accurate disease evaluation by capturing patchy inflammation and mucosal granularity across the entire colon. The model demonstrated excellent performance with strong external validation across diverse VCE modalities, highlighting its potential as a reliable tool for objective and reproducible endoscopic inflammation assessment.

DOI 10.1055/s-0046-1820670

Aims Up to 30 % of patients with Crohn's disease (CD) develop intestinal strictures during their disease course, leading to impaired quality of life and posing a major therapeutic challenge. Fibrotic strictures respond poorly to medical therapy and surgery carries substantial risks of complications and recurrence. Endoscopic balloon dilation (EBD) is widely used but often requires repeated sessions. Endoscopic stricturotomy (ES) with an IT-knife has recently emerged as a minimally invasive alternative, potentially improving long-term outcomes, although real-world evidence remains limited. To evaluate safety, technical feasibility, and long-term outcomes of ES for CD-related strictures.

Methods We prospectively analyzed 22 patients with stricturing CD who underwent ES at Hospital Clínic of Barcelona between 2018 and 2024. Eligible strictures were ≤ 3 cm long, native or anastomotic, and endoscopically accessible. The primary outcome was surgery-free survival at 12 months, defined as absence of surgical intervention for symptomatic recurrence. Secondary outcomes included: technical success (scope traversability after the procedure), clinical success (symptom improvement at follow-up), complications, need for additional endoscopic procedures and predictors of therapeutic success.

Results Twenty-two patients were enrolled (mean age 45.0 ± 12.8 years; 59.1 % anastomotic, 40.9 % native strictures). Magnetic resonance enterography was performed in all cases, revealing proximal dilation (≥ 3 cm) in 54.5 %. Immediate technical success was achieved in 91 % (20/22) of procedures. Adverse events were infrequent, limited to two cases of delayed post-procedural bleeding (9 %), one requiring endoscopic haemostasis. Surgery-free survival was 91 % (20/22) at 12 months and 88 % (15/17) at 24 months, with no significant difference between native and anastomotic strictures (89 % vs 92 %, $p = 0.5$). Among the surgery-free patients, clinical success was maintained in 95 % (19/20) at 12 months and 80 % (12/15) at 24 months. Overall, four patients underwent repeat endoscopic interventions for symptomatic recurrence (one within 12 months, three within 24 months), all with 100 % technical success.

Conclusions Endoscopic IT-knife ES appears safe, feasible, and effective for short CD-related strictures, achieving durable symptom control and surgery-free survival with a low complication rate. This study provides the longest systematic follow-up reported to date, reinforcing the long-term utility of ES in real-world practice. These findings support incorporating ES into the thera-

peutic algorithm alongside EBD, with multicentre prospective studies warranted to validate outcomes, standardize protocols, and redefine patient selection.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP016 Safety and Efficacy of Endoscopic Submucosal Dissection for Colorectal Dysplasia in Inflammatory Bowel Disease: A Systematic Review and Meta-Analysis

Authors Bartocci B[1], Chiappetta MF[2], Ciuffini C[2], Papparella LG[2], Vadalà Di Prampero SF[2], Borrelli de Andreis F[2, 1], Costamagna G[2], Bulajic M[2]

Institutes **1** Università Cattolica del Sacro Cuore, Rome, Italy; **2** Digestive Endoscopy Unit, Ospedale Isola Tiberina – Gemelli Isola, Rome, Italy

DOI 10.1055/s-0046-1820671

Aims Patients with inflammatory bowel disease (IBD) are at increased risk of colorectal neoplasia. Endoscopic submucosal dissection (ESD) has emerged as an organ-preserving alternative for the management of dysplastic lesions. However, pooled data on efficacy, safety, and long-term outcomes in the IBD population remain limited. We performed a systematic review and meta-analysis to evaluate the procedural and clinical outcomes of ESD for colorectal colitis-associated neoplasia (HR-CAN).

Methods Multiple databases were searched, and studies were retrieved based on pre-specified criteria until April 2025. The outcomes assessed were resection rates, procedural complications, local recurrence, metachronous tumors and the need for surgery after ESD in IBD. Standard meta-analysis methods were followed using the random-effects model. Heterogeneity was assessed with I^2 and τ^2 statistics. Continuous variables, including lesion size and follow-up, were summarized descriptively.

Results Fifteen studies including 441 patients with 571 lesions (65 % ulcerative colitis, 35 % Crohn's disease) were included. The median lesion size was 30 mm (IQR 20–50 mm) and median follow-up was 24 months (range 6-60 months). Pooled en bloc resection was 92 % (95 % CI 88–95) and R0 resection 81 % (95 % CI 74–87). Procedure-related bleeding occurred in 6 % (95 % CI 3–11) and perforation in 9 % (95 % CI 5–15). Local recurrence after ESD was 6 % (95 % CI 4–9), whereas metachronous dysplasia was observed in 16 % of patients (95 % CI 9–25 %). Overall, 17 % of patients required surgical intervention post-ESD (95 % CI 12–23), due to incomplete resection, recurrence, or histological findings.

Conclusions ESD is a safe and effective procedure for the treatment of colorectal dysplastic lesions in IBD patients, achieving high en bloc and R0 resection rates with low local recurrence. Nevertheless, a significant proportion of patients develop metachronous lesions or require surgery, underscoring the necessity of structured endoscopic surveillance and multidisciplinary management. Further prospective multicenter studies with longer follow-up are still needed.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP017 Outcomes of endoscopic submucosal dissection (ESD) for dysplasia in inflammatory bowel disease (IBD): A retrospective single-centre analysis

Authors Toskas A[1], Suzuki N[2]

Institutes **1** St Mark's National Bowel Hospital, London, United Kingdom; **2** Wolfson Unit for Endoscopy, St Mark's The National Bowel Hospital, London, United Kingdom

DOI 10.1055/s-0046-1820672

Aims En bloc resection with advanced endoscopic techniques was suggested in the BSG 2025 Guidelines for the management of visible, clearly demarcated dysplastic lesions, in patients with IBD. Our study aims to demonstrate the safety, efficacy, and long-term outcomes of ESD as treatment option in selected patients, allowing for bowel preservation in IBD.

Methods We retrospectively followed 37 patients with extensive IBD-related colitis and visible dysplastic lesions treated with ESD from 2017 to August 2025. The mean patient age was 63 years and 54.1 % were male. Majority of the lesions were rectal (67.6 %) and 45.9 % had a flat component. Their size was ≥ 20 mm in 73 %. Follow-up endoscopic evaluations were performed at 6 months,1-year and 3-years post-procedure. Ten patients were lost to follow up.

Results En bloc resection was achieved in 91.9 % of cases, and R0 resection in 75.7 %. Histologically confirmed clear vertical and horizontal margins were observed in 75.7 % of patients. At 6 months, there was no recurrence. At 1-year follow-up, 97.3 % of patients remained recurrence-free, and 100 % in 3-year follow up. No metachronous lesions were detected in 86.5 % of patients. Significant discrepancy was noted between pre-resection biopsy and final histology, with 32.4 % of the lesions biopsied before resection, showing different histology from the excision specimen. Specifically, 8 out of 19 lesions (42.1 %) with low grade dysplasia (LGD) before excision, were upgraded to high grade dysplasia (HGD) or cancer post resection and 2 out of 3 non-dysplastic serrated lesions were found to have LGD. Adverse events (bleeding, perforation) occurred in 5 patients (13.5 %) with two of those (1 patient for suturing of bleeding vessel and 1 patient due to delayed perforation of a lesion on the ileorectal anastomosis) requiring surgical management.

Conclusions ESD is a feasible, safe, and effective method for treating visible dysplasia in IBD patients, offering significant benefits in accurate histopathology from excision specimen, a low risk of early recurrence and colon-sparing benefit. While promising, further long-term and larger-scale studies are needed to confirm these findings, particularly regarding the risk of late and metachronous recurrence in this high-risk population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP018 Redefining Ulcerative Colitis Assessment Through Multimodal Virtual Chromoendoscopy: The MONET Study

Authors Iacucci M[1], Pugliano CL[1], Zammarchi I[1, 2], Lo Bello A[1], Santacroce G[1, 3], Nardone OM[4], Hughes R[1], Tan CK[5], Dal Buono A[6], Di Tonno I[7], Principi M[7], Ghosh S[1], Bisschops R[8], Maeda Y[9]

DOI 10.1055/s-0046-1820673

Aims Despite normal-appearing mucosa at white light endoscopy (WLE), up to 30 % ulcerative colitis (UC) patients experience persistent histological activity, with increased risk of adverse outcomes [1]. Virtual electronic chromoendoscopy (VCE) can enhance visualisation of subvisual alterations, potentially bridging this gap [2]. The MONET study aims to develop a novel endoscopic scoring system based on multimodal VCE features to distinguish between quiescent and active colitis in UC.

Methods We developed a scoring system incorporating three VCE modalities of the EVIS-X1 CV 1500 (Olympus, Japan) platform: Narrow-Band Imaging (NBI), Texture and Colour Enhancement Imaging (TXI) and Red Dichromatic Imaging (RDI). Eight international IBD-experienced endoscopists participated in a two-round modified Delphi process: an initial in-person consensus meeting followed by an anonymised online survey (*Qualtrics platform*) to select mucosal and vascular patterns representative of different UC activity grades. Consensus was defined as ≥ 75 % participant agreement. Twenty-one high-quality videos encompassing varying grades of inflammation were prospectively recorded using WLE, NBI, TXI, and RDI according to a standardised protocol from the ongoing multicenter international MONET study (NCT06709209). Videos were independently scored according to selected features. Interobserver agreement was evaluated using Gwet's AC1/AC2 coefficient.

Results Overall, 12 mucosal and 12 vascular features were initially identified (**Table 1, Figure 1**). Among mucosal features, crypt architecture (AC1 0.76), microerosions (AC1 0.76) and erosions (AC1 0.80) demonstrated substantial agreement. For vascular features, crowded and intramucosal bleeding showed substantial agreement (AC1 0.78 and 0.73, respectively), while honeycombing showed moderate agreement (AC1 0.50). NBI-specific features, including honeycombing, branching vessels, and intramucosal bleeding, demonstrated substantial agreement (AC1 0.63, 0.73, and 0.65, respectively). Using TXI, crypt architecture (AC1 0.7), microerosions (AC1 0.72), and erosions (AC1 0.78) yielded substantial agreement. Deep vessels visibility, assessed through RDI, yielded substantial agreement (AC1 0.77). The agreement for the remaining features was almost perfect. The anonymised Delphi voting survey confirmed consensus for all 24 identified elements into the final MONET score.

Conclusions The novel VCE-based MONET score demonstrated high interobserver agreement across mucosal and vascular features, supporting its robustness and clinical relevance. It holds potential to bridge the gap between endoscopic assessment and histologic activity, particularly in mildly active UC. Multicenter prospective validation is underway to support broader adoption and future integration into AI-assisted endoscopic evaluation.

DOI 10.1055/s-0046-1820674

Aims Biliary drainage (BD) in distal malignant biliary obstruction (DMBO) is often hampered by difficult biliary cannulation (DBC) during endoscopic retrograde cholangiopancreatography (ERCP). Advanced cannulation techniques (aERCP) may overcome DBC but still fail in up to 15 % of cases, increasing the risk of adverse events (AEs). Early endoscopic ultrasound-guided BD (eEUS-BD) is a potential alternative. The aim of this study is to directly compare safety and efficacy of EUS-BD and aERCP [1–24].

Methods This is a retrospective, multicentric study (30 centres in United States, Canada, Europe), including patients with DMBO and common bile duct (CBD) diameter > 12 mm treated between 2019 and 2024. DBC cases managed with either eEUS-BD or aERCP were analysed. A 1:2 propensity score-matched cohort was generated to ensure comparability, with regression modelling and

inverse probability of treatment weighting (IPTW) performed as sensitivity analyses. AEs rate was the primary outcome; secondary outcomes included BD failure and clinical success.

Results Standard cannulation failed in 2066/10,738 (19.2 %) ERCPs. aERCP and eEUS-BD were attempted in 1733 and 333 cases, respectively. After matching, 313 patients per EUS-BD group and 626 patients per aERCP group were analyzed. AEs occurred in 18.2 % of aERCPs and 9.3 % of eEUS-BD ($p < 0.01$), with post-procedural pancreatitis the most frequent AE after aERCP (55 cases, 12.0 %). Both regression and IPTW confirmed the robustness of these findings on the entire cohort. Technical success was significantly lower with aERCP (82.0 % vs. 95.9 %, $p < 0.01$), clinical success was comparable (94.5 % vs. 96.4 %, $p = 0.89$).

Conclusions In patients with DMBO and dilated CBD, eEUS-BD is associated with fewer AEs and higher technical success than aERCP, supporting its role as a safer, more effective option in DBC.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Endoscopic ultrasound-guided choledochoduodenostomy (EUS-CDS) has emerged as a viable alternative to endoscopic retrograde cholangiopancreatography (ERCP) for the primary management of distal malignant biliary obstruction (DMBO). Several randomized controlled trials (RCTs) have evaluated the performance of EUS-CDS with cautery-enhanced lumen-apposing metal stents (CE-LAMS) vs ERCP. This systematic review and meta-analysis aims to assess the efficacy and safety of EUS-CDS with CE-LAMS for DMBO, and compare its outcomes with ERCP

Methods A systematic search was conducted in the MEDLINE, Embase, and Scopus databases from inception until September 2024, to identify RCTs evaluating the performance of EUS-CDS with CE-LAMS for primary biliary drainage in patients with DMBO and dilated biliary duct, compared to ERCP with SEMS. Technical success was defined as the pooled rate of accurate placement of either LAMS (for EUS-CDS) or SEMS (for ERCP) within the CBD, with bile flowing through the stent. In case of technical failure the pooled rate of successfull crossover to the other technique was reported. Clinical success the pooled rate of patients with a ≥ 50 % reduction in serum bilirubin to < 3 mg/dL within two weeks (and clinical improvement in case of concomitant cholangitis). Safety outcomes included adverse events, classified per the American Society for Gastrointestinal Endoscopy lexicon, with severe events including unplanned admissions > 10 days, ICU stays > 1 day, surgery, or permanent disability. Pooled mortality rate was also reported.Pooled estimates and relative risk (RR) with 95 % confidence intervals (CI) were calculated using a random effects model, and heterogeneity was assessed using the I^2 statistic [1–4].

Results Four randomized controlled trials, including a total of 555 patients were included. The meta-analysis revealed a higher technical success rate of EUS-CDS performed with CE-LAMS compared to ERCP with SEMS placement, with a pooled relative risk (RR) of 1.17 (95 % confidence interval [CI]: 1.07-1.28, I^2 = 28.6 %,) and an absolut risk difference of 13.6 % (95 % CI: 6.0 to 21.2) No significant differences were found between the two groups in term of clinical success (RR = 1.00, 95 % CI: 0.95-1.07, I^2 = 0 %), with a clinical success rate of 89.0 % (95 % CI: 84.1 to 93.9; I^2: 32.6 %), and 88.5 % (95 % CI: 84.8 to 92.2; I^2:0 %) in EUS-CDS and ERCP group, respectively. The relative risk (RR) of the overall adverse event rate for EUS-CDS compared with ERCP was 0.97 (95 % CI: 0.68-1.43, I^2 = 0 %). The pooled incidence of adverse events was 15.8 % (95 % CI: 10.6 to 21.0; I^2: 21.9 %) among patients undergoing EUS-CDS, and 20.7 % (95 % CI: 11.3 to 30.1; I^2: 76.22 %) among those undergoing ERCP. No difference were assessed for severe adverse events across the studies, with a pooled RR of 0.88 (95 % CI: 0.38–2.07; EUS-CDS: 2.4 % vs ERCP: 3.1 %) In detail, EUS-CDS was associated with a reduced risk of post-procedural pancreatitis (RR = 0.13, 95 % CI: 0.03-0.60; I^2 = 0 %), with an absolute risk difference of -4.7 % (95 % CI: -7.6 to -1.5), while EUS-CDS showed an higher risk of stent misdeployment/migration comapared to ERCP (RR = 6.39, 95 % CI:1.61-25.40, I^2 = 0 %).

Conclusions EUS-CDS with CE-LAMS demonstrated superior technical efficiency compared to ERCP, while maintaining similar clinical with a lower risk of post-procedural pancreatitis. Considering EUS-CDS implies a higher risk of stent misdeployment, future research should aim to identify predictive factors that could improve patients selection, maximizing the benefits of the different approaches

Aims After failed endoscopic retrograde cholangiopancreatography (ERCP), endoscopic ultrasound-guided biliary drainage (EUS-BD) is recommended in centers with appropriate expertise. Evidence remains heterogeneous and rarely focuses specifically on endoscopic ultrasound-guided hepaticogastrostomy (EUS-HGS) for distal malignant biliary obstruction (dMBO) without duodenal stenosis. We aimed to evaluate the efficacy, safety, biliary stent patency and oncologic impact of EUS-HGS in this setting.

Methods Retrospective single-center cohort (2011–2024) including consecutive dMBO after failed ERCP without endoscopic/radiological duodenal ste-

nosis. Exclusions: duodenal tumor invasion, surgically altered anatomy, papillary involvement. EUS-HGS was performed via a standard transhepatic approach using self-expandable metal stents (SEMS); detailed stenting configurations are reported in the Results. Primary outcomes: technical and clinical success defined as resolution of cholangitis and normalization of total bilirubin (< 1.5 mg/dL) or a ≥ 50 % decrease from baseline within 14 days after EUS-HGS. Safety: 30-day procedure-related morbidity and mortality per AGREE lexicon. Patency: Kaplan–Meier (KM) and competing-risk (Fine–Gray; death as competing event). Oncologic endpoint: resumption of systemic therapy at a pre-specified 61-day landmark among survivors. Multivariable logistic, Cox and competing-risk models (Firth penalized logistic for rare events). Follow-up was calculated from EUS-HGS to death or last contact (database lock 1st December 2024). Median follow-up was not reached by reverse KM.

Results Among 769 EUS-HGS procedures performed in the center, 51 patients met inclusion criteria; 50 technically successful procedures (98 %) were analyzed. Median age 78 years; 58 % women. Pancreatic adenocarcinoma was most frequent (86 %); ampullary cancer and cholangiocarcinoma were 6 % each; 48 % had metastatic disease. Stenting strategies varied: the predominant configuration was a partially covered (PC)-SEMS alone (34/50, 68 %); combined strategies were used according to anatomy and drainage needs: PC-SEMS + internal fully covered (FC)-SEMS (7/50, 14 %), PC-SEMS + coaxial plastic stent (5/50, 10 %), FC-SEMS alone (2/50, 4 %), and FC- SEMS + coaxial plastic stent (2/50, 4 %). Clinical success at D14 was 92 % (46/50). Median total bilirubin fell from 15.4 to 2.3 mg/dL (median relative reduction 80.8 %); median post-procedural hospital stay was 3 days. Procedure-related morbidity 8 % (4/50: one cholangitis, one mild hemobilia, two early stent dysfunctions managed endoscopically). Thirty-day mortality 10 % (5/50), including 4 % (2/50) procedure-related deaths due to one obstruction and one migration complicated by severe cholangitis, and 6 % (3/50) non–procedure-related deaths. At D61, 40/42 survivors (91 %) had resumed systemic therapy. Biliary patency by Kaplan–Meier (deaths without dysfunction censored) was 92 %, 76 % and 65 % at 30, 90 and 180 days, with a median of 429 days. In the competing-risk model (death as competing event), cumulative dysfunction was 8 %, 23 % and 35 % at 30, 90 and 180 days, with ~45 % dying before any dysfunction; overall, 21/50 (42 %) developed stent dysfunction (4 early ≤ 30 days: two migrations, two obstructions; 17 delayed > 30 days, mostly obstructions). No independent predictors of clinical success, early events or dysfunction were identified. Median overall survival was 283 days (76 %, 60 % and 39 % at 90, 180 and 365 days). At database lock, 12 % of patients were alive; among survivors, the maximum observed follow-up was 1565 days.

Conclusions In a homogeneous cohort of dMBO after failed ERCP without duodenal stenosis or altered anatomy, EUS-HGS achieved high efficacy and acceptable 30-day safety (procedure-related morbidity 8 %, mortality 4 %), with durable biliary patency (median 429 days). The 91 % resumption of systemic therapy at D61 suggests preservation of the oncologic pathway. In experienced centers, EUS-HGS may be considered a rescue strategy after failed ERCP and warrants prospective validation.

Aims The introduction of EUS-guided cholangiopancreatography (EUS-CP) represented a breakthrough in the management of patients with complex biliopancreatic disease. Initial national results of this technique showed moderate success[1]. The aim of this study is to evaluate current outcomes of the first EUS-CP cases performed by each endoscopist and to analyze endoscopist- and center-related factors [1].

Methods Members of the ERCP and EUS working group of the national endoscopic society were invited to participate. Consecutive first EUS-CP cases performed independently by each endoscopist were collected, up to a maximum of 20 procedures. Endoscopists who participated in the previous national registry, those who started EUS-CP before 2013, or whose cases were not consecutive were excluded from the study. Additionally, a survey was conducted among the endoscopists to inquire about their training in EUS, ERCP, prior experience with EUS, volume of procedures performed, and assistance during procedures.

Results A total of 316 patients treated by 23 endoscopists from 18 centers were analyzed. Fourteen endoscopists (60.9 %) performed EUS-CP without prior center experience. The training time for endoscopists before performing an EUS-CP procedure was 13 ± 8 months for EUS and 14 ± 6 months for ERCP. The procedures included 147 choledochoduodenostomies (CDS), 60 hepaticogastrostomies (HG), 97 biliary rendezvous (EUS-RV), 8 pancreatic rendezvous, and 4 pancreaticogastrostomies (PG). LAMS stents were used in 42.4 % of procedures.

Overall technical success was 83.2 %, and by procedure: CDS 95.9 %, biliary EUS-RV 59.8 %, HG 91.7 %, pancreatic EUS-RV 62.5 %, PG 100 % ($p < 0.001$). Most technical failures (77.4 %) were related to guidewire manipulation difficulties. Technical success was significantly higher in transmural versus rendezvous procedures (94.8 % vs 60.0 %, $p < 0.001$).

A total of 55 adverse events occurred (17.4 %), with no differences among procedures. 54.5 % of all AE were managed conservatively, 32.7 % endoscopically, and 12.7 % by interventional radiology. Fifteen stent malpositions were reported.

Conclusions EUS-CP currently shows high technical success rates during initial implementation, particularly for transmural drainage techniques. The rendezvous approach is associated with greater technical difficulty, with guidewire manipulation being the most limiting step.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims EUS-guided choledochoduodenostomy using a lumen-apposing metal stent (EUS-CDS) is evolving as an effective alternative to endoscopic retrograde cholangiopancreatography (ERCP) for malignant distal biliary obstruction (MDBO). However, there are currently no long-term data beyond 1-year in the literature. We evaluated long-term (>1-year) outcomes, including stent dysfunction, defined as any unplanned stent related endoscopic or radiological re-intervention, adverse events, and mortality in patients originally enrolled in the ELEMENT and DRAMBO RCTs who survived beyond 1-year following randomization (▶ **Table 1**).

Methods This study is a long-term extension of the previously published ELEMENT and DRA-MBO RCTs, which prospectively compared EUS-CDS with ERCP for MDBO. For the present long-term analysis, we conducted a retrospective chart review of participants to capture clinical events occurring beyond 12 months. Retrospective data, including survival status, stent dysfunction, adverse events, were extracted. The resulting integrated dataset included prospective follow-up through 12 months and retrospective data thereafter. All long-term analyses were performed on this combined dataset [1, 2].

▶ **Table 1**

Variable	Overall n = 299	EUS-CDS (n = 152)	ERCP-M (n = 147)	p-value
Borderline/locally advanced	243 (81.3 %)	31 (20.4 %)	25 (17.1 %)	0.45
Unresectable	56 (18.7 %)	121 (79.6 %)	122 (83.0 %)	0.08
Baseline Bilirubin level (umol/L)	240.6 ± 141.1	235.3 ± 130.3	246.0 ± 151.6	0.51
Stent dysfunction (missing data in 19 patients, 14 EUS-CDS and 5 ERCP)	29/280 (10.4 %)	13/138 (9.4 %)	16/142 (11.3 %)	0.83
Time to death (days)	252.7 ± 273.4	259.6 ± 303.5	245.8 ± 240.2	0.68
30 days adverse event	42 (14.0 %)	19 (12.5 %)	23 (15.6 %)	0.56
Fatal	11 (26.2 %)	4 (21.1 %)	7 (30.4 %)	0.73
Severe	3 (7.1 %)	1 (5.3 %)	2 (8.7 %)	1.00
Moderate	19 (45.2 %)	13 (68.4 %)	6 (26.1 %)	0.01
Mild	9 (21.4 %)	1 (5.3 %)	8 (34.8 %)	0.03
Adverse event occurring > 1 year	5/69 (7.2 %)	3/31 (9.7 %)	2/38 (5.2 %)	0.65
Cholangitis	3 (60.0 %)	1 (33.3 %)	2 (100.0 %)	0.17
Bleeding	1 (20.0 %)	1 (33.3 %)	0 (0.0 %)	1.00
Pancreatitis	1 (20.0 %)	1 (33.3 %)	0 (0.0 %)	1.00
Other	0 (0.0 %)	0 (0.0 %)	0 (0.0 %)	-
Severity of Adverse events				
Severe	2 (40.0 %)	1 (33.3 %)	1 (50.0 %)	1.00
Mild	3 (60.0 %)	2 (66.7 %)	1 (50.0 %)	1.00

Endoscopy 2026; 58: S1–S1041

Results The ELEMENT and DRAMBO trials randomized an aggregate of 299 patients. Mean age of the cohort was 73 ± 12 years with 43.1 % of female sex. The most common etiology of obstruction was pancreatic cancer (93.3 %). There were no differences in baselines characteristics according to drainage allocation**.** Comparable survival was noted between the two groups with median time to death of 259.6 ± 303.5 days and 245.8 ± 240.2 days in the EUS-CDS and ERCP groups, respectively (p = 0.68)**.** Stent dysfunction occurred in 9.4 % with EUS-CDS and 11.3 % with ERCP, p = 0.83. 30-day adverse events (AEs) occurred in 12.5 % of EUS-CDS and 15.6 % of ERCP, p = 0.56. Delayed AEs after 1 year follow up occurred in 9.7 % (3/31) of EUS-CDS and 5.5 % (2/38) of ERCP, p = 0.65). There was no significant differences in severity of the AEs.

Conclusions EUS-CDS and ERCP demonstrated comparable long-term clinical effectiveness and safety in patients with MDBO with no difference in overall patient survival. EUS-CDS appears to be a viable alternative in MDBO even in patients who survive beyond 1-year.

DOI 10.1055/s-0046-1820679

Aims Endoscopic retrograde cholangiography (ERC) represents the gold standard for therapeutic interventions in the biliary tract. However, altered surgical anatomy, strictures in the upper gastrointestinal tract, or high-grade stenoses at the papilla or distal bile duct can render conventional ERC technically challenging or impossible. In these scenarios, endoscopic ultrasound-guided biliary drainage (EUS-BD), including direct drainage or rendezvous techniques, presents a valuable alternative to percutaneous transhepatic drainage (PTCD) or surgical approaches. While EUS-BD has been established for malignant distal bile duct obstruction, data on its application in benign distal strictures remain limited to case reports. This study aims to address this gap by evaluating the effectiveness, safety and long-term outcomes of EUS-guided choledochoduodeno/gastrostomy (EUS-CDS) in benign distal bile duct obstruction.

Methods This multicenter retrospective analysis included all cases of EUS-CDS for benign distal biliary strictures performed since the introduction of the technique in the participating centers. Data were collected using a standardized case report form. The primary endpoint was clinical success, defined as a ≥ 50 % bilirubin decrease or normalization or inflammatory markers within 14 days. Secondary endpoints included technical success, type of stent, adverse events, stent patency time, type/timing of stent removal and frequency of stent-related complications (e.g., dislocation, occlusion).

Results Forty-six patients (52 % female; age 21–97 years) were included. The indications were extrahepatic cholestasis, with 20 % of cases presenting without and 72 % with cholangitis. Additionally, 35 % of patients had bile duct stones (isolated in 9 % and combined with cholestasis in 26 %). Underlying conditions were chronic pancreatitis (33 %), choledocholithiasis (30 %), postinflammatory strictures (13 %), acute pancreatitis (7 %), papillary sclerosis (2 %), iatrogenic causes (4 %) and others (11 %, incl. anastomotic strictures following liver transplantation, stenosing duodenitis, duodenal diverticulum).

Main reasons for performing EUS-CDS were failed ERCP access to the bile duct (62 %), failed access to the papilla due to duodenal stenosis (24 %), altered anatomy (7 %) and other causes, including anastomotic strictures after liver transplantation (7 %).

In total, 44 choledochoduodenostomies and 2 choledochogastrostomies were performed. Stents used were Hot AXIOS (91 %), plastic stents (4 %), biliary fcSEMS (2 %), and Hot Plumber/BCF (2 %). Technical success was achieved in 96 %, with maldeployment in 4 %. Clinical success was 80 %. The rate of adverse events was 13 % (two bleedings, one cholangitis, two duodenal obstructions, one post-ERCP pancreatitis). Median follow-up was 102 days (range 7–2,065 days). The median stent patency time was 50 days (range 7–1061 days). Stent occlusion occurred in five events among four patients. Five stent dislocations occurred (one complete, four partial). At last follow-up, 19 stents remained in situ, 23 were removed endoscopically, one surgically, and one had migrated spontaneously. Among patients with endoscopic stent removal, the fistulous tract created by the LAMS remained patent in 12 cases and had closed in 11. The median time to endoscopic stent removal or spontaneous complete dislocation was 44 days (range 9–343 days).

Conclusions In this large multicenter cohort on EUS-CDS for benign distal biliary strictures, technical and clinical success was high, with moderate rates of AEs and stent occlusion. These data support EUS-CDS as a safe and effective option in benign distal bile duct obstruction. In patients with uncomplicated clinical course, elective stent removal after four weeks may be feasible, but standardized protocols are lacking.

The Difficult ERCP: From failed access to successful cannulation

14/05/2026, 10:00–11:00 Sky 1

OP025 Comparative Safety and Efficacy of Difficult Biliary Cannulation Strategies during ERCP: A Network Meta-Analysis

Authors Jagtap N[1], Koduri KK[1], Rughwani H[2], Giri S[3], Chavan R[4], Shujaath A[1], Sundaram S[5], Nabi Z[2], Reddy DN[1]

Institutes 1 AIG Hospitals, Hyderabad, India; 2 Aig, Hyderabad, India; 3 Kalinga Institute of Medical Sciences (KIMS), Bhubaneswar, India; 4 Bharati Vidyapeeth Deemed University Pune, Pune, India; 5 TATA MEMORIAL HOSPITAL, Parel, Mumbai, Mumbai, India

DOI 10.1055/s-0046-1820680

Aims Difficult biliary cannulation during ERCP is a major contributor to technical failure and post-ERCPpancreatitis (PEP). Multiple advanced cannulation strategies are used in clinical practice, but thereare few head-to-head randomized comparisions. We performed a network meta-analysis (NMA) tocompare the safety and efficacy of commonly used advanced cannulation strategies.

Methods A systematic network meta-analysis of randomized controlled trials evaluating advanced ERCPcannulation techniques was performed. Techniques included standard cannulation (STD), earlyprecut sphincterotomy, late precut sphincterotomy, transpancreatic sphincterotomy (TPS), double-guidewire technique (DGW), pancreatic duct stenting, forceps-assisted access, and EUS-guidedrendezvous (EUS-RV). Two outcomes were analyzed: PEP and successful biliary cannulation.Treatment effects were pooled as risk ratios (RRs) using a frequentist random-effects NMA with STDas the reference. Treatments were ranked with P-scores (SUCRA-equivalent), and inconsistency wasassessed by node-splitting analysis. Sensitivity analyses included alternative continuity correctionsand leave-one-out influence analysis (▶ **Table 1**).

Results A total of 21 randomized controlled trials were included (n = 2764). Overall heterogeneity was low for bothendpoints ($\tau^2 \approx 0.04–0.05$), and no evidence of local inconsistency was detected on node-splitting analyses (all $p > 0.05$). Compared to standard cannulation, PEP risk ranked lowest to highest as EUS-RV (RR 0.32), Early precut (RR 0.55), TPS, STD, DGW, Forceps,Pancreatic duct stent, and late precut.Transpancreatic sphincterotomy (TPS) showed a numerical, but not statistically significant, reduction in PEP. Successful biliary cannulation as compared with standard cannulation was highest with TPS (RR 1.35) followed by DGW (RR 1.25). Forceps-assisted access showed modest benefit. Late precut and pancreatic duct stenting were associated with inferior success rates. Findings were consistent across sensitivity analyses, with no single study influencing overall conclusions.

Conclusions Advanced ERCP cannulation techniques differ substantially in their safety and efficacy. EUS-RV andearly precut sphincterotomy provide the greatest protection against post-ERCP pancreatitis,whereas TPS and the DGW offer the highest cannulation success rates. Late precut consistentlyperformed worst across both outcomes. These results support a precision-based, early escalationstrategy for difficult biliary access to optimize both procedural success and patient safety in difficultbiliary access.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP026 Immediate double guidewire technique with systematic pancreatic stenting versus standard guidewire-assisted cannulation in patients undergoing ERCP – results from a propensity score matched trial

Authors Fuso A[1], Masciangelo G[1], Arena R[2], Fusaroli P[3], Lisotti A[1]

DOI 10.1055/s-0046-1820681

Aims Biliary cannulation remains one of the crucial challenges of ERCP; several techniques have been proposed to improve the technical success. Among them, the double-guidewire technique (DGT) seems to be associated with an increased risk of post-ERCP pancreatitis (PEP); however, available studies differ in terms of timing of DGT application and the proportion of patients receiving pancreatic stenting (PS), despite guideline recommendations [1–3]. The aim of this study was to assess PEP risk in case of immediate use of DGT after first unintended pancreatic duct cannulation combined with systematic prophylactic PS placement (DGT + PS), and to compare PEP incidence to standard guidewire-assisted technique (ST).

Methods A retrospective analysis of a prospectively maintained database was conducted including all adult patients with naïve papilla who underwent ERCP from 2021-2025 in a single hospital center. Post-surgical anatomy, non-biliary indications and EUS-guided biliary access were excluded. ESGE criteria for difficult biliary cannulation and PEP were adopted. Clinical and procedural variables were collected. The primary outcome was the incidence of PEP; secondary outcomes were ERCP technical success and incidence of other adverse events. DGT + PS cases were compared to ST using 1:2 propensity score matching (PSM).

Results 613 ERCP were performed during the study period; of them, 388 (71.7 %) patients with naïve-papilla underwent ERCP for biliary indications (49.5 % male, median 75.5 [64.2 – 84.1] years old). Among the entire population, 120 (30.9 %) cases matched ESGE criteria for difficult biliary cannulation. Immediate DGT + PS was used in 45 cases and other advanced cannulation techniques in 39 cases.

▶ **Table 1** SUCRA (P-score) ranking of cannulation strategies for PEP (safety) and successful biliary cannulation (efficacy)

Cannulation strategy	PEP P score(%)	Sucra Rank PEP	Cannulation Success P score (%)	Sucra rank Cannulation success
EUS RV	93.6	1	54.4	4
Early Precut	76.0	3	45.5	5
TPS	76.3	2	96.3	1
DGW	40.8	4	71.8	2
Standard cannulation	40.8	4	20.4	8
Forceps assisted access	29.6	6	68.4	3
PD stenting	27.8	7	22.2	6
Late precut	15.1	8	20.9	7

Endoscopy 2026; 58: S1–S1041

After PSM, 135 patients were analyzed (45 DGT + PS and 90 ST); no baseline difference was observed in terms of gender, age, benign indication for ERCP, ASGE complexity, urgent ERCP, history of pancreatitis, rectal NSAIDs administration, aggressive hydration, presence of peri-ampullary diverticulum, and difficult biliary cannulation.

DGT + PS showed similar technical success compared to ST (97.8 % vs 93.3 %; p = 0.42), and similar incidence of adverse events (6.6 % vs 14.4 %; p = 0.26). PEP incidence was significantly lower in the DGT + PS group (2.2 % vs 14.4 %; p = 0.03). Logistic regression identified rectal NSAIDs (OR 0.18 (0.05-0.71); P = 0.01), aggressive hydration (OR 0.07 (0.01-0.98); P = 0.04), and benign indications (OR 0.17 (0.04-0.72); P = 0.02) as factors independently and inversely associated with PEP. DGT + PS showed a trend towards a further reduction in PEP risk on multivariate analysis (OR 0.10 (0.02-1.10); p = 0.06).

Conclusions When performed immediately after the first unintended PD cannulation and combined with systematic prophylactic PS, DGT appears to be a safe and effective advanced cannulation strategy. In this cohort, DGT + PS was associated with a significantly lower incidence of PEP while maintaining high procedural success compared to standard guidewire-assisted technique in a matched cohort of patients. Prospective multicenter trials are needed to confirm these findings.

OP027 Transpancreatic Sphincterotomy: The Key to Difficult ERCP Access

Authors Moutzoukis M[1], Theopistos V[1], Tzampouras N[1], Mastorogianni N[1], Christodoulou D[1]

DOI 10.1055/s-0046-1820682

Aims Achieving successful biliary access during endoscopic retrograde cholangiopancreatography (ERCP) can often be technically challenging, particularly in cases of difficult cannulation. Such situations frequently interrupt the flow of the procedure and may increase the risk of complications. In this context, transpancreatic sphincterotomy (TPS) has emerged as an alternative advanced cannulation technique designed to overcome these obstacles. The aim of our study was to assess the clinical efficacy of TPS when used in conjunction with prophylactic pancreatic stenting, to document the adverse events associated with the technique, and to explore whether specific patient- or papilla-related factors were associated with its use. Additionally, we sought to identify potential confounders that might influence the decision to employ TPS or the outcomes following its application.

Methods All consecutive patients who underwent ERCP in our department between 2020 and 2025 were screened for eligibility. TPS was performed only in cases where standard cannulation attempts failed, and the approach was routinely combined with the placement of a pancreatic duct stent as a preventive measure against post-procedure pancreatitis.Apart from basic demographic parameters, a detailed dataset was compiled for each patient. This included the primary indication for ERCP, the morphological characteristics of the papilla, the presence or absence of a periampullary diverticulum, and procedural variables such as the need for TPS or fistulotomy, the success of these techniques, and any complications encountered. Associations between TPS and independent variables were first analyzed using the chi-square (x^2) test. Variables showing statistical significance were then incorporated into a multivariable regression model to further examine their predictive value.

Results A total of 481 patients met the inclusion criteria. Of these, 233 (48.4 %) were male and 248 (51.6 %) were female, with a mean age of 70.81 ± 15.28 years. TPS was ultimately used in 43 patients (8.9 %). Despite the inherent technical difficulty of these cases, the method yielded a high cannulation success rate of 97.67 %. Neither papillary morphology nor the presence of a periampullary diverticulum demonstrated a statistically significant influence on the decision to proceed with TPS. However, both features showed a trend toward association with malignant obstruction of the common bile duct (CBD) as the procedural indication. Patients whose indication for ERCP was malignant CBD obstruction appeared more likely to undergo TPS, displaying an elevated relative risk (RR = 1.563, 95 % CI 0.99–2.4) and odds ratio (OR = 2.81, 95 % CI 0.99–7.94). Although these findings did not reach strong statistical certainty, the Pearson x^2 test indicated borderline significance with a p-value of 0.048 at a = 0.05.In terms of post-procedural adverse events, TPS did not increase the incidence of post-ERCP pancreatitis (PEP). Rates of bleeding were also unaffected. While the number of complications was low and therefore limited the statistical power of our analysis, no signal suggested that TPS heightened the overall risk profile of the procedure when accompanied by pancreatic duct stenting.

Conclusions Our findings suggest that transpancreatic sphincterotomy, when performed together with routine prophylactic pancreatic stent placement, is both a highly effective and a safe approach for managing difficult biliary cannulation. Given the excellent cannulation success rate of 97.67 % and the absence of increased complication rates, TPS could be considered as a preferred alternative strategy, particularly in cases where malignant CBD obstruction is suspected or confirmed. These results support the role of TPS as a valuable technique in advanced ERCP practice, especially when conventional cannulation attempts are unsuccessful.

DOI 10.1055/s-0046-1820683

Aims Endoscopic retrograde cholangiopancreatography (ERCP) remains the cornerstone of therapy for pancreaticobiliary disorders, yet bile duct cannulation fails in 5–20 % of cases, even in expert hands. The Haraldsson classification (2017) describes four major papilla types, some of which have been linked to increased cannulation difficulty and higher complication rates. However, evidence on how papilla morphology influences the selection and timing of rescue cannulation techniques remains limited.

This study aimed to evaluate how ERCP practitioners adapt their cannulation strategies to different papilla types. We hypothesized that adjustments based on papilla morphology may improve cannulation success and reduce procedure-related complications.

Methods An international web-based survey was distributed to ERCP-performing physicians to capture practice patterns related to major papilla morphology and cannulation techniques. The questionnaire was developed in REDCap, a secure web-based data collection platform, and disseminated through professional societies, mailing lists, and social media channels. It included items on respondent demographics, ERCP experience, use of papilla classification systems, and preferred primary and rescue cannulation techniques. Responses were collected anonymously. Descriptive statistics were used to summarize

practice patterns, and additional analyses explored associations between papilla morphology and technique selection. Participation was voluntary, and the survey period remained open long enough to ensure broad geographic and professional representation [1, 2].

Results A total of 150 ERCP practitioners completed the survey. Overall, 59 % worked in university hospitals, 45 % in high-volume centers, and 66 % had more than five years of ERCP experience; 53 % had performed over 1000 procedures, and 55 % practiced in certified training centers. Only 26 % routinely used a papilla classification system.

Rescue cannulation preferences varied according to papilla type and guidewire position. For type I papilla, when the guidewire did not enter the pancreatic duct, respondents most frequently selected needle-knife precut (NKP) (36.7 %), needle-knife fistulotomy (NKF) (32.3 %), or continued with standard cannulation (31 %). In contrast, inadvertent guidewire entry into the pancreatic duct shifted preference toward the double-guidewire technique (DGT) (51.8 %), followed by prophylactic pancreatic stent (PPS) placement combined with NKF (21.2 %) and transpancreatic precut papillotomy (TPPP) (10 %). For type II papilla, standard cannulation and NKP were equally preferred as primary strategies (41.7 % each), while DGT became the dominant choice (56.3 %) when the guidewire was already positioned in the pancreatic duct. For type III papilla, DGT was preferred in the presence of a pancreatic guidewire (48.2 %), whereas NKP was most frequently chosen when no guidewire was present (41 %). For type IV papilla, DGT was again the predominant choice when the guidewire entered the pancreatic duct (52.7 %), whereas standard cannulation was most often continued when no guidewire was in place (44.7 %).

Across all scenarios, notable differences in technique preference were observed between center types and operator experience: high-volume, university-based and teaching centers showed a clear tendency to select NKP more frequently, whereas lower-volume and community settings more often favored standard cannulation or PPS + NKF combinations.

Conclusions Rescue cannulation patterns showed considerable variability across papilla types and clinical settings. The findings illustrate the absence of uniform practice and highlight the need for clearer, evidence-based recommendations to support consistent decision-making in difficult biliary access.

DOI 10.1055/s-0046-1820684

Aims The effect of periampullary diverticulum (PAD) on Endoscopic retrograde cholangiopancreatographys' (ERCP) safety and effectiveness is a controversial subject. Aim of our study was to evaluate PADs impact on ERCP safety and effectiveness in a real -world study in Greece.

Methods We retrospectively analysed prospectively documented clinical, epidemiological and data from ERCP from consecutive patients being submitted to ERCP, with an intact papilla, during a 20- year period (1/2001- 1/2021)

Results In total 3147 patients were included in our study (mean age:68 ± 16, Female: 51 %, < 80 years old :70.3 %). Existence of PAD was observed in 20 % of the study population and was more common among patient ≥ 80 years old (17.0 % vs 27.6 %), p < 0.001). The cannulation of the common bile duct (CBD) was successful in 96.1 % and was observed in an increased rate; among patients without PAD (93.4 % vs 96.7 %, p < 0.001). Additionally, PAD existence was found to be independently factors correlated to successful CBD cannulation (OR:1.678, p < 0.001). Upon the existence of a PAD, ≥ 5 attempts to cannulate were made in a lesser rate (p < 0.001) while the use of Needle Knife (NK) was observed in a decreased rate (p < 0.001). No difference in the probability of Pancreatic Duct cannulation was observed upon PAD existence or not (p = 0.634). Bleeding during the procedure was more common upon PAD existence PAD (37.9 % vs 32.9 %, p = 0.020), if antiplatelet or anticoagulants were used (p < 0.001 and p = 0.012) as also if NK was used (p < 0.001). All of the above were confirmed also in the multivariate analysis (OR:1.354, p = 0.002, OR:1.323, p = 0.005, OR1.275, p = 0.049 and OR: 1.610, p < 0.001 respectively). PAD existence was not correlated with post ERCP-pancreatitis (p = 0.876), perforation (p = 0.704) or post-ERCP clinically significant bleeding (p = 1.000).

Conclusions The existence of PAD is observed more commonly among the elders. PAD was independently correlated with decreased rate of CBD cannulation and increased rate of intraprocedural bleeding but not with ERCPs complications as post ERCP pancreatitis, clinical significant bleeding or perforation.

OP030 Comparison of Early Double Wire Technique with Repeat Single Wire Technique for Successful Bile Duct Cannulation: A Systematic Review and Meta-Analysis

Authors Alabdulkarim B[1], Zheng K[2], Khalaf K[2], Yuan Y[3], Bucheeri MAGA[1], Li H[2], Teshima C[2], May G[2], Mosko J[4], Calo N[2]
Institutes **1** University of Toronto, Toronto, Canada; **2** St. Michael's Hospital, Toronto, Canada; **3** McMaster, hamilton, Canada; **4** Division of Gastroenterology, St. Michael's Hospital, Toronto, Canada
DOI 10.1055/s-0046-1820685

Aims Inadvertent pancreatic duct cannulation during endoscopic retrograde cholangiopancreatography (ERCP) presents a dilemma in achieving selective bile duct cannulation. Two potential strategies include the early double-guidewire (EDG) technique where a second guidewire is introduced into the common bile duct, and repeated single-guidewire (RSG) technique, though comparative effectiveness remains unclear. We aim to evaluate the efficacy and safety of EDG versus RSG in patients with unintentional pancreatic duct cannulation during ERCP in patients undergoing ERCP for biliary interventions

Methods We conducted a systematic review and meta-analysis of randomized controlled trials and cohort studies comparing EDG and RSG from Cochrane Central Register of Controlled Trials, Embase and Ovid MEDLINE until February 25, 2025. The primary outcome was bile duct cannulation success. Secondary outcomes included time to cannulation and post-ERCP pancreatitis (PEP). Meta-analysis was performed using a random-effects model, and study heterogeneity was assessed using I^2 statistics. Risk of bias was assessed.

Results Three studies comprising 464 patients (228 EDG, 236 RSG) were included. The pooled risk ratio for successful biliary cannulation favoured EDG (1.38, 95 % CI 0.96–1.99, p = 0.08). Time to cannulation favored EDG (mean difference –3.22 minutes; 95 % CI –7.32 to 0.88), though not statistically significant (p = 0.124). Rates of PEP were similar between groups (risk ratio 1.12, 95 % CI 0.69–1.82, p = 0.64). Subgroup analyses suggested greater benefit of EDG when performed by expert endoscopists (risk ratio 1.42, 95 % CI 1.05-1.91, p = 0.02)

Conclusions EDG may improve cannulation success in select populations, particularly under expert operators, without increasing PEP risk. However, considerable heterogeneity underscores the need for further large-scale studies to clarify its role.

OP031 Automated feedback reports to endoscopists improve polyp detection and other colonoscopy key performance indicators (KPIs) outside of a clinical trial environment: Outcomes from the interim analysis of the NED-APRIQOT pilot roll-out

Authors Pohl K[1], Bhakta A[2], Feeney M[1], Catlow J[3], Beaton D[4], Lee T[4], Burr N[5], Rutter M[6]

Institutes **1** Torbay and South Devon NHS Foundation Trust, Torquay, United Kingdom; **2** St George's University Hospitals NHS Foundation Trust, London, United Kingdom; **3** The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; **4** Northumbria NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; **5** The Mid-Yorkshire Hospitals NHS Trust, Wakefield, United Kingdom; **6** North Tees and Hartlepool NHS Foundation Trust, Stockton-on-Tees, United Kingdom

DOI 10.1055/s-0046-1820686

Aims The UK National Endoscopy Database (NED) automated performance reports to improve quality outcomes trial (APRIQOT) demonstrated that monthly automated feedback of colonoscopy key performance indicators (KPIs) to endoscopists improved polyp detection within a randomised controlled trial setting. [1] This year-long pilot, funded by the Health Foundation, tests the feasibility and impact of such reports delivered on a quarterly basis outside a trial environment, across two geographical regions of the UK. Now at its midpoint, we aimed to evaluate the impact of this intervention on colonoscopy outcomes.

Methods All procedures performed at centres enrolled in the pilot were extracted from NED from the pre- (Apr-Jun 2025) and post-intervention (Jul-Oct 2025) periods. For each endoscopist in both periods, median withdrawal time, Buscopan use, caecal intubation rate (CIR), moderate/severe discomfort rate, polyp detection rate (PDR), proximal PDR, mean number of polyps (MNP) and case-mix adjusted mean number of polyps (aMNP) were calculated and compared using Wilcoxon signed-rank tests. To estimate adjusted intervention effects, procedure-level mixed effects models were fitted with endoscopist as a random effect. Logistic regression was used for PDR and negative binomial regression for polyp counts, adjusting for age group, sex and indication for colonoscopy. A random slope for period assessed variation in improvement. Finally, an endoscopist-level linear regression model examined whether engagement with feedback reports (sum of individual email and report views and web page visits) predicted improvement in PDR, adjusting for baseline PDR.

Results Data from 125,521 procedures performed by 744 endoscopists were analysed. Pairwise comparison showed several KPIs improved after the introduction of automated feedback. Buscopan use doubled (median 5.01 % ◄10.20 %, $p<0.001$), and small but significant gains were seen in PDR (increase of 0.60 %, $p=0.005$) and MNP (+ 3.19 polyps/100 procedures, $p=0.022$). The improvement in aMNP was non-significant (+ 2.0 polyps/100 procedures, $p=0.096$). In the mixed-effects models, post-intervention procedures had 6 % higher adjusted odds of polyp detection (aOR 1.06, 95 % CI 1.03-1.09, $p<0.001$) and a 4 % higher adjusted rate of polyps detected per procedure (aIRR 1.04, 95 % CI 1.03-1.06, $p<0.001$). Allowing random slopes indicated modest heterogeneity of improvement across endoscopists (slope SD 0.18; intercept-slope corr. -0.34), suggesting greater improvement among lower-baseline performers. Engagement analysis showed higher total interaction with the reports and NED predicted greater PDR improvement after adjusting for baseline (β 0.0011 ± 0.00035, $p=0.001$). Comparing endoscopists, those who opened at least one report demonstrated a 3.1 % improvement in PDR compared to those who didn't (β 0.031, SE 0.012, $p=0.007$).

Conclusions Our results mirror those of the original NED-APRIQOT trial. Despite targeting all endoscopists rather than just those engaged in a trial, and lengthening the gap between reports to quarterly, the automated feedback reports significantly improve polyp detection. As was seen in the original trial, endoscopists with lower baseline performance and those engaging more with feedback saw the greatest gains, highlighting the value of sustained data-driven feedback.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820687

Aims 1) Define adherence to key performance indicators (KPIs) and dysplasia detection rates (DDR) in patients with Barrett's oesophagus having an upper GI endoscopy as part of an all Wales audit and 2) Evaluate differences in KPIs and DDR where patients had endoscopy for another symptomatic indication or a dedicated assessment of the Barrett's segment.

Methods We performed a retrospective, trainee-led, All-Wales audit of all diagnostic OGDs between 01/04/2025 and 30/06/2025 where Barrett's oesophagus (BO) was included in the diagnosis. Data was collected from the Medilogik EMS endoscopy database and the Welsh Clinical Portal using a standardized Excel proforma, anonymized at the local level, and submitted centrally for analysis. Data fields included age, sex, procedure details and findings (including Prague classification, inspection time, use of blue light imaging (BLI) or acetic acid chromoendoscopy (AAC), adherence to Seattle Biopsy Protocol (SBP), targeted biopsy and presence and assessment of visible nodules. Histological findings were also noted including presence of indefinite for dysplasia (IFD), low grade dysplasia (LGD), high grade dysplasia (HGD) or oesophageal adenocarcinoma (OAC). Planned follow-up was also noted. Adherence to inspection times (IT) was defined as at least 1 minute inspection for every 1cm of BO, with short segment defined as < 3cm, and long segment > 3cm. Comparison between the two groups was performed using the Chi-squared test with significance set at a p-value of 0.05.

Results 557 patients were included in the analysis, 398 male. 293 patients had UGI endoscopy for a symptomatic indication (198 male, mean age 66.9yrs) and 264 had a dedicated UGI endoscopy for planned surveillance or where the only diagnosis was a Barrett's segment. Significantly more patients in the 'dedicated' group had longer segments (> 3cms) 180 vs 132 in the 'symptomatic' group. Operator KPIs were significantly better in the 'dedicated' group compared to the 'symptomatic': BLI 56.1 vs 21.2 % ($p<0.00001$); AAC 70 vs 6.4 % ($p<0.00001$) and adherence to SBP 75.6 vs 34.6 % ($p<0.00001$). Whilst there was no difference between IT adherence for short segments between 'dedicated' and 'symptomatic' groups, for longer segments (> 3cm) the 'dedicated' group showed significantly better IT adherence ($p<0.00001$).

Dysplasia detection rates (DDR) were calculated for each group. Rates of adenocarcinoma were not different between groups. Significantly higher rates of dysplasia were detected in the 'dedicated' group, both for all dysplasia and advanced dysplasia (see ▶ **Table 1**). Whilst in the Dedicated Group DDR rates were higher in short (4.2 % vs 1.4 %) and longer (11.1 vs 6.1 %) segments this did not reach statistical signifcance. Analysis of BO segments over 10cms did show a significant increased DDR: Dedicated 7/19 (36.8 %) vs Symptomatic 1/15 (6.6 %), p = 0.04.

▶ **Table 1**

FINDINGS	SYMPTOMATIC INDICATION N = 293	SURVEILLANCE OR SOLE INDICATION FOR BARRETTS N = 264
Indefinite for dysplasia	8 (2.7 %)	11 (4.2 %)
Low grade dysplasia	4 (1.4 %)	10 (3.7 %)
High grade dysplasia	2 (0.7 %)	11 (4.2 %)
Oesophageal adenocarcinoma	4 (1.4 %)	3 (1.1 %)
ALL DYSPLASIA*	10 (3.4 %)	24 (9.1 %)
ADVANCED DYSPLASIA**	6 (2 %)	14 (5.3 %)

*Difference between groups significant, p = 0.005; **Difference between groups significant, p = 0.04

Conclusions This retrospective audit data reflects real world assessment of patients with Barrett's oesophagus. It suggests operator performance in terms of key performance indicators and adherence to guidance is improved when this is the dedicated focus of the endoscopic procedure and this is associated with an increased dysplasia detection rate. Increased focus on training to improve operator KPIs further and networked planned to increase the availability of dedicated lists may improve quality and outcomes of BO surveillance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP033 Looking Back Through a New Lens: Applying BSG/ACPGBI 2025 Guidelines on Colorectal Polyps Management in Patients with Limited Life Expectancy

Authors Awais M[1], Basford P[2], Cripps N[2], Levy B[2], Mcfall M[3], Baig K[3], Juniper R[2]

Institutes **1** St Richard's Hospital, Chichester, United Kingdom; **2** St Richard's Hospital, Chichester, United Kingdom; **3** Worthing Hospital, Worthing, United Kingdom

DOI 10.1055/s-0046-1820688

Aims The BSG/ACPGBI published guidelines in 2025 which provide a patient-centred framework for managing colorectal polyps in individuals with limited life expectancy (LLE). By combining comorbidity burden, polyp size, and antithrombotic use, these guidelines help clinicians balance the potential benefits of polypectomy against procedural risks in patients with significant comorbidities or frailty.

This study aimed to retrospectively evaluate how historical practice at University Hospitals Sussex NHS Trust, England, aligns with the updated BSG/ACPGBI recommendations and to determine how many procedures might, in hindsight, have been approached more conservatively under the new LLE guidelines.

Methods 950 large non-pedunculated colorectal polyps (LNPCP) managed between January 2016 and May 2025 were prospectively recorded in a digital LNPCP database. A retrospective analysis was performed using the LLE guidelines. The Charlson Comorbidity Index (CCI) and anticoagulant/antiplatelet use at the time of procedure were extracted from clinic correspondence and endoscopy unit documentation. Each patient's estimated life expectancy was categorised according to the BSG/ACPGBI 2025 guidelines LLE framework, and cases were reviewed on a per-patient basis to evaluate the appropriateness of polypectomy. Patients were stratified as Green (favours polypectomy), Amber (marginal), or Red (favours conservative management). Demographic data, lesion size, lesion histology, recurrence rate and post-procedural complications were recorded and analysed descriptively.

Results This study included 950 LNPCPs in 835 patients, with a mean age of 67.2 years; 47.5 % were female and 52.5 % were male. The mean lesion size was 29.8 mm. 601 polyps were SMSA (Size/Morphology/Site/Access) level 3 and 349 were level 4. On histological examination, 329 lesions were sessile serrated lesions (SSLs), 586 were adenomas, including 128 with high-grade dysplasia, and 35 were diagnosed as cancer.

At the first and second site check procedures, recurrence rates were 14 % and 3.8 %, with corresponding mean recurrent polyp sizes of 7.9 mm and 5.9 mm, respectively. The majority of recurrent polyps (99 %) were treated endoscopically, with one case requiring surgical management.

Complications included 5 cases of post-polypectomy syndrome, 10 delayed bleeds, 1 perforation, and 1 micro perforation with associated bleeding. There were 15 unplanned admissions, 1 case requiring both unplanned admission and transfusion, and 2 cases requiring surgical intervention. 17 patients died within nine years of the index procedure.

When reclassified according to the 2025 BSG/ACPGBI framework, 783 patients (93.77 %) were categorised as Green (favours polypectomy), 34 (4.07 %) as Amber (marginal), and 18 (2.15 %) as Red (favours conservative management). Furthermore, out of 17 recorded complications, 12 (71 %) occurred in the green cohort and 5 (29 %) in amber and red cohort. This corresponds to approximately a ten-fold higher relative risk of complications in amber and red cohort.

Overall, approximately 6 % of cases (Amber and Red categories) would, under new guidance, be considered for conservative rather than interventional management.

Conclusions Applying the BSG/ACPGBI limited life expectancy guidelines to nearly a decade of practice at a large UK centre showed that most historical polypectomy decisions were consistent with the new recommendations. However, a small but important subset of procedures might have warranted a more cautious, conservative approach.

Adopting the LLE guidelines and using them in decision making regarding all LNPCPs, including SPEC (Significant Polyp and Early Cancer) should help further reduce performing polypectomy in patients who derive minimal or no benefit.

OP034 Real-world performance of FIT triage for symptomatic colonoscopy: analysis of the UK National Endoscopy Database (NED)

Authors Beaton D[1], Mohamed M[2], Sharp L[3], Pohl K[4], Rutter M[2]

Institutes **1** Northumbria NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; **2** University Hospital of North Tees, Stockton-on-Tees, United Kingdom; **3** Newcastle University, Newcastle upon Tyne, United Kingdom; **4** Torbay and South Devon NHS Foundation Trust, Torquay, United Kingdom

DOI 10.1055/s-0046-1820689

Aims Quantify diagnostic yield and independent effects of FIT, age, sex, and symptoms on cancer and polyp detection in symptomatic colonoscopy.

Methods Nationwide analysis of prospectively collected colonoscopy reports (June 2023–August 2025) through the National Endoscopy Database. Symptomatic procedures, including iron-deficiency anaemia (IDA), were identified and diagnostic yields calculated. Mixed-effects logistic regression estimated adjusted odds ratios (aORs) with age, sex, symptom group and FIT as fixed effects. Post-estimation margins modelled cancer yield by age, FIT, and symptoms.

Endoscopy 2026; 58: S1–S1041

Results Analysis of 447,109 symptomatic colonoscopies identified cancer yield of 1.9 % (95 % CI 1.8–1.9). FIT ≥ 10µg Hb/g cancer yield was 3.8 % (95 % CI 3.7–3.9) overall; 2.5 % (95 % CI 2.3-2.7) in patients aged 40-49 and 0.6 % (95 % CI 0.5-0.7) in those aged 16-39. Cancer yield in FIT < 10 was 0.3 % (95 % CI 0.2–0.3). FIT concentration was strongly associated with cancer; aOR 46.1 (95 % CI 37.2–57.1) at ≥ 300 vs FIT < 10. IDA was associated with cancer versus rectal bleeding (aOR 2.2, 95 % CI 2.0–2.3; p < 0.01).

Modelled estimates showed that with FIT < 10, cancer yield exceeded 1 % only in IDA patients aged > 80, remaining < 0.5 % otherwise. A model combining FIT, age, and IDA detected > 94 % of cancers while reducing colonoscopy demand by > 40 %

Conclusions This national analysis demonstrates the superiority of FIT-based triage over symptom-based referral, with FIT ≥ 10 identifying high-risk patients, including those aged 40-49, while FIT < 10 signified very low risk across all ages and indications [1–5].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP035 Can introduction of a local protocol improve adherence to endoscopic guidance leading to a reduction in unnecessary biopsies whilst maintaining standards in Upper GI Endoscopy?

Authors Evans B[1], Aoife M[1], Daniel W[1], Emma W[1]

Institute **1** Musgrove Park Hospital, Taunton, United Kingdom

DOI 10.1055/s-0046-1820690

Aims To determine whether implementation of a local biopsy guidance protocol could reduce unnecessary biopsies whilst improving overall adherence to best practice guidelines in upper gastrointestinal endoscopy. Secondary objectives included assessing baseline knowledge among endoscopists and evaluating the impact of educational intervention on different practitioner groups.

Methods This quality improvement project comprised three phases. Phase one involved developing an evidence-based guidance poster incorporating recommendations from British Society of Gastroenterology (BSG) and European Society of Gastrointestinal Endoscopy (ESGE) guidelines, organised by anatomical region (oesophagus, stomach, duodenum) with clear "do biopsy" and "don't biopsy" recommendations. Phase two consisted of a retrospective baseline audit of 100 randomly selected upper GI endoscopies performed over one week in 2024, documenting all biopsies taken, their indications, and correlation with clinical findings. Phase three involved knowledge assessment of local endoscopists through a seven-question survey targeting understanding of current guidance, particularly in areas prone to practice variability. Following baseline data analysis, the guidance poster was distributed throughout the endoscopy unit both physically and electronically, emphasising key messages including avoiding biopsies of typical fundic gland polyps below size criteria, eliminating D2 biopsies for iron deficiency anaemia when tissue transglutaminase (TTG) is negative, not biopsying gastritis unless concerned about intestinal metaplasia or atrophy, and the limits of biopsy/CLO test for Helicobacter pylori assessment in patients taking PPI. A post-intervention audit of 100 upper GI endoscopies using identical methodology enabled direct comparison.

Results Survey results revealed variable endoscopist knowledge: 90 % correctly identified eosinophilic oesophagitis biopsy protocols, whilst 60 % would incorrectly biopsy Grade C oesophagitis. Only 20 % recognised that CLO testing and biopsy are unreliable for H. pylori detection in patients on PPI therapy. Baseline audit demonstrated 77 % overall guideline adherence (consultants 78.9 %, registrars 88.9 %, nurse endoscopists 70.5 %). Common deviations included gastritis alone, duodenal biopsies despite negative coeliac serology and Barrett's oesophagus not biopsied per protocol. Post-intervention showed significant improvement in overall adherence (89 %, p < 0.05), with notable reductions in inappropriate duodenal biopsies with negative TTG (75 % reduction) and complete elimination of Barrett's surveillance protocol deviations. Nurse endoscopists demonstrated the greatest improvement (+ 13.6 % adherence), while consultants and registrars showed modest improvements (+ 4.8 % and + 3.8 % respectively). There was improved recognition of pathology not requiring biopsy, such as fundic gland polyps and a 50 % reduction in unnecessary biopsies for gastritis alone

Conclusions Implementation of a simple educational intervention with clear visual guidance significantly improved adherence to best practice guidelines in upper GI endoscopy from 77 % to 89 %. The protocol was particularly effective in reducing unnecessary duodenal biopsies in patients with negative coeliac serology and eliminating Barrett's surveillance protocol deviations. Nurse endoscopists showed the greatest improvement, suggesting structured protocols may be particularly valuable for standardisingpractice. While not powered to demonstrate overall reduction in biopsy numbers, improved adherence indicates a shift toward more appropriate resource utilisation. The focus on appropriate sampling whilst avoiding unnecessary biopsies is particularly relevant given Post-Endoscopy Upper GI Cancer rates of 5.3-11.8 %, where missed lesions during index endoscopy are significant contributors. By ensuring appropriate biopsies in high-risk scenarios whilst avoiding unnecessary sampling, this protocol promotes systematic endoscopic evaluation and may help focus endoscopy and histopathology resources on higher-risk cases. Further higher-powered studies could assess whether the protocol reduces total biopsy numbers and identify additional areas for tool development.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP036 Assessing endoscopist- and service-level engagement with automated colonoscopy key performance indicator feedback reports: Outcomes from the interim analysis of the NED-APRIQOT pilot roll-out

Authors Pohl K[1], Bhakta A[2], Feeney M[1], Catlow J[3], Beaton D[4], Lee T[4], Burr N[5], Rutter M[6]

Institutes **1** Torbay and South Devon NHS Foundation Trust, Torquay, United Kingdom; **2** St George's University Hospitals NHS Foundation Trust, London, United Kingdom; **3** The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; **4** Northumbria NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; **5** The Mid-Yorkshire Hospitals NHS Trust, Wakefield, United Kingdom; **6** North Tees and Hartlepool NHS Foundation Trust, Stockton-on-Tees, United Kingdom

DOI 10.1055/s-0046-1820691

Aims The United Kingdom (UK) National Endoscopy Database (NED) automated performance reports to improve quality outcomes trial (APRIQOT) demonstrated that providing endoscopists with regular automated feedback on colonoscopy key performance indicators (KPIs) can lead to measurable improvements in polyp detection. [1] Building on this evidence, a pilot funded by the Health Foundation is delivering similar reports every quarter across two

UK regions to test their real-world feasibility and impact at scale. Early analysis from the pilot indicates meaningful gains in detection, particularly among clinicians who engage with the feedback. In this analysis, we focus specifically on patterns of engagement with the programme during the first half of implementation.

Methods The pilot commenced in July 2025 in two regions of the UK. Information was dispersed to endoscopists and service leads via regional endoscopy networks. Services were encouraged to assign an "APRIQOT lead" (typically the service lead) prior to the pilot. Reports take the form of a summary email and a link through to the NED website, where the full report can be viewed along with summary KPIs and plots that allow endoscopists to anonymously compare themselves to their colleagues. APRIQOT-lead reports summarise the KPIs from all endoscopists at that unit. NED records when an email is opened, as well as logins to the website and individual page views. This data was extracted. Logins to NED from January to April (prior to the pilot being announced to endoscopists and services) were compared to those in the post-intervention period. Differences in baseline pre-intervention polyp detection rate between those who interacted with the reports vs. those who didn't were compared using a chi-squared test for proportions.

Results 744 endoscopists received quarterly performance emails, the first of which was on 01 July 2025. 66.8 % (n = 497) read the first email and 52.3 % (n = 389) read the second. 21.1 % (n = 158) read neither. Of those who read the emails, 49.1 % (n = 244) viewed further data on the NED website after the first email, and 57.1 % (n = 222) after the second. The baseline pre-intervention polyp detection rate (PDR) of those who opened the emails (45.2 %, 95 % CI 44.8-45.7) was significantly higher than that of those who opened neither (40.5 %, 95 % CI 39.7-41.4, p < 0.001). NED logins increased significantly following the pilot (median logins per quarter 0 --> 1, p < 0.001). The mean number of logins per quarter rose from 2.8 to 3.5 per endoscopist, and 43.4 % of endoscopists increased their log-in frequency.

11 out of the 48 units in the catchment area (22.9 %, n = 2 NHS & n = 9 Independent) did not assign an APRIQOT lead despite prompting. 44 % of the allocated APRIQOT leads interacted with at least one report. By sector, at least one lead from 63.6 % of NHS sites and 37.5 % of independent sites interacted with at least one report. No significant improvement was seen in NED logins by Service Leads (p = 0.20).

Conclusions This interim evaluation shows strong endoscopist-level engagement with automated feedback, with most clinicians opening at least one report and a substantial proportion exploring further detail on NED. Importantly, those who opened the reports had significantly higher baseline PDRs, indicating that clinicians already invested in delivering high-quality colonoscopy may be disproportionately represented among those who engage. This is critical, as outcomes from the original trial and the pilot suggest that both those with lower baselines and those who engage derive the greatest benefit. [1] Engagement from service leads was more variable with uptake markedly poorer in the independent sector, where several sites did not nominate an APRIQOT lead and fewer leads accessed the reports. These findings suggest that while automated reporting is well received by many endoscopists, structural and organisational factors, particularly outside the NHS, may limit penetration. Targeted support for low-engagement users and sites may be required to ensure maximum benefit from national quality-improvement initiatives.

OP037 Tradition vs Innovation: automated brushless pre-cleaning as a green revolution in reprocessing: Preliminary Results of a Prospective Randomized Study

Authors Parrella A[1], Bonura GF[1], Gabbani T[1], Gualandi N[1], Algeri E[1], Soriani P[1], Manno M[1]

Institute 1 Gastroenterology and Digestive Endoscopy Unit, AUSL Modena, Modena, Italy

DOI 10.1055/s-0046-1820692

Aims Endoscope reprocessing is a critical step in ensuring the safety of endoscopic procedures, as it eliminates the risk of cross-contamination and infection [1]. The increasing prevalence of multidrug-resistant organisms has further underscored the importance of strict adherence to every phase of the reprocessing cycle [2]. Protein debris contributes to biofilm formation, which protects microorganisms from disinfectants and plays a key role in antibiotic resistance. As a result, inadequate protein removal may reduce the efficacy of high-level disinfection and increase the risk of cross-contamination [3]. Furthermore, reprocessing is strongly influenced by human factors, particularly during manual cleaning with channel brushing, detergent-soaked cloths and enzymatic solutions [4]. The automated brushless pre-cleaning device used in this study is an innovative pre-cleaning system that enables automated brushless cleaning of all channels in just 2 to 7 minutes, thereby minimizing the impact of human factors during a critical phase of the reprocessing cycle. The aim of the study is to evaluate the efficacy of this new automated brushless cleaning system.

Methods This was a prospective randomized single-center study.

Three operators, trained in duodenoscope swabbing and reprocessing, were included in the study. Duodenoscopes from the same manufacturer but with different distal-end configurations were evaluated: one with a fixed distal cap, one with a removable reusable cap, and one with a removable disposable cap. We estimated a sample size of 250 cases. After each endoscopic procedure, bedside cleaning was performed in the endoscopy room. The duodenoscope was then transferred to the reprocessing area, where a leak test was conducted. Subsequently, after the randomization, duodenoscope underwent pre-cleaning either using the automated brushless device or traditional manual with immersion and channel brushing. After the step with the automated pre-cleaner or manual pre-cleaning, a swab was inserted into the operating channel. Once the swab exited from the distal tip, its terminal portion was cut and placed into the test vial. Duodenoscopes pre-cleaned with the automated brushless pre-cleaning system subsequently underwent traditional manual pre-cleaning and the remaining reprocessing steps according to internal protocol. The primary outcome was to evaluate the efficacy of the automated brushless compared with traditional manual pre-cleaning, defined as the rate of contaminated duodenoscopes, measured by residual protein testing (Pyromol Test) of the operating channel. Contamination above the action level threshold (≥ 6.4 µg/cm²) was considered positive. Secondary outcomes included distribution of samples across predefined contamination levels: target level 0–3 µg/cm², alert level 3–6.4 µg/cm² at the Pyromol Test.

Results We report the preliminary results from the first 55 cases performed between September and November 2025. None of the 27 duodenoscopes pre-cleaned with the automated brushless system reached the Pyromol test action level. In contrast, 1 out of 28 (3.5 %) duodenoscopes pre-cleaned manually reached the action level. Regarding secondary outcomes, all 27 duodenoscopes pre-cleaned with the automated system tested negative at any level of Pyromol test. Among the 28 duodenoscopes pre-cleaned manually, 4 (14.3 %) tested

Endoscopy 2026; 58: S1–S1041

negative, 22 (78.6 %) showed positivity at the alert level, and 1 (3.5 %) reached the target level.

Conclusions These preliminary results highlight the potential role of the automated brushless system in improving the quality and reliability of the pre-cleaning phase of duodenoscope reprocessing. The absence of action level contamination suggests that automated, brushless channel irrigation may enhance the removal of protein debris and reduce the risk of cross-contamination. In addition, this innovative automated pre-cleaning system could potentially decrease the variability associated with human factors.

OP038 Microbiological Monitoring of Endoscopes: A Single-Center Observational Study

Authors Dolcini J[1], Giacomelli S[1], Fiorenza S[1], Firmani G[1], D'agostino S[1], Belvedere A[1], Gioia MG[1], Larcinese L[1], D'errico MM[1], Barbadoro P[1], Montori M[1], Bendia E[1], Benedetti A[1]
Institute 1 Azienda Ospedaliero Universitaria delle Marche, Ancona, Italy
DOI 10.1055/s-0046-1820693

Aims Preventing endoscopy-related infections is a key patient-safety priority. Although reprocessing procedures are regulated by international guidelines [1], persistent contamination has been documented—particularly in duodenoscopes—due to their structural complexity [2]. Periodic microbiological monitoring is an essential tool for verifying reprocessing efficacy and identifying potential critical issues [3].To evaluate the effectiveness of endoscope reprocessing through microbiological monitoring and to identify criticalities associated with specific endoscope types or individual instruments.

Methods A single-center observational study was conducted, including all microbiological samples collected from January to September 2024 on endoscopes in clinical use. For each sample, the following data were recorded: instrument type and ID, sampling date, isolation of High-Concern Organisms (HCO) or Low-Concern Organisms (LCO), bacterial load (CFU), and corrective actions undertaken. Absolute and relative frequencies of positive samples were calculated, stratified by endoscope type and by individual instrument. Descriptive statistical analyses were performed using R (version 4.2.3; R Foundation for Statistical Computing, Vienna, Austria).

Results A total of 71 samples were collected from 39 endoscopes. The overall rate of HCO positivity was 20.4 %. Thirty-three resampling procedures were required, and one instrument was temporarily withdrawn from service; no corrective action was necessary in 37 episodes. The most frequently isolated microorganisms were Neisseria subflava (8 isolates) and Micrococcus luteus (7 isolates), followed by coagulase-negative staphylococci (Staphylococcus epidermidis, S. hominis). Pseudomonas aeruginosa, the clinically most relevant pathogen, was isolated in three episodes. Distribution by endoscope type showed higher HCO positivity in duodenoscopes and gastroscopes, whereas colonoscopes (including pediatric models) yielded almost exclusively LCO. Several instruments with ≥ 3 samplings (IDs: 2300238, 2201874, 2200941, 1210792) demonstrated recurrent HCO contamination.

Conclusions Microbiological monitoring revealed specific criticalities, particularly in duodenoscopes and in instruments exhibiting recurrent HCO positivity. These findings suggest that monitoring should not focus solely on isolated episodes but rather consider the longitudinal performance of each device. Instruments with recurrent HCO contamination may harbor micro-damage or structural defects that facilitate bacterial persistence. In such cases, intensified surveillance, reinforced reprocessing protocols, or instrument replacement may be warranted. Our data confirm the essential role of microbiological monitoring in enhancing the safety of endoscopic procedures and provide insights for future personalized maintenance strategies.

OP039 Optimising Endoscopy Workflow Efficiency: A Multi-Level, Burnout-Aware Intervention Framework

Author Costa H[1]
Institute 1 Hospital do Divino Espírito Santo , Ponta Delgada, Portugal
DOI 10.1055/s-0046-1820694

Aims To synthesise contemporary evidence on burnout, workload, ergonomics, and workflow efficiency in endoscopy, to examine their impact on quality indicators, and to develop a practical, multi-level intervention framework—including a "Burnout-Aware Endoscopy List" Toolkit—that integrates workforce well-being into endoscopy service performance.

Methods A narrative review (2019–2025) was conducted, drawing on peer-reviewed studies, systematic reviews, clinical guidelines, educational interventions, and organisational reports. A thematic synthesis explored the interplay between workload intensity, turnover dynamics, ergonomic design, team culture, and staff well-being. These stressors were mapped onto real endoscopy workflows—from scheduling and room setup to intraprocedural flow, turnovers, and post-list tasks—and integrated with ergonomic principles, quality-improvement models, and established endoscopy quality frameworks.

Results Burnout was strongly associated with reduced procedural quality, higher error rates, impaired situational awareness, and diminished capacity for supervision and training. Five major stressor domains emerged: high caseload and pace, ergonomic hazards, staffing and skill-mix constraints, cognitive load, and administrative burden. Mapping these stressors identified predictable workflow "pressure points" where efficiency demands conflict with staff well-being. Synthesised findings shaped a three-level intervention framework spanning individual ergonomics (micro), team structure and list design (meso), and unit-wide organisational practices (macro). From this, it was developed a Burnout-Aware Endoscopy List Toolkit, comprising a complexity-weighted list design template, staffing matrix, a brief burnout-aware team huddle, ergonomic micro-checks, a structured end-of-list debrief, and an integrated dashboard combining well-being, quality, and efficiency metrics. Units adopting similar workflow and ergonomic redesigns report better staff well-being and improved performance on key quality indicators [1–24].

Conclusions Burnout in endoscopy units is not simply an occupational health issue – it is a systems-level quality concern. Teams well-being must be embedded within endoscopy quality frameworks, and operational strategies such as complexity-balanced scheduling, ergonomic redesign, realistic turnover targets, and improved room flow should be treated as core quality interventions. Sustainable endoscopy services depend on a sustainable workforce. Aligning efficiency with staff safety directly supports the Quadruple Aim and leads to better patient outcomes.

OP040 Standardized sedation protocol for endoscopy: safety and effectiveness

Authors Lavín Expósito C[1], Castellanos Ramirez C[1], Bouhmidi Assakali A[1], Cofrade Delgado AM[1], Jurado Monroy RM[1], Velasco Del Burgo M[1], Vozmediano Sánchez P[1], Teno Félix MG[1], Rodriguez Romero V[1], Lopez Calero R[1], Solís Montes JE[1], Pinilla Sánchez J[1], Bonillo Merino C[1], Muñoz Trenado C[2], Gallardo Recuero B[1], Sanchez Pardo A[3], Barreto E[1], Sanchez Alonso M[1], Ramirez Martínez D[1], Peña M[1]
Institutes **1** Hospital Público Santa Bárbara, Puertollano, Spain; **2** Hospital Santa Bárbara, Puertollano, Spain; **3** Hospital Público Santa Bárbara, Calle Malagón, Puertollano, Spain, Puertollano, Spain
DOI 10.1055/s-0046-1820695

Aims Sedation is essential in digestive endoscopy to enhance patient comfort and optimize procedural quality. The implementation of a Standardized Operating Procedure (SOP), based on ASA risk stratification and staff competency, enables systematic safety measures and comprehensive monitoring. Specialized nursing staff lead these critical processes, contributing significantly to the efficiency and safety of the service [1–6].

The objectives were to describe the organization and outcomes of the sedation model in our unit, highlight the role of nursing in preparation, administration, and recovery, define competency allocation according to ASA risk classification, and identify key indicators of safety and clinical effectiveness.

Methods A structured protocol was implemented across three clinical phases, based on ASA risk stratification:

1. **Pre-procedure Phase: Stratification and Planning**

Specialized nursing conducts a comprehensive clinical assessment through patient interview, medication review, and evaluation of airway-related risks and comorbidities.

Patients are classified according to ASA, determining:

- Sedation performed by gastroenterology staff for ASA I–II patients, by personnel accredited in deep sedation with propofol through SEED-endorsed specialized training (Spanish Society of Digestive Endoscopy).
- Sedation performed by anesthesiology for ASA III–IV patients or when additional risks are identified.2. **Intra-procedure Phase: Administration and Monitoring**Nursing responsibilities include preparing the procedure area and administering medication according to protocol, continuous monitoring of vital signs from induction to the end of the procedure, and early detection of changes in the level of sedation, providing ventilatory support when needed, and managing pain.3. **Recovery Phase: Surveillance and Discharge**

Endoscopy 2026; 58: S1–S1041 |

- Led by nursing staff: serial monitoring of vital signs and neurological status.
- Discharge criteria based on standardized post-procedure recovery scales.**Results**
- **Safety:** Minor complications were infrequent (< 2.5 %), mainly transient mild desaturations, with no severe adverse events or sedation-related deaths. This favourable safety profile has remained consistent since 2019, particularly in low-risk patients (76 % ASA I–II) managed by accredited nursing staff throughout preparation, propofol administration, and post-sedation monitoring.
- **Effectiveness:** The standardized sedation workflow proved highly effective in ensuring patient comfort and optimizing procedural times. Protocol implementation significantly shortened recovery, achieving a 30-minute mean, which improved patient flow and overall unit efficiency.
- **Patient Satisfaction:** The protocol substantially improved patient experience, achieving an overall satisfaction rate of 98 %. Since 2019, 99 % of endoscopic procedures have been performed under sedation, directly contributing to increased comfort, reduced anxiety, greater tolerance to the procedure, and enhanced perceived safety.
- **Efficiency:** Reorganization based on ASA stratification and the active role of nursing reduced waiting times from 730 to 30 days, improving accessibility and service performance. The model also increased team satisfaction, strengthened interdisciplinary coordination, and lowered procedure cancellations, reinforcing its operational sustainability.

Conclusions The implementation of a structured sedation protocol based on ASA risk classification is a safe and effective method for performing digestive endoscopy procedures. The training and leadership of specialized nursing staff are essential for comprehensive risk management and patient safety. Assigning sedation responsibilities according to ASA category standardizes clinical practice, optimizes resources, and ensures appropriate safety levels for each risk group. This model contributes to continuous quality improvement, enhances patient satisfaction, and supports the sustainability of the service.

DOI 10.1055/s-0046-1820696

Aims While minimally invasive, endoscopic procedures present significant risks to patient safety, including complications such as perforation, bleeding, infection, and pancreatitis. Implementing safety checklists in various medical fields has been shown to improve patient outcomes by standardizing processes and enhancing communication. However, the role of safety checklists, specifically in endoscopic procedures, remains underexplored.To evaluate the effectiveness of safety checklists in improving patient safety, reducing complications, and enhancing procedural efficiency in endoscopic practices across multiple centers [1–4].

Methods This prospective, multicentric study was conducted across twenty endoscopic units, 14 national health service providers, and six private practices between 20.01.2025 and 14.02.2025. A total of 4,926 patients underwent endoscopic procedures. Hungarian endoscopy experts translated the safety checklist recommended by the European Society of Gastrointestinal Endoscopy into Hungarian and revised it before circulation. Online training was held twice with the participating centers before the study period. Key safety components included patient identification, consent, comorbidities, medication, anticoagulation, procedural plan, equipment, vital signs, observation, and post-procedural checks. We collected data on the identified deficiencies and preventable errors and performed a statistical descriptive analysis. We also collected and narratively reviewed all users' feedback on implementing the checklist [5, 6].

Results Among the 4,926 patients, 4,013 underwent procedures with the checklist protocol, and the use of the checklist identified 327 correctable deficiencies and errors in 4,013 (8.14 %) endoscopies, with 117 (2.91 %) procedures with more than one deficiency and error. The rate of endoscopies with correctable errors varied between 0 % and 70.34 % in the different centers. The checklist identified correctable errors in 2,054 colonoscopies, 1,648 gastroscopies, 326 endoscopic retrograde cholangiopancreatography, and endoscopic ultrasound with a rate of 9.01 %, 6.43 %, 4.29 %, and 0 %, respectively. Fourteen endoscopic (70 %) units, including three private practices (50 %), plan to continue using the checklist. Users commented on the following benefits: improved teamwork, more focused pre-procedural assessment, and more atten-

tion to crucial details such as coagulation. However, nearly all users stated that the additional time, lack of willingness to use, and more paperwork impeded its introduction into practice.

Conclusions Implementing safety checklists in endoscopic procedures significantly improves patient safety by identifying preventable errors. This study proves the feasibility of using safety checklists in endoscopy and highlights the importance of standardized safety protocols in endoscopic units. By verifying routine procedures, the checklist minimizes the potential for human error and problems arising from forgotten steps. Implementing a checklist has been shown to improve communication among members of the multidisciplinary team.

OP042 The Endoscopy Nurse: Profiling and Evaluating Advanced Competencies – Preliminary Results

Authors Minciullo A[1], Tartaglini D[2], Filomeno L[3], Riccardo G[2], Dhurata I[2]
Institutes **1** Università degli Studi di Roma Tor Vergata, Rome, Italy; **2** Bio-Medico Campus University Hospital, Rome, Italy; **3** Sapienza University of Rome, Roma, Italy
DOI 10.1055/s-0046-1820697

Aims The aim of this research is to define the core and advanced competencies of endoscopy nursing through an exploration of routine activities, required knowledge and skills and expected levels of professional autonomy.

Methods A qualitative study was conducted using the interview to the double methodology, in which 6 participants instruct the interviewer—imagined as their "double"—on how to replace them at work without being recognized by colleagues [2]. Nurses employed in a private healthcare facility, with at least three years of experience in endoscopy and adequate comprehension of Italian, were included. Interviews were audio-recorded, transcribed verbatim, and analyzed using NVivo 11.0.

Results Preliminary results reveal 5 main domains of nursing competence. Technical and care competencies include anatomical knowledge, infection prevention and control, pharmacological management, endoscopic instrumentation, reprocessing, emergency recognition, and direct patient support. Organizational and management competencies involve coordinating clean/dirty pathways, ensuring equipment functionality, stock management, documentation, and procedural traceability. Communicative and relational competencies encompass effective patient communication, anxiety reduction, teamwork, and collaboration with anesthesiologists and endoscopists. Educational competencies refer to patient education, peer training, and promotion of best practices. Safety and infection-prevention competencies include adherence to sterilization norms, use of PPE, waste management, monitoring of sterile integrity, and prevention of cross-contamination.

Conclusions The emerging competency framework highlights the high degree of specialization required in modern endoscopy nursing [1]. The five identified domains reflect a complex professional role that integrates technical expertise, organizational leadership, communication skills, educational function, and rigorous infection-prevention practice. These findings underscore the need for updated national standards, structured training programs, and a clearly defined professional profile to support competency development and ensure the delivery of safe, high-quality, patient-centered endoscopic care. Further consensus work will refine competency levels and inform the creation of a standardized job description for the Endoscopy Nurse in Italy.

Aims Lynch Syndrome (LS) is an autosomal dominant genetic predisposition responsible for multiple cancers, including the rare small bowel (SB) adenocarcinoma. There is no formal recommendation regarding the need for screening. Since the 2000s, small bowel capsule endoscopy (SBCE) has become the reference method for SB exploration. The diagnostic and therapeutic yield of screening for neoplastic lesions by SBCE is poorly documented. The aim of this study was to evaluate the diagnostic yield of a first (index) screening SBCE in patients with LS.

Methods We conducted a European multicenter cohort study. Patients carrying a pathogenic variant of a DNA mismatch repair (MMR) gene, who were

asymptomatic and screened by SBCE for suspected neoplastic lesions, were included. Data was collected between January 2000 and December 2024. The primary endpoint was the diagnostic yield of an index SBCE, defined as the proportion of patients diagnosed with neoplastic lesions. Secondary endpoints were the diagnostic yield of follow-up SBCE, adverse events, technical performance, age at lesion diagnosis, impact of SBCE on management, and lesion frequency depending on the type of pathogenic variant.

Results A total of 346 patients were screened in the study, with 21 (6.1 %) excluded due to symptoms. A total of 325 patients were included for analysis. The mean age was 51.0 (± 11.2) years, and 146 patients (45 %) were male. The genetic variants identified were MLH1 (94, 29.2 %), MSH2 (144, 44.5 %), MSH6 (66, 20.5 %), PMS2 (21, 6.5 %), and EPCAM (0, 0 %). Two hundred and eighteen (63.0 %) patients had a personal history of LS-related cancer, and 289 (83.5 %) had a first-degree family history of small bowel adenocarcinoma.

SBCE was ingested in 324 (99.8 %) cases. Small bowel examination was complete in 325 (100 %) patients. The bowel cleanliness rate was adequate in 287 (88.2 %) of cases. In terms of adverse events, aspiration was noted in 0 (0 %) patients, and retention was noted in 2 (0.4 %) patients, requiring extraction (endoscopic or surgical) in 1 (0.2 %) patient.

The diagnostic yield of the index SBCE was 7.1 %, identifying a neoplastic lesion in 23 patients, including 4 adenocarcinomas. The mean age at diagnosis of neoplastic lesions was 64 (± 11.7) years. Among the 302 patients with a normal SBCE, 111 underwent a second SBCE after a mean interval of 3.8 years (± 1.9). The diagnostic yield for the second SBCE was 8.1 % (9 patients), none of whom had adenocarcinoma. The mean age at diagnosis of neoplastic lesions was 56 (± 9.5) years.

Conclusions In this European multicenter study including 325 patients with LS, the first small bowel SBCE performed for screening purposes had a diagnostic yield of 7.1 %. The diagnostic yield of a second SBCE performed after a 3.8-year interval was 8.1 %. The adverse event rate was 0.4 %. These results suggest that screening SBCE is warranted or to the least has a definite role, in patients with LS.

OP044 OMOM SmartScan Provides Noninferior Assessment of Lewis Score and CECDAI in Crohn's Disease vs Full-Video Review

Authors Pedro M[1], Rolando P[1], Rodrigues A[1], Costa C[1], Teixeira P[1], Ferreira R[1], Ponte A, Freitas T[1]

Institute **1** Unidade Local de Saúde de Gaia e Espinho, Vila Nova de Gaia, Portugal

DOI 10.1055/s-0046-1820699

Aims Small bowel capsule endoscopy (SBCE) is central to Crohn's Disease (CD) care but limited by lengthy review and reader variability. We tested whether an artificial-intelligence (AI)–triaged, human-reviewed workflow (SmartScan, SS) can replace full-video (FV) review while reducing reading time and maintaining safety (▶ **Table 1**).

Methods Single-center, randomized, assessor-blinded, dual-reader, 2 × 2 crossover non-inferiority study of OMOM HD videos. Adults with established CD had paired FV and SS reads. The primary endpoint was non-inferiority of the agreement on Lewis Score [LS] activity category and stricture status. Secondary endpoints included LS category agreement, equivalence of continuous LS/CECDAI, within-tolerance agreement, stricture sensitivity, performance with short transit and low Brotz quality, and reading-time superiority [1, 2].

Results We analyzed 153 paired studies. SS and FV agreed on both LS category and stricture in 96.1 % (147/153), surpassing the non-inferiority margin ($p = 0.005$). LS category exact-match was 96.7 %. Continuous scores were equivalent, within-tolerance agreement was 91.5 % (140/153) and stricture sensitivity 100 %. Results were similar with short transit and low Brotz quality. Mean reading time fell from 41.5 to 12.8 minutes ($p < 0.001$).

Conclusions SS achieved non-inferiority, preserved continuous score equivalence, and markedly reduced reading time, while maintaining safety. These data support an AI-first, human-verified SBCE workflow with selective escalation to FV.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP045 Diagnostic Yield of Small Bowel Capsule Endoscopy in Refractory Coeliac Disease: A systematic review and meta-analysis

Authors Lei II[1, 2, 3], Naresh R[2], Arasaradnam R[1, 4, 3]

Institutes **1** University Hospital Coventry & Warwickshire, Coventry, United Kingdom; **2** Department of Gastroenterology, Royal Berkshire Hospital, Reading, United Kingdom; **3** Warwick Medical School, University of Warwick, Coventry, United Kingdom; **4** Leicester Cancer Centre, University of Leicester, Leicester, United Kingdom

DOI 10.1055/s-0046-1820700

Aims Small-bowel capsule endoscopy (SBCE) is an established diagnostic modality, yet its role in coeliac disease remains limited. Current guidelines recommend SBCE as a second-line investigation in refractory or complicated coeliac disease, following serology, histology, and dietary adherence assessment. However, no prior systematic review and meta-analysis has synthesised evidence on SBCE specifically in refractory or active coeliac disease.

Methods We systematically searched EMBASE, MEDLINE, Cochrane Central, and PubMed for studies using capsule endoscopy in patients with coeliac disease, particularly those with persistent gastrointestinal symptoms or suspected refractory disease. Two reviewers independently screened studies and ex-

▶ **Table 1** Continuous agreement (equivalence) between SmartScan (SS) and full video (FV)

Endpoint	Mean Δ [90 % CI]	Margin	Decision(TOST)	Sensitivity Bounds
LS inflammatory subtotal (primary)	− 16.4 [− 30.5, − 2.3]	± 120	Equivalent	Within ± 100/ ± 150
LS total (sensitivity)	− 44.9 [− 77.4, − 12.4]	± 120	Equivalent	Within ± 100/ ± 150
CECDAI – full index	− 0.24 [− 0.39, − 0.10]	± 3	Equivalent	Within ± 2/ ± 4
CECDAI A × B (inflammation)	− 0.20 [− 0.34, − 0.06]	90 % CI within ± 3(not driven by inflammation alone)		
CECDAI C (stenosis)	− 0.04 [− 0.07, − 0.01]	90 % CI within ± 3(not driven by stenosis alone)		

tracted data. Risk of bias was assessed using ROBINS-I, and certainty of evidence using GRADE. We performed random-effects meta-analyses using a generalised linear mixed model (GLMM) to estimate pooled diagnostic yields for active refractory coeliac disease and secondary outcomes (ulcerative lesions and small-bowel tumours). Random-effects meta-regression, fitted using restricted maximum likelihood (REML), explored whether variation in diagnostic yield was associated with prespecified covariates (mean age, ulcer and tumour diagnostic yield, completion rate, coeliac serology, proportion with known refractory coeliac disease, and symptom burden).

Results Twelve studies, including 715 patients, were eligible. The mean age was approximately 50.9 years, and 28.7 % were male. Disease duration was variably reported, with a median duration of approximately 7.1 years among studies providing extractable data. The pooled diagnostic yield for active refractory coeliac disease was 0.68 (95 % CI 0.57–0.77; $I^2 = 70$ %). Pooled diagnostic yield for small-bowel ulcers was 0.06 (95 % CI 0.02–0.13; $I^2 = 71$ %), and for small-bowel malignancy 0.03 (95 % CI 0.02–0.04; $I^2 = 0$ %). Neither univariate nor multivariate meta-regression identified any covariates that significantly modified diagnostic yield. Capsule retention ranged from 0.53 % to 1.0 %, and adequate bowel preparation ranged from 53 % to 100 %. Across seven eligible studies, the meta-analytic pooled estimate indicated that 40 % of patients experienced a change in management following SBCE (95 % CI 18–67 %; $I^2 = 94$ %). Only one study reported using patency capsules, whereas three reported converting some selected procedures to device-assisted enteroscopy due to concerns about capsule retention.

Conclusions SBCE has a high diagnostic yield in refractory coeliac disease, with a relatively low frequency of ulcerative jejunitis and small-bowel malignancy, supporting its role as a second-line, non-invasive investigation and a filter test before device-assisted enteroscopy in complicated coeliac disease. Future studies should assess the role of artificial intelligence in improving the detection and characterisation of complex coeliac disease on SBCE.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP046 Small bowel rebleeding after capsule endoscopy: Effects of device-assisted enteroscopy on rebleeding rate, risk factors, and mortality in a Nationwide Big Data Cohort

Authors Huh KC[1], Song JH[2], Moon JR[3], Jeon SR[4], Kim HG[5]

Aims Although the use of device-assisted enteroscopy (DAE) has increased, few large-scale studies have examined long-term outcomes focused on small bowel (SB) bleeding. We analyzed National Health Insurance Service (NHIS) data to evaluate the clinical utility of DAE in patients with SB bleeding who underwent capsule endoscopy (CE).

Methods We constructed a cohort of 11,690 patients who underwent CE for SB bleeding (identified using ICD-10 codes) between 2002 and 2022. Patients were categorized into three groups: no DAE, diagnostic DAE, and therapeutic DAE. We assessed four major outcomes, including the probability and factors associated with SB rebleeding, severe SB rebleeding, rebleeding-related mortality, and all-cause mortality.

Results Of 11,690 patients, 5,221 were eligible for analysis (no DAE, n = 4,960; diagnostic DAE, n = 173; therapeutic DAE, n = 78). The probability of SB rebleeding and severe SB rebleeding was highest in the therapeutic DAE group, followed by diagnostic DAE and no DAE groups ($p < 0.001$), with 7-year rebleeding probabilities of 19.8 %, 15.8 %, and 5.0 %, respectively. Rebleeding-related and all-cause mortality were also highest in the therapeutic DAE group, followed by diagnostic DAE and no DAE groups ($p < 0.001$ for both), with 7-year rebleeding-related mortality probabilities of 9.3 %, 5.9 %, and 2.7 %, respectively. Risk factors for both rebleeding-related and all-cause mortality included age, male sex, liver cirrhosis, and malignancy.

Conclusions In patients with SB bleeding, therapeutic DAE is associated with higher risks of rebleeding and mortality, likely reflecting greater underlying disease burden. Long-term, individualized monitoring and careful management of comorbidities are required, even after therapeutic intervention.

DOI 10.1055/s-0046-1820702

Aims Double-balloon enteroscopy (DBE) plays a central role in the diagnosis and management of small-bowel disease, allowing direct visualisation of mucosal abnormalities, targeted tissue sampling, and the delivery of precise endotherapy within the same procedure [1]. As DBE is technically demanding and performance can vary across centres, the ESGE has introduced specific quality indicators to standardise practice and optimise clinical outcomes [2]. This study aimed to evaluate how DBE practice in our centre aligns with these established quality benchmarks over a two-year period.

Methods All DBE procedures performed at the Royal Free Unit for Endoscopy between July 2023, and October 2025 were retrospectively reviewed from our prospectively-maintained institutional database. Baseline characteristics, performance outcomes, major and minor performance indicators were analysed. ESGE performance indicators and their thresholds were used as reference standards.

Results A total of 359 DBE procedures were included in our study. DBE was performed for an appropriate indication in 98.3 % of cases. Adequate pre-procedure preparation occurred in 345 patients (96.1 %). Multidisciplinary team (MDT) discussion took place pre-procedurally in 200 cases (55.7 %). Maximum insertion depth was documented in 99.7 % of cases (n = 358) and marking with a submucosal tattoo of sterile carbon particles was performed in 72.7 % of clinically indicated cases. The overall diagnostic yield was 79.4 % and accurate photo-documentation was obtained in 70.8 %. Among lesions requiring further therapeutic intervention, 95.1 % were marked appropriately. Therapeutic intervention was performed in 60.2 % of procedures, with therapeutic success achieved in 98.6 %. Patient comfort was adequate in 96.9 % of procedures, and adverse events occurred in 0.8 % (3/359).

Conclusions Our 2-year quality asessment showed that achieving established ESGE quality thresholds for DBE is feasible in routine clinical practice. In our high-volume centre, both diagnostic yield and safety outcomes exceeded current ESGE targets, while the remaining indicators were consistently within expected benchmark ranges. These findings provide real-world support for the application of ESGE quality measures in DBE services and may help inform future updates as more data become available.

DOI 10.1055/s-0046-1820703

Aims Crohn's Disease (CD) demands accurate and repeated assessment of inflammatory activity. Capsule endoscopy (CE) and intestinal ultrasound (IUS) are patient-friendly non-invasive modalities to evaluate the small bowel, yet head-to-head comparisons are scarce, particularly for mild inflammatory burden [1]. We aimed to compare IUS with CE in detecting ileal inflammation.

Methods In this prospective, blinded study, patients with known or suspected CD referred for CE underwent same-day IUS, performed immediately prior to capsule ingestion. Inflammatory activity was quantified by the Lewis score (LS) for CE and the International Bowel Ultrasound Segmental Activity Score (IBUS-SAS) for IUS. Diagnostic accuracy was evaluated by ROC curve analysis.

Results We included 98 patients, 58.2 % female, with a mean age of 41.5 ± 13.9 years, of those 68.4 % had suspected CD and 31.6 % established inflammatory type (B1) CD. CE was performed as small-bowel CE in 82.7 % and pan-intestinal endoscopy in 17.3 %. Median fecal calprotectin was 46.3 µg/g and CRP 1.9 mg/L. Spearman's rho was 0.432 ($p < 0.001$) between 3rd tertile LS and IBUS-SAS. The AUROC for IBUS-SAS was 0.65 ($p = 0.09$; 95 % CI, 0.54–0.76) for non-significant inflammation (LS < 135), 0.798 ($p < 0.001$; 95 % CI, 0.69–0.90) for mild inflammation at high-risk of flare (LS ≥ 350), and 0.810 ($p < 0.001$; 95 % CI, 0.69–0.93) for moderate-to-severe inflammation (LS ≥ 790). For LS ≥ 350, an IBUS-SAS cut-off of 12.7 yielded 86.4 % sensitivity, 68.5 % specificity, 45.2 % Positive Predictive Value (PPV), 94.3 % Negative Predictive Value (NPV) and a $\kappa = 0.416$ ($p < 0.001$). For LS ≥ 790, a cut-off of 15.8 provided 78.6 % sensitivity, 77.8 % specificity, 37.9 % PPV, 95.5 % NPV and a $\kappa = 0.390$ ($p < 0.001$).

Conclusions IUS showed high accuracy and excellent negative predictive value for detecting clinically relevant ileal inflammation. These findings position IUS as an effective non-invasive strategy to exclude significant inflammatory activity in the ileum, while CE remains the reference for confirming and staging disease burden, by evaluating the whole extension of small bowel mucosa.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Endoscopic submucosal dissection (ESD) is one of the options for management of early gastric cancer (EGC) with positive horizontal margins (HM1) after initial ESD. Data regarding the feasibility and safety of ESD in this setting is limited, which we aimed to study.

Methods A retrospective analysis of patients who underwent salvage ESD for EGC after initial ESD showed HM1 between January 2014 and April 2024 at three centers was done. Technical success, procedure time, complications, and histologic outcomes were assessed.

Results A total of 5855 patients had undergone ESD for early gastric cancer in the three centers combined, out of which 75 (1.28 %) turned out to have indeterminate (HMx) or positive (HM1) horizontal margins. Twelve out of these patients had undergone re-ESD. The Technical success rate was 100 % (12/12). The median procedure time was 65.5 minutes for the re-ESD and 34 minutes for the initial ESD, and the difference was statistically significant($p = 0.0499$). The median resection speed was similar in both groups (21.58 mm/min versus 14.43 mm/min, $p = 0.239$). There were no major adverse events (▶ **Table 1**). En-bloc resection rate could be achieved in all patients (12/12; 100 %) and R0 resection in 9 patients (75 %) (▶ **Table 2**). Out of the patients who did not have negative vertical margins, two had indeterminate vertical margins (VMx) whereas one had positive vertical margins (VM1). All the three patients have had no additional treatment and are currently under follow-up with no local recurrence noted till date.

▶ **Table 1** Adverse events

		Initial ESD	Re-ESD	P value
Intraprocedural	Deep muscle injury	1 (8.33 %)	1 (8.33 %)	1
	Perforation	0 (0 %)	0 (0 %)	-
	Severe bleed	0 (0 %)	0 (0 %)	-
Delayed	Bleeding	0 (0 %)	0 (0 %)	-
	Perforation	0 (0 %)	0 (0 %)	-
	Other	0 (0 %)	0 (0 %)	-

▶ **Table 2** Histologic outcomes of re-ESD

Negative horizontal margins	12 (100 %)
Negative vertical margins	9 (75 %)
Lymphatic invasion	0 (0 %)
Vascular invasion	0 (0 %)
R0 resection	9 (75 %)
Curative resection	9 (75 %)

Conclusions Preliminary data from this study shows that salvage ESD for patients with EGC with positive horizontal margins after initial ESD appears to be feasible and safe at high volume centres.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP050 Outcomes of endoscopic resection of gastric dysplasia lesions in FAP: results from a large prospective registry

Authors Grimaldi J[1], De Cristofaro E[2], Figueiredo Ferreira M[3], Masgnaux LJ[4], Calavas L[5], Rostain F[6], Rivory J[1], Lupu A[6], Pioche M[1], Saurin JC[1]

DOI 10.1055/s-0046-1820705

Aims Familial adenomatous polyposis (FAP) is an autosomal dominant disease leading to extensive colorectal polyposis and a very high risk of colorectal cancer. Standardized management with prophylactic colectomy and endoscopic surveillance has markedly improved colorectal cancer prevention, shifting the main challenge toward the diagnosis and treatment of rarer extracolonic manifestations, notably gastric cancer [1, 2]. We recently described the endoscopic features of gastric dysplasia in Western FAP cohorts, characterized mainly by flat whitish fundic lesions overlying fundic gland polyps, and antral nodular lesions [3, 4]. However, no study to date has evaluated the outcomes of endoscopic treatment for these lesions. We aimed to assess the efficacy and morbidity of endoscopic resection for gastric dysplasia in a large prospective cohort.

Methods Within a large prospective FAP cohort (NCT01987518), we included all patients who underwent endoscopic resection of gastric dysplasia between 2015 and 2025. Efficacy outcomes included rates of en bloc and R0 resection, while morbidity was assessed by perforation rates. Survival analyses evaluated the occurrence of new dysplastic lesions, gastric cancer, or indications for gastrectomy. Subgroup analyses compared antral and fundic lesions.

Results Among 230 patients in the cohort, 28 endoscopic resections were performed in 22 patients. Fundic gland polyposis was present in 82 % of cases, and none had Helicobacter pylori infection. Most lesions were fundic (85 %), with 15 % located in the antrum. Resection techniques included endoscopic submucosal dissection (ESD) (46 %), hybrid ESD (7 %), hot-snare EMR (18 %), and cold-snare EMR (28 %). Mean lesion size was 41 mm. En bloc and R0 resection rates were 57 % and 53 %, respectively, with a perforation rate of 10 %. In the ESD subgroup, the en bloc resection rate reached 92 % with 7 % perforations. During follow-up (mean 52 months), 52 % of patients developed new dysplastic lesions, with a median time to recurrence of 71 months. Two patients (9 %) required gastrectomy due to excessive lesion burden. Only one intramucosal adenocarcinoma was identified, on gastrectomy specimen. Recurrence occurred in 65 % of fundic lesions (median 57 months) but in none of the antral lesions.

Conclusions This is the first study to evaluate the outcomes of endoscopic treatment for gastric dysplasia in patients with FAP, and to our knowledge the largest Western cohort addressing this issue. Endoscopic management appears effective and safe, enabling timely referral for surgery when needed. However, the high recurrence rates suggest that gastric lesions should be better integrated into upper gastrointestinal surveillance strategies, which currently rely exclusively on the Spigelman score driven by duodenal disease.

Endoscopic treatment of gastric dysplasia in FAP patients appears effective and safe in a large prospective cohort and highlights the need to optimize upper gastrointestinal surveillance strategies for this high-risk population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820706

Aims Endoscopic submucosal dissection (ESD) for early gastric cancer (EGC) without the risk of lymph node metastasis (LNM) is now the standard treatment. Recently, a scoring system named the "eCura system" was developed in Japan to help in decision-making about the additional treatment for patients resulted in non-curative resection after ESD. The eCura system is a well-validated scoring model; however, over 80 % of the cases in the cohorts consisted of differentiated-type EGC, and its applicability to undifferentiated-type EGC in non-curative resection remains uncertain. Therefore, we conducted a multicenter retrospective study to investigate the risk factors for LNM in undifferentiated-type EGC in non-curative resection, establish a risk scoring system, and analyze long-term prognosis.

Methods This nationwide multicenter retrospective study included consecutive patients with undifferentiated-type EGC. These patients resulted in non-curative resection at 64 institutions in Japan between January 2011 and March 2019. Undifferentiated-type EGC was defined as a poorly differentiated adenocarcinoma, signet ring cell carcinoma, or mucinous adenocarcinoma. This study included two cohorts: patients who underwent additional surgery after ESD and those who were followed without additional surgery.

First, we investigated risk of LNM in patients who underwent additional surgery after ESD. Second, to establish a risk score for predicting LNM, we assigned weighted points proportional to the β regression coefficient values of factors that were statistically significant. The new exploratory scoring system was compared with the eCura system to evaluate the predictive performance for LNM. Third, the cancer-specific survival (CSS) and cumulative recurrence in the follow-up without additional surgery group were examined using a risk scoring system with the highest area under the curve (AUC) among risk score models compared.

Results Overall,1049 patients were divided into additional surgery (716) and follow-up without additional surgery (333) groups. LNM was found in 5.7 % of patients who received additional surgery. Tumor size > 30 mm and lymphatic invasion were independent risk factors for LNM. The area under the curve (AUC) for the new exploratory simple scoring system in LNM was 0.768 (95 % CI 0.687–0.848), the AUC for the eCura system in LNM was 0.783 (95 % CI 0.703–0.864), and there were no statistically significant differences ($p = 0.464$). Finally, the eCura system was applied to the additional surgery group; The CSS at 5 years significantly differed in the low-, intermediate-, and high-risk groups (99.6 %, 96.9 %, and 60.6 %, respectively; $p < 0.001$). The HR of cancer recurrence for intermediate- and high-risk was 6.54 (95 % CI 0.41–104.2), and 98.2 (95 % CI 12.10–798.5), respectively ($p < 0.001$).

Conclusions Our findings suggest that lymphatic invasion and tumor size > 30 mm are associated with the risk for LNM, and the eCura system can be applied to undifferentiated-type EGC in non-curative resection.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP052 Effect of Dabigatran Replacement on Post-ESD Bleeding in Anticoagulated Patients Undergoing Gastric ESD: A Multicenter Prospective Study

DOI 10.1055/s-0046-1820707

Aims Patients taking anticoagulants, including direct oral anticoagulants (DOACs) and warfarin, are considered high-risk in gastric endoscopic submucosal dissection (ESD) because of their significantly increased risk of postoperative bleeding and thromboembolic complications. In a previous retrospective study, we reported that post-ESD bleeding in patients taking dabigatran was less frequent compared to those with other anticoagulants, which can be explained by the differences in their metabolic pathways. We hypothesized that replacing other DOACs and warfarin with dabigatran after gastric ESD could reduce post-ESD bleeding.

Methods We conducted a single-arm multicenter prospective study in which anticoagulants were replaced with dabigatran after ESD in patients with gastric neoplasms eligible for ESD who were continuously taking rivaroxaban, apixaban, edoxaban or warfarin to prevent thromboembolism due to nonvalvular atrial fibrillation. Patient enrollment occurred from February 2019 to February 2025 at 20 institutions across Japan. DOACs were discontinued on the day of ESD, and dabigatran was taken starting from the next day for 28 days. Patients on warfarin either stopped the medication one day before or on the day of ESD depending on PT-INR. Another option was to discontinue warfarin four days prior and use heparin bridging. Dabigatran was initiated after ESD when PT-INR dropped less than 2.0. Anticoagulant therapy was switched back to the original agent on postoperative day 28, with follow-up continuing until day 56, at which point the patient underwent endoscopy and final evaluation. The primary outcome was the post-ESD bleeding rate. Delayed bleeding was significantly reduced with dabigatran bridge when the 90 % confidence interval (CI) did not exceed the 18 % threshold, which represented the estimated rate for patients on other anticoagulants.

Results In total, 150 patients were enrolled, and 140 patients completed the protocol treatment. Male patients accounted for 86 %, with a median age of 77.5 years. Antiplatelet use was observed in 12 %, and the median $CHADS_2$ score was 2. The post-ESD bleeding rate was 10 % (90 % CI, 6.3-15.0). Although thromboembolism occurred in one case (0.7 %) as a cerebral infarction, the patient recovered without significant paralysis. Two cases (1.3 %) of perforation during ESD were observed and were successfully managed with conservative treatment.

Conclusions Switching to dabigatran reduces postoperative bleeding following gastric ESD in patients taking anticoagulants for nonvalvular atrial fibrillation, and represents a simple and effective strategy that can be easily combined with other preventive measures. (UMIN-CTR000035353)

DOI 10.1055/s-0046-1820708

Aims The BANDING-SET study demonstrated that endoscopic band ligation without resection combined with single-incision needle-knife (SINK) biopsy achieved successful clinical management in 92.7 % of subepithelial tumours (SETs) ≤ 10 mm at one-year follow-up (GIE 2023). The primary objective of this long-term study was to evaluate the 5-year recurrence rate in SETs with inadequate or potentially malignant histology (ip-SETs). Secondary objectives included all long-term SETs (g-SETs) global recurrence, associated risk factors, long-term clinical success and impact, follow-up of "unsuccessful" cases, and final biopsy diagnostic yield (▶ **Table 1**).

▶ **Table 1**

	GLOBAL	*SETs ≤ 10-mm*	*SETs > 10-mm*
Recurrence	5 (6.6 %)	1 (1.6 %)	4 (28.6 %)
No Recurrence	71 (93.4 %)	61 (98.4 %)	10 (71.4 %)

Methods A 5-year follow-up was conducted on patients included in a prospective multicentre study (7 centres), from March 2017 to May 2025. The ip-SET group underwent specific surveillance using endoscopic ultrasound (EUS) and tissue sampling. Overall recurrence was analysed for all g-SET included in BANDING-SET study (ClinicalTrials.gov NCT03247231).

Results SETs with clinical success at one-year accounted for = 78/122 (68.4 %; 95 %CI: 59.1-76.8). The ip-SETs subgroup included 42 cases; 6 were lost to follow-up, yielding 36 patients for analysis (18 inadequate histology, 12 neuroendocrine neoplasms [NENs], 6 GISTs).

At 5-year follow-up, recurrence in the ip-SET group was 2.8 % (n = 1/36; 1 NEN). While overall recurrence in the g-SET group was 6.6 % (n = 5/76; 2 inflammatory fibroid polyps [IFPs], 1 ectopic pancreas, 1 inadequate histology, 1 NEN), recurrence subanalysis (g-SETs) by SET size showed a significantly higher rate in lesions > 10-mm compared to ≤ 10-mm (28.6 [n = 4/14] vs. 1.6 % [n = 1/61]; multivariable RR: 23.3 (95 %CI: 1.06-511; p = 0.046).

Clinical success among g-SETs was 65.7 % (n = 71/108), with an overall clinical impact of 77.6 % (n = 90/116), rising to 92.1 % (n = 70/76) in the ≤ 10-mm subgroup [1–3].

Among the 37 "unsuccessful" SET cases, initial SINK biopsy revealed benign histology in 13; clinical decision against further follow-up due to age or comorbidities was made in 8; EUS surveillance was continued in 12; and definitive treatment was performed in 4 (endoscopic submucosal dissection: 2 IFPs, 1 GIST); surgical resection: 1 GIST). Overall histological diagnostic yield: 71.8 % (n = 79/110).

Conclusions The 5-year recurrence rate for both ip-SETs (with inadequate histology or potentially malignant histology) and all g-SETs was low (2.8 % and 6.6 %, respectively). SET size > 10-mm was identified as a significant risk factor for recurrence. The BANDING-SET technique offers a safe and effective long-term alternative for the management of small SETs, with sustained clinical impact in lesions ≤ 10-mm

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820709

Aims Local excision (LE) is increasingly used for early rectal cancer (cT1-2N0M0). However, its role in pT2 rectal cancer remains controversial due to a 20-30 % lymph node metastasis (LNM) risk. As LNM is strongly associated with adverse histological features, pT2 rectal cancer without risk factors may obviate the need for completion total mesorectal excision (cTME). Nevertheless, evidence supporting risk-adapted treatment strategies in pT2 rectal cancer is limited. This study aimed to evaluate the risk of LNM after complete LE in pT2 rectal cancer and explore whether the absence of histological risk factors permits safe omission of cTME.

Methods Patients with pT2 rectal cancer undergoing complete en bloc LE between 2015-2024 were retrospectively enrolled from eight international centres. Post-LE management consisted of cTME or active surveillance with at least two years of MRI-based follow-up. Exclusion criteria were positive resection margins (< 0.1 mm), synchronous/recurrent colorectal cancer, and (neo) adjuvant therapy. LNM were confirmed by TME histology or considered absent if no suspicious lymph nodes appeared on surveillance MRIs. A systematic histopathological re-assessment was conducted by dedicated pathologist at each centre. Predefined histological risk factors included: 1) adverse histology (poor differentiation, mucinous subtype, or signet ring cell), lymphovascular invasion, high-grade tumour budding and/or poorly differentiated clusters (grade 2-3), and perineural invasion. Active surveillance involved regular serum CEA measurements, endoscopies, and pelvic MRI with/without CT imaging. The primary outcome was the LNM rate in pT2 rectal cancer without risk factors. Secondary outcomes included associations between individual risk factors and LNM, and 3-year locoregional and distant recurrence rates after cTME and active surveillance, including pT2 cancer without risk factors

Results A total of 130 patients with pT2 rectal cancer were included (mean age 67 years; 57 % male; median lesion size 28 mm). Surgical LE was perfomed in 87 patients (67 %) and endoscopic LE in 43 (33 %). The median follow-up duration was 44 months (IQR 33.5).

Histopathological re-assessment of LE specimens revealed no risk factors in 36.2 % (47/130), one risk factor in 33.1 % (43/130), and multiple risk factors in 30.8 % (40/130).

Following LE, 87 patients (67 %) underwent cTME, whereas 43 (33 %) opted for active surveillance (19 without risk factors; 24 with at least one risk factor).

The overall LNM rate was 20 % (26/130). Among 47 pT2 rectal cancers without risk factors (36 %), the LNM rate was 6.4 % (3/47). In those with one or multiple risk factors, LNM rates were 14.0 % (6/43) and 42.5 % (17/40), respectively. In univariate analyses, all histological risk factors were significantly associated with LNM.

In the active surveillance group (n = 43), the 3-year locoregional recurrence rate was 14.3 % (95 % CI 3.6–25.1), comprising either intramural (n = 5) or nodal (n = 1) recurrences. The 3-year distant metastasis rate was 5.4 % (95 % CI 0–12.9). All four patients with isolated locoregional recurrences underwent successful salvage therapy, while only of two patients with combined locoregional recurrence and distant metastases was salvageable.

In the active surveillance group without risk factors (n = 19), the 3-year locoregional recurrence rate was 16.5 % (95 % CI 0-34.2), with two intramural and one nodal recurrence. The 3-year distant metastasis rate was 7.1 % (95 % CI 0–21.1). All locoregional and distant recurrences were successfully salvaged.

Among patients undergoing cTME (n = 87), no locoregional recurrences occurred at three years (0 %, 95 % CI 0-0). The 3-year distant metastasis rate was 8.6 % (95 % CI 1.9–15.1), with salvage treatment possible in one of six patients.

Conclusions After detailed histopathological re-assessment, LNM were observed in 6.4 % of pT2 rectal cancers without histological risk factors. Among these 'low-risk' patients managed with active surveillance (n = 19), the 3-year locoregional and distant recurrence rates were 16.5 % and 7.1 %. All recurrences were detected promptly, permitting successful salvage treatment.

These findings provide preliminary support for risk-adapted management strategies in selected patients with pT2 rectal cancer. While further validation in larger cohorts is needed, our results suggest that cTME may be omitted after complete LE in patients with low-risk pT2 rectal cancer, provided rigorous surveillance is implemented.

DOI 10.1055/s-0046-1820710

Aims To assess the prognostic value of conventional and novel histopathological markers in pT1 cancers.

Methods A retrospective, two-center study was conducted including 150 patients with histologically confirmed pT1 colorectal adenocarcinoma treated between 2010 and 2023. Clinical follow-up data were verified and updated using the National Cancer Registry. The primary endpoint of the study was the local recurrence or distant and locoregional metastases. For the purpose of the analysis, patients were divided into two groups: group 1, consisting of patients who reached the primary endpoint (n = 20, 13.3 %), and group 2, consisting of patients without recurrence or metastasis during follow-up (n = 130, 86.7 %) The following novel prognostic factors included: width of submucosal invasion, poorly differentiated clusters (PDCs), desmoplastic response, tumor-infiltrating lymphocytes (TILs), and epithelial–mesenchymal transition (EMT). EMT was assessed using the following markers: β-catenin, SNAIL, GREM, alpha-smooth muscle actin (αSMA), caudal type homeobox 2 (CDX2), fibroblast activation protein (FAP) and transforming growth factor beta (TGFβ). Selected conventional and novel histopathological factors are presented in the ▶ **Table 1**. All histopathological evaluations were conducted by a single experienced gastrointestinal pathologist (AM) blinded to clinical information [1–32].

▶ **Table 1** Selected conventional and novel factors predicting negative outcome among patients with pT1 colorectal cancer. Not all markers had been assessed by the time the abstract was submitted.

Histopathological factor	Group 1 (n = 20)	Group 2 (n = 130)	P-value
Angioinvasion (hematoxylin-eosin staining)	1/17	16/120	0.383
Neuroinvasio (hematoxylin-eosin staining)	0/17	2/115	0.584
Lymphovascular invasion – D2-40	2/17	15/119	0.098
Tumour Budding Score (high, > = 10)	6/15	36/120	0.430
Width of submucosal invasion (µm)	13523	4962.5	0.023
Poorly differentiated clusters, PDC (> = 10 clusters/ 0,785 mm2)	15/20	114/119	0.469
Desmoplastic reaction	5/16	58/119	0.188
Tumour infiltrating lymphocytes (CD8)	15/16	110/120	0.842
Epithelial Mesenchymal Transition EMT – alfa SMA	14/17	54/117	0.008
Epithelial Mesenchymal Transition, EMT – SNAIL	9/18	90/121	0.033

Results The median patient age was 63 years, and 59.3 % of the patients were male. The median lesion size was 22 mm (IQR 17–30 mm), and most were located in the sigmoid colon and rectum (74.7 %). There were no statistically significant clinical or demographic differences between the two groups. Endoscopic treatment (endoscopic submucosal dissection, endoscopic mucosectomy or full-thickness resection) was performed in 50 % of patients, surgery in 32.7 %, and surgery following endoscopic treatment in 17.3 %. Initial R0 resection was obtained in 118 patients (78.6 %). During a median follow-up of 4.8 years 10 local recurrences and 10 distant metastases were detected (group 1). Our analysis showed that the median width of submucosal invasion was 4962.5 µm, but was significantly greater in patients with recurrence or metastasis (13523 µm vs. 4962.5 [JR1] µm; p = 0.0226). Immunohistochemical evaluation demonstrated that EMT markers, specifically αSMA (p = 0.008) and SNAIL (p = 0.033), exhibited statistically significant associations with recurrence or metastasis

Conclusions Our analysis demonstrates that of the novel histopathological factors studied, the width of submucosal invasion and Epithelial Mesenchymal Transition expressed by αSMA and SNAIL may influence the risk of recurrence and/or metastasis following treatment of pT1 colorectal cancer.

OP056 Risk Factor Stratification for Residual Cancer and Lymph Node Metastasis after Non-Curative Endoscopic Resection of Colorectal Cancer: A Multicenter Retrospective Study

Authors Oh HH[1, 2], Soo Young O[3], Chan-Muk I[1], Won-Kyung K[4], Hyun-Soo K[1, 5], Young-Eun J[1, 2], Dong-Hyun K[1, 5]

DOI 10.1055/s-0046-1820711

Aims Following a non-curative endoscopic resection of T1 colorectal cancer, current guidelines recommend additional surgery based on high-risk pathological features. However, the actual rates of residual disease, such as residual cancer and lymph node metastasis (LNM), remain unclear and risk factors vary significantly across studies. We aimed to determine the true incidence of residual cancer and LNM and identify independent risk factors to guide surgical decision-making.

Methods This multicenter retrospective study included patients who underwent radical surgery after non-curative endoscopic resection of T1 colorectal cancer at four hospitals between 2015 and 2020. Non-curative resection was defined by positive margins, deep submucosal invasion (≥ 1000 µm), poor differentiation, lymphovascular invasion, or high-grade tumor budding in accordance with current guidelines.

Results Among 517 patients, residual cancer was found in 3.7 % and LNM in 7.7 % of the cases. Independent predictors of residual cancer were ESD procedure (OR 9.87, $P < 0.001$), piecemeal resection (OR 5.51, $P = 0.017$), positive lateral margin (OR 5.88, $P = 0.004$), and positive deep margin (OR 10.30, $P = 0.003$). For LNM, submucosal invasion depth ≥ 1000 µm (OR 4.66, $P = 0.015$), poor differentiation (OR 4.30, $P = 0.026$), lymphovascular invasion (OR 2.42, $P = 0.016$), and positive deep margin (OR 2.26, $P = 0.018$) were significant risk factors. Risk increased substantially with cumulative factors: patients with 0-1 risk factors had minimal residual cancer rates (< 1 %), while those with ≥ 2 factors showed exponentially higher risks.

Conclusions The actual incidence of residual cancer and LNM after non-curative endoscopic resection is relatively low. Our cumulative risk stratification model can help identify patients with low or high risks for residual disease. This model supports individualized risk stratification, potentially sparing low-risk patients from radical surgery while ensuring appropriate intervention for high-risk patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP057 Short Term outcome of Endoscopic Resection of Malignant, Non-Pedunculated Colorectal Polyps at Tertiary Centers in Norway and Sweden

Authors Blomberg A[1, 2], Nilsen JA[3, 4, 5], Mottacki N[1], Eskeland S[3], Schult AL[3, 6], Tandberg P[3], De La Croix H[7], de Lange T[8, 2], Frigstad SO[3], Papachrysos N[2, 1]

DOI 10.1055/s-0046-1820712

Aims Endoscopic resection of early T1 colorectal cancer without high-risk features for lymph node metastasis has emerged as an accepted alternative to conventional surgery. Traditionally, a free resection margin has been defined as ≥ 1mm, although increasing evidence indicates no additional benefit beyond ≥ 0.1 mm. Furthermore, submucosal invasion > 1 mm (sm2/3) may not represent a strong risk factor in the absence of other adverse histologic features. Bærum Hospital (Oslo, Norway) and Sahlgrenska University Hospital/Östra (Gothenburg, Sweden) serve as referral centers for advanced colorectal polypectomy in Southern Norway and Western Sweden. The aim of this study was to report short-term outcomes after endoscopic resection of malignant, non-pedunculated colorectal polyps at two tertiary centers.

Methods Since 2019, all advanced polypectomy procedures at both centers have been prospectively registered. We performed a retrospective analysis of all malignant non-pedunculated lesions treated endoscopically. All JNET 3 lesions were discussed in a multidisciplinary setting and referred for planned endoscopic resection when considered technically feasible and oncologically acceptable by colorectal surgeons.

Results From 2019 to 2024, a total of 167 patients (59.3 % male) with a median age of 72 years (range 33–90) underwent endoscopic treatment for malignant, non-pedunculated colorectal polyps. Median lesion size was 40 mm (IQR 20-60). The most common morphology was Paris 0-IIa + Is (38.9 %). Nearly half of the lesions showed a JNET 2b vascular pattern (47.3 %), while 32.1 % were JNET 3. Lesions were most frequently located in the rectum (56.8 %), with the proximal and distal colon each accounting for 21.6 %. The most frequently used technique was ESD (36,5 %), followed by uEMR (19.2 %), eFTR (18 %), c/pEMR (11.3 %), hybrid techniques (9 %), and EID (6 %). *En bloc* resection was achieved in 124/166 (74.7 %). Among piecemeal resections, the invasive carcinoma component was resected in a single fragment ("pseudo-en bloc") in 18/42 cases.
Complications were infrequent: intraoperative perforation occured in 6 cases (3.6 %), delayed perforation in 1 case (0.6 %), and delayed bleeding in 6 cases (3.6 %). According to the Clavien-Dindo classification, complications were graded as I (4.8 %), II (2.4 %), IIIa (1.2 %), and IIIb (0.6 %). Most patients (91.6 %) were managed as outpatients.
Free-margin rates varied by deep margin definition: 62/156 (39.7 %) using a ≥ 1mm margin vs 124/165 (75.1 %) using a ≥ 0.1mm definition. At least one histopathologic risk factor for lymph node metastasis was present in 42/126 (33.3 %). Lymphovascular invasion was identified in 22/145 (15.2 %), tumor budding grade 2–3 in 26/119 (21.8 %), and poor differentiation in 7/145 (4.8 %). Submucosal invasion depth was SM1 in 57/115 (49.6 %), SM2 in 25/115 (21.7 %), SM3 in 21/115 (18.1 %); 11 patients had T2 invasion and 1 had T3.
Overall, 62/150 (41.3 %) patients met criteria for endoscopic curative treatment (free margin ≥ 0.1mm, no LVI, tumor budding grade 0–1, and no poor differentiation). Applying a stricter margin requirement (≥ 1mm), curative resections decreased to 35/149 (23.5 %). When adding a requirement for SM1 invasion only, the curative proportion was further reduced to 22/150 (14.7 %).
Following multidisciplinary team (MDT) discussion, 78/158 (49.4 %) were assigned to endoscopic follow-up, 66/158 (41.8 %) were referred to surgery and 14/158 (8.9 %) received supportive care due to comorbidity, patient preference, or advanced disease. Complementary surgery was performed in 64 cases; residual malignant tumor was detected in 13 colon specimens (including 2 with free deep margins—one after piecemeal resection and one with multifocal cancer). Following endoscopic removal, eight patients were diagnosed with metastatic disease (N1 in seven; M1 in three). Six patients received adjuvant chemotherapy and three radiotherapy.

Conclusions Endoscopic resection of malignant, non-pedunculated colorectal polyps at experienced tertiary centers is safe, with high en bloc resection rates and low complication rates. Using broader criteria, 41 % of patients may be considered curatively treated endoscopically, whereas stricter definitions markedly reduce this proportion. MDT-guided decision-making remains essential for optimal post-resection management.

DOI 10.1055/s-0046-1820713

Aims Advances in gastrointestinal endoscopy have revolutionized the management of colorectal neoplasia, reducing the need for laparoscopic resections, shortening hospital stays, and lowering complication rates. While previous studies focus on procedural and oncological outcomes, limited evidence exists on socioeconomic and quality-of-life differences. This study compares EMR, ESD, and laparoscopic surgery for right-colon neoplastic lesions in terms of cost-effectiveness and patient-reported quality of life.

Methods This retrospective cohort study included patients referred for right-colon neoplastic lesion resection between January 2025 and October 2025 at two Greek tertiary hospitals. Patients underwent laparoscopic right hemicolectomy for neoplastic right-colon lesions ≤ pT2 stage, EMR or ESD for lesions ≤ pT1 stage. Data collected included baseline characteristics, lesion features, procedural and safety outcomes, complications, and material costs. Health-related quality of life was assessed using two validated questionnaires including the Gastrointestinal Quality of Life Index (GIQLI) two weeks post-procedure and the SF-12 questionnaire one month post-procedure, generating Physical Component Summary (PCS-12) and Mental Component Summary (MCS-12) scores. Statistical analyses included Kolmogorov-Smirnov, one-way ANOVA, and Kruskal-Wallis tests.

Results In total, 35 patients were included (mean age 68.3 ± 9.95 years; 45.7 % female). 10 patients underwent EMR, 10 ESD, and 15 right hemicolectomy. Mean lesion size was 38.1 ± 15.94 mm. Surgically treated lesions presented more advanced pathological stage (66.6 % pT2) compared to endoscopically resected lesions (80 % LGD/HGD/Tis; $p < 0.001$). Lesion location was predominantly cecum (51.4 %), followed by ascending colon (37.1 %) and transverse colon (11.4 %). Mean procedural times were shorter for EMR (43 ± 33.7 min), followed by ESD (79 ± 30.3 min), and longest for surgical treatment (207 ± 56.2 min; $p < 0.001$). Hospitalization averaged 1 day for EMR/ESD versus 5 days for surgery ($p < 0.001$). No complications occurred with endoscopic procedures, while one surgical patient experienced anastomotic leak (6.7 %). Median material costs were 970€ (EMR), 1275€ (ESD), and 6500€ (surgery; $p < 0.001$).

Overall, there were no statistically significant differences in quality of life based on SF-12 and GIQLI questionnaires among patients submitted to endoscopic removal with EMR or ESD technique. Interestingly, GIQLI total score did not differ significantly among the three different techniques (EMR 136.4; ESD 138; surgery 125.1; p = 0.132). Nevertheless, when separated GIQLI dimensions were analyzed, EMR and ESD were accompanied by higher physical functioning (p = 0.008) and emotional well-being (p = 0.003) scores. Similarly, the summary of the Mental Component of SF-12 (MCS-12) was significantly improved for endoscopic procedures compared to surgery (p = 0.002) while no statistical difference was observed among the three techniques concerning the Physical Component Summary (PCS-12) (p = 0.547).

Conclusions EMR or ESD for right-colon neoplastic lesions demonstrate shorter procedural duration, reduced hospitalization, lower material costs, and a more favorable safety profile compared to laparoscopic surgery. EMR or ESD are linked with superior mental and emotional quality of life compared to surgery, supporting EMR and ESD as cost-effective, safe, and clinically advantageous alternative to surgical resection for appropriately selected lesions.

DOI 10.1055/s-0046-1820714

Aims Endoscopic submucosal dissection (ESD) can achieve curative resection for T1 colorectal cancers fulfilling low-risk histological criteria. However, optical diagnosis does not always accurately predict submucosal invasion depth, and lesions with focal deep invasive patterns (FDIP) are often referred directly to surgery. A first-line diagnostic ESD strategy, performing en bloc resection in these lesions to obtain definitive histopathology before deciding on surgery, may represent a safe and cost-effective alternative. This study compared the clinical, environmental, and economic impact of diagnostic ESD versus upfront surgery for FDIP lesions [1–6].

Methods This prospective multicenter study included patients with colorectal FDIP lesions (Connect IIC + /III, Kudo Vn or Sano IIIb; < 10 mm in the colon or < 20 mm in the rectum) from the FECCO database. We excluded patients with lesions without invasive patterns, ulcerated (Paris III) lesions, and with distant metastases, or stenosis. Surgery was recommended for high-risk lesions (> T1 or T1 with lymphovascular invasion, high-grade budding, or poor differentiation) and discussed for intermediate-risk cases (> 1000 µm invasion without other risk factors). Independent predictors of curative resection were identified by multivariable logistic regression. Carbon footprint (CO_2e) and economic analyses were based on life-cycle data for ESD, surgery, and hospitalization.

Results Between January 2024 and May 2025, 190 patients (16 centers) underwent diagnostic ESD. Curative resection was achieved in 43 % (n = 86) of cases. In 16 % (n = 31) of cases the resection was considered at intermediate (expanded curative resection), and after multidisciplinary discussion only 6 patients underwent surgery. Seventy-three per cent (n = 73) were considered at high risk (non-curative resection) and surgery was recommended. Overall, 107 patients (56 %) avoided surgery and continued with endoscopic surveillance. CONNECT III classification (OR 0.42, 95 % CI 0.18–0.98) and presence of retraction sign (OR 0.48, 95 % CI 0.23–0.99) were independent negative predictors of curative resection. Compared with systematic upfront surgery, the diagnostic ESD strategy resulted in lower carbon emissions (222.2 *vs* 240.2 kg CO_2e per patient), reduced hospital stay (0.98 *vs* 3.5 days), and lower overall cost (€7,930 *vs* €12,960 per patient).

Conclusions A diagnostic ESD-first strategy for FDIP colorectal lesions enables definitive staging while reducing the need for surgery, environmental impact, and healthcare costs, supporting its use as a sustainable alternative to upfront surgery in selected patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820715

Aims Several RCTs have shown the positive impact of CAD-E on improving the polyp detection rates during colonoscopy. However, they were either early studies with potential for bias or single centre or performed in eastern population. The aim of our study was to perform this RCT in a western setting after the endoscopists have been using AI in routine practice.

Methods This was a prospective, randomized controlled trial (RCT) conducted across multiple tertiary centres. Patients were randomized (1:1) to either the control arm (AI off) or the intervention arm (AI on). The CAD-E device used for this study was WISE VISION (NEC Japan). This was a superiority trial, powered to demonstrate a 10 % difference in ADR between the two groups with an 80 % power. Adenoma per colonoscopy (APC) and ADR were calculated for the full sample and stratified for expert(> 2000 colonoscopy) and non-expert endoscopist (< 2000 colonoscopies). Finally, as a safety endpoint, we used the adenoma per extraction (APE) defined as the percentage of all adenomas, sessile serrated lesions, and large (> 10mm) hyperplastic polyps (only in the proximal colon) out of total number of polyps resected & extracted during colonoscopy in each arm.

Results A total of 653 patients were included, 328 and 324 in the control and intervention arm, respectively from three centres in UK. The mean age was 60.34 + - 12.28 and 60.44 + - 13.11 (p = 0.92), in the control and intervention group and a significantly lower rate of male (49.39 % vs 57.72 %, p = 0.04) was observed for control. No significant difference was observed in terms of total procedural length between control and intervention (31.62 vs 33.36 min, p = 0.17) and withdraw time (19.36 vs 22.84, p = 0.06). The ADR in the AI arm was 53.1 % which was statistically not different from the control arm at 46 % (p = 0.08).The APC rate was also similar between the control and AI arm at 1.11 vs, 1.32, p = 0.15, respectively.

APE rates indicative of unnecessary polypectomies were also similar between the control and AI arms at (0.65 vs 0.62, p = 0.25) respectively.

Interestingly, when data was stratified by endoscopist experience, there is a significant improvement in terms of APC 1.29(AI) vs 0.78 (control) (p < 0.001) for the non-experts but AI did not improve APC for the experts 1.34(AI) vs 1.33(control), (p = 0.96).

Similarly, we saw a significant improvement in ADR for non-experts from 40 %(Control) to 53.07 % (AI), (p = 0.049). The ADR for experts did not improve significantly with 49.8 %(control) vs 53.1 %(AI), (p = 0.57).

However, experts do show a lower APE in the intervention arm (0.64 vs 0.71, p = 0.04), while no significant difference has been observed for non-expert (0.53 vs 0.59, p = 0.19)

Conclusions Our data demonstrates that CAD-e doesn't improve ADR or APE across the board for AI experienced Endoscopists.

CAD-E does improve ADR and APE for non-expert endoscopists

Use of CAD-E doesn't cause any harm / hindrance / compromise care of colonoscopy patients as reflected in no difference in procedure times and APE (unnecessary polypectomy) rates.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP061 Learning and deskilling effects of artificial intelligence in colonoscopy among endoscopists with different experience levels

Authors Pedersen TA[1, 2, 3], Mori Y[4], Botteri E[5], Engjom T[2, 3], Seip B[6], Dimcevski G[7], Flesland Havre R[2, 3]

Institutes **1** Haraldsplass Deaconess Hospital, Bergen, Norway; **2** Haukeland University Hospital, Bergen, Norway; **3** University of Bergen, Department of Clinical Medicine (K1), Bergen, Norway; **4** Clinical Effectiveness Research Group, University of Oslo, Oslo, Norway, Oslo, Norway; **5** Cancer Registry of Norway, Norwegian Institute of Public Health, Oslo, Norway, Oslo, Norway; **6** Vestfold hospital, Tønsberg, Norway; **7** Kanalspesialistene, Bergen, Norway

DOI 10.1055/s-0046-1820716

Aims The effect of computer-aided detection (CADe) on colonoscopists' performance across different experience levels is not well understood. This study aimed to assess whether CADe-use promotes learning or deskilling. We hypothesized that real-time use of CADe would increase PDR-5 (the proportion of at least one polyp ≥ 5mm per colonoscopy) in both inexperienced and experienced endoscopists. We also hypothesized that the increased PDR-5 would persist after CADe was removed.

Methods We performed a prospective, multicenter, crossover, registry-based, pragmatic clinical trial. From November 2021 until June 2025, we included outpatient colonoscopies for patients of all ages and clinical indications at one university hospital, one local hospital and one private outpatient practice. Each endoscopist performed colonoscopies in three successive phases: 1) before CADe-exposure, 2) during CADe-use, and 3) after CADe-removal. GI Genius from Medtronic was used as CADe system. We collected colonoscopy related data from the Norwegian quality registry for endocopy (Gastronet) for 13 individual endoscopists with varying levels of experience. PDR-5, Gastronet's surrogate marker for adenoma detection rate, was used as a key measurement and is independent of histology. Experienced endoscopists were defined as having performed > 1000 colonoscopies in their career at the beginning of inclusion. We anticipated a PDR-5 of 30 % before CADe-use and an improvement to 35 % during CADe-use for both experience groups. To ensure adequate statistical power, we aimed to include 5,000 colonoscopies. Generalized linear mixed models were used, and analyses were performed both overall and stratified by the experience levels of the endoscopists. The primary endpoints of the study were changes in PDR-5 between phases 1 and 2, and between phases 1 and 3, for both inexperienced and experienced endoscopists.

Results 13 endoscopists (seven inexperienced and six experienced) performed 5013 colonoscopies; median patient age was 59 years (IQR 44-71), 2703 (53.9 %) were women and 2310 (46.1 %) men. Sex and age were similar across the two experience groups, whereas indications differed (e.g., more inflammatory bowel disease among the inexperienced). CADe temporarily increased PDR-5 among inexperienced endoscopists from phase 1 to phase 2 (31.9 % (216/678) to 39.5 % (257/651); OR 1.43, 95 % CI 1.11-1.84), while there was no significant change between phases 1 and 3 (31.9 % (216/678) to 36.3 % (173/476); OR 1.03, 95 % CI 0.79-1.34). There was no significant effect of CADe on PDR-5 of experienced endoscopists between each of the three phases, with a PDR-5 of 28.3 % (304/1075), 26.7 % (291/1088), and 27.2 % (284/1045), respectively.

Among the inexperienced, two endoscopists deskilled, two remained unchanged, and three were upskilled between phases 1 and 3. Similarly, among the experienced, three deskilled and three upskilled.

Conclusions In this study, in a real-world clinical setting, PDR-5 among inexperienced endoscopists increased during CADe-use. As for non-CADe-assisted colonoscopy, no upskilling nor deskilling was observed after CADe-exposure for endoscopists, regardless of experience level.

OP062 A comparison of white-box and black-box models in computer-aided diagnosis for colon polyps: a randomized controlled trial

Authors bae JH[1], Kim J[1]

Institute **1** Seoul National University Hospital, Seoul, Republic of Korea

DOI 10.1055/s-0046-1820717

Aims Computer-aided diagnosis (CADx) for optical characterization of colorectal polyps is intruduced into colonoscopy practice, yet concerns regarding the poor collaboration and the "black-box" nature of deep learning (DL) models persist. Limited interpretability may impede clinicians' trust, appropriate reliance, and real-world adoption. "White-box" explainable AI (XAI) systems that provide human-interpretable reasoning have been proposed as a solution, but direct empirical evidence comparing white-box and black-box CADx models in

clinical decision-making remains scarce. This randomized controlled trial evaluated whether a white-box XAI model improves diagnostic performance, confidence calibration, and technology acceptance compared with a conventional black-box DL CADx model [1].

Methods We conducted a prospective, two-stage multicenter study involving 112 endoscopists. In the baseline ex vivo assessment, participants performed optical diagnosis without AI support on 200 narrow-band imaging (NBI) still images (120 adenomas, 80 hyperplastic polyps). Baseline overall accuracy (OA), high-confidence accuracy (HCA), and high-confidence rate (HCR) were calculated. After a one-month washout period to minimize recall bias, participants were stratified as high vs. low performers based on baseline HCA and HC, then randomized 1:1 to either a black-box DL CADx group or a white-box XAI CADx group. During the second stage, participants re-evaluated the identical image set using their assigned CADx system, which differed only in explainability features while maintaining comparable core classification architecture.

To evaluate psychological determinants of adoption, participants completed a validated Unified Theory of Acceptance and Use of Technology (UTAUT)-based questionnaire assessing performance expectancy, effort expectancy, social influence, facilitating conditions, and resistance bias. Structural equation modeling was applied to examine differential effects on behavioral intention across the two CADx modalities.

Results Baseline performance without AI showed moderate diagnostic proficiency across participants: OA 66.2 %, HCA 70.8 %, and HCR 62.0 %. When CADx support was introduced, significant differences emerged between white-box and black-box models. The XAI group achieved higher OA than the DL group (80.6 % vs. 77.2 %; p = 0.025) and a markedly superior HCA (88.8 % vs. 83.0 %; p < 0.001). Conversely, the HCR was lower in the XAI group (61 % vs. 71 %; p = 0.005).

Stratified analyses revealed distinct effects based on baseline expertise. Among high performers, only HCA improved significantly with white-box XAI, while OA and HCR did not differ. Among low performers, however, XAI substantially improved OA, HCA, and HCR.

Technology acceptance analysis further differentiated the two systems. In the black-box DL group, resistance bias exerted a significant negative influence on behavioral intention. In contrast, in the white-box XAI group, resistance bias did not significantly predict behavioral intention. Other UTAUT constructs showed similar directional trends across groups, reinforcing explainability as the key distinction.

Conclusions The white-box XAI model significantly outperformed the black-box DL model in overall accuracy and high-confidence accuracy, with particularly striking benefits among lower-performing endoscopists. Crucially, white-box explanations neutralized the detrimental effect of resistance bias on behavioral intention, suggesting that interpretability is critical for clinician trust and future adoption. These results highlight explainability as a central determinant of effective human–AI interaction and underscore the importance of transitioning from black-box to white-box CADx systems for safe, trustworthy, and widely accepted optical diagnosis in colonoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820718

Aims Computer-aided polyp detection (CADe) could enhance adenoma detection rate (ADR) during colonoscopies. Adding mucosal exposure devices on top of CADe remains investigational (▶ **Table 1**).

Methods We performed a multicenter, parallel, randomized controlled trial in Hong Kong, Singapore and Germany from March 2023 to January 2025. Subjects aged 45-85 undergoing colonoscopies for screening, surveillance or diagnostic indications were randomized 1:1 to receive procedures with both CADe (ENDO-AID(OIP-1), Olympus Co., Japan) and Endocuff Vision (combined arm), or CADe alone. Randomization was stratified by endoscopist experience (junior vs senior, < 500 vs > 500 procedures). Treatment allocation was blinded to outcome assessors. Subjects with incomplete colonoscopies or inadequate bowel preparation were excluded. The primary outcome was ADR. Secondary outcomes were ADR for different sizes and locations, adenomas per colonoscopy (APC), and non-neoplastic resection rate [1–3].

Results 1726 subjects were randomized. After exclusion, 767 and 772 subjects were included in the combined and CADe alone arms during the modified intention-to-treat analysis. Baseline parameters were comparable, except a shorter intubation time in the combined arm (6.9 vs 8.4 minutes). The overall ADR was significantly higher in the combined arm (62.1 % vs 55.6 %, adjusted relative risk 1.18, 95 %CI 1.04-1.34, $p = 0.01$). The left colon ADR (39.1 % vs 32.1 %) and non-pedunculated ADR (59.6 % vs 53.6 %) were also significantly higher in the combined arm. The overall APC (1.72 vs 1.38), < 5mm APC (1.09 vs 0.86), 5-10mm APC (0.58 vs 0.46) and left colon APC (0.72 vs 0.53) were significantly higher in the combined arm. The withdrawal time and non-neoplastic resection rate were similar between two arms.

Conclusions The additional use of EndoCuff could further enhance the performance of CADe during colonoscopies, with shorter intubation time and higher ADR/APC, especially in the left colon. (ClinicalTrials.gov: NCT05414448)

Endoscopy 2026; 58: S1–S1041

Aims Red Density (RD) is an automated endoscopic scoring tool, and ESGE innovation of the year 2018, developed for the objective evaluation of endoscopic disease activity in ulcerative colitis (UC). RD correlates with established histological and endoscopic scoring systems. The PROCEED-UC trial aimed to assess and validate the predictive value of the Red density score for sustained clinical remission.

Methods Patients with UC in clinical remission included in 10 centers in the PROCEED-UC study (NCT04408703) underwent blinded endoscopic assessment with RD in the rectum and sigmoid at baseline, week 52 or early termination (ET) visit. Protocolised biopsies were scored for the Geboes score (GBS), Robart's Histological Index (RHI), Nancy Histological Index (NHI) and Picasso Histological Remission Index (PHRI) in a blinded fashion after initial scoring convention training. Primary endpoint was sustained clinical remission ((SCCAI) < 3 AND no new UC treatment, escalation of therapy, UC related hospitalization or colectomy). Comparison of the means using t-test, cut-off assessment through receiver operating curve analysis (ROC), and correlation testing based on Spearman analysis.

Results In total 212 patients from 10 centers were enrolled, 120 completed the 52 weeks follow-up period, 16 had a relapse before 52 weeks, 36 did not complete 52 weeks follow-up and 40 patients had to be excluded (24 due to technical issues and 16 drop outs). A total of 4343 RD images of 1064 colonic segments with biopsies and corresponding RD score. Mean (± SEM) rectal RD score was 40.37 (± 3.19), 41.90 (± 3.91) and 66.49 (± 12.82) at baseline, week 52 and ET respectively. Mean sigmoidal RD score was 42.40 (± 2.98), 40.95

(±3.77) and 101.9 (±21.57) at baseline, week 52 and ET respectively. Pooled mean RD scores at baseline in patients with sustained clinical remission was 32.71 and 52.94 in patients with clinical relapse (difference 20.24±18.52; p=0.033). Pooled mean RD score at week 52 was 42.13 and 130.0 in case of clinical relapse (difference 87.87±21.06; p=0.0008). Based on ROC-analysis, the RD score cut-off at baseline for disease relapse within 52 weeks appears to be 63.50 (AUC 0.8291 (95%CI 0,7049 to 0,9533, LR 3.905). Correlation analysis with histology was moderate but significant for NHI (r=0.47, p<0.0001), PHRI (r=0.51, p<0.0001) and RHI (r=0.55, p<0.0001).

Conclusions Red Density demonstrates a significant predictive value for clinical relapse within 52 weeks with a sustainable cut-off and maintains meaningful correlations with multiple histological indices. These findings support RD as a reliable, objective tool for monitoring disease activity in UC and highlight its potential to guide earlier intervention and improve long-term patient management.

DOI 10.1055/s-0046-1820720

Aims Artificial intelligence (AI)-assisted colonoscopy increases polyp and adenoma detection, but its real-world economic impact remains unclear. Studies suggest higher short-term costs due to additional polypectomies and subsequent surveillance, which may be offset by long-term savings through reduced colorectal cancer incidence. However, evidence remains mainly simulation-based and highly heterogeneous. Robust, trial-based economic data are needed to guide policy. We therefore aimed to compare costs and resource use between AI-assisted and conventional colonoscopy.

Methods We conducted a randomized controlled trial between January 19, 2023, and October 10, 2024. Participants were randomly assigned to one of two groups: (1) AI-assisted colonoscopy using a CADx system (GI Genius or CAD EYE) or a CADe system (ENDO-AID), or (2) conventional colonoscopy (CC). Patients aged 40–90 years undergoing colonoscopy in the Region of Västra Götaland, Sweden, were eligible. Procedures were performed at both university and community hospitals. Direct costs for each investigation were recorded prospectively and included the cost of the AI system, procedure and histopathology costs, procedure-related fees, and additional costs associated with the follow-up strategy.

Results A total of 1,117 colonoscopies were included, of which 560 (50.1%) were performed with AI assistance and 557 (49.9%) without AI. The groups were comparable in terms of age (mean 66-67 years, SD 11), males were slightly more prevalent in the non-AI (46% and 54%, respectively, OR 1.35 95%CI 1.06, 1.70). Most colonoscopies were indicated due to red flag symptoms (44%) and organized screening (17%), and the vast majority were performed by senior consultants or experts (>90%), these parameters were all comparable between the AI and non-AI group.

AI assistance led to the identification of more polyps than conventional colonoscopy (70% vs 62%; OR 1.42, 95% CI 1.11–1.83), with more polyps removed (OR 1.38, 95% CI 1.07–1.76) and a modest increase in the number sent for histopathology (OR 1.19, 95% CI 0.94–1.51). Use of procedural materials between the two groups was comparable in terms use of hyoscine butylbromide, biopsy forceps, hot snares, clips and endoloops, however, a greater number of cold snares was utilized in the AI group compared to non-AI, OR 1.56 (95%CI 1.23, 1.97). Rates of polyp surveillance colonoscopies, repeat colonoscopy for polypectomy and surgery referrals were comparable between the two groups. The median total cost per colonoscopy was the same between AI and non-AI groups, *i.e.* 1,618€ (interquartile range 1,520, 1,703) and 1,618€ (1,520, 1,667). There was no difference in cost by trainer level, however, the cost was marginally higher in those undergoing organized screening using AI compared to non-AI, median €1,695 (1,619, 1,747), €1,644 (1,610, 1,702) with a moderate standardized mean difference of 0.35 which had a wide confidence interval (95%CI 0.05, 0.64).

Conclusions AI-assisted colonoscopy increased polyp detection and the use of cold snares without increasing overall or short-term costs compared with conventional colonoscopy. Long-term follow-up is needed to determine whether these short-term benefits translate into cost-effectiveness through cancer prevention.

DOI 10.1055/s-0046-1820721

Aims Barrett's esophagus (BE) is a premalignant condition that predisposes to the development of dysplasia—low-grade (LGD), high-grade (HGD)—and eventually esophageal adenocarcinoma (EAC). Current surveillance recommendations for patients with known BE include targeted biopsies of visible lesions and systematic four-quadrant biopsies (Seattle protocol) during careful examination with white-light endoscopy (WLE) and chromoendoscopy. With the advent of high-resolution endoscopes capable of detecting subtle lesions, the question arises whether surveillance could be limited to targeted biopsies, especially since systematic biopsies are time-consuming and not always performed by gastroenterologists. The aim of this study was to evaluate the impact of high-resolution endoscopy combined with electronic chromoendoscopy (EC) on the detection of HGD and EAC compared with WLE combined with Seattle protocol.

Methods This was a prospective tandem comparative study conducted in 11 French centers. Inclusion criteria were adult patients with long-segment non-dysplastic BE or flat dysplastic BE scheduled for endoscopy between May 2022 and December 2024, who provided informed consent. Main exclusion criteria were previously treated BE, known EAC, and coagulation disorders. BE was examined sequentially with WLE and EC by two blinded expert operators. Targeted biopsies were performed on lesions identified by either or both operators, followed by systematic four-quadrant biopsies. Diagnostic performance of the different modalities (CE, WLE + Seattle protocol, WLE + CE) was compared.

Results A total of 110 patients were enrolled, of whom 95 (mean age 67 years; 86 % male) were analyzed. Mean BE length was 6 cm. Before the procedure, BE was classified as nondysplastic, LGD, HGD, or indeterminate in 16 %, 53 %, 29 %, and 2 % of patients, respectively.

After the procedure, final diagnoses were nondysplastic BE (35 %), LGD (37 %), HGD (16 %), and EAC (13 %). A total of 59 HGD and EAC lesions were detected in 27 patients.

EC with targeted biopsies (34/59) did not detect significantly more HGD/EAC lesions than WLE combined with systematic biopsies (47/59; $p < 0.001$), with a sensitivity of 58 % vs 80 %, a specificity of 72 % vs 5 %, a positive predictive value of 25 % vs 12 % and a negative predictive value of 92 % vs 78 %, respectively. Combination of EC and WLE detected 47 lesions and therefore had a sensitivity of 80 %, a specificity of 60 %, a positive predictive value of 24 % and a negative predictive value of 96 %.

EC with targeted biopsies, WLE with systematic biopsies and combination of EC and WLE had a patient-level sensitivity for HGD/EAC diagnosis of 74 %, 93 % and 89 %, respectively, a specificity and a positive predictive value of 100 %, a negative predictive value of 92 %, 78 % and 96 %, respectively. HGD was detected only by systematic biopsies in 3 of 15 patients. EAC was always detected by the combination of WLE and CE. LGD was identified only through systematic biopsies in 15 of 35 patients.

Mean procedure time of electronic chromoendoscopy, biopsies after electronic chromoendoscopy, white light endoscopy, biopsies after white light endoscopy, and Seattle protocol was 6.7 min ± 3.0, 4.8 min ± 6.3, 5.1 min ± 2.6, 3.9 min ± 5.9 and 5.9 min ± 3.7, respectively.

Conclusions Systematic four-quadrant biopsies remain valuable for detecting HGD despite the high sensitivity of combined WLE and CE. They remain indispensable for the detection of LGD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP067 Evaluating the quality of Barrett's oesophagus surveillance in the UK: Findings from the National Endoscopy Database (NED)

Authors Pohl K[1], Srinivasa A[2], Bhakta A[3], Feeney M[1], Beaton D[4], Burr N[5], Lee T[4], Rutter M[6], Trudgill N[2]

DOI 10.1055/s-0046-1820722

Aims Barrett's oesophagus predisposes to oesophageal adenocarcinoma, and surveillance upper GI (UGI) endoscopy aims to detect early neoplasia. High-quality surveillance is required to reduce post-endoscopy upper GI cancer (PEUGIC) and associated harm from delayed diagnoses or failing to prevent cancer. [1] The UK National Endoscopy Database (NED) provides a platform for large-scale evaluation of endoscopic performance. [2] As part of a broader assessment of UGI endoscopy quality, we evaluated Barrett's surveillance practice across the UK and examined sources of potential variation.

Methods All UGI endoscopies submitted to the latest iteration of NED (NEDi2) for the year 2024 were analysed. Barrett's surveillance procedures were identified using recorded indication fields. Key performance indicators (KPIs) assessed included sedation use, procedure duration, compliance with the recommended Barrett's inspection time (≥ 1 minute per centimetre of Barrett's segment), and compliance with the Seattle biopsy protocol (four biopsies per 2 cm). Focal lesion detection was captured using NED diagnostic fields. Mixed-effects multivariable regression models were used to evaluate the association between annual procedure volume (all UGI endoscopies), and Barrett's surveillance frequency (≥ 25 procedures per year vs. < 25) and KPI performance, adjusting for endoscopist profession, Barrett's length, patient age and sex, with endoscopist as a random effect (to account for clustering).

Results A total of 653,803 UGI endoscopies were submitted to NEDi2 in 2024, of which 26,898 (performed by 2,828 endoscopists) were labelled as Barrett's surveillance. Sedation was used in 45.5 % (95 % CI 44.9-46.1). Among sedated patients, 55.2 % (95 % CI 55.4-56.0) received combined opioid + midazolam, and 13.4 % (95 % CI 12.8-14.0) received above the recommended dose for age. The focal lesion detection rate was 3.7 % (95 % CI 3.5-4.0). 68.7 % (95 % CI 67.8-69.6) of procedures were compliant with the Seattle biopsy protocol, and 74.7 % (95 % CI 73.9-75.6) met the Barrett's inspection-time target. 14.8 % of endoscopists undertook ≥ 25 surveillance procedures per year.

In adjusted analyses, sedated procedures showed significantly greater odds of focal lesion detection (OR 1.66, 95 % CI 1.36-2.01, $p < 0.001$). Endoscopists performing ≥ 25 surveillance procedures per year showed significantly higher focal lesion detection (OR 1.36, 95 % CI 1.11-1.68, $p = 0.003$). Those performing ≥ 25 surveillance procedures per year had longer total procedure durations (+ 0.79 minutes, 95 % CI + 0.27 - + 1.31, $p = 0.003$), but were not associated with increased Barrett's inspection time recommendation compliance (OR 1.48, 95 % CI 0.92-2.38, $p = 0.11$).

Conclusions Substantial variation exists in the quality of Barrett's surveillance across UK endoscopists. Endoscopists performing regular surveillance appear to achieve better lesion detection. Variation in sedation practice, particularly under-use of combined sedation, represents a potentially modifiable factor that may further improve performance. NED data are limited as it relies on endoscopists completing thorough and accurate reports, but it may provide a scalable mechanism for national quality assurance and future enhancement of Barrett's surveillance practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Despite its widespread use to enable early detection of neoplastic progression in non-dysplastic Barrett's esophagus (NDBE), endoscopic surveillance

lacks robust evidence of clinical benefit in esophageal adenocarcinoma (EAC)-specific survival, overall survival, or cost-effectiveness. Therefore, recent revisions of the Dutch national guideline advise against routine endoscopic surveillance in low-risk patients, defined as NDBE < 5 cm, age > 55 years, and no prior dysplasia. This study assesses the long-term risk of progression to high-grade dysplasia (HGD) or EAC in a large, community-based NDBE cohort.

Methods We initiated a prospective cohort study in 2003, enrolling patients with NDBE or low-grade dysplasia (LGD) with ≥ 1 cm BE extent across six Dutch community hospitals. Primary outcome was the annual risk for HGD or EAC. Data were collected prospectively until 2017. Follow-up then continued retrospectively using prospectively recorded histological data from the nationwide pathology archive, extended through 2024. Additional clinical information was retrieved from electronic health records in neoplastic cases. Progression risk and predictors were assessed using descriptive statistics and multivariable Cox regression. A predefined subgroup analysis included patients classified as low-risk per Dutch guidelines.

Results Of 985 patients initially enrolled, 973 (99 %) were matched with the national pathology database for extended follow-up. 74.1 % were male; mean age was 57.1 years at index endoscopy. Median BE length was C1M3. The median surveillance duration was 11.3 (IQR 6.8–15.9) years. The annual progression risk to HGD/EAC was 0.84 % (95 % CI 0.68–1.02 %). Of the 98/973 patients (10.1 %) who progressed to HGD/EAC, 75.5 % had early disease amenable for endoscopic treatment, 13.3 % had curative non-endoscopic treatment, and 5.1 % were managed palliatively due to advanced stage. In multivariable analysis, age (HR 1.05, 95 % CI 1.03–1.08), BE length (HR 1.13, 95 % CI 1.07–1.19), and baseline LGD (HR 2.32, 95 % CI 1.51–3.51) were independent predictors of progression (all $p < 0.001$). Overall, the number needed to test (NNT) to detect one case of HGD/EAC was 59 endoscopies. Among 553/973 patients (57 %) classified as low-risk, under the revised Dutch guideline, the annual progression risk was 0.32 % (95 % CI 0.20-0.49) with an NNT of 144. In contrast, the remaining 420/973 patients (43 %) who still qualify for surveillance had an annual progression risk of 1.50 % (95 % CI 1.19-1.88 %), and a NNT of 35.

Conclusions Among 973 BE patients with a median follow-up of 11 years, the annual progression risk was low. Most patients (57 %) are classified as low-risk, with an annual progression risk of only 0.32 % versus 1.50 % in surveillance-eligible patients. Moreover, not all cases were detected at an early, endoscopically treatable stage, and the NNT was high. Surveillance, therefore, appears neither fully effective nor efficient. These findings challenge the clinical value of routine endoscopic surveillance for all BE patients, particularly in patients with low-risk features.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP069 Evaluation of a real-time Computer-aided Detection and Diagnosis system for Barrett's neoplasia during live endoscopic procedures: A multicenter prospective study

DOI 10.1055/s-0046-1820724

Aims Computer-aided detection (CADe) systems have the potential to improve endoscopic detection of early neoplasia in Barrett's esophagus (BE). Additionally, computer-aided diagnosis (CADx) systems may assist in subsequent characterization of detected lesions. We aimed to test a recently developed combined CADe/CADx system for BE neoplasia during live endoscopic procedures [1, 2].

Methods CADe and CADx were evaluated during endoscopic procedures of BE patients undergoing regular surveillance or endoscopic work-up for low-grade dysplasia (LGD), high-grade dysplasia (HGD), or esophageal adenocarcinoma (EAC) in 3 tertiary centers. All procedures were performed by expert endoscopists with over 5 years' experience with diagnosis and treatment of early BE neoplasia. First, ground truth for CADe (i.e. the presence or absence of a visible lesion requiring targeted biopsy) was established by the expert endoscopist using white light endoscopy (WLE). If a visible lesion was identified, it was subsequently characterized using narrow band imaging (NBI) as either normal mucosa or suspicious of neoplasia, serving as ground truth for CADx. Then, the CADe/CADx study protocol was initiated, which involved endoscopic examination in 2cm intervals throughout the BE segment, with real-time support of CADe. Any lesion identified by CADe was then evaluated by CADx after which targeted biopsies were obtained or the lesion was resected. Random biopsies were obtained according to standard protocol. Primary outcomes were the stand-alone sensitivity of CADe, and the mean number of false-positive CADe detections per patient. Secondary outcomes were the stand-alone sensitivity of CADx for characterizing CADe-detected lesions, and the reduction of CADe false-positive detections by CADx.

Results In total, 182 patients were enrolled in the study. In 74 patients, a visible lesion was found in WLE by the expert endoscopist. The CADe system detected 67/74 of these lesions, resulting in a sensitivity of 91 %. Of all detected lesions, histopathological examination confirmed neoplasia in 63 % (i.e. EAC, HGD, or LGD). Of the 7 lesions missed by CADe, 5 were neoplastic (2x EAC, 1x HGD, 2x LGD), and 2 did not contain neoplasia. In 108 procedures, no visible lesion was identified by the expert endoscopist in WLE. In these procedures, CADe generated 69 false-positive detections in total, resulting in 0.63 false-positives per procedure.

Of all 67 CADe-detected lesions, 58 were considered suspicious for neoplasia during NBI assessment by the expert endoscopist. All 58 lesions were correctly classified as neoplastic by CADx, resulting in a sensitivity of 100 %. Furthermore, CADx discarded 35 of the 69 CADe false-positive detections, reducing the mean number of false positives per procedure from 0.63 to 0.31. Extrapolated to clinical practice, this would result in one additional targeted biopsy every 3 patients.

Conclusions This is the largest study to date to evaluate a combined CADe/CADx system for real-time detection of BE neoplasia. The CADe system demonstrated a per-patient sensitivity of 91 % for all visible lesions identified by the expert endoscopist, with an acceptable number of false positive detections. The CADx system showed potential to further reduce false-positives, without discarding any prior CADe true positive detections.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims While some guidelines suggest Wide-Area Transepithelial Sampling with 3D analysis (WATS3D) as adjunct to random forceps biopsies (RFB) in Barrett's Esophagus (BE) surveillance, its clinical benefit in detecting high-grade dysplasia (HGD) and esophageal adenocarcinoma (EAC) remains uncertain as longitudinal follow-up (FU) data on WATS3D-positive-RFB-negative cases is lacking.

Methods Patients with C ≥ 2 + /- M ≥ 4 BE without visible lesions were enrolled in 6 expert centers for a 3-year FU and grouped into those with non-dysplastic BE (NDBE) and those with low-grade dysplasia (LGD), HGD or EAC. RFB were evaluated by expert pathologists. WATS3D brushes were evaluated by CDx Diagnostics expert cytopathologists, blinded to each other assessment. Primary endpoints were a) concordance in detecting HGD/EAC between WATS3D and RFB, and b) progression to HGD/EAC in WATS3D-positive-RFB-negative cases during FU. Secondary endpoint was concordance in LGD/HGD/EAC detection. A training phase was included to ensure adequate WATS3D sampling.

Results In study training phase, 183 baseline endoscopies revealed an initial 40 % WATS3D sample inadequacy rate. After retraining and individual feedback, this rate dropped to 8 %. Of 363 enrolled patients, 290 cases had complete baseline results: n = 129 LGD/HGD/EAC, n = 161 NDBE (Fig 1). An intention-to-diagnose (ITD) analysis found no significant difference in HGD/EAC detection between WATS3D and RFB (16/290 vs 10/290; p = 0.32, McNemar test, Fig 2A). In the post-training phase (n = 179), WATS3D again showed no significant diagnostic advantage for diagnosing HGD/EAC (4/179 vs 9/179, p = 0.32). Results were comparable in per-protocol analysis (4/158 vs 8/158, p = 0.34, Fig 2A). For detecting all dysplasia (LGD/HGD/EAC), both ITD and per-protocol analyses demonstrated diagnostic superiority of RFB over WATS3D, (p < 0.001, Fig 2B). WATS3D identified 13 HGD/EAC cases negative on RFB, which were prospectively followed for median 19 (95 %CI: 14–24) months and median 3 (95 %CI: 2-3) endoscopies: 10/13 developed HGD/EAC in RFB during FU and underwent curative endoscopic treatment, all these ten RFB-progressors had multifocal LGD in RFB at baseline; 1/13 completed 3-year FU without progressing to HGD/EAC, showing NDBE on RFB across four separated endoscopies. Two remaining patients are still under FU without demonstrating progression to HGD/EAC.

Conclusions Under optimized WATS-sampling, a comparable number of discordant HGD/EAC cases for WATS3D and RFB was found. WATS3D was inferior to RFB for detecting LGD/HGD/EAC. In this population, enriched for BE neoplasia, the adjunctive value of WATS3D was virtually absent: all discordant HGD/EAC cases detected by WATS3D that truly progressed had already been identified as at-risk due to baseline multifocal LGD in RFB. In all 161 NDBE cases no HGD/EAC diagnosed by WATS3D was confirmed in RFB during 3 years FU.

OP071 Barrett's Esophagus with Low Grade Dysplasia : Impact of Expert Histopathological Review and Expert Endoscopic Reassessment on Oncological Staging : A Retrospective Bicentric Belgian Study

Authors Bastens G[1], Eisendrath P[2], Plomteux O[3], Bletard N[3], Verset L[4], Lemmers A[4], Leclercq P[5]

Institutes 1 CHC Montlégia Clinic, Luik, Belgium; 2 CHU Saint-Pierre, Brussels, Belgium; 3 Clinical Chc Montlégia, Luik, Belgium; 4 Hospital Erasme HUB, Brussels, Belgium; 5 UZ LEUVEN, Leuven, Belgium
DOI 10.1055/s-0046-1820726

Aims Low grade dysplasia (LGD) in Barrett's esophagus (BE) carries a heterogeneous risk of progression and substantial diagnostic variability. Previous studies have shown that up to 85 % of LGD diagnoses made in community settings are downgraded to non-dysplasic BE (NDBE) or indefinite for dysplasia (IND) after expert panel review. In contrast, when LGD is confirmed by a panel of at least two expert pathologists, the risk of progression rises sharply.

Additionally, patients should undergo restaging endoscopy at a specialized center, using high-definition imaging, acetic acid or virtual chromoendoscopy, and meticulous inspection to detect visible lesions. Previous multicenter data have shown that expert endoscopic restaging significantly altered patient management, with 25 % of the patients ultimately reclassified as having high grade dysplasia (HGD) or esophageal adenocarcinoma (EAC).

Expert histopathological review and expert endoscopic reassessment are recommended by international guidelines, but their real-world practice implementation added value requires further studies.

Our aim was to evaluate the diagnostic impact of expert histopathological review and expert endoscopic restaging in patients with LGD managed in two Belgian expert centers.

Methods We conducted a retrospective bicentric cohort study across two Belgian BE expert centers including all endotherapy-naïve patients with at least one diagnosis of LGD between January 2018 and December 2024 and at least one follow-up endoscopy. Data were extracted from electronic endoscopy and pathology records and manually validated. Patients with prior HGD, EAC, IND or previous endoscopic therapy were excluded. Three main subcohorts were defined: (1) a **Histopathology Review Cohort,** including patients whose LGD biopsies underwent expert gastrointestinal (GI) pathology review; (2) an **Expert Endoscopy Cohort**, including patients referred for LGD restaging by a Barrett's expert endoscopist; and (3) a **Combined Expert Cohort,** including patients who underwent both expert histology review and expert endoscopy.Primary outcomes were (1) diagnostic reclassification after expert histopathological review and (2) detection of visible lesions and histologic outcomes at the first expert endoscopy. The secondary outcome was the diagnostic concordance and clinical impact of combined expert histological and endoscopic reassessment. Only descriptive statistics were performed.

Results A total of 148 patients with a diagnosis of LGD in the context of BE were included. Median age was 67 years and 79.7 % were male. The median Prague classification was C1M4. Expert histopathology review was performed in 107/148 patients (72.8 %). A diagnostic change occurred in 27 cases (25.2 %). LGD was confirmed in 80 patients (74.8 %). Among reclassified case, 10 (9.3 %) were upgraded to HGD and 17 (15.9 %) were downgraded (14 to IND, 3 to NDBE). Expert endoscopic reassessment was performed in 85 patients referred specifically for LGD evaluation; 79 were included after excluding 6 upgraded to HGD on expert pathology review. At the first expert endoscopy, histologic outcomes were: HGD/EAC in 11 patients (13.9 %), persistent LGD in 26 (32.9 %), IND in 6 (7.6 %) and NDBE in 36 (45.5 %). A visible lesion was identified in 18/79 patients (22.8 %). The combined expert cohort (patients with expert-confirmed LGD undergoing expert endoscopy) included 62 patients. In this group, first expert endoscopy revealed HGD/EAC in 15 (24.2 %), persistent LGD in 24 (38.7 %), IND in 6 (9.7 %) and NDBE in 17 (27.4 %). Among 10 patients whose LGD was not confirmed by expert pathology, none showed dysplasia on expert endoscopy. Overall, expert pathological review and expert endoscopic restag-

ing led to substantial diagnostic reclassification, frequently identifying previously unrecognized visible lesions and higher-grade neoplasia.

Conclusions LGD in BE requires cautious management given its diagnostic variability. Our findings align with international series in demonstrating the critical role of expert histopathology review and expert endoscopy to confirm the diagnosis, detecting missed visible lesions and guiding the appropriate therapy. These results support systematic referral of all patients with suspected or confirmed LGD to expert centers before any therapeutic decision.

DOI 10.1055/s-0046-1820727

Aims Oncological principles favor enbloc, R0 excision of cancer to achieve curative resection. In Barrett's neoplasia, endoscopically curable cancers include T1a and early T1b disease. Although both endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are accepted treatments, criteria for selection remain a subject of debate. Our aim was to compare two Barrett's cancer resection strategies, (1) Historical strategy (HS, 2004-2016): ESD reserved for more advanced lesions (predominantly T1b), or (2) Selective resection algorithm (SRA, 2017-2024): ESD applied to all suspected Barrett's cancers > 15 mm, with EMR used for the remaining lesions. Allocation was based on endoscopic prediction of depth of invasion.

Methods Outcomes compared between strategies included R0 (basal) excision, recurrence, curative resection and adverse events (delayed bleeding and deep muscle injury).

Results A total of 581 resections were performed in 542 patients (median lesion size 20 mm, IQR 10-30). Adverse events occurred in 2.2 % (5.3 % ESD vs 0.3 % EMR).

Cancer was present in 271 cases (T1a 178, T1b 93). Of these, basal R0 was achieved in 233/271 (86 %). For T1a, R0 was similar between ESD and EMR (96.9 % vs 90.2 %, p = 0.067). For T1b lesions, R0 was higher with ESD (77.6 % vs 41.2 %, p = 0.003).

Under the HS (n = 189), ESD was performed in 19 cases (14 cancers; 7 T1a, 7 T1b), achieving basal R0 in 10/14 (71.4 %; 42.9 % T1b, 100 % T1a). EMR (n = 170; 118 dysplasia, 38 T1a and 14 T1b) achieved basal R0 in 36/52 (69.2 %) cancers (T1a 84.2 %; T1b 28.6 %).

Under the SRA (n = 392), ESD was performed in 207 cases (158 cancers; 89 T1a, 69 T1b), achieving basal R0 in 142/158 (89.9 %; 96.6 % T1a, 81.9 % T1b). EMR (n = 185; 138 dysplasia, 44 T1a and 3 T1b), achieved basal R0 in 45/47 (95.7 %) cancers (T1a 95.5 %; T1b 100 %).

Overall basal R0 improved from 46/66 (69.7 %) under the HS to 187/205 (91.2 %) under the SRA (P < 0.001). For T1a disease, R0 improved (86.7 % vs 96.2 %, p = 0.021), but there was no difference in curative resections or recurrence. For T1b disease, R0 improved (33.3 % to 81.9 %), curative resection increased (9.5 % vs 30.5 %, p = 0.043), and recurrence decreased (55.6 % vs 23.6 %, P = 0.048).

Overall 2 year cancer-free survival (follow-up adherence 230/240 of eligible) was 92 %, with no difference between periods (P = 0.656). There was no difference in precusor lesions treated by EMR between strategies (HS 69.4 % vs SRA 74.6 %).

Conclusions Transitioning to a structured algorithm prioritising ESD for lesions > 15 mm resulted in substantial improvement in R0 resection, cure and recurrence for T1b disease. This approach maintained safety and durable cancer-free survival, without the over-treatment of precusor lesions by ESD. These results provide strong support for routine use of ESD in larger Barrett's cancers.

DOI 10.1055/s-0046-1820728

Aims While sarcopenia is recognized as a prognostic factor in advanced esophageal cancer, its relevance in patients undergoing endoscopic submucosal dissection (ESD) for superficial esophageal squamous cell carcinoma (SESCC) remains unclear. Bioelectrical impedance analysis (BIA) allows simultaneous assessment of muscle quantity and quality using the skeletal muscle mass index (SMI) and extracellular water/total body water ratio (ECW/TBW). In recent years, elevated ECW/TBW—reflecting poorer muscle quality—has been associated with reduced physical performance and a higher prevalence of sarcopenia compared with individuals with lower ratios. We examined whether these parameters influence clinical outcomes after ESD for SESCC.

Methods We retrospectively analyzed 251 consecutive patients with SESCC who underwent ESD between 2018 and 2023. Muscle quantity was assessed using SMI, and low muscle quantity (sarcopenia) was defined as SMI < 7.0 kg/m² for men and < 5.7 kg/m² for women. Muscle quality was evaluated using ECW/TBW, and poor muscle quality was defined as an elevated ECW/TBW (> 0.39). Patients were categorized as: Group A: normal muscle quantity and quality, Group B: abnormality in either muscle quantity or quality, Group C: abnormalities in both muscle quantity and quality. Patient and lesion characteristics, short-term outcomes, and long-term survival were compared across the groups.

Results The three groups were almost evenly distributed (A/B/C: 32.2 %/34.3 %/33.5 %). Tumor size increased across groups (A/B/C: 17.0 / 22.1 / 23.2 mm), and procedure time also lengthened (A/B/C: 38.3 / 45.9 / 49.6 min). The incidence of delayed adverse events (DAE) was 1.2 %, 3.5 %, and 8.3 % in Groups A, B, and C, respectively, and post-procedural pneumonia occurring in 0 %, 1.2 %, and 4.8 %. Length of hospital stay was 7.0, 7.1, and 7.5 days in Groups A, B, and C. Compared with Group A, Group C showed significantly more DAEs (P = 0.036), a trend toward higher pneumonia rates (P = 0.065), and longer hospitalization (P = 0.045).

Regarding long-term outcomes, tumor depth and additional treatment rates did not differ across groups. The median follow-up duration was 965 days (range, 15–2178 days). The cumulative 3-year overall survival rates were 100 %, 92.0 %, and 88.7 % in Groups A, B, and C, respectively. Compared with Group A, Group C showed significantly shorter overall survival (P = 0.019), while Group B tended to have shorter survival (P = 0.053). In multivariate analysis, combined low muscle quantity and poor muscle quality (Group C) remained an independent predictor of mortality (HR 10.53, P = 0.028). PNI ≤ 45 (HR 3.29, P = 0.018) and SM2 or deeper invasion (HR 3.23, P = 0.048) were also independent predictors.

Endoscopy 2026; 58: S1–S1041

Conclusions Patients with concurrent low muscle mass and poor muscle quality experienced more procedural complications and significantly poorer long-term survival after ESD for SESCC. These findings highlight that muscle quality, not only quantity, is clinically relevant and that incorporating BIA into pre-ESD evaluation may help identify high-risk patients before treatment.

OP074 Vessel-specific Factors to Predict Intra-Procedural Bleeding in Third Space Endoscopy

Authors Capogreco A[1], Dibitetto S[2, 1], de Sire R[3, 4, 1], Massimi D[1], Alfarone L[1], Spadaccini M[5, 1], Boustani C[6, 1], Minini F[5, 1], Vadalà V[5, 1], De Deo D[5, 1], Spertino M[5, 1], Maselli R[3, 5, 1], Hassan C[5, 1], Repici A[5, 1]

DOI 10.1055/s-0046-1820729

Aims Intra-procedural bleeding (IPB) is the most frequently encountered adverse event during third space endoscopy (TSE). It poses several challenges, including reducing the visibility of the dissection field, prolonging the duration of the procedure, and increasing the risk of perforation or delayed bleeding. These factors can contribute to less desirable outcomes, primarily lower en bloc and complete (R0) resection rates, as well as the risk of incomplete or aborted procedure if there is inadvertent injury to the underlying muscularis propria layer [1–7].

By exploiting the control group–i.e. without pre-coagulation of a recent randomized controlled trial on vessel pre-sealing, we performed a post hoc analysis to identify the main predictive features of IPB.

Methods This is a post-hoc analysis of the CURRENT trial to assess the efficacy and safety of a new pre-sealing technique for reducing IPB risk during endoscopic submucosal dissection (ESD). Briefly, consecutive patients aged ≥ 18 years who were referred for ESD for superficial GI neoplastic lesions in the upper or lower gastrointestinal tract, or POEM for esophageal achalasia, were included (Trial NCT05804266, conducted at Humanitas Research Hospital, Rozzano, Italy). In the control group, vessels were dissected without any pre-sealing treatment (control arm) in order to have a reliable estimate of IPB without a pre-sealing intervention. In detail, vessels greater than 1.2 mm in diameter allocated in the control arm were dissected with a standard high-voltage current without the use of coagulation forceps or alternative currents. For the purpose of the study, all procedures were performed in a CO2 setting and with the same knife. Thus, the control group of this RCT represents an ideal setting to identify the vessel-specific risk factors contributing to IPB.

The primary aim of this post-hoc analysis is to identify specific vessel related risk factors contributing to IPB during TSE, after adjusting for patient, procedure, and anatomical confounding factors.

Results 33 patients in the control group were included in the modified intention-to-treat analysis. A total of 421 vessels with a diameter of at least 1.2 mm in the 33 patients were considered for evaluation in the post-hoc analysis. After excluding clips with low image quality or lack of video footage recording, a total of 204 vessels were incorporated into the post-hoc analysis.

In the multivariable model including all covariates (N = 204), two variables remained independent predictors of IPB: large vessel diameter with adjusted OR 3.19 (1.58–6.43; P = 0.001), and penetrant morphology with adjusted OR 3.97 (1.05–16.60; P = 0.049). Vessel pulsatility and bifurcation did not reach statistical significance (all P > 0.3). Model fit: LR $\chi^2(8) = 45.91$, $P < 0.001$; pseudo-$R^2 = 0.1788$.

Conclusions Large vessel diameter and penetrant morphology increased the risk of IPB by approximately 3-fold. These significant findings provide the endoscopist with additional insight into a vessel's risk of bleeding, which may then alter their approach in terms of utilizing pre-coagulation with coagulation graspers, or performing vessel pre-sealing under saline immersion.

OP075 Strictures After Widespread Endoscopic Resection in Esophageal Neoplasia

Authors Younis F[1], Guido S[2], Dautel P[2], Rösch T[3]

Institutes **1** Tel Aviv Sourasky Medical Center – Ichilov, Tel Aviv-Yafo, Israel; **2** University Medical Center Hamburg-Eppendorf, Hamburg, Germany; **3** UKE, Hamburg, Germany

DOI 10.1055/s-0046-1820730

Aims Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are established methods for removing Barrett's-related esophageal lesions. A major limitation is the risk of post-resection strictures, often requiring repeated dilatation. Reported stricture rates vary widely and can reach 94 % when two-thirds or more of the esophageal circumference is removed. The primary objective of this study was the incidence of post-endoscopic resection stricture in a large patient cohort with neoplastic BE and at least 50 % circumferential resection by either EMR or ESD. Secondary objectives were success rates of endoscopic dilatation therapy and identification of risk factors for stricture formation.

Methods We performed a retrospective bicentric analysis (2009–2023) of endoscopically resected Barrett's-associated esophageal lesions, using a general strategy of removing half of the lesion-bearing circumference. Demographic, clinical (including dysphagia resolution), endoscopic, and histological data were collected for patients with and without post-resection strictures requiring endoscopic dilatation, along with treatment outcomes.

Results A total of 440 resections were performed: 275 EMR, 153 ESD and 12 hybrid, with cancer diagnosed in 335 cases (76.1 %). Median resection length was 60 mm, and 96.7 % involved the attempted > 50 % of the circumference. The overall stricture rate was 11.4 %. On multivariable analysis, resection of ≥ 75 % of the circumference was the only independent predictor of stricture formation, while strictures occurred in 7.3 % when the extent was 50 %. Strictures were most common after circumferential resections (58.3 %) and occurred more often in cancer lesions. Clinical success of stricture therapy was 86.7 %: initial dilatation (1–5 sessions) resolved 62.2 %, and additional dilatation (me-

dian 8 sessions) succeeded in 24.5 %. In six patients, dilatation failed, requiring stenting or surgery.

Conclusions Esophageal strictures are uncommon even after extensive (> 50 %) endoscopic resection of Barrett's-associated lesions, but the risk rises when 75 % or more of the luminal circumference is removed. Most cases resolve with repeated endoscopic dilatations, without requiring early salvage therapy.

DOI 10.1055/s-0046-1820731

Aims Flexible endoscopic septotomy (FES) is considered standard treatment of Zenker diverticulum (ZD) because of its safety and excellent efficacy. However, it usually requires multiple sessions and recurrencies seem frequent because of incomplete cutting of the septum. Moreover, it involves an incision of the full thickness of diverticular septum hence, the risk of adverse events might be higher. Peroral endoscopic myotomy for ZD (Z-POEM) is a new emerging technique, with theoretical potential to overcome the limitations mentioned above. Our aim was to compare the efficacy and safety of the Z-POEM and FES.

Methods We performed a prospective, randomized multicenter, single-blind, trial in 7 centers accross Europe and the United States. Patients with symptomatic ZD (at least 3 points as per Kothari–Haber Symptom Score (KHSS) measuring 10–50 mm were eligible. All investigators had extensive experience with both third space endoscopy (including Z-POEM) and FES. Procedures were standardized through online meetings and shared instructional videos. Symptoms were assessed at baseline and 1, 6, 12 and 24 months after treatment using multiple scores, with the KHSS as a primary measure. Main outcome was clinical success at 24 months. Clinical success was defined as KHSS < 3 points without a need for additional treatment. Adverse events were assessed 1 month after the procedure according to the appropriate classification (AEs during third space endoscopy).

Results A total of 158 patients (mean age 70 years, 43.7 % female, mean Charlson comorbidity index 2.9) were randomly assigned to Z-POEM (79 patients) or FES (79 patients). Baseline ZD size was 26.8 mm, median symptom duration 22 months, and mean KHSS 6.6; Milano–Zenker scores were similar between groups (mean 4.8).All procedures were technically successful. Mean procedure time was 25.1 min in the Z-POEM group and 17.2 min in the FES group ($p = 0.001$). Adverse events were observed in 2 patients (2.5 %) in the Z-POEM group and in 6 patients (7.6 %) in the FES group ($p = 0.14$). All four (5.5 %) severe adverse events were observed in the FES group ($p = 0.036$).

Of the 158 patients, 111 (70.3 %) completed full 2-years follow-up (47 patients died, dropped out due to severe illness or were lost to follow up) and 154 (97.5 %) underwent at least one follow up visit. Among patients completing full follow-up, clinical success at 24 months was achieved in 89.7 % (52/58) with Z-POEM and 81.1 % (43/53) with FES ($p = 0.199$). In the cohort with at least one follow-up assessment, clinical success at the last available visit was 90.9 % (70/77) following Z-POEM and 79.2 % (62/77) after FES ($p = 0.042$).

Conclusions Z-POEM demonstrates a trend toward higher long-term clinical success compared with FES and is associated with fewer severe adverse events.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP077 Comparative Outcomes of Conventional Flexible Endoscopic Septotomy and Third-Space Per-Oral Endoscopic Septotomy for Zenker's Diverticulum: A Propensity Score–Matched Analysis

Authors de Sire R[1], Maselli R[2], Massimi D[3], Alfarone L[4], Capogreco A[4], De Deo D[5], Dibitetto S[6], Boustani C[7], Spadaccini M[8], Hassan C[9], Repici A[10]

DOI 10.1055/s-0046-1820732

Aims Endoscopic management of Zenker's diverticulum (ZD) is increasingly shifting toward third-space techniques. Per-oral endoscopic septotomy (POES) may enable a more controlled and complete cricopharyngeal myotomy compared with conventional flexible endoscopic septotomy (FES), but direct comparative data remain scarce. We evaluated the efficacy and safety of POES versus FES in symptomatic patients with naïve ZD.

Methods Consecutive patients undergoing endoscopic treatment for symptomatic naïve ZD at two tertiary referral centers were retrospectively identified. Propensity score matching (1:1) was performed based on age, sex, ASA class, septum length, and operator expertise. Primary outcomes were technical success and 12-month clinical success. Adverse events (AEs) were classified using the ASGE lexicon and assessed for safety. Secondary endpoints included procedure time and length of hospital stay [1].

Results A total of 106 matched procedures (53 POES, 53 FES) were included with well-balanced baseline characteristics (54 % < 75 years; 39 % male; 65 % ASA I–II; 63 % short septum; 81 % deep sedation without intubation; 75 % expert operators; all $p > 0.05$). Technical success was achieved in all cases (100 % for both; $p > 0.99$). AE rates were low and comparable (FES 7.5 % vs POES 1.9 %; $p = 0.4$). POES was associated with one perforation, while FES with two intraprocedural bleedings and two perforations. Twelve-month clinical success did not differ significantly (POES 94.3 % vs FES 84.9 %; $p = 0.20$). Mean procedure time was shorter with FES (17 ± 4 min) than POES (23 ± 5 min; $p < 0.001$). Length of hospitalization favored POES (1.3 ± 0.2 vs 1.9 ± 0.4 days; $p < 0.01$).

Conclusions In this multicenter propensity-matched analysis, POES and FES achieved equivalent technical and clinical outcomes for naïve ZD. Although POES required slightly longer procedure time, it offered similar safety with shorter hospital stay. These findings support POES as a safe, effective, and feasible alternative to conventional FES in appropriately selected patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is the most common and potentially serious adverse event after ERCP. Because trypsin activation occurs at the earliest stage of pancreatitis, serum trypsin (TRY) may serve as a rapid biomarker for predicting PEP. Recently, a latex agglutination turbidimetric immunoassay has enabled quick and automated measurement of TRY, allowing immediate clinical use. This multicenter prospective study aimed to evaluate the diagnostic performance of TRY measured immediately and two hours after ERCP compared with conventional serum pancreatic enzymes.

Methods This multicenter prospective study was conducted at 12 tertiary centers in Japan between February 2024 and February 2025. TRY, serum amylase (AMY), pancreatic-type AMY (P-AMY), and lipase (LIP) were measured immediately after ERCP (0 h), and 2 h post-ERCP. All pancreatic enzymes were analyzed using a latex agglutination turbidimetric immunoassay, which provides results within minutes on standard automated chemistry analyzers.

The primary outcome was to evaluate the diagnostic performance of 0-h TRY and 2-h TRY for predicting PEP. Diagnostic accuracy was assessed using four cutoff strategies: (1) the optimal value yielding the highest area under the receiver operating characteristic curve (AUC) and (2) fixed cutoffs of 2 × , 2.5 × , and 3 × the upper limit of normal (ULN), based on previous studies. Secondary outcomes included comparisons of the AUC of TRY with AMY, P-AMY, and LIP at 0 h and 2 h using DeLong's test. For patients who developed PEP, the magnitude of enzyme elevation was expressed as a ratio to the respective ULN. PEP was defined and graded according to consensus and Cotton's criteria [1–4].

Results A total of 463 patients were analyzed, and 48 (10.3 %) developed PEP (mild 40, moderate 6, severe 2).The optimal 0-h TRY cutoff was 2043 ng/mL, yielding an AUC of 0.83, with 68.7 % sensitivity and 84.6 % specificity. When defined as multiples of the ULN, the sensitivity of 0-h TRY was 75 % at 2 × ULN, 71 % at 2.5 × ULN, and 69 % at 3 × ULN, while specificity increased stepwise (69 %, 76 %, and 81 %, respectively).The optimal 2-h TRY cutoff was 2436 ng/mL, with an AUC of 0.89, 81.2 % sensitivity, and 84.3 % specificity. Using ULN-based values, sensitivity was 92 % at 2 × ULN, 90 % at 2.5 × ULN, and 85 % at 3 × ULN, with corresponding specificities of 66 %, 74 %, and 78 %.

TRY outperformed conventional enzymes in early prediction. The AUC of 0-h TRY was significantly higher than those of AMY (0.74, p = 0.002), P-AMY (0.78, p = 0.007), and LIP (0.80, p = 0.048). At 2 h, 2-h TRY (AUC 0.89) remained significantly superior to AMY (AUC 0.84, p = 0.033) and comparable to P-AMY (AUC 0.89) and LIP (AUC 0.90). In addition, when cut-off values were defined as multiples of the ULN according to previous studies, AMY and P-AMY showed very low sensitivities at 0 h (≤ 44 %). Although their sensitivities improved at 2 h (AMY 60–69 %; P-AMY 52–77 %, depending on the threshold), they consistently remained inferior to those of 0-h TRY and 2-h TRY across all ULN-based cutoffs. TRY also tended to demonstrate higher sensitivity than LIP when fixed ULN-multiple thresholds were applied. Among patients who developed PEP, TRY showed the greatest proportional increase relative to ULN immediately after ERCP (median ratio: TRY 6.85, AMY 1.53, P-AMY 1.53, LIP 4.07). At 2 h, LIP exhibited the most pronounced elevation (median ratio: LIP 16.37, compared with TRY 13.52, AMY 3.03, P-AMY 5.02). These temporal patterns highlight the earlier rise in TRY compared with other pancreatic enzymes, underscoring its potential as the earliest measurable biochemical indicator of PEP. Taken together, these findings indicate that measuring 0-h TRY enables highly accurate prediction of PEP at an ultra-early stage, well before conventional pancreatic enzymes show meaningful elevation.

Conclusions TRY can be measured immediately after ERCP using a rapid, automated latex agglutination immunoassay, demonstrating superior early diagnostic performance compared with conventional pancreatic enzymes. This simple and rapid assay has the potential to improve the safety and efficiency of post-ERCP patient management by providing real-time risk assessment during the critical early phase of PEP development.

Conflicts of Interest Dr. Masayuki Kitano has received grants from Boston Zeon Medical, Medtronic, and Medicous Hirata outside the submitted work. All other authors have no conflicts of interest or financial ties to disclose. This study received funding from Sumitomo Bakelite.

Aims To systematically evaluate the association between pancreatic steatosis and the risk and severity of PEP.

Methods Systematic review and meta-analysis were conducted following PRISMA guidelines. MEDLINE, Embase, and Cochrane databases were searched through May 2025 for studies comparing PEP incidence in patients with and

without PS. Pooled relative risks (RRs) were calculated using random-effects models. Subgroup analyses examined the impact of demographic factors, procedural variables, and diagnostic indications.

Results Six studies involving 2,611 patients were included. PS was associated with a significantly increased risk of PEP [Relative Risk (RR):2.87; 95 % confidence interval:1.53–5.40; p < 0.001), with an incidence of 21 % in patients with PS compared to 8 % in those without. PS was also linked to higher risk of mild (RR: 2.79), moderate (RR: 5.73), and severe PEP (RR: 4.92). Compared to non-PS, patients with PS had higher prevalence of diabetes (RR: 1.41) and female sex (RR: 1.15). No significant differences in procedural variables or diagnostic indications were observed between the PS and non-PS groups.

Conclusions Pancreatic steatosis is associated with an increased risk and severity of PEP. Further high-quality prospective studies are warranted to validate this association and determine whether PS should be incorporated into pre-procedural risk stratification and targeted preventive strategies.

DOI 10.1055/s-0046-1820735

Aims Post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP) remains the most frequent adverse event after ERCP. Although rectal nonsteroidal anti-inflammatory drugs (NSAIDs) and aggressive intravenous hydration are guideline-recommended prophylactic strategies, the incremental benefit of combining both interventions compared with NSAIDs alone remains uncertain. We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) to assess the efficacy of NSAIDs plus aggressive hydration versus NSAIDs alone for PEP prevention.

Methods This review was conducted in accordance with PRISMA and registered in PROSPERO (CRD420251006252). Comprehensive searches of MEDLINE, Scopus, and the Cochrane Library were performed up to October 2025. Eligible studies included RCTs with patients undergoing ERCP, assigned to receive either rectal NSAIDs + hydration or NSAIDs. The primary endpoint was assessing PEP risk; secondary endpoints included post-ERCP amylase/lipase levels. Random-effects models (DerSimonian–Laird) were used to estimate pooled risk ratios (RRs) with 95 % confidence intervals (CIs). Statistical heterogeneity was assessed using I^2 statistics. Arm-specific PEP incidences were estimated via single-arm meta-analysis using the Freeman–Tukey transformation. Meta-regression on hydration volume in the form of a weighted linear regression analysis was performed. The certainty of evidence was assessed using GRADE.

Results Nine studies (7 fully published, 2 abstracts) encompassing 2,863 patients met the inclusion criteria. The pooled incidence of PEP was 3 % (95 % CI 1–6) in the NSAID + hydration group versus 7 % (95 % CI 5–9) with NSAIDs alone. The combined intervention significantly showed a reduction of PEP risk (RR 0.72; 95 % CI 0.54–0.96; p = 0.03; I^2 = 0 %). Sensitivity analysis restricted to fully published RCTs yielded consistent results (RR 0.73; 95 % CI 0.54–0.98). Subgroup analysis of studies explicitly excluding control-group with any hydration confirmed the benefit (RR 0.66; 95 % CI 0.45–0.96). Post-ERCP amylase (mean difference − 36.2 U/L; p = 0.07) and lipase (mean difference − 122.9 U/L; p = 0.37) reductions did not reach significance, but these outcomes were reported only by two and three studies respectively. Meta-regression revealed a dose-dependent association between higher hydration volumes and greater PEP risk reduction (p = 0.046). GRADE rated the certainty of evidence for the primary outcome as moderate, with importance deemed critical.

Conclusions This meta-analysis of RCTs shows that combining rectal NSAIDs with aggressive periprocedural hydration significantly reduces PEP risk compared with NSAIDs alone, with low heterogeneity and moderate-quality evidence. Given its safety, simplicity, and low cost, NSAID + hydration prophylaxis represents a pragmatic and potentially superior approach for PEP prevention when aggressive hydration is not contraindicated. Further adequately powered, standardized RCTs are warranted to define the optimal hydration protocol (type, timing, and volume).

DOI 10.1055/s-0046-1820736

Aims Endoscopic retrograde cholangiopancreatography (ERCP) has a pivotal role as an endoscopic procedure performed for the treatment of pancreatobiliary disorders. Post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP) is the most frequent and clinically relevant adverse event of ERCP, with an incidence ranging from 3 % to 10 % in unselected populations. Despite advances in pharmacologic and procedural prophylaxis, PEP still accounts for significant morbidity and hospital costs. While rectal NSAIDs and pancreatic stenting are well-established preventive measures, the potential role of chronic medications, particularly statins, acetylsalicylic acid (ASA), remains uncertain. This study aimed to assess the association between chronic drug therapy and the incidence and severity of PEP in a large Italian cohort.

Methods A retrospective single-center cohort study was conducted at the UOC of Gastroenterology and Endoscopy, Morgagni–Pierantoni Hospital (Forlì, Italy). Patients undergoing ERCP between January 2019 and June 2025 were included. Chronic pharmacological therapies were recorded and categorized (statins, ASA, thyroid hormones, antihypertensives, anticoagulants, and others). The primary endpoint was the association between chronic drug use and PEP occurrence; the secondary endpoint was the relationship between chron-

ic therapies and PEP severity. Multivariate logistic regression identified independent predictors of PEP.

Results A total of 1,001 patients that performed ERCPs were analyzed. The overall incidence of PEP was 6.4 % (n = 64), predominantly mild (90.3 %), with moderate and severe cases accounting for 6.5 % and 3.2 %, respectively. In univariate analysis, statin therapy was significantly less frequent among patients who developed PEP (9.4 % vs. 21.9 %; p = 0.018), suggesting a potential protective effect. Conversely, thyroid hormone use was more common in patients with PEP (15.6 % vs. 7.5 %; p = 0.02). In multivariate analysis, low BMI (OR 0.92, p = 0.034) and cirrhosis (OR 6.7, p = 0.005) emerged as independent risk factors, whereas statin therapy retained a significant protective association (OR 0.37, 95 % CI 0.15–0.89; p = 0.03). Thyroid hormone therapy did not remain significant after adjustment (p = 0.17). Prophylactic pancreatic stenting was associated with PEP (OR 0.34, 95 % CI 0.15–0.81; p = 0.016), likely reflecting selection bias due to its preferential use in high-risk patients.

Conclusions PEP is a complication influenced by clinical, anatomical, procedural, and pharmacological factors. In this large Italian cohort, chronic statin therapy was independently associated with a reduced risk of PEP, supporting its potential anti-inflammatory and endothelial- stabilizing role. Cirrhosis and low BMI were confirmed as strong predictors of PEP. Thyroid hormone therapy showed a possible association with greater PEP severity but did not retain significance after adjustment. These findings are exploratory and should be interpreted cautiously; prospective multicenter studies and randomized controlled trials are needed to confirm these findings.

OP082 Prospective multicenter evaluation of the ARCHIMEDES biodegradable pancreatic stent for the prevention of post-ERCP pancreatitis

Authors Marcellier G[1], Giovannini M[2], Rivallin P[1], Ratone JP[2], Hoibian S[2], Dahel Y[2], Jais B[1], Berri K[2], Solovyev A[2], Prat F[1], Caillol F[2]

Institutes **1** Hospital Beaujon AP-HP, Clichy, France; **2** Institute Paoli-Calmettes, Marseille, France

DOI 10.1055/s-0046-1820737

Aims Post-ERCP pancreatitis is the most frequent complication of ERCP. Two preventive measures are currently recommended: rectal indomethacin for all patients and temporary pancreatic stenting for those at high risk. However, stents may cause ductal injury, require follow-up imaging, and often need a second endoscopy for removal. A biodegradable stent could provide the same preventive benefit while avoiding these drawbacks. The ARCHIMEDES biodegradable pancreatic stent has demonstrated encouraging feasibility and safety results in preliminary studies. We conducted a prospective multicenter study to assess the safety, efficacy, and spontaneous clearance of this stent for the prevention of post-ERCP pancreatitis.

Methods A polymer resorbable stent (Archimedes, Q3 Medical, USA) with fast resorption (12 days) was positioned under endoscopic and fluoroscopic control during high-risk ERCP defined following ESGE guidelines (Endoscopic papillectomy, known or suspected sphincter of Oddi dysfunction, pancreatic sphincterotomy, precut sphincterotomy, pancreatic guidewire–assisted biliary cannulation, and papillar dilation) or the combination of 2 among 3 risk factors (Women gender, Thin biliary duct, history of pancreatitis). Patients signed informed consent. The main outcome was clearance of the stent at D-30 after ERCP.

Secondary outcomes included side effects (Pancreatitis among others, graded regarding AGREE classification) and the ability to technically insert the stent during the procedure. The study was single armed, multicenter (Paoli Calmette Institute, Marseille & France Beaujon Hospital, Clichy, France). We planned to include 46 patients in the study with 45 days of follow-up.

Results A total of 52 patients were included in the study. The median age was 65 years (IQR 20–93), and 55.8 % were male while 44.2 % were female.

Indications for pancreatic prophylactic stenting were the following: 22 patients underwent endoscopic papillectomy, 3 had sphincter of Oddi dysfunction, 18 underwent pancreatic sphincterotomy, 3 required an endoscopic precut, 1 underwent papillary dilation, 19 required double-guidewire technique for difficult biliary canulation, 11 had a narrow biliary duct, and 9 had a history of pancreatitis.

Regarding the primary outcome, 3 patients (5.8 %) still had residual stent fragments at day 30. None developed pancreatitis, and the stents fully resorbed during follow-up.

Technical success for stent insertion was 100 %.

Regarding ERCP-related complications, 4 patients (7.7 %) developed acute pancreatitis (mild to moderate, AGREE ≤ 2), 8 experienced bleeding (15 %) (AGREE = 3), 1 had a perforation (1.9 %), and 1 developed cholangitis (1.9 %); the latter two were also classified as severe (AGREE = 3).

Conclusions This is the first prospective study evaluating the benefit of Archimedes biodegradable stents in preventing acute pancreatitis during high-risk endoscopic procedures. No patient required subsequent endoscopy for stent removal. Because the study was single armed and involved high-risk interventions, analyzing complication rates is challenging; however, fewer than 8 % of patients developed pancreatitis, none of them being severe.

These findings are encouraging regarding the safety profile of Archimedes stents and support their potential use for preventing post-ERCP pancreatitis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP083 Pancreatic Duct Stenting to Prevent Post-ERCP Pancreatitis: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

DOI 10.1055/s-0046-1820738

Aims Prophylactic pancreatic duct (PD) stenting has been proposed to mitigate the risk of post-ERCP pancreatitis (PEP), particularly in high-risk populations. The aim of this study was to systematically review the evidence of the efficacy of prophylactic PD stenting in reducing the incidence of PEP in patients undergoing ERCP, including subgroup analyses of high-risk and average risk populations (▶ **Table 1**).

Methods A systematic review and meta-analysis were conducted according to PRISMA guidelines. Randomized controlled trials (RCTs) evaluating prophylactic PD stenting versus no stenting in adults undergoing ERCP were included. The primary outcome was incidence of PEP. Secondary outcomes included PEP incidence in high-risk subgroups, adverse events unrelated to PEP, mortality.

Results Eighteen RCTs comprising 4,637 participants (2,380 in the stent group and 2,257 in the no-stent group) were included. Prophylactic PD stenting significantly reduced the risk of PEP compared to no stenting (RR 0.45; 95 % CI 0.32–0.62), with moderate heterogeneity (I^2 = 57.2 %). In the subgroup analysis, stenting reduced PEP risk in high-risk and average-risk populations (RR 0.48; 95 % CI 0.31–0.73; I^2 = 66.4 % and RR 0.41; 95 % CI 0.25-0.69; I^2 = 41 %, respectively). The pooled incidence of adverse events unrelated to PEP was low (1 %; 95 % CI 0–3 %), and mortality rates did not differ between groups (RR 0.44; 95 % CI 0.09–2.07).

Conclusions Prophylactic PD stenting appears to significantly reduce the risk of PEP, in both high- and average-risk patients. However, considerable heterogeneity and methodological limitations across studies highlight the need for future trials to refine patient selection, stent characteristics and combination of prophylactic strategies.

DOI 10.1055/s-0046-1820739

Aims The detection and resection of adenomatous polyps during colonoscopy decrease the incidence of colorectal cancer and associated mortality [1, 2] with adenoma detection rate (ADR) being a key quality performance indicator. While higher ADR is associated with lower post-colonoscopy colorectal cancer (PCCRC) rates, the latter varies significantly across the UK, and the true 'baseline' ADR is unknown [3, 4]. Meeting the rising demand for high quality colonoscopy is a significant challenge.

The use of computer assisted detection (CADe) is associated with a significant improvement in ADR across multiple clinical trials [5, 6], but real-world performance data is lacking.

We sought to evaluate effect on adenoma detection of implementing CADe in a 'real-world' setting, in the largest such study to date.

Methods This was randomised; stepped-wedge, open-label trial evaluated the site-level effect of the GI Genius (GIG) computer-aided detection (CADe) system on adenoma detection. Both District General Hospitals and Teaching Hospitals participated, with procedures performed by expert (≥ 2,000 lifetime colonoscopies; PDR > 40 %) and non-expert (< 2,000 lifetime colonoscopies) endoscopists.

All patients undergoing routine colonoscopy were eligible, excluding those attending for polyp or IBD surveillance. The study reflected real-world practice, with no procedural modifications other than CADe activation.

Data were collected over three consecutive 3-month phases: Phase 1 (baseline; CADe inactive), Phase 2 (intervention; CADe active), and Phase 3 (post-intervention; CADe withdrawn).

The primary outcome, adenoma detection rate (ADR), was analysed using generalised linear mixed-effects models, with study phase, patient age, endoscopist gender and expertise, bowel preparation quality, hospital type, and withdrawal time as fixed effects, and site and endoscopist as random effects to account for clustering.

Results Between November 2023 and February 2025, 4,514 colonoscopies from 25 hospitals (England, Scotland, Wales) were analysed. ADR increased from 30.0 % in Phase 1 to 34.8 % during the GI Genius intervention (Phase 2) and declined to 27.6 % post-intervention ($p < 0.001$) (▶ **Table 1**). After adjustment, Phase 2 was associated with a 17 % higher ADR (aOR 1.17, 95 % CI 1.01–1.35, $p = 0.040$). Older age, endoscopist expertise, male gender, and withdrawal time independently predicted higher ADR.

Endoscopy 2026; 58: S1–S1041

▶ **Table 1** Adenoma detection rates across the three phases

	Phase 1	Phase 2	Phase 3	p-value
Overall ADR	30.0 % (27.8–32.3)	34.8 % (32.4–37.3)	27.6 % (25.3–29.9)	<0.001
Average Site	29.9 % (7.9; 16.4–45.3)	34.3 % (8.9; 14.7–47.9)	27.9 % (7.4; 15.2–44.2)	0.001†
DGH	27.3 % (24.6–30.2)	35.0 % (31.9–38.2)	27.6 % (24.8–30.6)	<0.001
TH	34.4 % (30.7–38.3)	34.5 % (30.9–38.4)	27.5 % (24.0–31.3)	0.014
Expert	33.8 % (29.9–37.8)	37.6 % (33.6–41.9)	30.7 % (26.7–35.0)	0.068
Non-expert	28.0 % (25.3–30.8)	33.3 % (30.3–36.3)	26.1 % (23.4–28.9)	0.002

Conclusions CADe use was associated with an average 4 % absolute and 17 % relative increase in adenoma detection after adjustment for covariates. However, this effect was not sustained following system withdrawal. These findings support the integration of real-time CADe to enhance colonoscopy quality, while emphasising the importance of preserving endoscopist skill and long-term performance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820740

Aims Computer-aided detection (CADe) can improve colonoscopy adenoma detection rates (ADR). However, prolonged exposure to repeated alerts may lead to alert fatigue, potentially diminishing its effectiveness. We aimed to determine whether alert fatigue occurs during CADe use and, if so, how it influences ADR throughout the day [1–5].

Methods We conducted a secondary analysis of a prospectively collected cohort to evaluate how ADR varied with and without CADe in a pragmatic, real-world implementation. Elective colonoscopies performed at the University of Montreal Hospital Center were analyzed according to their position within the endoscopist's daily schedule. The primary outcome was ADR across procedure order, adjusted for withdrawal time (WT). Secondary outcomes included adenomas per colonoscopy (APC), ADR by time of day, and ADR across different WT categories.

Results A total of 1,700 colonoscopies were analyzed, including 880 with CADe assistance and 820 without. In the CADe-unassisted group, ADR remained stable throughout the day (1st–3rd procedures: 39.4 %, 95 % CI [35.1–43.8]; 4th–7th procedures: 40.9 %, 95 % CI [32.9-49.5]). By contrast, ADR in CADe-assisted procedures was markedly higher in the first three procedures (49.9 %, 95 % CI [45.5–54.3]) but dropped significantly to 39.9 % (95 % CI [33.8–46.3]) in later procedures. This pattern was consistent when ADR was assessed by time of day. Similarly, APC were significantly higher in early CADe-assisted procedures (mean increase + 0.27, 95 % CI [0.14–0.41], p < 0.001), but this benefit disappeared in later procedures (+ 0.11, 95 % CI [−0.09–0.31], p = 0.51). WT analysis further supported this effect: ADR gains per additional minute were higher in unassisted colonoscopies (21.6 % early vs. 15.3 % late) than in CADe-assisted colonoscopies (10.5 % early vs. 10.1 % late).

Conclusions CADe assistance significantly improved ADR during early-day colonoscopies, but this benefit disappeared in later-day procedures. This pattern suggests that alert fatigue may limit endoscopists' responsiveness to CADe prompts as the day progresses.

Problem to solve The Lewis Score (LS) is an established capsule endoscopy (CE) index for grading small-bowel inflammation in Crohn's disease (CD) and guiding therapy decisions. However, deriving an LS requires full CE video review, making it time-consuming and prone to inter-observer variability. As the number of CE procedures grows, manual scoring has become increasingly impractical. While most AI models operate at the frame level, clinical interpretation depends on the study level. Bridging this gap requires automated tools that provide both accuracy and interpretability at clinically meaningful LS thresholds.

Innovation We developed a video-level classification framework that transforms frame-wise probabilities into interpretable temporal features, facilitating automated LS classification across severity thresholds. A fine-tuned convolutional network produced frame probabilities for four categories: normal mucosa, ulcer, stricture, and uninterpretable frames. From these probabilities, we derived 42 summary features for each study, including the longest contiguous ulcer sequence, the duration above high-probability thresholds, and the distribution of ulcer and stricture signals throughout bowel segments [1–3].
These features served as inputs to logistic regression and a multilayer perceptron (MLP). In parallel, a 1D convolutional neural network (CNN) with attention operated directly on the sequence of per-frame probabilities. We evaluated how accurately these models assigned videos above vs below predefined LS thresholds (▶ **Table 1**).
The dataset included 1,135 CE videos analyzed using five-fold, patient-grouped cross-validation to prevent patient leakage and ensure robust generalization. Models were trained and tested across LS thresholds of ≥ 135 (mild), ≥ 790 (moderate), and ≥ 2000 (severe).

Results Across thresholds, models achieved substantial and consistent discrimination. Average AUROC reached 0.81 (95 % CI 0.79–0.83) at LS ≥ 135, 0.89 (0.89–0.90) at LS ≥ 790, and 0.88 (0.82–0.91) at LS ≥ 2000. Sensitivity and specificity were well balanced (≈ 0.7–0.8 and 0.82–0.85, respectively). CNN attention maps consistently highlighted the distal third of the small bowel—where Crohn's pathology typically peaks—while logistic regression and MLP importance analyses emphasized ulcer burden and distal involvement. The convergence between spatial attention and feature-level importance provides explainability and supports the clinical plausibility of the approach. These results show that video-level LS classification can be achieved without direct manual annotation of the entire video, using only frame-wise probabilities as input.

Conclusions Frame-wise probabilistic outputs enabled video-level models to distinguish between various studies across multiple LS thresholds effectively. This framework also provided interpretable, threshold-specific feature profiles offering insights into relevant characteristics at different LS thresholds that are consistent with expected patterns. These results indicate promise for triage support; however, external, multi-centre validation, calibration, and prospective assessment within clinical workflows are necessary. This work was performed with a generous support of the Leona M. and Harvey B. Helmsley Foundation.

▶ **Table 1** Performance Metrics by Model and Threshold

Model	AUROC (95 % CI)	Sensitivity (95 % CI)	Specificity (95 % CI)
LS ≥ 135			
Logistic Regression	0.832 (0.810–0.854)	0.701 (0.679–0.723)	0.895 (0.857–0.932)
MLP	0.793 (0.767–0.817)	0.705 (0.684–0.728)	0.745 (0.692–0.796)
CNN (1D + attention)	0.806 (0.806–0.806)	0.709 (0.709–0.709)	0.819 (0.819–0.819)
LS ≥ 790			
Logistic Regression	0.897 (0.880–0.915)	0.787 (0.750–0.825)	0.856 (0.838–0.873)
MLP	0.889 (0.871–0.906)	0.810 (0.776–0.846)	0.827 (0.808–0.846)
CNN (1D + attention)	0.888 (0.869–0.907)	0.726 (0.686–0.771)	0.876 (0.860–0.893)
LS ≥ 2000			
Logistic Regression	0.907 (0.866–0.956)	0.851 (0.774–0.929)	0.876 (0.861–0.891)
MLP	0.908 (0.872–0.947)	0.851 (0.774–0.931)	0.859 (0.843–0.876)
CNN (1D + attention)	0.818 (0.818–0.818)	0.809 (0.809–0.809)	0.798 (0.798–0.798)

DOI 10.1055/s-0046-1820742

Aims In recent years, several studies have evaluated artificial intelligence (AI)-powered optical-diagnosis systems (CADX) in characterization. Accurate real-time characterization of colorectal lesions can substantially reduce pathology-related costs and procedure time. However, studies are lacking in the Middle East populations which differ in endoscopist training, disease prevalence and adherence to colorectal cancer (CRC) screening recommendations. Given the rising incidence of CRC in this region and limited implementation of organized screening programs, it is critical to evaluate whether AI-driven optical diagnosis can be effectively optimized for local clinical practice. This multicenter RCT is the first in the Middle East to assess the real-time performance of CADx in polyp characterization and its potential role in implementation of resect-and-discard strategies [1–3].

Methods A prospective RCT across seven healthcare centers in Egypt, Bahrain, Iran, Jordan, Saudi Arabia, and Kuwait. Expert endoscopists performed colonoscopies in patients aged 40–80 using AI-equipped colonoscopes (CAD EYE, Fujifilm). The primary endpoint was sensitivity for neoplastic polyps by CADx and visual inspection, compared with histopathology. Secondary end points were specificity and diagnostic accuracy.

Results Overall, 523 polyps in 441 patients were documents (n = 200 adenomas, n = 323 hyperplastic polyps). CADx demonstrated a sensitivity of 64.8 %, specificity 91.1 %, positive predictive value (PPV) of 87.7 % and negative predictive value (NPV) of 72.7 % for neoplastic polyps. Expert endoscopists had a sensitivity of 91.6 %, specificity of 55.4 %, PPV of 60 % and NPV of 90 %. The overall diagnostic accuracy was **78.0 %** for CADx versus **70.7 %** for endoscopists ($p < 0.05$).

Conclusions This is the first multicenter RCT in the Middle East to evaluate real-time AI-assisted optical diagnosis of colorectal polyps. CADx achieved higher specificity and diagnostic accuracy than expert visual assessment, suggesting its potential role in improving efficiency, reducing unnecessary pathology submissions, and enabling safe resect-and-discard practice in the region. Future research should focus on algorithmic tuning for regional lesion characteristics and cost-effectiveness modeling to inform large-scale adoption.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820743

Aims Although several AI-based endoscopic diagnostic systems for early gastric cancer have been developed in East Asia, their clinical utility remains limited due to false-positive detections. On the other hand, magnifying endoscopy with narrow-band imaging (M-NBI) has already been established as a useful diagnostic modality. To improve endoscopic diagnostic accuracy, we developed an AI system using M-NBI (M-NBI AI) and conducted a multicenter prospective study to evaluate its real-time performance and incremental benefit to endoscopists.

Methods From July 2022 to October 2023, M-NBI was performed in patients with high risk of gastric cancer at four Japanese institutions. When gastric lesions needed to be distinguished as cancer or non-cancer, biopsy was performed. A total of 241 M-NBI videos (early gastric cancer: 126, non-cancerous lesion: 115) from these procedures were collected prospectively and randomly edited into a test format for answering by 32 endoscopists. Using the answer software, endoscopists submitted their diagnostic results of collected videos, classified as cancer or non-cancer. As the initial comparison test, diagnostic accuracy, sensitivity, specificity, PPV, and NPV were compared with those of M-NBI AI. Six months later, a second test of same videos was conducted to assess the additive benefit of AI support by allowing endoscopists to make diagnoses with reference to the AI results. The endoscopists were divided into expert and non-expert groups, and these comparisons with AI were performed for all endoscopists, experts, and non-experts.

Results Diagnostic performance (accuracy/sensitivity/specificity/PPV/NPV) was: **M-NBI AI:** 80.1 % [74.5-84.9]/ 93.7 % [87.9-97.2] / 65.2 % [55.8-73.9]/ 74.7 % [67.2-87.3]/ 90.4 % [81.9-95.7], **All endoscopists:** 68.9 % [67.9-70.0] / 65.4 % [63.9-66.8] / 72.9 % [71.4-74.3] / 72.5 % [71.0-74.0] / 65.7 % [64.3-67.2], **Experts:** 73.7 % [72.0-75.4] / 69.6 % [67.1-72.0] / 78.3 % [75.9-80.5] / 77.8 % [75.4-80.1] / 70.2 % [67.7-72.5], **Non-experts:** 66.4 % [65.1-67.7] / 63.1 % [61.2-65.0] / 70.0 % [68.1-71.8] / 69.8 % [67.9-71.6] / 63.4 % [61.5-65.2]. With AI assistance, diagnostic performance improved as follows: **All endoscopists:** 77.7 % / 77.0 % / 78.6 % / 79.8 % / 75.7 %, **Experts:** 80.0 % / 81.7 % / 78.1 % / 80.3 % / 79.5 %, **Non-experts:** 75.9 % / 73.0 % / 79.0 % / 79.2 % / 72.8 %. M-NBI AI showed significantly higher accuracy, sensitivity, and NPV than the average of all endoscopists, and higher sensitivity and NPV compared with experts. In addition, M-NBI AI support significantly improved diagnostic performance in most metrics, particularly among non-experts.

Conclusions M-NBI AI demonstrated superior diagnostic performance compared with endoscopists. When used as an assistive tool, it is particularly effective for non-expert endoscopists and may contribute to standardizing diagnostic quality and improving early gastric cancer detection in clinical practice.

OP089 EUS-Guided Radiofrequency Ablation for IPMNs with Worrisome Features: Promise or Illusion?

Authors Barthet M[1], Barras J[2], Lorenzo D[3], Gasmi M[1], Gonzalez JM[4]
Institutes **1** Hospital Nord, Marseille, France; **2** Hospital De La Citadelle (CHR), Liège, Belgium; **3** Hospital Beaujon AP-HP, Clichy, France; **4** Hôpital Nord, Marseille, France
DOI 10.1055/s-0046-1820744

Aims Branch-duct intraductal papillary mucinous neoplasms (BD-IPMNs) are precancerous cystic lesions. Surgery is advised for high-risk stigmata (HRS) or multiple worrisome features (WF) but entails substantial morbidity, and many resections reveal only low-grade dysplasia. Endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) is a minimally invasive alternative, yet long-term data are limited (▶ **Table 1**).

▶ **Table 1** WF/HRS at baseline and local control/complete response after EUS-RFA in BD-IPMN (N = 52)

	Mural nodule ≥ 5mm	22 (42 %)	21/22	2/22
HRS	Obstructive jaundice	0 (0 %)	0	0
	Main pancreatic duct ≥ 10mm	0 (0 %)	0	0
WF	Rapid growth (≥ 5 mm over 2 years)	24 (46 %)	24/24	5/24
	Mural nodule ≤ 5mm	10 (192 %)	10/10	0
	Cyst ≥ 30mm	12 (23 %)	12/12	0
	Pancreatitis due to the IPMN	13 (25 %)	12/13	0
	Thickened/enhancing cyst wall	10 (19 %)	10/10	1/10
	Main duct size 5-9mm	6 (11.5 %)	6/6	0
	Abrupt change in caliber of main pancreatic duct with distal pancreatic atrophy	2 (4 %)	2/2	1/2
	New onset diabetes at diagnosis	2 (4 %)	2/2	0
Number of HRS and WF per treated IPMN	0	1	1/1	1/1
	1	26	26/26	7/26
	2	12	11/12	1/12
	3	9	9/9	0/9
	4	3	3/3	0/3
	5	1	1/1	0/1

Methods We retrospectively analyzed a prospectively maintained cohort of consecutive patients who underwent EUS-RFA for BD-IPMNs with WF/HRS at a tertiary referral center (2015–2024). Eligible patients were inoperable or declined surgery. Outcomes included technical success, adverse events (AEs), local control (resolution of WF/HRS with no cancer arising from the treated lesion), radiologic response, and pancreas-wide events.

Results Fifty patients (62 procedures; 58 lesions) were treated. Mean follow-up was 4.1 ± 2.8 years after RFA (9 years from IPMN diagnosis). Technical success was 100 %. AEs occurred in 27 %, mostly mild abdominal pain; significant AEs occurred in 8 % (acute pancreatitis); there were no procedure-related deaths. Local control was achieved in 98 % of lesions; 17 % showed complete radiologic disappearance and 86 % decreased in size. No treated lesion progressed to cancer. Pancreas-wide disease control was maintained in 80 % of patients; four (8 %) developed pancreatic cancer remote from the treated cyst. Smaller cyst size and fewer WF were associated with better outcomes.

Conclusions EUS-RFA is feasible, safe, and provides durable local control of BD-IPMNs with WF/HRS in patients unsuitable for surgery or declining resection. These results support EUS-RFA as a promising therapeutic option in carefully selected patients. Larger prospective studies are needed to refine selection criteria and confirm long-term oncologic benefit.

Foundation Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; **4** San Camillo Forlanini Hospital, Roma, Italy; **5** University Hospital St. Pölten, Sankt Pölten, Austria
DOI 10.1055/s-0046-1820745

Aims To present, on behalf of the OSPREY Registry Investigators, the first interim analysis of outcomes for patients with unresectable locally advanced pancreatic cancer (uLAPC) treated with EUS-guided Phosphorus-32 (^{32}P) microparticle implantation plus chemotherapy and enrolled in the OSPREY registry.

Methods OSPREY is a post-market, multi-centre, observational, prospective registry in which data is recorded from patients with uLAPC receiving gemcitabine-based chemotherapy who had EUS-guided implantation of ^{32}P microparticles (OncoSil Medical) device as part of their routine clinical care. Enrolment commenced April 2022 and is ongoing. Registry objectives include safety/tolerability (Adverse Device Effects [ADEs] possibly or probably related to ^{32}P device and/or implantation) and efficacy outcomes.

Results At 1 August 2025, 64 patients (median age 66.5 years; 50 % female) had enrolled in the registry from 19 centres in Austria (3 patients [4.7 %]), Italy (12 [18.8 %]), Greece (12 [18.8 %]) and Spain (37 [57.8 %]). 48 (75 %) patients had ^{32}P microparticles implanted during 1st-line chemotherapy, 25 (39.1 %) at ≤ 4 months from chemotherapy start and 22 (34.4 %) at 4–12 months of chemotherapy start; 14 (21.9 %) patients were implanted during 2nd-line chemotherapy, primarily (17.2 %) at ≤ 4 months of commencing 2nd-line chemotherapy. In total, 15.6 % of patients reported ADEs. All ADEs were considered mild; 9 (14.1 %) patients reported Grade 1 abdominal pain and 1 (1.6 %) reported Grade 2 asthenia/fatigue, also possibly related to chemotherapy. All ADEs were anticipated, transient, managed conservatively and resolved without clinical sequelae. There were no Grade > 3 or serious ADEs (SADEs), no acute complications, no pancreatitis and no patient required hospital admission. The Local Disease Control Rate at 12 weeks post-implant (alive; no tumour progression) was 91.4 % in 1st-line chemotherapy patients and 77.8 % at 2nd-line. To date, 7 patients had their tumours surgically resected with curative intent: 3 implanted ≤ 4 months from starting 1st-line chemotherapy, 3 implanted at 4–12 months from starting 1st-line chemotherapy, and 1 implanted ≤ 4 months from starting 2nd-line chemotherapy; 5/7 (71.4 %) patients had R0 resection margins and 2/7 (28.6 %) had R1 margins. In 50 patients with imaging follow-up, pro-

Endoscopy 2026; 58: S1–S1041

gressive disease (PD) was more frequently reported at distant sites (26.0 %) *vs.* locally (14.0 %) or synchronously (2.0 %); 1 (2.0 %) patient died without imaging and no PD was observed in 56.0 % to date. Median Overall Survival was 20.6 months (95 % CI 16.9–20.1) from diagnosis and 17.3 months (95 % CI 15.7–23.7) from starting chemotherapy in patients implanted at ≤ 4 months from starting 1st-line chemotherapy, 22.0 months (95 % CI 17.2–22.7) from diagnosis and 20.0 months (95 % CI 16.0–22.2) from starting chemotherapy in patients implanted at 4–12 months from starting 1st-line chemotherapy, and 17.0 months (95 % CI 11.3–20.0) from diagnosis and 10.5 months (95 % CI 8.4–12.9) from starting 2nd-line chemotherapy in patients implanted ≤ 4 months from starting 2nd-line chemotherapy.

Conclusions EUS-guided implantation of ^{32}P microparticles added to chemotherapy for patients with uLAPC receiving routine clinical care was safe and well tolerated, and appears to provide local disease control, downstaging to surgical resection in a proportion of patients and encouraging overall survival. Enrolment in the registry is ongoing and follow-up continues.

OP091 Endoscopic ultrasound guided radiofrequency ablation for treatment of pancreatic neuroendocrine tumors- disappointing results after 3 years experience?

Authors Tsvetkov M[1], Petkova Y[2], Karagyozov P[3]

Institutes **1** Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofi, Bulgaria; **2** Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofia, Bulgaria, Sofia, Bulgaria; **3** Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofia, Bulgaria

DOI 10.1055/s-0046-1820746

Aims Endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) is an emerging minimally invasive therapeutic technique that represents a promising alternative for selected patients with both functional (F-) and non-functional (NF-) pancreatic neuroendocrine tumors (PanNETs). The aim was to present the initial experience, focusing on safety and efficacy.

Methods A retrospective analysis of a prospective database was performed. We included all consecutive patients with PanNETs treated with EUS-RFA between August 2022 and July 2025. Baseline patient characteristics, procedural parameters, and therapeutic outcomes were collected from electronic medical records. We analysed data on technical aspects of the procedure- size of electrode, system settings, number of applications per session and number of sessions. Primary endpoint was the technical success, defined as successful insertion of the electrode into the target lesion. Secondary endpoint was the rate of complete response, defined as not detectable lesion on CT scan at 3 or 6 months follow-up.

Results A total of 13 EUS-RFA sessions were performed in 11 patients (mean age 68.64 years, 64 % female). The mean lesion size was 16.52 mm. All lesions were **well-differentiated G1 PanNETs** (Ki-67 ≤ 2 %). According to lesion type, 54,5 % (N = 6)were nonfunctioning pancreatic neuroendocrine tumors (NF-PanNETs) and 45.5 % (N = 5) were functioning (F-PanNETs, all insulinomas). Procedures were performed using a 10mm **19G EUSRA needle (Taewoong Medical, South Korea)**. Power settings were **50 W**, with **1–6 applications per session**. Technical success was achieved in 100 % of patients.Complete radiologic response (defined as 100 % absence of viable tissue) after 3 months postprocedure was observed in 27.27 % (N = 3) of cases — two patients with F- and one patient with NF-PanNET. A partial response was observed in36,4 % (N = 4) of cases, while in two patients follow-up imaging studies are still not performed. Two patients were lost to follow-up and also two patients underwent a second ablation session 3 months after the first session, resulting in additional tumor reduction. Complete resolution of symptoms related to hormonal hypersecretion was documented in 100 % of patients with insulinoma after EUS-RFA. Adverse events included one case (N = 1; 9.09 %) of gastrointestinal bleeding from the puncture site due to a duodenal ulcer, successfully managed endoscopically and **three cases (27.3 %) of transient asymptomatic hyperamylasemia**. No pancreatitis or procedure-related mortality occurred. Median follow-up was 12 **months (range 2–35 months)**. Lesions located in the pancreatic head tended to show better radiologic outcomes, whereas those in the uncinate process demonstrated a less pronounced response to ablation. Smaller lesions (< 1 cm) appeared to respond more effectively than larger ones.

Conclusions The procedure is feasible, safe and highly effective in treating insulinoma. The symptoms disappear in 100 % of patients despite not achieving complete radiological response in some cases. No recurrent symptoms were observed after at least 6 months follow-up. In cases of NF NETs the effectiveness of the procedure remains unclear. The most appropriate settings of the system and number of sessions remain to be clarified. Unified follow-up protocol is also needed and clear definition of complete response needs to be established. Probably the delayed immunological effect of RFA needs also to be taken into account.

DOI 10.1055/s-0046-1820747

Aims Percutaneous radiofrequency ablation (PT-RFA) is an established curative treatment for early-stage hepatocellular carcinoma (HCC) [1, 2]. In some patients the percutaneous route can be technically challenging, particularly for lesions located in the caudate or left hepatic lobe close to the stomach, or those adjacent to major vascular structures and the gallbladder. Endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) has recently emerged as a minimally invasive alternative option for solid hepatic lesions difficult or impossible to treat percutaneously. The evidence supporting its use mostly to treat hepatocellular carcinoma (HCC) remains limited to few case reports and one case series [3–7]. We report our experience in utilizing EUS-RFA for hepatic solid lesions over a 3-year period.

Methods Retrospective single center study performed in patients who underwent endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) for liver lesions at our institution between April 2021 to July 2024. Patients were selected during a multidisciplinary meeting involving hepatologists, surgeons, interventional radiologists, oncologisyts, and endoscopists. All the procedures were performed with EUSRA (Taewoong Medical, Gyeonggi-do, South Korea) 19-gauge needle, attached to a dedicated VIVA RFA generator (starMed, South Korea) and a cooling system. Before EUS-RFA, contrast enhancement was utilized to delineate the lesion. Multiple RFA passes were performed inside the lesion, with attention to fully ablate the margins. Need for further RFA passes was re-evaluated using contrast enhahcement. The primary outcome was treatment efficacy, defined as radiological response at 1 month according to modified RECIST (mRECIST) criteria [8]. Alpha-fetoprotein (AFP) levels were also measured at the 1-month follow-up. Secondary outcomes included the assessment of tumour control at 3 and 6 months and recurrence during follow-up, technical success and safety.

Results Overall seven patients (6 HCC, 1 intrahepatic cholangiocarcinoma) were treated with a mean age of 70 ± SD; M:F 6:1. All patients with HCC were cirrhotic, with HCC classified as BCLC stage 0 or A [9]. Two patients had a Child-Pugh score (CPS) of B7, one of whom presented with mild ascites. The iCCA patient had no underlying liver disease and presented with extrahepatic spread. Technical success was achieved in all cases. All but one patient underwent sin-

gle session RFA. Among HCCs patients, all patients achieved complete response (CR) at 1 month evaluated with computed tomography. AFP levels decreased in all HCC patients at 1-month post-procedure, with the exception of one patient who presented an additional lesion in segment VII. At the 3-month radiological follow-up, all cases maintained response to treatment. The patient with the largest lesion (33x28 mm), who had previously declined surgical resection, had disease progression (PD) at 6 months CT-scan and underwent a second EUS-RFA session, but ultimately progressed. The iCCA patient achieved complete response of the treated lesion at 1 month, consistent with local control. At a mean follow-up of 24 months, PD occurred only in the patient who had partial response at 6 months follow-up; all other patients maintained durable local response. Two minor transient mucosal bleeding occurred and were successfully treated endoscopically, with no severe adverse events [10].

Conclusions Our findings suggest that EUS-RFA is technically highly feasible and safe, even in cirrhotic patients with borderline liver function for thermal ablation treatment. Complete response, for small HCCs, can be achieved in more than 80 % of cases in a single treatment and without recurrence at 2-year. Selected iCCA cases unsuitable for conventional ablation routes may also be considered for EUS-RFA.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820748

Aims Intraductal radiofrequency ablation (ID-RFA) is increasingly used as an adjunct to stenting in patients with unresectable perihilar cholangiocarcinoma (pCCA). Two dedicated catheters are available in routine practice, the bipolar ELRA probe and the monopolar Habib probe, but comparative data on technical performance and safety in pCCA are scarce. We aimed to compare technical success and adverse events rates of ID-RFA performed with these two probe types in inoperable pCCA.

Methods We performed a multicentric retrospective analysis of ID-RFA delivered through endoscopic retrograde cholangiopancreatography (ERCP) in patients with inoperable pCCA. Key inclusion criteria included a confirmed diagnosis of pCCA and endoscopic therapy in a palliative setting. Exclusion criteria included ID-RFA in previously placed metallic stents (defined as secondary RFA). Owing to differences in treatment protocols in each participating unit, some patients underwent multiple ID-RFA sessions. Accordingly, each ERCP with RFA was analyzed as a separate procedure. Demographic, tumor- and procedure-related variables, including Bismuth classification, number of territories treated, RFA settings and stent type were collected in a standardized database. The primary outcomes were technical success (successful delivery of RFA and planned stent placement across all targeted strictures) and procedure-related adverse events (AEs). Comparison of outcomes in the Habib and ERLA groups was performed using χ^2/Fisher's exact tests for categorical variables and t tests for continuous variables. A multivariable logistic regression explored independent predictors of AEs.

Results Overall, 225 ID-RFA procedures were performed in 143 patients (106 Habib, 119 ELRA). Mean patient age was 67.3 years (SD 10.7) and mean bilirubin levels prior to the procedure was 7.01mg/dL (SD 16.1). Disease stage differed between groups: Habib was used significantly more often in advanced hilar strictures (Bismuth ≥ III: 86.8 % vs 46.2 % for ELRA; $p < 0.001$). Technical success was 100 % (106/106) for Habib and 99.1 % (116/117) for ELRA ($p = 1.00$). Overall, AEs occurred after 47/225 procedures (20.9 %). The AE rate was higher with Habib than with ELRA (27.4 % [29/106] vs 15.1 % [18/119]; $p = 0.03$). Cholangitis was the most frequent AE (57 % of all AEs), followed by bleeding ($n = 5$), cholecystitis ($n = 3$) and pancreatitis ($n = 1$) including 7 severe adverse events, according to the AGREE classification. In a multivariable logistic regression adjusting for age, Bismuth grade, cholangitis severity, territories treated and individual endoscopy center, pre-procedure cholangitis and endoscopy center were the only significant independent predictors of adverse events. Each increase in Tokyo cholangitis grade more than doubled the risk of AEs (aOR 2.65, $p = 0.003$). After adjustment for these factors, probe type (Habib vs ELRA) was not significantly associated with AE risk (aOR 0.13, $p = 0.051$). Patient age, stricture grade and number of territories treated with ID-RFA were not significant predictors of AE.

Conclusions To our knowledge, this is the first multicenter retrospective cohort study comparing technical and safety outcomes of the ELRA and Habib probes. While use of both probe types was associated with very high technical success rates in terms of safety outcomes, the Habib probe was identified as a potential risk factor of procedure-related adverse events, however significant differences of outcomes between centers were noted, most likely because of differences in probe use related to the complexity of the endoscopic procedure. As a result, further prospective studies should focus on exploring the safety

profiles of each probe type and clarify the best way to deliver ID-RFA in this clinical setting.

DOI 10.1055/s-0046-1820749

Aims Ex vivo experiment showed that sugar added to an isotonic solution decreases conductivity in endothelial cells and rapidly increases heat when associated with radiofrequency ablation.

Endoscopic ultrasound sugar-augmented radiofrequency ablation (EUS-SARFA) in pancreatic perivascular space increased pancreatic necrosis and facilitated pancreatectomy in a swine model. Our aim is to analyze the sugar booster effect on radiofrequency ablation in a swine pancreatic model according to three different devices/systems with different combinations of setting for a same energy of 300 joules (Watts x seconds).

Methods Eighteen swine pancreatic glands were harvested en bloc. A prospective monocentric ex vivo study evaluated three different radiofrequency ablation (RFA) systems/devices (Taewoong medical South Korea, F Care Systems Belgium and Covidien France) and each were tested on six perfused pancreatic models. Using an ultrasound (US) miniprobe two parallel thermometric probes were positioned near the ablation site to record tissue temperature before, during and after pancreatic perivascular SARFA [1–4].

54 RFA procedures were performed—three per pancreas—delivering 300 Joules of energy using different combinations of power (Watts = W) and time (seconds = s).

In one of the 3 RFA systems/devices (Taewoong medical South Korea), the RFA generator also recorded maximum impedance (Ohms) for each setting.

In 12 pancreases (36/54 ablations), under US guidance, RFA was applied after injection of

1 mL of 50 % glucose solution into the pancreatic parenchyma (head, body, and tail sites). In the remaining six pancreases (18/54 ablations), RFA was performed using either 0.9 % saline injection (n = 9) or without any adjunct (alone) (n = 9). All pancreases were evaluated using histopathological analysis with three-dimensional measurements, US and 1.5 Tesla magnetic resonance imaging (MRI) to assess the extent of tissue ablation. MRI ablation volumes were segmented from T1 sequences using 3DSlicer software (open source, BSD licence).

Results Both histopathology and T1-weighted MRI consistently demonstrated that SARFA using 40W-7.5s and 75W-4s produced significantly larger ablation and necrotic volumes compared to RFA with saline or alone. Although the 10W-30s resulted in smaller overall ablation volume at MRI they had greater histopathological necrosis than RFA with saline and alone groups.

The splenic vessels (artery and vein) were intact after all ablations in the pancreatic tissue near them, maybe related to the controlled necrosis created by sugar-augmented RFA.

SARFA also achieved higher intrapancreatic temperatures (45.63 °C [23.3-59.5] in SARFA, 8.65 °C [6,9-10,4] in saline, and 37,23 °C [27.7-53.8] in RFA alone) which were inversely correlated to the impedance which reflects a better heat conductivity when compared with RFA alone (430.5 Ohms [350-622] in SARFA, 327.3 Ohms [128-450] in saline-RFA; and 679.3 Ohms [222-916] in RFA alone).

Conclusions SARFA applied to the pancreatic perivascular tissue in an ex vivo swine model showed controlled necrotic ablation when compared with saline-RFA and RFA alone. This was due to induced sugar better heat conductivity using specific settings for 300 joules of energy. These results should be confirmed by a second a preclinical phase. This technique could be promising for dowstaging in pancreatic cancer surgery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

How to drain a walled off necrosis without drowning

14/05/2026, 15:30–16:30 **Sky 2**

OP095 Comparison of outcomes of bi-flanged metal stent alone versus bi-flanged metal stent with co-axial plastic stent in endoscopic ultrasound-guided drainage of walled-off pancreatic necrosis: a prospective randomized controlled trial

Author Sri Atchuta Satya Maharshi T[1]

Institute **1** Asian Institute of Gastroenterology, Hyderabad, India

DOI 10.1055/s-0046-1820750

Aims To evaluate whether placement of a co-axial double-pigtail plastic stent (DPS) within a bi-flanged metal stent (BFMS) reduces adverse events during endoscopic ultrasound (EUS)-guided drainage of walled-off pancreatic necrosis (WON), compared with BFMS alone.

Methods This prospective single-centre randomized controlled trial was conducted from July 2021 to December 2022 at a tertiary endoscopy unit. Consecutive adults with symptomatic WON, confirmed on cross-sectional imaging according to revised Atlanta criteria, were enrolled. Patients were randomized 1:1 to BFMS alone or BFMS plus co-axial DPS. Interventions were performed under conscious sedation by experienced endoscopists using standardized technique. Patients were followed clinically and radiologically at 48–72 hours, 1 week, and 4 weeks.The primary endpoint was global adverse events at 4 weeks, defined as intraprocedural bleeding, stent clogging, stent migration, perforation, buried-stent syndrome, or death. Secondary endpoints included technical success, re-intervention rates (declogging, nasocystic irrigation, direct endoscopic necrosectomy, percutaneous drainage), and clinical success (symptom resolution with ≥ 50 % reduction in collection size). Statistical anal-

ysis used chi-square testing for categorical variables with significance at $p \leq 0.05$ (▶ **Table 1**).

▶ **Table 1**

Outcome	BFMS (n = 38)	BFMS + DPS (n = 38)	p-value
Global adverse events	36.8 %	15.8 %	0.04
Stent clogging	34.2 %	15.8 %	0.05
Stent migration	7.8 %	0 %	0.12
Reintervention required	39.5 %	26.3 %	0.44
Clinical success (4 weeks)	92.1 %	94.7 %	0.35

Results Seventy-six patients were randomized (BFMS n = 38; BFMS + DPS n = 38). Baseline demographics, etiology of pancreatitis, WON dimensions, and EUS-estimated debris percentage were comparable between groups. Technical success was achieved in all cases [1–7].

Global adverse events occurred significantly less frequently in the BFMS + DPS group compared with BFMS alone (15.8 % vs 36.8 %; p = 0.04; odds ratio 0.32). Stent clogging was also significantly reduced with adjunct DPS (15.8 % vs 34.2 %; p = 0.05). Stent migration occurred only in the BFMS group (7.8 % vs 0 %; p = 0.12). Intraprocedural bleeding was infrequent and similar between groups, with one major bleed requiring angioembolization in the BFMS arm and one minor self-limited bleed in the BFMS + DPS arm. No perforation or buried-stent events occurred. One death due to sepsis occurred in the BFMS arm and was not procedure-related.

Re-interventions were numerically lower in the BFMS + DPS group (26.3 % vs 39.5 %; p = 0.44). Mean number of re-interventions was lower with co-axial DPS (1.9 vs 2.6). Direct endoscopic necrosectomy was required equally in both groups (21.1 % vs 21.1 %; p = 0.33). Clinical success at 4 weeks was high and comparable (94.7 % vs 92.1 %; p = 0.35).

Conclusions In this randomized controlled trial, the placement of a co-axial DPS within BFMS during EUS-guided drainage of WON significantly reduced global adverse events and stent clogging without affecting technical or clinical success. These findings support the adoption of co-axial DPS placement as a simple strategy to enhance safety in endoscopic management of WON. Larger multicentre studies with longer follow-up are warranted to assess long-term outcomes, including disconnected pancreatic duct syndrome.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820751

Aims Pancreatic walled-off necrosis (WON) has typically been managed using a step-up strategy, in which endoscopic necrosectomy (EN) is performed only if patients fail to improve after initial drainage. Recent randomized controlled trials (RCTs) have suggested that an accelerated approach with upfront EN at the index procedure and subsequent necrosectomy until resolution of the WON may improve clinical outcomes. This study aimed to evaluate the healthcare costs associated with accelerated versus step-up management of WON, and to identify which cost categories primarily drive any differences between strategies [1, 2].

Methods This cost analysis used data from two RCTs conducted at Copenhagen University Hospital Hvidovre between August 30, 2019 and April 19, 2024. Patients were managed according to either the step-up protocol or an accelerated protocol. Initial drainage in the step-up group used either double-pigtail stents (DPS) or lumen-apposing metal stents (LAMS); all accelerated-protocol patients received LAMS. Cost data were extracted from the hospital accounting system and categorized into hospitalization, procedures, devices, imaging, medication, and outpatient care. Multivariable analyses were adjusted for baseline characteristics and calendar time. Step-up patients were further stratified by stent type (step-up–LAMS, step-up–DPS). Results are presented as adjusted mean cost differences with 95 % confidence intervals (CI) (▶ **Table 1**).

Results A total of 64 patients were included: 12 managed with the accelerated protocol and 52 with the step-up protocol. Baseline characteristics were comparable between groups.In the primary comparison, the accelerated group had a significantly lower adjusted mean total cost than the step-up group (€41,656 vs €73,999), corresponding to an adjusted mean difference of –€32,343 (95 %CI –€54,838 to –€5,616; p = 0.0122). Category-level decomposition showed that hospitalization costs were the main contributors to the cost difference.

When stratifying the step-up cohort by stent type, the accelerated strategy remained significantly less costly than step-up–LAMS (–€35,404; 95 %CI –€59,052 to –€5,948; p = 0.0372). In contrast, the cost difference between accelerated and step-up–DPS was smaller (–€22,700; 95 %CI –€57,111 to €9,541) and insignificant.Device-related costs were highest in the accelerated group (€6,174), followed by step-up–LAMS (€4,753) and step-up–DPS (€3,127), though these differences did not reach statistical significance after correction for multiple comparisons. Device expenditures represented the only category in which the accelerated strategy exceeded the cost of step-up management.

Conclusions Accelerated endoscopic management of WON was associated with substantially lower overall treatment costs compared with the conventional step-up approach, primarily due to reduced hospitalization expenses. The findings emphasize that clinical improvements demonstrated with an accelerated management also translate into meaningful reductions in resource utilization.

▶ **Table 1** Detailed breakdown of costs in accelerated vs. step-up groups

Category	Accelerated (adjusted mean)	Step-up (adjusted mean)	Adjusted mean difference	95 % CI	*p*-value
Overall cost	€41,656	€73,999	-€32,343	-€54,838 to -€5,616	0.0122
Hospitalization	€22,145	€46,912	-€24,767	-€38,427 to -€8,482	0.0224
Endoscopy time	€2,880	€3,572	-€693	-€2,221 to €1,410	1.00
Endoscopy devices	€6,157	€3,315	€2,842	€815 to €5,275	0.0882
Surgery	€0	€733	-€733	-€1,520 to -€207	1.00
Antibiotics	€4,887	€10,236	-€5,349	-€10,758 to €834	0.273
Parenteral nutrition	€574	€1,758	-€1,184	-€2,053 to -€184	0.0882
Radiology	€1,235	€2,875	-€1,640	-€2,556 to -€569	0.0231
Follow-up	€4,003	€4,642	-€640	-€5,057 to €4,385	1.00

OP097 Feasibility and Safety of Endoscopic Vacuum Treatment (EVT) of Walled-Off Necrosis in Acute Necrotizing Pancreatitis

Authors Ewald P[1], Cahyadi O[1], Zeidler C[1], Tophof M[1], Ayoub M[1], Nagl S[2], Scheppach MW[2], Wedemeyer J[3], Hourneaux De Moura DT[4], Hourneaux de Moura EG[5], Messmann H[2], Uhl W[6], Ebigbo A[1]

DOI 10.1055/s-0046-1820752

Aims Infected walled-off necrosis (WON) represents one of the most challenging complications of acute necrotizing pancreatitis (ANP). Endoscopic drainage of WON is usually done with a lumen-apposing metal stent (LAMS). Subsequent management following LAMS placement remains highly heterogeneous. Recent studies suggest that an accelerated approach, aiming for early removal of intracavitary debris and necrosis, may improve outcomes [1]. Endoscopic vacuum therapy (EVT) has become an established treatment approach for insufficiencies, leaks and cavities, but has not been evaluated for WON. In this study, we analyzed data from patients with WON and ANP who underwent EVT as an adjunctive treatment modality.

Methods Between 2022 and 2024, data were collected in a multicenter, retrospective case series from four tertiary care centers in Germany and Brazil. Patients with infected WON and ANP (Revised Atlanta Classification), treated with EVT, were included. The primary endpoint was clinical success defined as a conjunctive endpoint of sepsis control, complete resolution of WON and fistula closure. Secondary endpoint was intracavitary bleeding, defined as hemorrhage requiring endoscopic, radiological or surgical intervention. The decision to commence EVT was based on spontaneous perforation of WON into the gastrointestinal tract in five patients, treatment-refractory sepsis in five patients, extensive size of WON in four patients, and treatment-refractory WON in two patients.

Results Sixteen patients (10 male, 6 female, mean age 57,2 years) with infected WON and ANP were included. In total, 87 EsoSponge devices (79 intracavitary, 8 intraluminal), 38 individualized open-pore film drainage (OFD) devices (intracavitary), and 4 VacStent devices (intraluminal) were utilized. A median of 6,8 device exchanges or removal (range 1 – 26) were necessary. 12 patients underwent at least one session of direct endoscopic necrosectomy (DEN) with a total of 81 necrosectomy procedures performed.

Clinical success was achieved in 14 of 16 patients within a median time of 30,6 days. Two patients died on days 15 and 37 after EVT initiation due to ongoing, uncontrollable sepsis. One further patient died two months after successful treatment of WON due to pulmonary sepsis. In a total of 108 EVT device exchanges or removals and 81 DEN, intracavitary bleeding occurred in two patients. In one patient, bleeding after EsoSponge removal was successfully managed endoscopically using a standard hemoclip. In the second patient, bleeding following OFD removal was insufficiently controlled endoscopically and ultimately required interventional radiology. Although the per-patient bleeding rate was 12,5 %, the bleeding rate relative to the number of EVT interventions (per-procedure bleeding rate) was only 1,9 %, lower than previously anticipated. The per-procedure bleeding rate is at the same level as in the established management of leaks in the upper gastrointestinal tract at 1,8 % [2].

Conclusions This study demonstrates the potential of EVT as an additional therapeutic step for managing WON. The small sample size of 16 patients and the retrospective analysis of a heterogeneous cohort treated with various multimodal approaches weaken the robustness of the findings. This feasibility study supports the need for larger, multicenter, prospective trials to confirm the benefits of EVT in this challenging patient population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP098 Impact of Vancomycin-Resistant Enterococcus on Step-Up Therapy After EUS-Guided Drainage of Pancreatic Fluid Collections: A Multicenter Propensity-Matched Study

Authors Razpotnik M[1], Jürgensen C[1], Herta T[1], Sigal M[1], Çelebi Ö[1], Adler A[1], Leonhardt S[1], Branchi F[2], Buchkremer J[2], Kouladouros K[1], Engelmann C[1], Siegmund B[2], Tacke F[1]

Institutes 1 Charité Campus Virchow/Campus Mitte, Berlin, Germany; 2 Charité Campus Benjamin Franklin, Berlin, Germany

DOI 10.1055/s-0046-1820753

Aims Vancomycin-resistant Enterococcus (VRE) is increasingly recognized in infected pancreatic fluid collections (PFCs), underscoring a rising burden of antimicrobial resistance. This study evaluated whether VRE infection independently increases the need for step-up therapy after endosonography (EUS)-guided drainage compared with vancomycin-susceptible Enterococcus (non-VRE) after adjustment for disease severity covariates.

Methods Data on EUS-guided drainage of PFCs performed between 2016 and 2024 across three endoscopy units at Charité Berlin, irrespective of etiology, were collected. The primary outcome was the need for step-up therapy, defined as endoscopic necrosectomy, percutaneous drainage, or laparoscopic/open surgery. Infection was diagnosed based on clinical presentation, microbiological culture, and Gram staining from PFC aspirates or blood, with other sources excluded. Antimicrobial susceptibility testing including vancomycin resistance followed EUCAST guidelines [1]. A propensity score was constructed using age, ASA score, PFC size, necrosis extent, and stent type as covariates. VRE cases were matched 1:3 to non-resistant cases using nearest-neighbour matching (caliper 0.2 standard deviations). Conditional logistic regression assessed the association between VRE and step-up therapy in the matched cohort.

Results Among 486 consecutive patients, 295 (60.7 %) had confirmed infected PFCs. The final analysis included only Enterococcus-infected collections (n = 134; mean age 59 ± 13.7 years; 75.4 % male), comprising 30 VRE (22.4 %) and 104 non-VRE (77.6 %) cases. Walled-off necrosis was present in 87 (64.9 %), and double pigtail plastic stents were utilized in 112 (83.6 %). Prior antibiotic exposure and pre-drainage organ failure did not differ between groups. Step-up therapy was required in 90 (67.2 %) cases: 67 (50.0 %) endoscopic necrosectomy, 32 (23.9 %) percutaneous drainage, 11 (8.2 %) multigate technique, 22 (16.4 %) laparoscopic or open surgery. After propensity score matching (▶ **Table 1**), step-up therapy was needed significantly more often in VRE [27 (90.0 %)] versus non-VRE [63 (60.6 %)] patients (OR 5.86, 95 % CI 2.46-13.93; p = 0.002). Overall mortality was higher in the VRE group (33.3 % vs. 14.9 %).

Conclusions VRE independently predicts the need for step-up therapy in infected PFCs. Microbial resistance should be integrated into risk stratification and management decisions in EUS-guided treatment protocols.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820754

Aims EUS-guided drainage and direct endoscopic necrosectomy (DEN) are primary treatment modalities for symptomatic pseudocysts and walled-off pancreatic necrosis (WOPN). Bleeding is a serious adverse event associated with drainage, also due to lack of effective endoscopic haemostatic techniques. Purastat demonstrated excellent results to managegastrointestinal bleeding. Our aim was to evaluate the efficacy and safety of this haemostatic gel in managing bleeding secondary to EUS-guided drainage and DEN ofpancreatic fluid collections (PFCs).

Methods In this multicenter, retrospective, observational study 27 patients underwent Purastattreatment because of active bleeding during or after PFCsEUS-guided drainage or WOPN DEN sessions between 2017 and 2024 [1, 2].

Results 38 bleeding episodes were recorded. The bleeding type was oozing in 36 cases and spurting in 2 cases.Purastat was successfully applied in 100 % of patients and achieved successful haemostasis in 96.5 % of cases (▶ **Table 1**).

Conclusions This novel haemostatic gel is a safe andeffective to manage oozing bleedings related to PFCs EUS-guided drainage or DEN.

OP100 Re-Intervention in Endoscopic Ultrasound (EUS) – Guided Walled Off Necrosis (WON) drainage with Metal stents: Identifying High-Risk Morphologies

Authors Jagtap N[1], Koduri KK[1], Memon SF[1], Inavolu P[1], Shujaath A[1], Basha J[1], Talukdar R[1], Ramchandani M[1], Lakhtakia S[1], Kalapala R[1], Rao GV[1], Reddy DN[1]

Institute 1 AIG Hospitals, Hyderabad, India

DOI 10.1055/s-0046-1820755

Aims Endoscopic ultrasound (EUS)-guided drainage with metal stents is standard therapy for walled-offnecrosis (WON). However, some patients require re-interventions such as stent unclogging,necrosectomy, or percutaneous drainage. This study aimed to identify predictors of re-intervention tofacilitate risk stratification and optimize management.

Methods This study included consecutive patients who underwent EUS-guided WON drainage with metalstents between January 2023 and December 2024 at a tertiary referral center. Demographic, clinical,and radiological data were collected prospectively. Multivariate logistic regression identifiedindependent predictors of re-intervention. Model performance was evaluated using ROC curve,calibration plot, and decision curve analysis. Model's diagnostic performance in evaluated invalidation cohort.

Results Of 500 patients (83.2% male), 28.6% had alcohol-related and 10% had biliary pancreatitis. Re-intervention was required in 24% (n = 120), primarily for stent unclogging (85.8%), nasocystic tubeplacement (70%), and necrosectomy (50%). Independent predictors included WON size (OR 1.38;95% CI, 1.25–1.52), paracolic extension (OR 9.96; 95% CI, 1.77–55.98), and solid debris content(OR 1.10; 95% CI, 1.08–1.13). The model demonstrated good discrimination (AUC = 0.85) andcalibration (Hosmer–Lemeshow p 0.19). The overall accuracy of model in validation cohort was86.67%(95%CI:73.21%-94.95%). Adverse events occurred in 6% of patients, including bleeding(n = 11), stent migration (n = 13), and sepsis-related death (n = 6).
https://aigrescuewoncalc.netlify.app/

Conclusions Larger WON size, paracolic extension, and higher solid debris content are independent predictors ofre-intervention after EUS-guided drainage. Early identification of these factors may allow forindividualized step-up therapy and improved clinical outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820756

Aims Pancreatic solid lesions are increasingly identified in asymptomatic individuals, yet the most common diagnosis, pancreatic ductal adenocarcinoma (P-DAC), continues to carry a dismal prognosis because detection still occurs at advanced and unresectable stages. Endoscopic ultrasound (EUS) remains the gold standard for evaluating and sampling these lesions, but even with improved imaging and tissue acquisition techniques, the diagnostic accuracy of EUS guided fine needle biopsy remains below optimal standards, leading to missed opportunities for earlier intervention. Artificial intelligence (AI) tools have shown compelling potential in distinguishing and characterizing pancreatic lesions at the frame level and in small controlled series. What is urgently needed now is robust real world clinical validation to convert this technological promise into faster and more accurate diagnoses and ultimately improve patient outcomes.Pancreatic solid lesions are increasingly identified in asymptomatic individuals, yet the most common diagnosis, pancreatic ductal adenocarcinoma (P-DAC), continues to carry a dismal prognosis because detection still occurs at advanced and unresectable stages. Endoscopic ultrasound (EUS) remains the gold standard for evaluating and sampling these lesions, but even with improved imaging and tissue acquisition techniques, the diagnostic accuracy of EUS guided fine needle biopsy remains below optimal standards, leading to missed opportunities for earlier intervention. Artificial intelligence (AI) tools have shown compelling potential in distinguishing and characterizing

pancreatic lesions at the frame level and in small controlled series. What is urgently needed now is robust real world clinical validation to convert this technological promise into faster and more accurate diagnoses and ultimately improve patient outcomes.

Methods This multicenter prospective study aimed to clinically validate an AI model for EUS image analysis. The study included 376 EUS exams across 15 centers in the United States of America, Spain, Brazil, Australia, Uruguay and the United Kingdom, using different EUS devices. Three hundred patients had a histopathological diagnosis of P-DAC. For each exam, up to 25 clinically relevant frames were selected by the endoscopist and uploaded to a web-based platform for AI analysis. The model performed both detection and differentiation of pancreatic solid lesions: detection was assessed by comparing AI-generated bounding boxes with expert-defined annotations using intersection-over-union (IoU), while differentiation of P-DAC was benchmarked against the histopathological gold standard (EUS guided biopsy or surgical specimen). Model performance was evaluated through accuracy, sensitivity, specificity, and positive and negative predictive values (PPV and NPV).

Results At a frame level, the AI model was capable of accurately detecting pancreatic solid lesions, with a mean IoU of 0.54, accuracy of 77.0 % and a PPV of 95.0 %. Regarding the identification of P-DAC lesions, AI-analysis had an accuracy of 79.5 %, with a sensitivity of 92.0 % and positive predictive value of 83.9 %. No significant differences in performance were observed across patient gender, age or device.

Conclusions This study represents the first global multicentric validation of an AI model applied in real life to the detection and differentiation of pancreatic solid lesions, with a central aim of identifying P-DAC at the earliest possible stage. By incorporating data from three continents and multiple EUS systems, it confirms that the model performs consistently and reliably across diverse clinical settings and patient populations. Crucially, this AI system is the first to demonstrate true real world impact in the most complex cases, precisely locating pancreatic lesions and strongly supporting the diagnosis of P-DAC when traditional assessment is most challenged. AI assisted EUS now emerges as a transformative tool, with the potential to identify smaller, earlier stage lesions, increase the proportion of patients eligible for curative surgery and shift the prognosis of P-DAC toward markedly better outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Endoscopic ultrasound (EUS) plays a central role in lymph node (LN) characterization, essential for accurate tumor staging. Current assessment relies on morphologic criteria that rarely occur together, limiting diagnostic confidence. Although EUS-guided fine-needle aspiration/biopsy (FNA/B) supports diagnosis, false-negative rates for malignancy remain approximately 15 %. Artificial intelligence (AI) may enhance diagnostic precision, yet evidence regarding LN characterization is lacking. This study aimed to evaluate the performance of a convolutional neural network (CNN) in detecting LNs and predicting malignancy from EUS images.

Methods The AI model integrated two components: a detection module generating bounding boxes around LNs, and a classification module predicting malignant versus benign features. Reference standards included positive FNA/B or surgical pathology; benign diagnoses required at least six months of clinical follow-up. Performance metrics included mean average precision at an intersection-over-union threshold of 50 % (mAP50), sensitivity, precision, accuracy, and area under the precision-recall curve (AUPRC).

Results This multicentric cohort comprised 96,287 EUS images from 116 patients across 12 centers in Spain, the United States, Brazil, Colombia, Argentina, and Australia. The CNN achieved an mAP50 of 0.978 for LN detection, with sensitivity of 97.2 %, precision of 97.0 %, and overall accuracy of 98.0 %. For malignant LN prediction, the AUPRC was 0.993.

Conclusions This is the first international study using data from multiple EUS devices to assess an AI system for both LN detection and malignancy prediction. The model demonstrated excellent performance, underscoring the promise of deep learning to support locoregional tumor staging and guide more personalized treatment strategies.

OP103 Artificial intelligence improves accuracy of pancreatic screening EUS by enhancing the detection of small solid lesions: a tandem randomized video study

Authors Montanelli J[1], Swanström L[1], Sosa Valencia L[1], Vilmann P[2]

Institutes **1** Ihu Strasbourg – Institute Surgery Guided Par L'image, Strasbourg, France; **2** Unit of Gastroenterology, endoscopic division, Copenhagen University Hospital, Herlev, Herlev, Denmark

DOI 10.1055/s-0046-1820758

Aims To evaluate the add-on effect of a novel Artificial Intelligence (AI) software system (mAI Companion©, Medi-Globe GmbH, Germany) on the performance of endosonographers in detecting small solid pancreatic tumours (SPTs) during endoscopic ultrasound (EUS) examinations.

Methods A randomized, controlled tandem video study was conducted. Sixteen EUS videoclips were selected, each containing a standardized complete pancreatic examination of small SPTs (9-19mm) in different locations of the pancreas. Each clip included case-related contextual information, followed by a frozen frame at the end, with or without a SPT. Each video was assessed twice by every participant: once with AI assistance and once without. Randomization (1:1) determined whether the first or second evaluation included AI assistance. For each clip, participants were asked to assess the frozen frame and to mark

the perceived lesion localization on a paper grid. Their assessments were compared with the ground truth established by an expert endosonographer.

Results Thirty-two endosonographers with varying levels of experience in EUS participated. Stand-alone AI showed a diagnostic accuracy of 93.75 %. Without AI support, participants achieved an overall accuracy of 70.51 % (95 %CI 66.35 %-74.43 %). With AI assistance, performance significantly improved to 82.03 % (95 %CI 78.43 %-85.26 %). The accuracy gain with AI was statistically significant ($p < 0.001$).

Conclusions AI assistance significantly enhanced endosonographers performance in detecting small solid pancreatic tumours in structured EUS video clips. These findings support the potential role of AI as a "second observer" for challenging, difficult to detect pancreatic lesions.

OP104 Machine-learning–based prediction of choledocholithiasis (AIG-CBDS) in ESGE-defined intermediate-likelihood patients: refining the diagnostic pathway

Authors Jagtap N[1], Rughwani H[1], Koduri KK[1], Kumari K[1], Tyagi A[2], Memon SF[1], Shujaath A[1], Kalapala R[1], Rao GV[1], Reddy DN[1]

Institutes 1 AIG Hospitals, Hyderabad, India; 2 Asian Institute of Gastroenterology (AIG Hospitals), Department of Medical Gastroenterology, Hyderabad, India

DOI 10.1055/s-0046-1820759

Aims ESGE recommends EUS or MRCP for patients with an intermediate likelihood of choledocholithiasis [1, 2]. However, the intermediate-likelihood group remains clinically heterogeneous, resulting in unnecessary EUS/MRCP in some patients and delayed ERCP in others. Recently published machine-learning(ML) models for choledocholithiasis prediction have included high-likelihood determinants, such as direct ultrasound visualization of bile duct stones, which limiting applicability [3]. We aimed to develop and internally validate a machine-learning–based prediction model exclusively in ESGE-defined intermediate-likelihood patients, excluding all high-likelihood criteria, to refine risk stratification and optimize diagnostic decision-making(NCT06066372).

Methods This was a prospective ML modeling study conducted at AIG Hospitals, Hyderabad, India. Consecutive patients evaluated for suspected choledocholithiasis were screened, and patients fulfilling ESGE intermediate-likelihood criteria were included. The reference standard for outcome adjudication was ERCP-confirmed common bile duct (CBD) stones or, in conservatively managed patients, clinical and radiological follow-up confirming absence or presence of stones.Five supervised ML algorithms were trained and evaluated. Model training and validation used a training–test split with cross-validation. Discrimination was assessed using the area under the receiver-operating characteristic curve(AUC). Overall performance was summarized using accuracy, precision, recall, and F1-score. Calibration was assessed using the Brier score and calibration plots. Clinical utility was evaluated using decision-curve analysis (DCA) (▶ **Table 1**).

Results A total of 2414 ESGE-defined intermediate-likelihood patients were included (mean age 49.6 ± 15.0years,56.2 %male).Choledocholithiasis was confirmed in 52.0 % (1256) of patients (training cohort:1931;validation cohort:483). Among all models, the Gradient Boosting model (AIG-CBDS) demonstrated the best overall performance with ROC–AUC:0.820 and accuracy:0.776. Other models showed slightly lower discrimination (AUC range 0.794–0.812). The model showed good calibration with a Brier score of 0.137, and calibration plots demonstrated close agreement between predicted and observed probabilities across clinically relevant risk ranges. DCA confirmed a consistently higher net benefit of the model compared with "treat-all" and "treat-none" strategies across threshold probabilities from approximately 10 % to 80 %. SHAP-based explainability identified dilated CBD as the dominant predictor, followed by age, ALT, bilirubin, and ALP, while sex had minimal influence.

Conclusions By focusing on the true diagnostic gray zone of intermediate likelihood of choledocholithiasis, the AIG-CBDS probability model provides a refined, individualized approach to downstream triage. It has the potential to personalize the ESGE diagnostic pathway, minimizing unnecessary EUS/MRCP, preventing avoidable ERCP, and expediting definitive biliary intervention in patients at the highest intermediate risk. AIGS-CBDS probability model requires external validation with further studies before routine clinical implementation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Biliary strictures are a clinically significant challenge, with malignant strictures frequently diagnosed at advanced stages, when curative options are limited and prognosis is poor. Digital single-operator cholangioscopy has transformed the field by providing high-resolution, direct visualization of the bile duct for diagnostic and therapeutic assessment, yet its diagnostic performance remains below optimal standards. Artificial intelligence offers a powerful opportunity to change this trajectory, with early studies demonstrating strong potential for accurate detection and differentiation of biliary strictures in both frame-level analysis and small clinical series. What is urgently needed now is robust real-world clinical validation to confirm these benefits and move toward earlier and more confident diagnosis.

Methods The aim of this multicenter prospective study is to clinically validate a deep learning model for D-SOC image analysis. The study included 170 D-SOC exams from 163 patients across 12 centers in the United States, Brazil, Spain, Colombia, Australia, and Saudi Arabia. Fifty-three patients had malignant biliary strictures (BS), while the remaining cases were benign. For each exam, up to 25 clinically relevant frames were selected by the endoscopist and uploaded to a web-based platform for AI analysis. The model performed both detection and differentiation of BS: detection was assessed by comparing AI-generated bounding boxes with expert-defined annotations using intersection-over-union (IoU), while differentiation (benign vs malignant) was benchmarked against the histopathological gold standard (brush cytology, D-SOC biopsy, or surgical specimen). Model performance was evaluated through accuracy, sensitivity, specificity, and positive and negative predictive values (PPV and NPV).

Results At the exam level, the AI model identified malignant BS with an accuracy of 76.5 %, a sensitivity of 81.1 %, and a specificity of 74.4 %. The model also demonstrated robust detection performance, achieving a mean intersection-over-union (IoU) of 70.3 %. No significant differences in performance were observed across patient gender, age, or participating center. Importantly, the model showed a strong ability to rule out malignancy, with a negative predictive value (NPV) of 89.7 %.

Conclusions This first multicentric validation study demonstrates the real-world performance of an AI-assisted approach for D SOC analysis across four continents and multiple device types, confirming robust accuracy in the detection and differentiation of BS. The system performed consistently at both exam and frame levels, addressing a context in which visual assessment and biopsy sampling often provide limited diagnostic yield, and showing high reliability in excluding malignancy in patients with indeterminate BS. These findings support the integration of AI as an adjunctive tool in D SOC, enhancing diagnostic confidence and contributing to a more informed clinical evaluation of patients with indeterminate BS.

DOI 10.1055/s-0046-1820761

Aims The expanding application of AI/ML in clinical diagnostics is hampered in gastrointestinal oncology by its reliance on complex raw *imaging data*, resulting in unexplainable (opaque) models.

This study is novel in its use of structured, human-readable EUS features to develop interpretable ML tools. The primary goal is to determine if these simpler models can match or exceed the performance of more complex approaches, and to assess the reliability (uncertainty handling) of their predictions for clinical diagnostic support.

Methods In this retrospective study, we enrolled 761 patients from three centers who underwent EUS for the characterization of a solid pancreatic lesion. We collected age, sex, and endosonographic features of the solid lesion in a database. These features were then used to train leading machine learning (ML) models to diagnose the presence of pancreatic ductal adenocarcinoma (PDAC). By dividing the database into a training set and an external test set, we were able to measure the models' main performance metrics (▶ **Table 1**).

Results Among the models tested, decision trees (DT), random forest (RF), and naive Bayes (NB) demonstrated strong performance, each achieving area under the ROC curve (AUC) ≥ 0.90 and an accuracy ≥ 0.88. The most sensitive models (the most crucial metric for avoiding false negatives) were Support Vector Machine (SVM) and NB, with results ≥ 0.90. The most specific models were DT, RF and NB, all achieving 0.85. Significant results were also obtained by DT, RF, SVM, and NB with an F1-score ≥ 0.92. Additional analyses on calibration and selective prediction confirmed the reliability of interpretable models under clinical uncertainty (Brier, ECE and Global ECI metrics).

Using these data and models, we developed a free and open-access online tool (https://mleus.pythonanywhere.com/) to predict the diagnosis of PDAC with varying degrees of confidence, based on endosonographic features, also giving the possibility to change the best performance of the model, choosing between sensitivity, specificity, balance or explainability. This tool, which is intended solely for testing and research purposes, could be improved in the future and validated for diagnostic support in clinical practice

Conclusions These results, support the integration of structured data ML pipelines in diagnostic workflows for PDAC, offering a feasible path towards AI implementable in clinical endoscopy, even in non-tertiary centers.

DOI 10.1055/s-0046-1820762

Aims Gastric cancer (GC) is a leading cause of cancer-related mortality, with premalignant lesions (PGLs) like gastric intestinal metaplasia (GIM) and dysplasia acting as key precursors. While surveillance is recommended, risk factors and progression rates in low-incidence regions remain underexplored. This study evaluates progression risk of patients with PGL in the Netherlands and Spain, both low GC incidence countries.

Methods Patients were recruited from the Progression and Regression of Gastric Lesions study (PROREGAL MEC-2009-090) in the Netherlands consisting of eight hospitals and Hospital Clínic de Barcelona, Spain. Eligible participants were under surveillance for GIM or dysplasia and had at least one follow-up endoscopy, with biopsies taken from standardized sites, between 2009 and 2025. Patient demographics, lifestyle factors, and clinical data were collected through standardized questionnaires and the electronic medical record. GIM stage was assessed using the OLGIM (Operative Link on Gastric Intestinal Metaplasia) staging system, and GIM progression was based on the increase in OLGIM. The primary outcome was annual neoplastic progression to high-grade dysplasia (HGD) or intramucosal cancer (IMC), with secondary outcomes including progression to any type of dysplasia and OLGIM progression rate. Surveillance was performed following the MAPS guideline. Statistical analyses included Chi-squared tests for categorical variables and t-tests for continuous variables between cohorts (▶ **Table 1**).

▶ **Table 1** OLGIM and neoplastic progression outcomes in Dutch and Spanish cohorts

	The Netherlands (n = 321)	Spain (n = 90)
OLGIM progression (yes), n (%)	95 (29.6)	26 (28.9)
Neoplastic progression (yes), n (%)	12 (3.8)	8 (8.9)
▪ LGD, n (%)	3 (0.9)	7 (7.8)
▪ HGD, n (%)	6 (1.9)	0 (0.0)
▪ IMC, n (%)	3 (0.9)	1 (1.1)

Results A total of 414 patients were enrolled in this study, 312 from the Netherlands and 90 from Spain with a median follow-up time of 50 and 37 months. The median age at index of the Dutch cohort was 59 years (SD 13) vs 64 years (SD 11) in the Spanish cohort (p = 0.001). The Dutch cohort had a higher proportion of males (54.2 % vs 34.4 %, p = 0.001). Smoking (29.3 % vs 15.6 %, p = 0.007) and alcohol use (53.9 % vs 11.1 %, p < 0.001) were more prevalent in the Netherlands, as was a family history of gastric cancer (28.3 % vs 8.9 %, p < 0.001). While autoimmune gastritis (15.3 % vs 36.7 %, p < 0.001) and *Helicobacter pylori* positivity (6.9 % vs 12.2 %, p = 0.04) were higher in Spain. At baseline, Dutch patients had a significant a lower OLGIM score (43.2 % vs 67.3 % with OLGIM < 2, p < 0.001). The annual OLGIM and any type of dysplasia progression rates were higher in Spain (62.5 vs 99.6 cases; 5.9 vs 26.8 cases per

1000 person-years, p = 0.003), while the annual neoplastic progression rate (5.9 vs 3.8 cases per 1000 person-years, p = 0.580) did not differ significantly.

Conclusions In two low-GC-incidence countries, significant differences in progression risk were found, which may highlight the need for more tailored approaches in surveillance and management, even within countries with similar GC incidence rate.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP108 Prevalence and endoscopic recognition of gastric precancerous conditions and H. pylori infection in routine diagnostic upper GI endoscopy at a tertiary-care university hospital

Authors Roser DA[1], Ganthaler H[2], Ignatenko Y[3], Messmann H[1]
Institutes **1** Department of Gastroenterology, University Hospital Augsburg, Augsburg, Germany; **2** Augsburg University, Augsburg, Germany; **3** Digital Medicine, University Hospital Augsburg, Augsburg, Germany
DOI 10.1055/s-0046-1820763

Aims Gastric atrophy and intestinal metaplasia (IM) are key precancerous conditions for gastric adenocarcinoma, but their recognition in routine esophagogastroduodenoscopy (EGD) is often suboptimal. We aimed to describe the prevalence and distribution of histologically confirmed gastric precancerous lesions and Helicobacter pylori infection in consecutive diagnostic EGDs at a tertiary-care university hospital, and to evaluate the diagnostic performance of routine endoscopic assessment compared with histology.

Methods We conducted a retrospective cohort study including all consecutive diagnostic EGD procedures with gastric biopsies in adult patients at a tertiary-care university hospital between 01 August 2022 and 31 March 2025. Emergency and primarily therapeutic procedures were excluded. Gastric biopsies were taken at the endoscopist's discretion in routine clinical practice. In total, 3,955 diagnostic EGDs in 3,907 patients were analyzed. In 3,418 procedures (86.4 %), biopsies were obtained from both antrum and corpus in line with the Sydney classification. Pathology reports from routine practice were reviewed for H. pylori infection, gastric atrophy and IM, including antral and corpus involvement where reported. All clinical and pathology data were de-identified before analysis. For each condition, the routine endoscopic impression (present vs absent) documented in the endoscopy report was compared with histology as reference standard, and prevalence, sensitivity, specificity, positive and negative predictive values (PPV, NPV) and overall accuracy were calculated. In a prespecified sensitivity analysis, diagnostic performance was re-evaluated in the subset of examinations with biopsies obtained according to the Sydney classification.

Results Histology showed H. pylori infection in 371 of 3,955 EGDs (9.4 %), IM in 775 (19.6 %) and atrophic gastritis in 165 (4.2 %). Endoscopic assessment of H. pylori yielded a sensitivity of 12.1 %, specificity 96.6 %, PPV 26.8 %, NPV 91.4 % and accuracy 88.6 %. For IM, sensitivity was 12.6 %, specificity 98.6 %, PPV 68.1 %, NPV 82.2 % and accuracy 81.7 %. For atrophic gastritis, sensitivity was 53.3 %, specificity 91.1 %, PPV 20.8 %, NPV 97.8 % and accuracy 89.6 %. Overall, 26.3 % of examinations had at least one of these precancerous conditions or H. pylori infection.

Diagnostic performance estimates were very similar when restricting the analysis to examinations with Sydney-pattern biopsies, indicating that the main findings were robust to biopsy strategy. Among patients with histological atrophy, corpus involvement was present in 91.5 %, whereas antral atrophy was reported in only 7.3 %. In contrast, among patients with IM, antral and corpus involvement were observed in 85.4 % and 25.9 %, respectively, consistent with the expected distal-predominant pattern and supporting the reliability of histological IM localization. The predominance of corpus-reported atrophy suggests that the histological ground truth for antral atrophy is uncertain and likely affected by diagnostic and reporting variability.

Conclusions In this tertiary-care cohort of 3,955 consecutive diagnostic EGDs, gastric IM and atrophic gastritis were present in 19.6 % and 4 % of examinations, respectively, and H. pylori infection in about 9 %. Overall, 26.3 % of examinations showed at least one of these conditions. Routine endoscopic assessment substantially underestimated H. pylori and IM, with very low sensitivity despite high specificity and NPV, and showed only moderate sensitivity for atrophy. The observed discrepancy between the distribution of IM and atrophy indicates both endoscopic under-recognition and limitations of histological assessment, particularly for antral atrophy. These findings reveal a relevant gap in the detection and documentation of gastric precancerous conditions and H. pylori in clinical practice and support efforts towards optimized biopsy strategies, structured endoscopic training, closer alignment with pathology reporting and supporting tools such as AI-assisted detection.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP109 Atrophic gastritis in a UK Hospital Trust: recognition, biopsy practice, and surveillance. Are we following the guidelines?

Authors Arif Z[1], Karelia S[1], Moyo S[1], Joshi A[1], Besherdas K[1], Hiner G[1]
Institute **1** Royal Free London NHS Foundation Trust, London, United Kingdom
DOI 10.1055/s-0046-1820764

Aims Atrophic gastritis (AG) is a recognised precursor to gastric adenocarcinoma, with a recent meta-analysis demonstrating a significantly increased risk of gastric cancer in affected individuals [3]. Current guidance, including European Society of Gastrointestinal Endoscopy (ESGE) MAPS III (2025) [1] and British Society of Gastroenterology (BSG) guidelines (2019) [2], recommends systematic gastric mapping using the Sydney protocol and 3-yearly endoscopic surveillance for patients with extensive AG involving both antrum and corpus. This audit aimed to evaluate the accuracy of endoscopic recognition of AG, adherence to guideline-recommended biopsy sampling when AG was suspected, and whether eligible patients were appropriately enrolled into surveillance within routine NHS practice.

Methods A retrospective review was conducted at Royal Free London NHS Foundation Trust, of histology samples showing atrophic gastritis between April–October 2025 were reviewed. Data was obtained from a histology database, endoscopy reporting software and electronic patient records. Data included demographics, H. pylori status, endoscopic suspicion of AG, biopsy practice when AG was suspected, histology results, and surveillance planning. Data were summarised descriptively.

Results 5307 gastroscopies were performed between April – October 2025. 206 cases were identified with atrophic gastritis.

Median age of patients was 65 years and 57.3 % were female. H pylori was tested in 202/206 (98.1 %) and 19 of 202 (9.4 %) patients were HP positive.

AG was present in 4/19 (26.3 %) of H. pylori–positive patients.

AG was confirmed on histology in 93/206 patients (45.1 %). AG was suspected endoscopically in 54/206 (26.2 %), of which 38/54 (70.4 %) were confirmed histologically.

Among 152 procedures where AG was not endoscopically suspected, histology detected AG in 55/152 (36.2 %)

Overall, 59.1 % (55/93) of all histologically confirmed AG cases were not identified at endoscopy.

When AG was suspected Sydney-protocol/ mapping biopsies were performed in 31/54 (57.4 %). Protocol biopsies detected AG in 61.7 %, vs 37.1 % with non-protocol sampling.

Extensive incisura/ corpus AG was seen in 54/93 (58.1 %). Surveillance was arranged for 31/54 (57.4 %) of these patients. 23/54 (42.6 %) eligible patients received no surveillance.

Conclusions This audit demonstrates that BSG and ESGE guidelines are not consistently followed with respect to gastric atrophy. Although AG was confirmed histologically in many patients, 59.1 % were not identified during the

Endoscopy 2026; 58: S1–S1041

procedure, as the visual features of AG are not always clear at endoscopy. Even when AG was suspected, only 57.4 % received Sydney-protocol biopsies, resulting in incomplete gastric mapping and missed opportunities to determine surveillance eligibility. Furthermore, over two-fifths of patients with extensive AG were not offered guideline recommended surveillance.

The most effective and immediately implementable intervention is targeted education. Presenting our audit findings to the endoscopy team, supported by concise, well-designed posters outlining the ESGE MAPS III and BSG recommendations placed in endoscopy rooms for immediate reference, will improve adherence to biopsy protocols and support consistent, guideline based surveillance decisions. These simple, high-impact steps offer a practical means to improve the detection and management of gastric premalignant pathology within our service.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP110 Impact of Screening Compliance on Gastric Cancer Risk and Eligibility for Endoscopic Treatment: a Nationwide Population-based Cohort Study

Authors Lim JH[1], Shin CM[2]

Institutes **1** Seoul National University Hospital Healthcare System Gangnam Center, Seoul, Republic of Korea; **2** Seoul National University Bundang Hospital, Seongnam-si, Republic of Korea

DOI 10.1055/s-0046-1820765

Aims Gastric cancer remains highly prevalent in East Asian populations, particularly in South Korea. Although national biennial endoscopic screening program has shown reduction in gastric cancer mortality, the association between screening compliance and both cancer risk and eligibility for endoscopic therapy has not been fully clarified. This study aimed to assess how compliance with gastric cancer screening influences cancer incidence and subsequent eligibility for minimally invasive endoscopic treatment.

Methods We conducted a nationwide population-based cohort study using the Korean National Health Insurance Service database. Individuals who underwent the national gastric cancer screening endoscopy in 2014 without any diagnosis of gastric cancer or adenoma were included and categorized according to their adherence to biennial screening until 2022: high compliance (HC; no missed screenings), moderate compliance (MC; one missed screening), and low compliance (LC; ≥ 2 missed screenings). Incidence of gastric cancer was analysed using a Cox proportional hazard model. Among those who were diagnosed with gastric cancer, the risks of non-eligibility for endoscopic treatment were analysed using logistic regression. Analyses were adjusted for relevant clinical and demographic confounders.

Results Among 2,700,237 individuals, 10,105 developed gastric cancer during a median follow-up of 8.4 years. The risks of gastric cancer increased significantly with lower compliance: MC group (adjusted hazard ratio [aHR] 3.27, 95 % CI 3.04-3.52) and LC group (aHR 8.19, 95 % CI 7.68-8.75) versus HC. Of the 9,846 individuals diagnosed with gastric cancer, non-eligibility for endoscopic treatment was reduced in both MC (adjusted odds ration [aOR] 1.10, 95 % CI 0.96-1.28) and LC (aOR 3.62, 95 % CI 3.13-4.18) groups versus HC.

Conclusions In a high-risk gastric cancer population, poor screening compliance was associated with both an increased risk of gastric cancer and a higher non-eligibility for endoscopic treatment. In regions with a high incidence of gastric cancer, adherence to endoscopic screening should be strongly encouraged to prevent cancer progression through the detection of premalignant lesions, and ultimately improve post-diagnosis quality of life.

DOI 10.1055/s-0046-1820766

Aims Gastric cancer poses a significant health burden globally being the fourth leading cause of cancer death. [1] Its epidemiology varies significantly by region and even within the same country. Although prevention strategies have traditionally relied on risk-factor profiling, the latest ESGE/EHMSG/ESP (MAPS III) guideline update recommends incidence-based endoscopic screening where cost-effectiveness is demonstrated and resources are available, a recommendation largely based on evidences from Asian countries. [2]

Starting from a Western high-risk region, the south-east of Lombardia [3], we aimed to assess whether OLGA/OLGIM-based surveillance together with epidemiologic risk profiling is sufficient to identify individuals at risk of presenting with dysplastic lesions (DL), early gastric cancer (EGC) or advanced intestinal-type adenocarcinoma (AADK).

Methods We conducted a single-center retrospective observational study including patients with DL managed endoscopically, EGC managed endoscopically or surgically and patients with surgically treated AADK at our Hospital in the time span of ten years, from 2015 to 2025. Demographics, risk factor-related informations, dysplastic/neoplastic lesions diagnosis and treatment-related data and background mucosal staging (OLGA/OLGIM) data were collected. All specimens underwent also to a second-look examination by an expert pathologist.

Results A total of 153 patients (45 DL, 42 EGC and 66 AADK) with a mean age of 75 years were included in the analysis. The sex distribution showed a slight male predominance (56.9 %). Overall, 21.6 % of patients were Helicobacter pylori positive at the time of the diagnosis and 17.6 % reported a family history of gastric cancer. One of the more relevant findings comes from OLGA/OLGIM staging distribution: 46.6 % of patients showed mild-to-moderate atrophy (OLGA I–II), 58.8 % mild-to-moderate intestinal metaplasia (OLGIM I-II) and approximatey the 13 % of the study population had no atrophy and no intestinal metaplasia at all.

Furthermore, no statistically significant differences in OLGA/OLGIM distribution were observed between patients presenting with DL/EGC and the ones affected by AADK (Mann–Whitney U test, $Z = -0.570$, $p = 0.569$).

Conclusions Our findings support the MAPS III guidelines, demonstrating that even in Western countries traditional risk factors for gastric neoplasia are insufficient to identify at-risk individuals in high-incidence areas. Therefore, histology- and risk-factor–based surveillance should be complemented with incidence-based endoscopic screening.

OP112 Diagnostic yield and clinical utility of routine biopsies during endoscopic surveillance in patients with chronic atrophic gastritis

Authors Cingolani S[1], Vavallo M[1], Pellicano A[1], Ligato I[1], Panzuto F[1], Annibale B[1], Lahner E[1], Esposito G[1]
Institute 1 Department of Medical-Surgical Sciences and Translational Medicine, Sapienza University of Rome, Rome, Italy
DOI 10.1055/s-0046-1820767

Aims According to the Correa Cascade, patients with atrophic gastritis(AG) and intestinal metaplasia(IM) may develop gastric dysplasia and intestinal-type gastric adenocarcinoma.
High-quality endoscopic surveillance using virtual chromoendoscopy(VCE) is essential for the early detection of neoplastic lesions(NL). MAPSII guidelines suggested follow-up with biopsies for stages OLGA/OLGIMIII/IV and autoimmuneAG, whilst the MAPSIII guidelines recommend against performing routine biopsies during surveillance upper gastrointestinal endoscopies(UGIEs) and support the performance of biopsies only in case of mucosal alterations [1, 2]. The aim of the study is to assess the diagnostic yield and clinical utility of performing routine biopsies during UGIEs in patients with AG/IM.
Methods Patients with OLGA/OLGIMIII/IV and/or autoimmuneAG who underwent at least two high-quality UGIEs between 2012 and 2024 at a tertiary referral center were included. VCE-guided targeted biopsies were performed in case of suspicious IM or other alterations; otherwise, biopsies were performed according to the Sydney System protocol. Histological staging was performed according to the OLGA/OLGIM systems, and histopathological assessment was evaluated using the updated Sydney system.
Results Overall, 158 patients and 530 UGIEs(median follow-up 65 months) were included. Overall, 37 NL(23 type 1 gastric NETs, 2 gastric adenocarcinomas, 7 low-grade dysplasia(LGD), 5 adenomas with LGD) were detected, whereas random biopsies identified only 2 NL(1 gastric NET and 1 LGD) in 0.4 % of UGIEs and 1.3 % of patients($p < 0.00001$). At the longest available follow-up, in 22 patients (13.9 %), biopsies showed regression of OLGA/OLGIM stages, allowing for discontinuation of follow-up.
Conclusions Random biopsies have no statistically significant performance or clinical utility, which supports the MAPS III recommendation against their efficacy during follow-up.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

Advanced Imaging and Elastography: Expanding the Diagnostic Horizon

15/05/2026, 09:00–10:00 **Sky 1**

OP113 How Accurately Does EUS-Shear Wave Elastography Identify Early Chronic Pancreatitis? A Prospective Study

Authors Basha J[1], Soma PR[2], Lakhtakia S[2], Nabi Z[2], Sayyed M[2], Gupta R[2], Jagtap N[2], Shujaath A[2], Talukdar R[2], Reddy DN[2]
Institutes 1 AIG Hospitals , Hyderabad, India; 2 Asian Institute of Gastroenterology, Hyderabad, India
DOI 10.1055/s-0046-1820768

Aims Early chronic pancreatitis (ECP) is a distinct clinical stage in the natural progression from recurrent acute pancreatitis to established chronic pancreatitis. Accurate diagnosis of ECP is clinically important, as it not only prevents unnecessary investigations for determining the etiology of pancreatitis but also aids in predicting the patient's future clinical course and prognosis. However, diagnosing ECP remains challenging due to its nonspecific symptoms and the limited ability of conventional imaging to detect subtle fibrotic changes. Endoscopic ultrasound–shear wave elastography (EUS-SWE) provides an objective, quantitative assessment of tissue stiffness—reported as shear wave velocity (Vs) and kPa—and may help overcome these diagnostic limitations. This study aimed to evaluate the diagnostic accuracy of EUS-SWE for ECP by correlating elastography measurements with minor features of the Rosemont criteria.
Methods This prospective observational study was conducted at a tertiary-care hospital over one year (July 2024–June 2025). Patients with recurrent acute pancreatitis or suspected ECP based on prior imaging (ultrasound, CT, or MRCP) underwent EUS evaluation. Those demonstrating features suggestive of ECP—defined by Rosemont minor criteria (hyperechoic foci, strands, hyperechoic pancreatic duct walls, or ductal dilatation)—were enrolled into the study arm. Two control groups were included: (1) patients with established chronic pancreatitis, and (2) patients with a normal pancreas.
EUS was performed using a linear echoendoscope (GF-UCT190, Olympus Inc.), and all examinations were conducted by four expert endosonographers. Shear wave elastography was performed using the EU-ME3 EUS processor (Olympus Inc.). Ten independent measurements of shear wave velocity (Vs, m/s) and stiffness (kPa) were obtained from the pancreatic body within a 5–10 mm region of interest, avoiding calcifications, vessels, and ducts; only readings with a confidence index (CI) > 50 % were included. Data were analyzed descriptively, and group comparisons were performed using the Kruskal–Wallis test.
Results A total of 57 patients were enrolled. Nineteen patients with features suggestive of ECP formed the study arm, and each control arm (chronic pancreatitis and normal pancreas) also included 19 patients. SWE parameters were compared across the three groups. A statistically significant difference in shear wave velocity (Vs, m/s) was observed among the groups ($p < 0.001$). The mean Vs in the ECP group was 2.39 ± 0.48 m/s, which was significantly higher than in the normal pancreas group (1.94 ± 0.37 m/s) and significantly lower than in the chronic pancreatitis group (3.20 ± 0.26 m/s).
Similarly, stiffness (kPa) values differed significantly between groups ($\chi^2 = 36.442$, $p < 0.001$). Mean stiffness values were 11.65 ± 5.21 kPa in the normal group, 18.28 ± 7.10 kPa in the ECP group, and 31.17 ± 4.60 kPa in the chronic pancreatitis group.
The area under the ROC curve (AUROC) for Vs (m/s) in predicting ECP was 0.729. A Vs cut-off of 2.0 m/s identified ECP with 90 % sensitivity and 57 % specificity.
Conclusions EUS-SWE effectively distinguishes normal pancreas, early chronic pancreatitis, and established chronic pancreatitis, demonstrating a clear stepwise increase in pancreatic stiffness across disease stages. These findings indicate that EUS-SWE is a valuable, objective modality for diagnosing early chronic pancreatitis and for monitoring disease progression, with the potential to facilitate earlier and more targeted intervention.

DOI 10.1055/s-0046-1820769

Endoscopy 2026; 58: S1–S1041

Aims Echo-endoscopic point shear-wave elastography (EUS-pSWE) bypasses subcutaneous adiposity and may provide weight-agnostic liver-stiffness assessment; however, reproducibility data in real-world endoscopy practice remain limited. We aimed to quantify intra-observer reproducibility under routine EUS conditions, benchmark stiffness values against vibration-controlled transient elastography (VCTE), and evaluate clinical and technical modifiers of measurement precision.

Methods In this single-centre prospective cohort (April 2024–February 2025), 120 consecutive adults undergoing diagnostic EUS were enrolled. Each hepatic lobe underwent two sets of five EUS-pSWE acquisitions without scope repositioning. Intra-observer reproducibility was assessed using ICC(3,1), with ICC ≥ 0.80 considered acceptable. Same-day VCTE served as an external comparator. The influence of BMI, underlying liver-disease etiology, and operator experience on acquisition validity and reliability was explored.

Results Forty-six participants were obese (BMI ≥ 30 kg/m²). Overall EUS-pSWE acquisition validity was 66.7 %, increasing to 87.9 % in obese versus 55.2 % in non-obese individuals (p < 0.001). Mean liver stiffness was 6.9 ± 3.1 kPa and correlated strongly with VCTE (r = 0.73, p < 0.001). Intra-observer reproducibility was excellent for both lobes: ICC 0.96 (95 % CI 0.93–0.98) in the left and 0.94 (0.90–0.97) in the right, exceeding World Federation for Ultrasound in Medicine and Biology (WFUMB) quality thresholds across all BMI strata. Single-measurement reliability was fair in non-obese individuals (ICC2,1 = 0.72) but poor in obese participants (0.08), supporting the need for averaging multiple measurements in high-BMI patients.

Conclusions EUS-pSWE provides weight-independent, guideline-compliant reproducibility and demonstrates higher acquisition validity in obesity compared with non-obese patients. These findings support its use when transcutaneous elastography is limited by poor acoustic windows. Averaging multiple acquisitions is recommended in individuals with BMI ≥ 30 kg/m² to optimise reliability.

OP115 Endoscopic ultrasound with Detective Flow Imaging (DFI) for predicting pancreatic neuroendocrine tumour grade: Single centre experience

Authors Stigliano S[1], Citterio N[2], Biasutto D[2], Marinaccio C[3], Di Matteo FM[4]
Institutes **1** Fondazione Policlinico Universitario Campus Bio-Medico, Roma, Italy; **2** Campus biomedico via alvaro del portillo 200, Roma, Italy; **3** Campus Bio Medico University of Rome, Selcetta, Italy; **4** Campus Bio Medico University of Rome, Rome, Italy
DOI 10.1055/s-0046-1820770

Aims Pancreatic neuroendocrine tumors (pNETs) are a heterogeneous group of tumors with different treatment options depending on pathological grading, clinical staging, and presence of symptoms related to hormonal secretion.
Their classification is made on mitotic count and Ki-67 index.
The current standard for Grading assessment is analysing the material obtained from EUS-guided fine needle aspiration/biopsy (EUS-FNA/FNB).
However this technique is not free from adverse events and could be challenging for NETs localization.
The evidence of high grade of fibrosis and microvascular density decrease (MVD) on tumor pathological specimens has led many authors to search for undirected malignant features of pNET extrapolated from non-invasive techniques.
The introduction of ancillary techniques, such as second-generation contrast agents (CH-EUS), has improved study of pNET. Particularly, at CH-EUS examination contrast pattern well correlates with behaviour and grading of NETs. However, the use of contrast agents entails a prolongation of procedure time and additional costs.
An innovative ultrasound Doppler technique, Detective Flow Imaging EUS (DFI-EUS), involves no additional time or cost as it doesn't require the administration of contrast agent. There is still no standardisation of this technique and few studies have validated its use.
The aim of this study is to evaluate the DFI role in defining NET vascularization and its correlation with CH-EUS. The second aim of the study is to assess DFI role in predicting histological grading.

Methods Single center retrospective analysis on consecutive patients with solid pancreatic lesions who underwent EUS at Therapeutic Digestive Endoscopy Unit of the Fondazione Policlinico Universitario Campus Bio-Medico in Rome.
After activation of DFI, each lesion was observed for at least 30 seconds. Lesions was classified into three grades, according to the degree of vascularisation at DFI: (grade 0 absence of microvascularization of the tumor; grade 1 minimal/isovascularization of the tumor; grade 2 markedly increased microvascularization).
All lesion with final hystological diagnosis of NET were enrolled.
Grading and Ki-67 index of tumors were reported.
Data about lesion's features and procedure were collected.

Results From April 2024 to September 2025, 28 patients were enrolled (60.7 % male; mean age 59 ± 12 years old). The majority of lesion (50 %) were localized in the body of the pancreas and the mean lesion' s size was 24.6 ± 17 mm.
The final histological diagnosis classified 60.7 % lesions as G1, 28.5 % G2 and 10.7 % G3.
At the CEH-EUS the 67.8 % of lesion showed hyper-enhancement.
About the DFI evaluation the 17.8 % of lesion was hypo-vascular, 21.4 % Iso-vascular and 60.7 % was hyper-vascular.
There was excellent correlation between DFI characterization of the lesion and the CH-EUS (ICC 0.9)
Among the NET G1, 64.7 % were Hypervascular at DFI and 29.4 % Isovascular. Among the G2, 62.5 % were Hypervascular at DFI and 37.5 % Hypovascular. The 66.7 % of G3 lesion was Hypovascular.
There was inverse correlation between the NET grade and the DFI grade (Pearson coefficient -0.27; p 0.1).

Conclusions DFI-EUS can provide a fast evaluation of the micro-vascularization of pNET with excellent correlation with CH-EUS. Hyper-vascular pattern at DFI correlates with low Ki-67 index.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP116 Endoscopic Ultrasound and Clinicodemographic Features to Distinguish Pancreatic Ductal Adenocarcinoma From Autoimmune Pancreatitis

Authors Sanchez Cordero M[1], Rivera-Troia F[2], Micames-Caceres CG[3]
Institutes **1** University District Hospital, San Juan, Puerto Rico; **2** Ponce Health Sciences University, Ponce, Puerto Rico; **3** Hospital Bella Vista, Mayagüez, Puerto Rico
DOI 10.1055/s-0046-1820771

Aims To systematically identify and characterize the clinicodemographic and endoscopic ultrasound (EUS) features that distinguish autoimmune pancreatitis (AIP) from pancreatic ductal adenocarcinoma (PDAC). The overarching goal is to enhance diagnostic precision, minimize unnecessary surgical interventions in AIP, and promote timely oncologic management in PDAC. Specifically, this study aims to determine demographic and clinical predictors associated with each diagnosis, delineate characteristic EUS patterns differentiating AIP from PDAC, and evaluate the diagnostic contribution of serologic markers such as IgG4 levels when integrated with imaging and clinical variables [1–17].

Methods We conducted a single-institution retrospective study of consecutive patients diagnosed with PDAC or AIP between January 2010 and December 2023. PDAC was confirmed by histopathology or cytology obtained by EUS-guided fine-needle aspiration/biopsy (EUS-FNA/B). AIP was diagnosed by histopathology, response to corticosteroids, IgG4 immunostaining, or evidence of extrapancreatic involvement consistent with IgG4-related disease. Continuous variables were compared using t-tests and categorical variables with Chi-

square tests. Univariate logistic regression was used to explore predictors of PDAC versus AIP. Statistical significance was defined as $p < 0.05$.

Results A total of 296 patients were included (272 PDAC, 24 AIP). Mean age was significantly higher in PDAC than AIP (70 vs 61 years, $p < 0.0001$). Male sex predominated in both groups (PDAC 56 %, AIP 67 %). Body habitus differed: a normal or low BMI (< 25) was more frequent in PDAC (9.6 %) than AIP (4.2 %, $p = 0.04$), whereas mean BMI did not differ significantly (24.4 vs 26.0, $p = 0.08$). Diffuse pancreatic enlargement with hypoechogenicity was markedly more common in AIP than PDAC (44 % vs 3.6 %, $p < 0.0001$). In contrast, focal pancreatic lesions predominated in PDAC (94 % vs 25 %, $p < 0.0001$), and main pancreatic duct dilation was also more frequent in PDAC (60 % vs 11 %, $p = 0.009$). Biliary dilation and lymphadenopathy were observed more often in PDAC, though these differences did not reach statistical significance. During EUS evaluation, liver metastases were identified in 16.9 % of PDAC cases. Elevated serum IgG4 (> 140 mg/dL) was present in 54 % of AIP patients (mean 246 mg/dL). Relapse occurred in 25 % of AIP cases and responded to steroid-based regimens (with azathioprine maintenance in most; one patient required rituximab for sustained remission).

On univariate analysis, age > 73 years was strongly associated with PDAC (odds ratio [OR] 18.5; 95 % CI 6.4–53.8; $p < 0.001$), as was the presence of a focal pancreatic lesion (OR 41.5; 95 % CI 13.2–130.6; $p < 0.001$). Lesion size > 30 mm showed limited discriminatory value (OR 1.3; 95 % CI 0.4–3.8; $p = 0.65$). Notably, the probability of PDAC remained high even among lesions < 30 mm, underscoring that size alone should not drive management decisions.

Conclusions Readily obtainable clinicodemographic and EUS features can meaningfully distinguish PDAC from AIP. Older age, focal parenchymal lesions, and main pancreatic duct dilation strongly favored PDAC, whereas diffuse gland enlargement with hypoechogenicity and elevated serum IgG4 supported AIP. Although larger lesion size correlated with malignancy in absolute terms, it added little discriminative power relative to lesion pattern and ductal features. A practical approach that integrates age, lesion distribution (focal vs diffuse), ductal morphology, and serologic markers improves diagnostic precision, helping to avoid unnecessary pancreatectomy in AIP while expediting oncologic care in PDAC. These data support incorporating a combined demographic-EUS-serologic framework into routine evaluation of pancreatic masses and highlight opportunities for future prospective studies using elastography and contrast-enhanced EUS to refine noninvasive differentiation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Accurate differentiation with endoscopic ultrasound (EUS) between malignant and benign pancreatic lesions remains a clinical challenge, and non-invasive EUS-imaging techniques, assessing tissue stiffness and vascularity, may support diagnostic decision-making. [1, 2] This study aimed to evaluate the diagnostic relationship between two elastography techniques—Shear Wave Elastography (SWE/SWM) and Tissue Doppler Imaging Elastography (TDI-E, both qualitative and quantitative forms)—and Detective flow imaging (DFI), in comparison with histological gold-standard findings in patients with pancreatic cancer. [3] Additionally, the elastography and vascularity features of patients were compared with a cohort of healthy pancreatic controls.

Methods A total of 76 individuals were included: 59 patients (77.6 %) with pancreatic lesions and 17 healthy controls (22.4 %). Demographic data, lesion dimensions, DFI (0–2 scale), SWE values (SWM, m/s), qualitative TDI-E stiffness grades (1–4), and quantitative TDI-E values were collected. Histology was categorized as normal tissue, adenocarcinoma, other tumor, or non-neoplastic condition (chronic pancreatitis. Normality was assessed using the Kolmogorov–Smirnov test; group differences were analyzed using Mann–Whitney U tests; correlations were evaluated using Pearson coefficients. Only the lesion dimension followed a normal distribution. All analyses were conducted with two-tailed significance thresholds of $p < 0.05$.

Results Healthy controls had a mean age of 57.5 ± 19.1 years, whereas patients were older (65.9 ± 11.1 years). Most patient lesions originated from the pancreas (98.3 %). Histology revealed adenocarcinoma in 79.3 % of cases, other pancreatic tumors in 5.2 %, and non-neoplastic changes in 12.1 %.

Significant differences emerged between patients and healthy controls across several imaging parameters. Patients exhibited substantially larger lesion dimensions ($U = 0.000$, $p < 0.001$) and markedly different vascularity, reflected by lower DFI scores ($U = 147.5$, $p < 0.001$). Elastography results demonstrated that cancerous lesions were significantly stiffer and less elastic: qualitative TDI-E stiffness grades were higher ($U = 220.5$, $p < 0.001$), while quantitative TDI-E values were lower ($U = 89.5$, $p < 0.001$). Quantitative and qualitative TDI-E meas-

ures showed internal consistency, with a strong inverse correlation (r = –0.356, p = 0.006). No significant differences were found between patients and controls in sex distribution, age, or SWE values.

Correlation analysis among pancreatic cancer patients demonstrated several notable associations. Higher vascularity (increased DFI) correlated with lower qualitative stiffness (r = –0.324, p = 0.013) and higher quantitative elasticity (r = 0.319, p = 0.014), suggesting that better vascularized lesions may retain softer or more heterogeneous tissue architecture. Quantitative elastography values were positively correlated with histology severity (r = 0.352, p = 0.007), indicating that elastography may reflect underlying malignant tissue transformation. Lesion dimension did not correlate with elastography or vascularity measures.

Conclusions This study demonstrates that elastography-derived tissue stiffness and Doppler-based vascularity parameters differ significantly between malignant pancreatic lesions and healthy pancreatic tissue. DFI, qualitative TDI-E, and quantitative TDI-E each show meaningful associations with histological severity, highlighting their potential value as non-invasive biomarkers for assessing malignancy. The findings support the integration of multimodal elastography with vascularity assessment to improve diagnostic accuracy in pancreatic cancer and to differentiate malignant lesions from normal pancreatic tissue. Further large-scale studies are warranted to validate these relationships and explore their role in clinical decision-making.

Aims Detective Flow Imaging (DFI) is an innovative endoscopic ultrasound (EUS) technique designed to detect microvessels with extremely slow blood flow enabling visualization of very small vascular structures without the need for contrast agents and motion-related artifacts. Only few studies have explored DFI role in lesions' characterization, particularly in the assessment of focal pancreatic lesions (FPLs). Only one study proposed a DFI-based classification of FPLs, including vascularity (hypervascular/hypovascular), vessel distribution (peritumoral/intratumoral), vascular morphology (spotted/linear). However, this classification has not yet been formally validated. This study aims to assess interobserver agreement in DFI-based vascular characterization among operators with different levels of expertise.

Methods This single-center retrospective study included consecutive images acquired during EUS examinations performed between June 2024 and October 2025 at the Digestive Diseases Unit, Sant'Andrea University Hospital, Rome. All procedures were performed using a Fujifilm linear-array echoendoscope in combination with a Fujifilm Arietta 850 ultrasound processor. DFI was systematically applied for the characterization of all lesions. Prior to the survey, examiners received the published DFI classification and example images to standardize interpretation. Each examiner independently reviewed 51 images and assessed four parameters: image quality, vascularity, vessel distribution, and vascular pattern. Interobserver agreement was calculated using Krippendorff's Alpha for nominal data, which accommodates missing ratings. Interpretation of Krippendorff's Alpha followed standard Landis and Koch thresholds: values < 0.20 were considered slight, 0.21–0.40 fair, 0.41–0.60 moderate, 0.61–0.80 substantial and > 0.80 almost perfect agreement.

Results Images were evaluated by 21 EUS examiners from 15 European centers with different procedural volumes. Thirteen examiners (61.9 %) performed more than 200 EUS procedures per year, 5 (23.8 %) performed 100–200 per year and 3 (14.3 %) performed fewer than 100 per year. DFI was available in 13 centers (61.9 %) and 13 examiners (61.9 %) routinely used CH-EUS. A total of 51 EUS–DFI images were assessed, including 30 pancreatic ductal adenocarcinoma (PDAC), 1 cholangiocarcinoma, 5 inflammatory lesions, 2 solid pseudopapillary tumors, 7 pancreatic neuroendocrine tumors (pNET) G1, 3 pNET G2, 2 renal metastases and 1 gastrointestinal stromal tumor (GIST). Global interobserver agreement was fair for image quality (α = 0.33), substantial for vascularity (α = 0.64), moderate for vessel distribution (α = 0.49) and vascular pattern (α = 0.49). PDAC were predominantly judged hypovascular in 89.5 % of ratings (α = 0.53), with a peritumoral vessel distribution in 63.2 % (α = 0.43) and spotted vascular pattern in 66.6 % (α = 0.34). Agreement was moderate for vascularity and vessel distribution and fair for vascular pattern. PNET G1 lesions were more frequently evaluated as hypervascular in 62.8 % of assessments (α = 0.34), with intratumoral distribution in 67.6 % (α = 0.15) and linear vascular morphology in 77.0 % (α = 0.49). In this group, agreement was moderate for vascular pattern, while remaining fair for vascularity and vessel distribution. Inflammatory lesions were mostly scored as hypovascular in 72.1 % of evaluations (α = 0.47), with intratumoral vessels in 54.7 % (α = 0.40) and a slight predominance of spotted morphology in 55.7 % (α = 0.20). Agreement was moderate for vascularity and fair for both vessel distribution and vascular pattern. Agreement estimates for the remaining lesion types were not considered reliable due to the very small number of cases [1–5].

Conclusions In a heterogeneous series of pancreatic and extrapancreatic lesions, DFI demonstrated moderate-to-substantial interobserver reproducibility across vascular parameters. Vascularity achieved the highest agreement in PDAC, which were consistently recognized as hypovascular, whereas vascular pattern showed the greatest reproducibility in pNET G1, where a linear intratumoral morphology was reliably identified.These findings suggest that DFI-derived features have variable diagnostic strength depending on lesion type, supporting the complementary role of DFI in vascular assessment during EUS.

Aims Endoscopic submucosal dissection (ESD) with traction is increasingly used to facilitate En Bloc resection of large superficial colorectal tumors, but the impact of gravity on procedural outcomes in this context remains unclear. This study aimed to assess the influence of gravity orientation on traction-assisted colorectal ESD performance and safety [1–4].
Methods Within a large international, multicenter, prospective cohort (22 centers), we included all patients who underwent traction-assisted colorectal ESD between July 2023 and May 2025. Lesions were classified by gravity (favorable, intermediate, unfavorable) based on luminal fluid distribution. The primary endpoint was dissection speed; secondary endpoints included R0 and En Bloc resection, perforation, bleeding, and intra-procedural position changes. Multivariable regression models were adjusted for lesion size, fibrosis, location, and operator expertise (▶ **Table 1**).

▶ **Table 1** Outcomes after adjustment for confounding factors

Outcome	β coefficient / OR (90 % CI)	p-value
Resection speed	β = –0.10 (–0.14 to –0.06)#	0.007 *
R0 resection	OR = 1.05 (0.75 to 1.50)	0.005†
En Bloc resection	OR = 0.87 (0.31 to 1.40)	0.004†
Perforation	OR = 1.11 (0.77 to 1.59)	0.209‡
Post-procedure bleeding	OR = 0.89 (0.57 to 1.35)	0.045‡
≥ 1 position changes	OR = 3.85 (2.98 to 5.00)	< 0.001§

Difference in log-speed, *One-sided non-inferiority test with a non-inferiority margin of 15 % relative reduction, † One-sided non-inferiority test with a non-inferiority margin of 5 % absolute reduction, ‡ One-sided test to rule out superiority, with a non-superiority margin of 2 % absolute increase § Two-sided superiority test

Results Among 3,738 procedures, 1,555 met inclusion criteria. Groups were comparable in lesion and operator characteristics. Mean dissection speed was 36.4 mm²/min with unfavorable gravity versus 38.6 mm²/min with favorable/intermediate gravity. Adjusted analysis confirmed non-inferiority of dissection speed in the unfavorable group (β = –0.10; 95 % CI –0.15 to –0.06; p = 0.007), with similar R0 (91.1 % vs 91.1 %) and En Bloc (97.9 % vs 98.7 %) resection rates. Perforation (8.0 % vs 6.5 %) and delayed bleeding (5.2 % vs 5.7 %) rates were comparable. Position changes were more frequent with unfavorable gravity (OR = 3.85; p < 0.001).
Subgroup analysis based on the use of the underwater strategy revealed an interesting pattern: when the underwater approach was applied, resection speed tended to be higher in the unfavorable-gravity group. In contrast, in the absence of the underwater technique, there was a trend toward a slightly slower resection speed in the favorable/intermediate-gravity group.
Conclusions In conclusion, when ESD is performed with traction assistance, the lesion's position relative to gravity does not significantly affect procedural efficacy or complication rates. These findings suggest that routine consideration of gravity orientation may be less critical in such settings, potentially contributing to procedural simplification. Moreover, to our knowledge, this is the first study to evaluate the influence of gravity on the performance of combined traction and underwater strategies. Our results support prioritizing this combined approach for lesions located in unfavorable-gravity positions.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Traction is increasingly becoming the reference strategy in colorectal endoscopic submucosal dissection (ESD) because of the gains it offers in terms of speed and safety [1. The main limitation of most traction devices is that they are highly useful at the beginning of the procedure, but their effectiveness decreases as dissection progresses. The A-TRACT device 3–4] is the first adaptive multipolar traction system, as it allows traction intensity to be increased throughout the procedure. We conducted a large retrospective study comparing the A-TRACT device with other traction strategies in terms of efficacy and safety.

Methods All patients who underwent colorectal ESD with traction in a high-volume French tertiary center between December 2021 and November 2025 were included. Non-conventional procedures were excluded, including those involving appendiceal lesions, the ileocecal valve, or diverticula. Procedures were categorized into two groups: those using the A-TRACT device (A-ESD) and those performed with another traction strategy (T-ESD). The primary outcome was resection speed. Secondary outcomes included R0 resection rate, perforation, delayed bleeding, and the proportion of positional changes during the procedure. Multivariate analysis was performed, adjusting for operator expertise (beginners ; experts ; super-experts), degree of fibrosis (F0/F1 ; F2), and lesion location (rectum; sigmoid and left colon; colonic flexures; transverse colon; right colon and cecum; ileocecal valve).

Results A total of 1,202 patients were included, with 416 undergoing ESD using A-TRACT and 786 using another traction method, mostly dental bands and non-adaptive multipolar systems. Mean resection speed was 37.2 mm^2/min in the A-ESD group versus 26.8 mm^2/min in the T-ESD group. The R0 resection rate was 85.5 % in the A-ESD group versus 84.0 %. Perforation occurred in 4.8 % of procedures in the A-ESD group versus 3.8 %, and delayed bleeding occurred in 7.9 % versus 10.9 %. Positional changes during the procedure were required in 22.4 % of A-ESD cases versus 25.4 %. After adjustment for potential confounders, resection speed remained significantly higher in the A-ESD group (β 6.77 [4.09–9.46], $p < 0.001$). R0 resection rates were similar (β 0.82 [0.55–1.22], $p = 0.327$). Perforation (β 0.74 [0.40–1.37], $p = 0.331$) and delayed bleeding (β 0.67 [0.42–1.08], $p = 0.097$) tended to be lower in the A-ESD group, although not statistically significant.

Conclusions The A-TRACT traction-assisted ESD strategy demonstrates a significant increase in resection speed without a corresponding rise in complication rates compared with conventional traction devices. A prospective randomized study is warranted to confirm these findings.

Aims Endoscopic resection is widely accepted as a local treatment for rectal neuroendocrine tumors (NETs) sized ≤ 10 mm. However, there is no consensus on the best method for the endoscopic resection of rectal NETs. As a simplified endoscopic procedure, endoscopic submucosal resection with a ligation device (ESMR-L) indicates a histologically complete resection rate comparable to that of endoscopic submucosal dissection (ESD). However, existing data are based

on retrospective studies, and no multicenter randomized controlled trials have directly compared these two techniques. Given the procedural simplicity of ESMR-L, we hypothesized that ESMR-L than ESD would be preferred for rectal NETs. Hence, this trial aimed to verify whether ESMR-L is non-inferior to ESD in terms of histologically complete resection rate [1].

Methods This was a prospective, open-label, multicenter, non-inferiority, randomized controlled trial of two parallel groups, conducted at 32 institutions in Japan.[1] Patients with a lesion endoscopically diagnosed as a rectal NET ≤ 10 mm were eligible for inclusion. Patients were randomized to undergo either ESD or ESMR-L. Adjustment factors were participating institutions and endoscopist expertise levels (expert or non-expert). Expert endoscopists were defined as those with experience in > 40 colorectal ESD procedures. The primary endpoint was the rate of en bloc resection with histologically tumor-free margins (R0 resection). Secondary endpoints included en bloc resection rate, procedure time, hospital stay, total devices and agents cost, and adverse events. Assuming R0 resection rates of 95.2 % (ESD) and 95.3 % (ESMR-L), with a non-inferiority margin of 8 %, one-sided α of 0.05, power of 80 %, and dropout rate of 15 %, the required sample size was 266 patients.

Results Of 266 enrolled patients, 135 and 131 were allocated to the ESD and ESMR-L groups, respectively. After excluding non-neoplastic lesions, 130 and 127 patients were included in the main analysis. A total of 93 endoscopists participated in the study, including 60 experts and 33 non-experts. Baseline characteristics, including age, sex, performance status, antithrombotic use, and lesion location, were comparable between groups. The mean tumor diameter was 5.4 mm in both groups. R0 resection rates were 92.3 % (ESD) and 96.9 % (ESMR-L), with a risk difference of 4.5 % (two-sided 90 % CI, − 0.1 to 9.7 %), confirming non-inferiority of ESMR-L to ESD (Farrington–Manning test; P < 0.001). Subgroup analyses based on the randomization stratification factor (expert vs. non-expert endoscopists) consistently showed a tendency toward a higher R0 resection rate in the ESMR-L group (expert: 3.2 % [− 1.8 to 8.7 %], non-expert: 8.0 % [− 4.0 to 20.7 %]). En bloc resection was achieved in all cases. The mean procedure time, hospital stay, and total device cost were significantly lower in the ESMR-L group (28.0 vs. 5.2 min; 4.4 vs. 3.4 days; 51,102 JPY vs. 24,382 JPY; all P < 0.001). Postoperative bleeding occurred in 3 (2.2 %) and 5 (3.8 %) patients in the ESD and ESMR-L groups, respectively (P = 0.496), with no perforations observed.

Conclusions For rectal NETs ≤ 10 mm, ESMR-L demonstrated non-inferior R0 resection rates compared with ESD and offered advantages of shorter procedure time, reduced hospitalization, and lower cost. These findings support ESMR-L as a simpler and more cost-effective standard treatment option.

OP122 Central Vessel-Modified Muscle Retraction Sign: A Novel Real-Time Stratification of Deep Invasion Risk in Colorectal Endoscopic Submucosal Dissection

Authors Aslan F[1], Ozer S[1], Gurses B[1], Aktas O[1], Ak B[1], Hatipoglu A[1], Saka B[1]
Institute 1 Koç University Hospital, Istanbul, Türkiye
DOI 10.1055/s-0046-1820777

Aims The muscle retraction sign (MRS) indicates increased submucosal invasion risk during colorectal endoscopic submucosal dissection (ESD) but lacks specificity for risk stratification. We investigated whether central vessel pattern (CVP) within the lesion modifies MRS-associated invasion risk.

Methods 1,267 colorectal lesions from 1,175 consecutive patients who underwent colorectal ESD between July 2013 and December 2024 were retrospectively analyzed. Lesions were classified based on MRS and CVP presence into three groups: MRS-negative/CVP-negative (low-risk), MRS-positive/CVP-positive (intermediate risk), and MRS-positive/CVP-negative (high risk). Primary outcome was deep submucosal invasion (SM2-SM3). Statistical analysis included Fisher's exact test and the Chi-squared test for categorical variables and the Mann-Whitney U test for continuous variables. Multivariable logistic regression adjusted for lesion size, lateral spreading tumor (LST) classification, anatomical location, gender, age, and JNET classification.

Results MRS identified 9.2 % (117/1,267) of lesions requiring enhanced assessment (OR 4.74 95 % CI 2.94-7.64, p < 0.001). Among MRS-positive lesions, CVP presence dramatically reduced invasion risk by 87 % (OR 0.13, 95 % CI 0.05-0.32, p < 0.001). After multivariable adjustment, high-risk lesions showed 16-fold increased invasion (OR 16.23, 95 % CI 7.89-33.41, p < 0.001) and dramatically reduced curative resection rates (47.1 % vs 95.9 %, OR 005, p < 0.001) compared to low-risk group. Intermediate risk lesion maintained favorable outcomes with 94.0 % curative resection and 100 % R0 resection rates.

Conclusions Central vessel pattern is the first identified protective modifier of MRS-associated invasion risk, enabling real-time three-tier risk stratififcation. This simple classification provides actionable clinical descision points during colorectal ESD procedure. Future prospective trials are required to assess generalizability of our findings.

OP123 Lyon ESD Dissection score (LEDs): A pre-procedure prediction model for operating time in colorectal endoscopic submucosal dissection

Authors De Cristofaro E[1], Grimaldi J[2], Giannarelli D[3], Djinbachian R[4], Jacques J[5], Wallenhorst T[6], Yzet C[7], Masgnaux LJ[2], Rostain F[2], Lupu A[2], Jerome R[2], Pioche M[2]
Institutes 1 University of Rome "Tor Vergata", Rome, Italy; 2 Hospital Edouard Herriot – Hcl, Lyon, France; 3 Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy; 4 CHUM, Montreal, France; 5 CHU Dupuytren 1, Limoges, France; 6 Pontchaillou University Hospital Center, Rennes, France; 7 CHU Amiens-Picardie, Amiens, France
DOI 10.1055/s-0046-1820778

Aims Colorectal endoscopic submucosal dissection (ESD) is an effective curative technique for superficial colorectal lesions but remains technically demanding, with highly variable procedure times. Predicting colorectal ESD duration is essential for scheduling, resource allocation, and training, yet currently available models are limited. This study aimed to develop and validate a pre-procedure predictive score for estimating colorectal ESD duration.

Methods We analyzed prospectively collected data from patients undergoing colorectal ESD at Edouard Herriot Hospital (Lyon, France). Baseline variables included demographic characteristics (age, sex, ASA score) and lesion-specific factors (location, predicted size, morphology, JNET pit pattern, and suspected fibrosis, defined as either inflammatory bowel disease or a previously attempted/recurrent lesion.). Operator dissection speed was categorized as fast (> 40 min/cm²), intermediate (20–40 min/cm²), or slow (< 20 min/cm²). The derivation cohort included 423 cases (Jan–Dec 2024), and an independent temporal validation cohort included 148 cases (Jan–May 2025). A generalized linear model with gamma distribution and log-link function identified independent pre-procedural predictors. Model performance was assessed using R^2, mean absolute error, and classification accuracy at predefined thresholds (60, 90, 120 minutes). A simplified point-based score (Lyon ESD Dissection Score, LEDs) and an online calculator were derived from model coefficients [1–4].

Results Median procedure time in the derivation cohort was 50 minutes (IQR 30–90). Independent predictors of ESD duration included operator dissection speed, lesion location (flexures, appendix, cecum, ileocecal valve), predicted

lesion size, and suspected fibrosis (all $p < 0.05$). A simplified point-based score (LEDs) was developed (▶ **Table 1**); each component contributed proportionally to the total score, which directly corresponded to the estimated procedure duration in minutes (https://lyonesddurationscore.github.io/leds/). The LEDs showed a strong correlation between predicted and observed duration ($R^2 = 0.52$), with classification accuracy of 76.1 %, 82.2 %, and 88.1 % at thresholds of 60, 90, and 120 minutes. Validation confirmed good performance ($R^2 = 0.48$), with 91.8 % accuracy for procedures ≥ 120 minutes.

▶ **Table 1** Lyon ESD Dissection score (LEDs)

	points
Constant	-26
Dissection speed of endoscopist	
Slow	+54
Moderate	+40
Fast	0
Lesion location	
Rectum	0
Sigmoid colon	+1
Left colon	+4
Splenic and hepatic flexures	+31
Transverse colon	+7
Right colon	+6
Ileocecal valve	+15
Caecum	+13
Appendix	+32
Predicted lesion size (max diameter), mm	Multiply by 1.3
Suspected fibrosis	
No	0
Yes	+12

Conclusions The LEDs is a simple, validated and clinically practical pre-procedure tool that reliably predicts colorectal ESD duration, particularly for longer procedures. It may facilitate scheduling, optimize resource allocation, and improve workflow in endoscopy units.

DOI 10.1055/s-0046-1820779

Aims To compare the outcomes of colorectal endoscopic submucosal dissection (ESD) performed under general anesthesia versus sedation.

Methods Retrospective analysis of the Spanish multicenter ESD registry, including all colorectal ESD procedures from June 2016 to June 2025. Patients were classified into two groups: General anesthesia (GA) , and Sedation (S). Clinical and endoscopic data including operator-reported maneuverability, en bloc, complete and R0 resection rates, and adverse events were evaluated. A propensity score matching (PSM) analysis (1:1) was conducted. Matching variables included age, sex, ASA status, endoscopic lesion size, and lesion location. The Average Treatment Effect on the Treated (ATET) was estimated using teffects psmatch and contrasted with classical matching via psmatch2 (Stata 14.2). Outcomes were analyzed pre- and post-matching (▶ **Table 1**).

Results A total of 2302 patients were included (S: 661; GA: 1641). Lesions treated under GA were significantly larger (median 40 mm vs 30 mm, $p < 0.001$), more frequently proximal, and occurred in patients with higher ASA classification. Procedure duration was comparable between groups (median 120 min in both). Differences were observed in complete resection rate: 96.5 % (GA) vs 93.9 % (S), $p = 0.005$; en-bloc resection: 91.7 % (GA) vs 85.5 % (S), $p < 0.001$; intraprocedural perforation: 15.3 % (GA) vs 10.4 % (S), $p = 0.002$.

PSM resulted in 211–230 matched pairs depending on the evaluated outcome. After PSM, anesthesia time was longer in the GA group (+41.3 min; $p < 0.001$) but the ESD duration showed no significant differences. Regarding en-bloc resection: GA showed a statistically significant advantage using classical matching (psmatch2, $p = 0.043$), but this difference was not confirmed by teffects psmatch ($p = 0.075$). Complete resection, maneuverability, and intraprocedural perforation did not differ significantly between groups. Intraprocedural bleeding was higher in the GA group (+23.6 %, $p < 0.001$).

Conclusions Colorectal ESD shows acceptable clinical outcomes under both sedation and general anesthesia. More studies are needed to clarify whether GA improves en bloc resection. Anesthesia modality should be selected according to patient profile, lesion complexity, and institutional resources.

▶ **Table 1**

ESD outcomes			
	Sedation (n = 661)	**General Anestesia (n = 1641)**	**p (< 0.05)**
Anestesia duration (min; median (IQR))	150 (104-200)	175 (120-240)	0,000
Procedure duration (min; mediana (RIQ))	120 (75-180)	120 (71-180)	0,840
Complete resection, n (%)	620 (93,9)	1579 (96,5)	0,005
En bloc resection, n (%)	530 (85,5)	1451 (91,7)	0,000
Intraprocedural complications, n (%)

OP125 Development and Prospective Validation of a Real-Time Artificial Intelligence System for Detection of Incomplete Photodocumentation During Esophagogastroduodenoscopy

Authors Misawa M[1], Kudo SE[1], Kondou K[1], Shibuya T[1], Ide Y[1], Kato S[1], Kuroki T[1], Okumura T[1], Kouyama Y[1], Sakurai T[1], Ogawa Y[1], Maeda Y[1], Ichimasa K[1], Ogata N[1], Hayashi T[1], Baba T[1]

Institute 1 SHOWA Medical University Northern Yokohama Hospital, Yokohama, Japan

DOI 10.1055/s-0046-1820780

Aims Approximately 10 % of gastric cancers are missed during esophagogastroduodenoscopy (EGD) [1], with exposure errors accounting for 23 % of these missed lesions [2]. Previous studies have demonstrated that providing feedback on incomplete photodocumentation can improve early gastric cancer detection [3]. We developed and validated an artificial intelligence (AI) system capable of real-time detection of incomplete photodocumentation during EGD.

Methods This single-center prospective cohort study enrolled patients from April 2024 to July 2024 for AI model training, followed by prospective validation during October 2025 in one endoscopy room. Patients who did not opt-out and had complete video recordings of their EGD procedures were included. Exclusion criteria included incomplete examinations, limited visualization due to gastric residue, and history of esophageal, gastric, or duodenal surgery. The AI model utilized EfficientNetB0 architecture to classify 15 anatomical locations across the pharynx, esophagus, stomach, and duodenum. Annotations were performed by two experienced endoscopists. For the prospective validation, a separate AI model first filtered out low-quality images (e.g., blur, insufficient air insufflation). The anatomical location AI performed inference only on images deemed of adequate quality. For the gastric body (upper, middle, lower), predictions of adjacent segments (e.g., AI predicting 'upper body' when the label was 'middle body') were considered correct.

Results The training dataset comprised 22,026 images from 496 patients. Internal validation achieved an accuracy of 92.5 % (95 % CI: 89.8-94.7 %). During prospective validation, 68 patients were enrolled (mean age ± SD: 70.9 ± 12.1 years; 37 females). Seventeen endoscopists performed the procedures, including eight board-certified endoscopists. A total of 3,623 still images were captured during these procedures. The quality-assessment AI identified 978 images (27.0 %) as low-quality. The anatomical location AI performed predictions on the remaining 2,645 adequate-quality images, achieving an accuracy of 95.5 % (95 % CI: 95.2-96.7 %).

Conclusions We successfully developed and prospectively validated an AI system for real-time detection of incomplete photodocumentation during EGD and demonstrated its high accuracy. This system has potential applications as a quality management tool and warrants further implementation in clinical practice.

Conflicts of Interest Masashi Misawa has received an ownership interest in Cybernet Systems Corp. and speaking honoraria from Olympus Corporation.

DOI 10.1055/s-0046-1820781

Aims Esophagogastroduodenoscopy (EGD) is a basic diagnostic tool indispensable in the diagnostic process of benign, pre-neoplastic and neoplastic diseases of upper gastrointestinal tract (UGI). Its diagnostic efficacy is strictly related with quality of the procedure. Currently, the miss rate of UGI neoplasms is estimated to exceed 10 % [1]. Quality indicators of EGD are established, however quality control bases on manual verification. The aim of this study was to create and validate artificial intelligence (AI) language model in the assessment of EGD quality indicators.

Methods It was a multicenter retrospective study. The RoBERTa-large LLM (Large Language Model) was used to analyze data from endoscopy and histopathology reports (both written as free text) of 15,917 EGDs performed in three endoscopy centers between 01.2019 and 12.2022. The data set was divided into training and validation dataset (12,733 EGDs, with 5-fold stratified cross-validation method, i.e. in separate runs, four folds were used for training the model, and the remaining one fold was used as the validation dataset to ensure the model's performance was consistently reliable on unseen data) and test dataset (3,184 EGDs) to maintain 80:20 ratio. A robust training methodology including constrained hyperparameter optimization, validation, monitoring and early stopping was used. Statistical rigor was ensured through 5-fold cross-validation, multiple random seeds and proper test set isolation to allow appropriate working on highly imbalanced data. The assessed parameters were: Barrett's esophagus, gastric precancerous conditions, neoplastic lesions, endoscopists biopsy rate, composite detection rate (detection of at least one: cervical inlet patch, gastric polyps, post ulcer, duodenal bulb deformation), endoscope type, sedation. Performance was evaluated using accuracy, F1 score, precision, recall and AUC with 95 % confidence intervals (▶ **Table 1**).

Results The model achieved mean test accuracy of 96.62 % (SD 1.83 %, range 94.03 % – 99.31 %) and mean test F1 score: 96.50 % (SD 1.85 %, range 94.14 % – 99.18 %) across all tasks with excellent generalization (mean CV-test gap: -0.16 %) with mean 250.6 samples per second during inference (SD 85.2, rangec179.3 – 364.9). The AUC for tasks ranged from 94.03 % to 99.31 %, F1 score from 94.14 % to 99.18 % and AUC from 0.8834 and 0.9863.

Conclusions Demonstrating very good to excellent performance across the analysis of endoscopy and histopathology reports, the created AI model enables the automatic auditing of clinical data. This capability allows for continuous monitoring of key quality indicators for EGD, such as the detection rate of neoplasia.

OP127 Standalone Performance Of Artificial Intelligence In Automated Measurement Of Colonoscopy Key Quality Indicators

Authors Antonelli G[1], Desideri F[2], Schiavone S[3], Iacopini F[3], Hassan C[4]
Institutes **1** Gastroenterology and Digestive Endoscopy Unit, Castelli Hospital, Roma, Italy; **2** Gastroenterology Department, San Maurizio Hospital, Bolzano, Italy; **3** Gastroenterology and Digestive Endoscopy Unit, Castelli Hospital, Rome, Italy; **4** IRCCS Humanitas Research Hospital, Digestive Endoscopy Unit, Rozzano, Italy
DOI 10.1055/s-0046-1820782

Aims Colonoscopy quality is strongly correlated to improved clinical outcomes for patients. The regular and accurate measurement of key performance indicators (KPI) such as withdrawal time, bowel cleanliness, and cecal intubation is pivotal in assuring a quality procedure and preventing pitfalls. However, implementation and reporting of KPIs is often suboptimal.

The recent availability of Artificial-Intelligence (AI) powered tools to automate KPI measurement and reporting may be able to address this variability and improve procedural quality.

Aim of this study was to test an AI-based tool developed to address these issues in a clinical setting.

Methods All procedures from two multicenter prospective studies enrolling adult patients undergoing colonoscopy for CRC primary screening, surveillance or FIT + were video recorded with high-quality settings. Experienced operators performed all colonoscopies.

For this analysis, colonoscopy videos were subsequently submitted to an FDA-cleared medical device with additional features specifically aimed at generating AI-based quality metrics.

Operating endoscopist evaluation of KPIs (procedure duration(PD), withdrawal time(WT), cleanliness using the Boston Bowel Preparation Scale, [BBPS] and caecum recognition and intubation) were recorded, and were used as Ground Truth.

Primary endpoints of the study were mean absolute percentage error (MAPE) when comparing AI predictions with ground-truth values. **Secondary endpoints** were mean absolute error (MAE), root mean square error (RMSE) and caecum recognition accuracy.

Results Overall, colonoscopy videos from **152 patients** (53.9 % female, mean age 66.59 years), were included in the study [1, 2].

Operating endoscopist KPIs were: mean PD 20:53 ± 8.06 minutes, mean WT 13:25 ± 6:49 minutes, BBPS score per class (optimal 81.0 %, adequate 16.4 %, inadequate 2.6 %). Caecum intubation was successful in 97.3 % of cases. AI-based KPIs were: mean PD 20:56 ± 8:09, mean WT 13:32 ± 6:58, BBPS score per class (optimal 86.2 %, adequate 11.8 %, inadequate 2 %).

When compared to ground truth, the AI performance showed a MAPE of 0.3 % and 8.1 % for **PD and WT**, respectively. MAE was 3.8 secs and 63.7 secs and RMSE was 9.5 secs and 128.4 secs for PD and WT, respectively. For **bowel cleanliness** AI showed Balanced accuracy 87.16 % and Spearman correlation 0.42 ($p < 0.001$). **Caecum detection** showed sensitivity 82.4 % [95 % CI 75.9 – 88.3] and specificity 95.4 % [95 % CI 91.8 – 98.6].

Conclusions We found an accurate and reliable performance of a fully AI-based system in automating measurement and reporting of validated colonoscopy KPIs. This tool may help in standardizing assessment of these indicators, eliminating the burdens and variability of manual reporting without disrupting clinical workflows.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP128 Automated recognition of upper GI anatomical sites in EGD using a deep learning model trained on public and tertiary-care data

Authors Roser DA[1], Weber Nunes D[2], Löffler P[3], Rauber D[2, 4], Ignatenko Y[5], Kaspar M[5], Palm C[2, 4], Messmann H[1]
Institutes **1** Department of Gastroenterology, University Hospital Augsburg, Augsburg, Germany; **2** Regensburg Medical Image Computing (ReMIC), OTH Regensburg, Regensburg, Germany; **3** Augsburg University, Augsburg, Germany; **4** Regensburg Center of Health Sciences and Technology (RCHST), OTH Regensburg, Regensburg, Germany; **5** Institute for Digital Medicine, University Hospital Augsburg, Augsburg, Germany
DOI 10.1055/s-0046-1820783

Aims Systematic visualization of predefined anatomical sites is essential for quality assurance and training in esophagogastroduodenoscopy (EGD), but objective, automated assessment of examination completeness in Europe is lacking. We aimed to develop and preliminarily evaluate a deep learning algorithm that classifies still images from the upper gastrointestinal tract (UGIT) into 28 standardized anatomical categories, including 22 gastric segments according to the Systemic Stomach Screening (SSS) protocol by Kenshi Yao. Primary outcomes were macro F1-score and overall accuracy for this 28-class classification task.

Methods In this retrospective diagnostic machine learning study, we collected endoscopic still images from two sources: (1) the publicly available GastroHUN dataset (Colombia; Bravo et al., Sci Data 2025) and (2) an internal dataset from a European tertiary referral centre (Augsburg, Germany). All images were obtained during routine EGD using Olympus endoscopes and anonymized prior to analysis. A total of 1,553 patients were included: 385 from GastroHUN (5,202 images) and 1,114 from UKA (2,793 images), yielding 8,095 images. Each image was labelled at image level into one of 28 anatomical classes: oropharynx, esophagus, esophagogastric junction, duodenal bulb, second part of the duodenum, papilla and 22 gastric segments based on the SSS classification using a multi-annotator process. We trained a ConvNeXt-Tiny convolutional neural network for image-level classification using patient-wise 5-fold cross-validation to prevent information leakage between training and test sets. Performance was evaluated as mean macro F1-score and overall accuracy across folds.

Results Across 5-fold patient-wise cross-validation, the model achieved a mean macro F1-score of 0.79 ± 0.01 and an overall accuracy of 0.79 ± 0.01 for 28-class anatomical site classification. The network differentiated major UGIT regions (esophagus, stomach, duodenum) and also assigned images to fine-grained gastric segments according to the SSS protocol. Qualitatively, performance was higher in broader anatomical regions and lower in some of the most detailed gastric segments (e.g., lower vs. upper corpus posterior wall), consistent with the increased difficulty of very fine-grained localization.

Conclusions This preliminary study demonstrates the feasibility of automated recognition of UGIT anatomical sites using a ConvNeXt-Tiny CNN trained on a combination of public and tertiary hospital data. The model achieved moderate performance across 28 predefined anatomical categories from the oropharynx to the second part of the duodenum, including 22 SSS gastric segments, indicating that fine-grained anatomical localization of the entire upper GI tract is achievable from still images alone. To our knowledge, this is among the first studies to leverage a public endoscopy dataset together with institutional data for upper GI anatomical site classification.

OP129 Expected values of artificial intelligence in colon capsule endoscopy: I-CARE group and AICE consortium Position Statement

Authors Triantafyllou K[1], Agache A[2], Arasaradnam R[3], González Suárez B[4], Keuchel M[5], Kyvik K[6], Schelde-Olesen B[2], Tziatzios G[7], Dray X[8], Sidhu R[9], Baatrup G[10], Koulaouzidis A[11]

Institutes **1** National and Kapodistrian University of Athens , ALIMOS, Greece; **2** Odense University Hospital, Odense, Denmark; **3** University Hospital Coventry & Warwickshire, Coventry, United Kingdom; **4** Hospital Clínic de Barcelona, Barcelona, Spain; **5** Agaplesion Bethesda Krankenhaus Bergedorf, Hamburg, Germany; **6** Department of Public Health, Department of Clinical Research, University of Southern Denmark, Odense, Denmark; **7** Department of Gastroenterology, General Hospital of Nea Ionia "Konstantopoulio-Patision", Athens, Greece; **8** Sorbonne University Hospital Saint-Antoine – APHP, Paris, France; **9** Academic Unit of Gastroenterology, Sheffield Teaching Hospitals, Sheffield, United Kingdom; **10** Department of Clinical Research, Odense University Hospital,, Odense, Denmark; **11** Surgical Research Unit, Odense University Hospital, Svendborg, Denmark

DOI 10.1055/s-0046-1820784

Aims The objective of this Position Statement is to outline the primary outcomes of artificial intelligence (AI) tasks within the context of established and emerging performance measures, projecting minimum and desirable values expected during the implementation of AI in colon capsule endoscopy (CCE) practice, focusing on the detection and characterization of colonic neoplasia. The assumption is that AI implementation can standardize quality metrics in CCE with an emphasis on clinical rather than technical validation.

Methods The AI-Supported Image Analysis in Large Bowel Camera Capsule Endoscopy (AICE) consortium and the CApsule Endoscopy REsearch (i-CARE) group have established a Task Force (TF) of CCE experts, technical information experts, patients representatives and an ethicist to define the expected values of AI performance measures in CCE, particularly focusing on GI neoplasia, within the framework of previously defined proxy performance measures, primarily conventional colonoscopy. To align AI tasks with performance measures and define their expected values, the existing methodology [1] was adopted, including task definition, integration of AI tasks with performance measures, the reference standard, and finally the expected value assessment defined for each outcome based on the clinical relevance of the performance measure related to the AI task and the expected benefit/harm of AI implementation. A super agreement of > 80 % on a maximum of three Delphi voting rounds using a 5-point scale ranging from "strongly disagree" to "strongly agree" was required for consensus on each statement. This project is funded by the European Union. Views and opinions expressed are, however, those of the authors only and do not necessarily reflect those of the European Union or the European Commission. Neither the European Union nor the European Commission can be held responsible for them.

Results The TF identified eight domains, namely pre-procedure, completeness of procedure, identification of pathology, management of pathology, complications, patient experience, post-procedure, and ethics. The TF defined 21 AI tasks (shown in the ▶ **Table 1**) with their performance measures, reference standards, and expected values. TThe Delphi method was employed to solicit votes on proposed statements regarding the acceptance of AI-assisted CCE in clinical practice. A super agreement was reached in the first round for 17 statements, while the remaining four were amended and approved in the second round.

▶ **Table 1**

Domain	Pre-procedure	Completeness of procedure	Identification of pathology	Management of pathology	Complications	Patient experience	Post-procedure	Ethics
AI Tasks	1. Prediction of failed CCE or need for subsequent examination 2. Adequate colon cleansing	3. Complete mucosa visualization 4. Identification of colon landmarks-segments 5. Correct assignment of pathology to colon segments 6. Polyp localization & CCE path reconstruction 7. Visualization of the small bowel	8. Reading time 9. Polyp matching 10. Polyp size measurement 11. Sensitivity & specificity for: CRC, and polyps 12. False positive rate 13. Non-malignant pathology detection	14. PIVI/SODA criteria for not recommending colonoscopy 15. Prediction of submucosal invasion	16. CCE retention 17. Colonic perforation	18. AI recognition or recording of patients' experience before, during, and after CCE	19. AI-generated report 20. AI-provision of alarm and interface with the clinician and patient.	21. AI-related ethics issues

Conclusions A Task Force of clinical and AI technology experts, patients' representatives, decision-making experts, and ethicists described CCE AI tasks and their performance measures and defined statements for acceptance of AI-assisted CCE in clinical practice, focusing on the detection of colorectal neoplasia.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820785

Aims Computational tools, particularly artificial intelligence (AI), are reshaping gastrointestinal (GI) endoscopy by automating essential but time-consuming tasks such as adenoma detection rate (ADR) calculation, quality-metric standardization, image documentation, and procedural reporting. These technologies also enhance consistency across operators and support real-time lesion detection. However, emerging evidence raises concerns about potential over-reliance on AI systems and the risk of endoscopist "deskilling," with implications for long-term safety, training, and clinical autonomy. This meta-analysis of existing systematic reviews and randomized controlled trials sought to quantify the diagnostic benefits of AI-assisted colonoscopy while synthesizing the available evidence on human-factors risks, including automation bias, vigilance decline, and skill degradation, as well as evaluating future directions such as the integration of large foundation models.

Methods We performed an umbrella review of randomized controlled trials (RCTs) and meta-analyses evaluating AI-assisted colonoscopy versus standard colonoscopy in adults undergoing colorectal cancer screening or surveillance. The PICO framework was defined as follows: Population—adults undergoing screening or surveillance colonoscopy; Intervention—AI-assisted colonoscopy using real-time computer-aided detection or other computational tools; Comparator—standard, non-AI-assisted colonoscopy; Outcomes—primary outcomes were adenoma detection rate (ADR) and adenoma miss rate (AMR), while secondary outcomes included polyp detection rate, procedure time, and human–AI interaction measures such as vigilance, operator dependence, and perceived deskilling. Additionally, a narrative synthesis was conducted for studies evaluating large "foundation models" and broader computational tools in GI endoscopy [1–4].

Results The strongest evidence to date comes from a meta-analysis of 28 randomized controlled trials involving 23,861 patients, which demonstrated that AI-assisted colonoscopy increases ADR by approximately 20 % and reduces adenoma miss rate by 45–55 % compared with standard colonoscopy. These benefits were achieved with minimal increases in procedure time. When observational and real-world effectiveness studies are included alongside RCTs, the total evidence base expands to nearly 30,000 patients, consistently confirming ADR improvements across diverse clinical settings while highlighting substantial inter-study heterogeneity.Beyond diagnostic performance, real-world and health-technology-assessment reports also underscore emerging human-factors risks. A recent multicentre study observed a decline in ADR during non-AI colonoscopies (from 28 % to 22 %) following widespread adoption of AI, suggesting potential operator over-reliance and skill degradation when AI support is unavailable. Surveys of practicing gastroenterologists echo these concerns, frequently identifying automation bias, operator dependence, and economic barriers as key perceived risks of AI implementation. In parallel, next-generation deep-learning "foundation models," trained on millions of endoscopy images or video frames, show early promise in multitask performance—including landmark recognition, lesion detection, inflammation scoring, and automated report generation. However, these systems remain largely pre-clinical, with limited prospective validation and unclear human–AI interaction effects.

Conclusions AI-assisted colonoscopy consistently improves ADR and reduces missed lesions, reinforcing its value as a quality-enhancing adjunct in GI endoscopy. However, emerging evidence of automation bias, operator over-reliance, potential deskilling, and unequal access highlights the need for human-centered implementation, well-defined usage policies, structured training, and prospective evaluation of long-term cognitive and technical effects. Next-generation foundation models and related computational tools should be developed and deployed within frameworks that emphasize safety, equity, transparency, and preservation of essential endoscopic skills. This underscores the need for rigorous study of human–AI dynamics and for designing AI systems that enhance, rather than replace, endoscopist performance through genuinely collaborative interaction.

Aims The introduction of Lumen-Apposing Metal Stents (LAMS) has significantly influenced clinical practice in biliary drainage. Several studies have confirmed the efficacy and safety of LAMS for EUS-guided gallbladder drainage (EUS-GBD) as a valid option for distal malignant obstruction with a patent cystic duct. While various LAMS are currently available, no direct comparison has been conducted between the two most widely used devices: the Hot Axios (Boston Scientific, USA) and the Hot Spaxus (Taewoong Medical, South Korea). This study aims to perform the first direct comparison of efficacy and safety between Hot Axios and Hot Spaxus stents in EUS-GBD for malignant distal obstruction

Methods This is an international, multicenter, retrospective study conducted in 9 tertiary centers. Outcomes were compared using 1:1 propensity score matching. The primary outcomes were clinical success and safety. Technical success was defined as adequate LAMS placement confirmed by endoscopic and radiologic assessment. Clinical success was defined as a decrease in total bilirubin of at least 15 % within 24 hours and decrease of > 50 % within 14 days after the procedure. Secondary outcomes included overall survival and Adverse Events (AEs). AEs were graded according to the AGREE classification, with Severe AEs (SAE) defined as > Grade II.

Results We enrolled 154 patients across the participating centers. After 1:1 propensity score matching, 82 patients were selected (41 per group). Baseline characteristics were well-balanced. The proportion of female patients was 51.2 % (21/41) in the Hot Axios group and 53.7 % (22/41) in the Hot Spaxus group. The mean age was 70.30 years (SD: 14.41) in the Hot Axios group and 70.39 years (SD: 11.30) in the Hot Spaxus group (p = 0.98).Regarding technical details, EUS-GBD was performed via the gastric route in 78.1 % (32/41) of the Hot Axios group and 73.2 % (30/41) of the Hot Spaxus group. In the Hot Spaxus group, 21 stents were 10x20 mm, while the other 20 were 8x20 mm. In the Hot Axios group, 20 out of 41 stents measured 10x10 mm. Global adverse events (AEs) were recorded in 14 patients: 19.5 % (8/41) in the Hot Axios group compared to 14.6 % (6/41) in the Hot Spaxus group (p = 0.770). According to the AGREE classification, two AEs were classified as severe (SAE). Specifically, bleeding occurred in 3 patients (7.3 %) in the Hot Axios group compared to 0 in the Hot Spaxus group (p = 0.241). No perforations were recorded. Stent occlusion due to food impaction occurred in 5 cases in the Hot Axios group compared to 6 in the other group (p = 0.981); all were successfully treated endoscopically with the placement of a coaxial plastic stent.Clinical success was achieved in 85.4 % of patients in the Hot Axios group and 88.4 % in the Hot Spaxus group (p = 0.683). Median total bilirubin levels before the endoscopist treatment were procedure were 10.6 mg/dL (IQR: 4.2 -16.1) and 11.5 mg/dL (IQR 7.3- 15.4:) for the Hot Axios and Hot Spaxus groups, respectively. At 14 days, the median total bilirubin levels decreased to 2.90 mg/dL (IQR: 1.70–4.25) in the Hot Axios group and 2.55 mg/dL (IQR: 2.00–4.48) in the Hot Spaxus group (p = 0.97).

Conclusions The Hot Spaxus stent demonstrates lower bleeding rate and similar efficacy to the Hot Axios stent for EUS-GBD in distal malignant obstruction jaundice treatment. Further prospective evidences with larger sample sizes are needed to confirm these initial findings.

OP132 Feasibility and Safety of Endoscopic Ultrasound-Guided Gallbladder Drainage for Niemeier Type II Acute Perforated Cholecystitis: A Multicenter Retrospective Pilot Study

Authors Chon HK[1], Jin BC[2]
Institutes **1** Wonkwang University Medical Center, Iksan, Republic of Korea; **2** Jeonbuk National University Hospital (JBNUH), Jeonju, Republic of Korea
DOI 10.1055/s-0046-1820787

Aims Acute perforated cholecystitis (APC), classified by the Niemeier system into types I–III, often requires urgent intervention. Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) has emerged as a minimally invasive alternative for high-risk surgical candidates. This multicenter retrospective pilot study aimed to evaluate the feasibility and safety of EUS-GBD in patients with APC.

Methods Patients diagnosed with APC who underwent EUS-GBD between January 2017 and December 2024 at 5 tertiary referral centers were retrospectively analyzed. The primary outcome was technical success. Secondary outcomes included clinical success, adverse events, stent patency, and all-cause mortality at 30 and 90 days post-procedure [1–5].

Results A total of 23 patients were included. Perforations were classified as Niemeier type I in 1 patient (4.3 %) and type II in 22 patients (95.7 %). Technical and clinical success were achieved in all patients (100 %). Adverse events occurred in 3 patients (13.0 %), including biloma, stent migration, and stent occlusion with recurrent acute cholecystitis. The median stent patency duration was 311 days (interquartile ranges, 176–411), with the probability of stent patency approximately 87.0 % at 2 months and sustained beyond 1.5 years. No deaths occurred within 30 days. All-cause 90-day mortality was observed in 1 patient (4.3 %) due to pneumonia.

Conclusions EUS-GBD appears to be a feasible and safe treatment option for high-risk patients with APC, particularly in cases of localized (Niemeier type II) perforation. These preliminary findings warrant further validation in larger prospective studies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820788

Aims Percutaneous trans-hepatic gallbladder drainage (PT-GBD) represents the gold standard approach in high-risk surgical patients suffering from acute cholecystitis (AC). However, PT-GBD long-term outcomes are burdened from high incidence of stent dysfunction and recurrent AC. Safety and long-term efficacy of endoscopic ultrasound gallbladder drainage (EUS-GBD) in AC patients have been demonstrated. EUS-guided internalization of percutaneous cholecystostomy (EPIC-GBD) has been proposed to improve long-term outcomes. We aimed to compare EPIC-GBD with LAMS to standard PT-GBD (sPT-GBD) management [1–4].

Methods All consecutive high-risk surgical patients with AC who underwent PT-GBD over a 2-year study period were retrieved from 25 Italian high-volume centers. Patients who became fit for surgery or diagnosed with malignant biliary obstruction were excluded. Patients considered suitable for cholecystostomy internalization on multidisciplinary team evaluation, underwent EPIC-GBD with LAMS. Technical and clinical success, adverse events (AE), and procedural details were recorded together with the incidence of recurrent AC, stent disfunction, biliary reinterventions, readmission, biliary-related mortality, and overall mortality. Patients were followed for ≥ 12 months. Outcomes of EPIC-GBD were compared to sPT-GBD using propensity score matching (2:1 nearest-neighbor, 0.2-caliper) based on age, gender, ASA score, Charlson Comorbidity Index, and antithrombotic use. A sensitivity analysis using IPTW with stabilized, trimmed weights estimated adjusted risk ratios using weighted generalized linear models.

Results 484 patients (49.6 % male, median 83-year IQR [75-88]) were retrieved; of them, 124 underwent an attempt of EPIC-GBD. Basal comparison showed higher age (85 [79 – 89] vs. 82 [74 – 87]; P = 0.001), lower ASA 4 (35.5 % vs. 45.8 %; P = 0.05), and a higher Charlson Comorbidity Index (7 [6 – 9] vs. 7 [6 – 8]; P = 0.02) in the EPIC-GBD group. A 10-mm LAMS was used in 73.4 % and a 15/16 mm in 19.3 % cases. Technical success was achieved in 117 (94.4 %) patients; among technical failures, in 4 cases cystic duct was patent, in 3 (2.4 %) a LAMS misdeployment was observed. No correlation with LAMS design or size was observed; all failures occurred when EPIC-GBD was performed > 14 days after PT-GBD (P = 0.01). Clinical success was obtained in 116 (93.5 %) patients. 17 (13.7 %) AE were reported: 13 mild and 4 severe (3 AGREE IIIb and 1 AGREE IVa). After PSM (▶ **Table 1**), the comparison of long-term outcomes between the two groups showed lower biliary reinterventions (14.4 % vs. 26.9 %; RR 0.54; P = 0.013), recurrent AC (6.7 % vs. 26.9 %; RR 0.25; P < 0.001), biliary-related mortality (1.0 % vs. 17.8 %; RR 0.05; P < 0.001), and overall mortality (22.1 % vs 40.9 %; RR 0.54; P = 0.001) in the EPIC-GBD group; similar readmission rate (24.0 % vs. 34.6 %; RR 0.69; P = 0.057) were observed. EPIC-GBD was confirmed to significantly decrease recurrent AC and biliary-related mortality at IPTW analysis.

Conclusions EUS internalization of percutaneous cholecystostomy is a safe and effective approach able to improve long-term outcomes of selected high-risk surgical patients with AC. EPIC-GBD reduces the risk of recurrent AC and stent disfunction as well as the need for biliary reintervention and biliary-related mortality compared to sPT-GBD.

DOI 10.1055/s-0046-1820789

Aims EUS-GBD has become an effective and minimally invasive alternative for the management of AC in patients who are not candidates for surgery. In EUS-GBD, the choice of access route—duodenal or gastric—depends on anatomical considerations and the endoscopist's experience; however, no studies have directly compared outcomes between both approaches.
The objective was to compare both techniques—cholecystogastrostomy (CG) and cholecystoduodenostomy (CD)—by analysing technical success (TS), clinical success (CS), adverse events (AE), and biliary readmissions (BR) in patients with acute cholecystitis who were not candidates for surgery.

Methods This was a multicentre, observational, retrospective cohort study including patients with acute cholecystitis who underwent EUS-GBD with a lumen-apposing metal stent (LAMS) between January 2020 and October 2025. BR was defined as any hospital readmission due to biliary colic, recurrent cholecystitis, cholangitis, choledocholithiasis, or acute pancreatitis.The choice of access route—gastric or duodenal—was determined by the endoscopist.

Results A total of 166 patients were included (115 cholecystoduodenostomies vs 51 cholecystogastrostomies), with a median age of 88 (RIQ 84-92) y-o with female predominance (59 %).
Both groups were comparable in age, Charlson index, clinical Tokyo-severity, and inflammatory parameters.No significant differences were found in TS (97 % vs 96 %) or CS (96 % vs 90 %) ($p > 0.05$).
The overall AEs rate was 15.5 % (36 AEs), with AGREE IIIA predominance (15 events). , Cholecystogastrostomies showed a higher incidence of AEs (25 % vs 11 %; $p = 0.020$). Early AEs (≤ 14 days) were also significantly more frequent with antral access ($p = 0.025$). The most common AEs were bleeding (20.69 %) and LAMS obstruction (16.2 %) .
The only relevant technical differences between the groups were a higher use of coaxial pigtail in antral access (53 % vs 24 % in CD; $p < 0.0005$) and a different distribution of stent sizes. A 10 × 10-mm stent was more frequently used in the CG group (67.6 %), whereas in the CD group the use of 15 × 10-mm and 10 × 10-mm stents was similar ($p = 0.008$)
Antral access showed a higher cumulative probability of readmission, in the survival analysis, (log-rank $p = 0.0117$) (fig 1). Multivariate cox analysis demonstrated a three-fold increased risk of readmission for antral access (HR 3.05; 95 % CI 1.23–7.58; $p = 0.016$).Neither Axios size, nor pigtail placement, nor prior or same-session ERCP showed a significant influence on the risk of readmission (▶ **Table 1**).

▶ **Table 1**

	Cholecystoduodenostomies, n(%)	Cholecystogastrostomies, n(%)	p
Technical success (TS)	112 (97,39 %)	49 (96,08 %)	0,648
Clinical success (CS)	110 (95,65 %)	46 (90,20 %)	0,173
Adverse events (AEs)	13 (11,30 %)	13 (25,49 %)	0,020
Procedure-related AEs	9 (18 %)	8 (29,63 %)	0,240

Conclusions Although both access routes provide very high rates of technical and clinical success in EUS-GBD, antral access is associated with a higher risk of adverse events and a significant increase in biliary readmissions. Therefore, although both techniques are valid, bulbar access should be considered the preferred route when anatomy allows. When gastric access was mandatory due to anatomical reasons, endoscopic follow-up may be considered (gallbladder stone clearance and LAMS removal or exchange for double pigtails) to reduce AEs and prevent recurrent biliary episodes.

DOI 10.1055/s-0046-1820790

Aims EUS-GBD is an effective and safe technique in non-surgical patients with acute cholecystitis (AC). In many cases, urgent percutaneous gallbladder drainage (PTGBD) is performed first, and the drain is later internalized via endoscopic ultrasound. Since it has been suggested that conversion from PTGBD may yield poorer outcomes, this study aimed to evaluate the efficacy and safety of EUS-GBD in patients with and without conversion of prior PTGBD.

Methods Retrospective study including all patients who underwent EUS-GBD for acute cholecystitis between 2016 and 2025 [1–4].

Results A total of 195 patients with AC were included (53 % male); mean age 83 ± 10 years. In 65 cases (34 %), prior PTGBD had been performed and subsequently converted. Overall technical success was 90.8 % (177/195). There were no differences between the conversion and non-conversion groups regarding technical success, clinical success, and intraprocedural or early (< 7 days) adverse events (AEs): 86.2 % vs 93.1 %, $p = 0.1$; 98.2 % vs 95.9 %, $p = 0.6$; 4.6 % vs 3.1 %, $p = 0.6$; 6.2 % vs 5.4 %, $p = 0.8$, respectively.In 20 patients without prior PTGBD, gallbladder puncture with saline instillation for distension was required. Technical success was significantly lower in these patients (80 %) compared with those with a naturally distended gallbladder (95.5 %), $p = 0.01$.

Conclusions EUS-GBD performed as a conversion from prior PTGBD is not associated with worse outcomes, indicating that patients initially treated with urgent PTGBD can safely undergo endoscopic drainage and benefit from its lower complication and recurrence rates. However, patients requiring gallbladder distension via direct puncture show lower technical success.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP136 Endoscopic ultrasound-guided gallbladder drainage with lumen-apposing metal stent vs laparoscopic cholecystectomy in frail elderly patients with acute cholecystitis: a retrospective cohort study

Authors Biancheri P[1], Shoval Y[1], Costanzo A[2], Locatelli R[1], D'addazio G[1], Cosimo P[1], Armellini E[1]
Institutes 1 Digestive Endoscopy Unit, ASST Bergamo Est, Seriate, Italy; 2 General Surgery Unit, ASST Bergamo Est, Seriate, Italy
DOI 10.1055/s-0046-1820791

Aims Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) with lumen-apposing metal stent (LAMS) is increasingly being performed as an alternative to laparoscopic cholecystectomy (LC) in frail elderly patients with high surgical risk and acute cholecystitis. We analyzed short-term safety and mortality of EUS-GBD *vs* LC in this setting.

Methods We performed a retrospective observational cohort study on consecutive patients aged ≥ 70 years with American Society of Anesthesiology (ASA) score III-IV, who were admitted to our Hospital with acute cholecystitis, and were treated with either EUS-GBD with LAMS or LC. Primary outcomes were 30-day mortality, 30-day adverse events (AE), 30-day readmissions, and length of stay (LOS) in hospital. Secondary outcome was cumulative mortality at 1 year. Group comparisons were performed using Fisher's exact test and Mann-Whitney U test for categorical and continuous variables, respectively.

Results Seventy-eight patients were included (EUS-GBD, n = 28; LC, n = 50). Patients in the EUS-GBD group were significantly older (mean 83.2 vs 78.7 years, p = 0.007), had more frequently an ASA IV score (39.3 % vs 10 %, p = 0.004), a Charlson Comorbidity Index (CCI) ≥ 5 (75 % vs 44 %, p = 0.010), and a Tokyo grade III cholecystitis (32.1 % vs 2 %, p = 0.001) compared to those in the LC group. Thirty-day mortality rates were 7.1 % (2/28) after EUS-GBD vs 2 % (1/50) after LC (p = 0.291). Thirty-day AE occurred in 7.1 % (2/28) of patients undergoing EUS-GBD vs 12 % (6/50) of those undergoing LC (p = 0.704). Thirty-day readmission rates were 7.1 % (2/28) after EUS-GBD vs 4 % (2/50) after LC (p = 0.615). Median LOS was 8 days [IQR 6–14] in the EUS-GBD group and 8 days [IQR 6–12] in the LC group (p = 0.745). Cumulative mortality at 1 year was 28.6 % (8/28) after EUS-GBD compared with 12 % (6/50) after LC (p = 0.070).

Conclusions EUS-GBD with LAMS was more frequently selected for older, frailer patients with higher surgical risk, as reflected by significantly higher ASA and CCI scores and more severe cholecystitis at baseline. Despite these unfavorable characteristics, short-term outcomes, including 30-day adverse events, readmissions, and hospital LOS, were comparable between EUS-GBD and LC. We observed a trend towards higher cumulative mortality at 1 year in the EUS-GBD group, which likely reflects underlying frailty rather than procedure-related complications. Our results suggest that EUS-GBD is a valuable option for high-risk patients with acute cholecystitis who are deemed unfit for LC.

Scope Meets Scale: Optimizing Endoscopy in Obesity

15/05/2026, 10:30–11:30 **Aqua 3 + 4**

OP137 Endoscopic Sleeve Gastroplasty Versus Oral Semaglutide for Obesity: A Real-World Comparative Study

Authors Jagtap N[1], Aman G[1], Katrevula A[2], Shujaath A[1], Reddy DN[1], Kalapala R[1]
Institutes 1 AIG Hospitals, Hyderabad, India; 2 AIG hospitals, Hyderabad, India, Hyderabad, Telangana, India, India
DOI 10.1055/s-0046-1820792

Aims Endoscopic sleeve gastroplasty (ESG) and glucagon-like peptide-1 receptor agonists are established therapies for obesity. However, comparative real-world data—especially with oral semaglutide—remain limited. We compared the short-term effectiveness and safety of ESG versus oral semaglutide 14 mg in obesity.

Methods We conducted a retrospective comparative cohort study between January 2024 and April 2025. Adults aged 18–65 years with BMI ≥ 30 kg/m² or ≥ 27 kg/m² with obesity-related comorbidity treated with either ESG or oral semaglutide 14 mg daily and having 6-month follow-up were included. Primary endpoint was percentage total body weight loss (%TBWL) at 6 months. Secondary outcomes included responder rates (≥ 5 %, ≥ 10 %, ≥ 15 % TBWL) and adverse events. Analyses included unadjusted t-tests, ANCOVA adjusted for age, sex, baseline BMI and diabetes, inverse probability of treatment weighting (IPTW), and 1:1 propensity-matched sensitivity analysis. Risk ratios for responder outcomes were estimated using modified Poisson regression.

Results A total of 150 patients were included (ESG n = 50; semaglutide n = 100). Baseline age, sex, BMI, and metabolic comorbidities were comparable between groups. At 6 months, mean %TBWL was significantly higher with ESG than semaglutide (12.72 ± 5.67 % vs 8.67 ± 3.84 %; mean difference 4.05 %; p = 0.0001). After covariate adjustment, ESG remained superior (β = -4.04 %; 95 % CI -6.08 to -1.99; p = 0.0001). IPTW analysis confirmed an adjusted mean difference of 4.20 % favoring ESG (95 % CI 2.12–6.28; p < 0.001) with excellent post-weighting balance. In 1:1 propensity-matched pairs, ESG maintained higher %TBWL (12.9 ± 5.4 % vs 9.8 ± 5.2 %; p = 0.021). Responder rates ≥ 10 % TBWL were achieved in 70 % with ESG versus 43 % with semaglutide (RR 0.62; 95 % CI 0.46–0.82; p = 0.0009), and ≥ 15 % TBWL in 36 % versus 7 % (RR 0.20; 95 % CI 0.09–0.44; p = 0.0006). Treatment effects were consistent across BMI classes and diabetes status. Adverse event rates were comparable and predominantly mild gastrointestinal symptoms, with no serious complications or mortality.

Conclusions In real-world practice, ESG provides significantly greater short-term weight loss and higher clinically meaningful responder rates than oral semaglutide 14 mg, with comparable safety. ESG should be considered a highly effective minimally invasive option for patients seeking obesity treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP138 The Fulness Study: Updated 12-Month Results of Endoscopic Vertical Gastroplasty and Gastric Mucosal Ablation in patients with obesity

Authors De Siena M[1], Bove V[2], Gualtieri L[2], Pontecorvi V[1], Matteo MV[1], Carlino G[1], Spada C[1], Boskoski I[1]

DOI 10.1055/s-0046-1820793

Aims Obesity has reached global pandemic proportions, affecting over one billion people and increasing the risk of metabolic, cardiovascular, and respiratory diseases. Many patients are not candidates for bariatric surgery or prefer less invasive options. Endoscopic therapies offer promising alternatives. The combination of endoscopic vertical gastroplasty (ESG) and gastric fundus mucosal ablation (GMA) using hybrid argon plasma coagulation may provide a safe and effective treatment that supports long-term weight reduction and metabolic improvement in patients with moderate obesity. The primary aim of this study was to assess the safety and efficacy of combining ESG with gastric fundus mucosal ablation using hybrid argon plasma coagulation. Secondary objectives included evaluating changes in body mass index, ghrelin levels, comorbidities, and patient-reported quality of life.

Methods This single-center pilot interventional study enrolled 21 patients with obesity (body mass index ≥ 30 kg/m²). All participants underwent endoscopic vertical gastroplasty followed by gastric fundus mucosal ablation and were assessed at 1, 6, and 12 months. Clinical, hormonal, histological, and quality-of-life evaluations were conducted. The primary outcome was the percentage of total body weight loss, and body mass index at 6 and 12 months was recorded. Nineteen patients completed the 12-month follow-up.

Results Among the 19 patients who completed the follow-up, mean total body weight loss was 17.32 % ± 7.16 at 6 months and 18.22 % ± 8.37 at 12 months, demonstrating sustained weight reduction over the one-year period. No patient required re-intervention, and endoscopic evaluation confirmed complete mucosal healing in all patients by 6 months.

Mean body mass index decreased from 35.12 ± 3.63 kg/m² at baseline to 29.87 ± 3.55 kg/m² at 6 months and 28.13 ± 3.78 kg/m² at 12 months, reflecting clinically significant improvements. Preliminary histological and hormonal analyses are ongoing; early observations suggest that gastric fundus mucosal ablation may modulate ghrelin secretion, potentially contributing to appetite regulation and long-term weight maintenance. Overall, the combined endoscopic approach appears effective, safe, and well tolerated in patients with moderate obesity who are not candidates for surgical interventions.

Conclusions The Fulness Study demonstrates that combining endoscopic vertical gastroplasty with gastric fundus mucosal ablation is a feasible, safe, and clinically effective strategy for weight reduction in moderate obesity. These findings support further studies with larger cohorts and extended follow-up to confirm long-term efficacy and metabolic benefits.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP139 Predictors of Follow-Up Discontinuation After Endoscopic Gastroplasty: A Secondary Analysis of a Randomized Trial

Authors Vadalà Di Prampero SF[1], Carlino G[2], Geraci M[3], Simonelli I[4], Fiorani M[5], Mancini MA[1], Costamagna G[1], Bulajic M[1]

DOI 10.1055/s-0046-1820794

Aims Loss to follow-up (LTFU) remains a substantial barrier to optimizing outcomes after endoscopic gastroplasty (EG) for obesity. This study aimed to identify clinical determinants of attrition and to develop predictive models able to detect patients at high risk of early discontinuation.

Methods We performed a secondary analysis of a randomized pragmatic trial including 183 patients who underwent EG. Demographic, anthropometric, clinical, radiologic and psychological variables collected over 18 months were evaluated. Three logistic regression models were developed to estimate LTFU risk, with performance assessed by area under the receiver operating curve(AUC) and classification metrics. Sensitivity analyses included weighted logistic regression and Synthetic Minority Over-sampling Technique (SMOTE).

Results A total of 154 patients (84 %) discontinued follow-up before 18 months. Dropouts were younger and had higher baseline weight compared with those retained. A simple model including age, sex and baseline weight showed modest discrimination (AUC 0.62). Models incorporating longitudinal weight trajectories and selected clinical and psychological variables improved accuracy (AUC 0.82 and 0.90). Slow or minimal weight loss was strongly associated with LTFU across all models, while psychological components did not demonstrate consistent associations after adjustment.

Conclusions This model reliably identifies patients at risk of LTFU after EG, highlighting baseline weight and weight-loss trajectory as key predictors. Integrating this tool into clinical practice may facilitate risk-adapted follow-up strategies, enabling intensified support for vulnerable patients and improving long-term outcomes in bariatric endoscopy.

OP140 Hidden Risks in the Young Obese: One Quarter of Bariatric Surgery Candidates Harbor Premalignant Gastric Conditions

Authors Pacheco T[1], Barros AR[2], Costa J[2], Rodrigues C[2], Pinto J[2], Silva J[2]
Institutes **1** Unidade Local de Saúde do Tâmega e Sousa, E.P.E., Penafiel, Portugal; **2** Unidade Local de Saúde do Tâmega e Sousa, E.P.E., Guilhufe, Portugal
DOI 10.1055/s-0046-1820795

Aims Gastric cancer progresses through premalignant stages, including atrophic gastritis (AG) and intestinal metaplasia (IM). Although the relationship between obesity and these lesions remains under investigation, candidates for bariatric surgery—despite being predominantly young adults—routinely undergo preoperative esophagogastroduodenoscopy (EGD) with biopsies. This study aimed to determine the prevalence of premalignant gastric conditions in this population and to evaluate the clinical relevance of routine endoscopic assessment.

Methods We conducted a retrospective observational study including consecutive patients referred for preoperative bariatric surgery assessment from january to november 2025. All subjects underwent EGD with biopsies following the Sydney System. Demographic, clinical and histological variables were collected. The primary outcome was the prevalence of AG and IM. Associations between potential risk factors and premalignant conditions were evaluated.

Results A total of 119 patients were included (mean age 44.9 years; mean body mass index 40.7 kg/m²). *Helicobacter pylori* infection was present in 56.3 % of subjects. AG and IM were identified in 25.2 % of cases. Patients with AG and IM were significantly older than those without these lesions ($p = 0.002$). No significant differences were observed regarding gender, body mass index, *H. pylori* infection, smoking habits or family history of gastric cancer. No dysplasia, gastric adenomas, early gastric cancers or advanced gastric cancers were detected.

Conclusions Premalignant gastric conditions were detected in one quarter of obese individuals undergoing preoperative bariatric assessment, with age being the only statistically significant associated factor. The high prevalence observed in this predominantly young population suggests that obesity may represent a relevant risk factor for premalignant gastric lesions. These findings support the routine use of preoperative endoscopy with systematic biopsies in bariatric candidates, both to guide surgical planning and to enable early detec-

tion of premalignant changes. Beyond bariatric surgery, the results highlight the potential value of targeted gastric surveillance in obese populations, with implications for early diagnosis and cancer prevention strategies in the general population.

DOI 10.1055/s-0046-1820796

Aims Anastomotic strictures (AS) after gastric bypass (GB) are a challenging complication traditionally managed with endoscopic dilation (ED). Lumen-apposing metal stents (LAMS) have emerged as an alternative, although comparative evidence remains limited. This study evaluated the efficacy and safety of LAMS for naïve post-GB AS and compared outcomes with ED.

Methods Single-center retrospective cohort study including all consecutive patients who developed naïve AS after Roux-en-Y or Omega GB and were treated with LAMS (16 × 30 mm) or ED (pneumatic/bougie) from January 2015 to August 2025. Technical success (TS) was defined as completion of the procedure. Clinical success (CS) was defined as improvement of ≥ 1 level in the Mellow–Pinkas Dysphagia Score. Recurrence was defined as dysphagia score 3–4 and/or inability to maintain a satisfactory luminal caliber within 4 weeks after achieving CS. Adverse events (AEs) were classified using AGREE. Recurrence-free survival (RFS) was assessed with Kaplan–Meier analysis.

Results A total of 146 patients were included (121 LAMS; 25 ED). Baseline characteristics were similar. In the LAMS group, TS and CS were 100 % and 95.9 %, respectively; recurrence was 5.2 % after a median 36-month follow-up. LAMS required one procedure in nearly all cases and achieved rapid symptom resolution with minimal hospitalization. AEs occurred in 7.4 %, mostly late and related to stent migration. Compared with ED, TS and CS were similar (100 % vs 100 %; 95.9 % vs 96.0 %). However, recurrence was significantly lower with LAMS (5.2 % vs 37.5 %; $P < 0.0001$), and RFS was markedly superior (log-rank $P = 0.0003$). AEs were significantly more frequent with ED (36.0 % vs 7.4 %; $P = 0.0244$), with more intraprocedural and early events. ED required more procedures and longer hospitalization.

Conclusions LAMS demonstrated superior long-term efficacy and safety over ED, supporting its use as a preferred first-line treatment for naïve post-GB AS.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP142V Modified G-POEM for Non-Helical Post-Sleeve Stenosis with Proximal Gastric Outpouching

Authors Rodrigues B[1], Mendo R[2], Pereira B[2], Lima P[2], Barreiro P[3, 2], Chagas C[2]

DOI 10.1055/s-0046-1820797

Abstract Text Nonhelical gastric sleeve stenosis (NHGSS) with proximal outpouching is an uncommon adverse event. Endoscopic experience in this setting remains limited, with only two case reports describing a modified gastric per-oral endoscopic myotomy (G-POEM) approach. We present a 65-year-old woman with severe post-sleeve food intolerance. Endoscopy presented a gastric outpouching above the sleeve lumen, separated by a muscular septum, with barium swallow showing contrast retention in the outpouch. A modified G-POEM was performed, including mucosotomy proximal to the septum, submucosal tunneling, septum exposure, and full-thickness myotomy extended 2 cm into the gastric body to achieve sleeve remodelling. The patient was discharged after two days and tolerated solid food at three weeks with high satisfaction. Modified G-POEM appears to be a promising therapeutic option for NHGSS [1–4].

OP143 Upskilling of Optical Diagnosis Performance over Time with Computer Assisted Diagnosis Use: Results from a Large Prospective Cohort

Authors Oleksiw M[1], Rex DK[2], Hassan C[3], Michal V[4], Djinbachian R[1], von Renteln D[1]

Institutes **1** CHUM – Centre hospitalier de l'Université de Montréal, Montréal, Canada; **2** Division of Gastroenterology and Hepatology, Indiana University School of Medicine, Indianapolis, United States of America; **3** Endoscopy, Humanitas University Hospitals, Humanitas Group, Rozzano, Italy; **4** CRCHUM – Centre de recherche du Centre hospitalier de l'Université de Montréal, Montréal, Canada, Montréal, Canada

DOI 10.1055/s-0046-1820798

Aims Artificial Intelligence (AI)-based Computer Assisted Diagnosis (CADx) enables histology prediction of colorectal polyps during colonoscopy. CADx may improve endoscopist optical diagnosis performance by providing real-time

diagnostic feedback to the endoscopist. However, whether use of CADx as a decisional support tool may impact endoscopists' diagnostic abilities over time leading to possible deskilling or upskilling remains uncertain [1, 2]. Few studies have documented CADx-assisted optical diagnosis performance longitudinally. This study aimed to assess the evolution of diagnostic performance over time in cases with and without CADx use.

Methods We conducted a secondary analysis of a large prospective cohort (IRB Nr. 22.013) of patients undergoing screening, surveillance, and diagnostic colonoscopies at the *Montreal University Hospital Center* between January 2021 and July 2025, with CADx being consistently available as of June 2022. Within this cohort, polyp characterization, including endoscopist optical diagnosis and CADx use, was systematically documented for all polyps visualized in enrolled patients during the procedure. All polyps with documented optical diagnosis, either CADx-assisted or unassisted, and available histopathology were included in the analysis. The primary outcome was the monthly evolution of the overall accuracy of CADx-assisted versus CADx-unassisted optical diagnoses, using polyp histopathology diagnosis as the reference standard, for all polyp types. We hypothesised that over time the accuracy of CADx-assisted optical diagnoses would increase at a higher rate than that of CADx-unassisted optical diagnoses given the possibility for endoscopist upskilling; to learn by integrating CADx diagnostic feedback. Secondary outcomes included the monthly evolution of adenoma sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) across both groups. All outcomes were estimated through logistic regressions using generalised estimating equations to account for intra-endoscopist and intra-patient correlations.

Results A total of 1321 patients (mean age 65.9, 46.2 % female) with 2855 polyps (mean size 7.25mm, 64.4 % adenomas, 19.9 % hyperplastic, 6.3 % sessile serrated lesions, 9.4 % other), of which 1257 (44 %) CADx-assisted cases and 1598 (56 %) CADx-unassisted cases, were included in our analysis. Proportions of histology types and polyp sizes were similar across CADx-assisted and unassisted cases. 30 endoscopists, of which 17 trainees, participated in this study, all of whom made at least one CADx-unassisted diagnosis, while 18 (60 %) made at least one CADx-assisted diagnosis, 10 of which performed ≥ 75 % of their colonoscopies with CADx. For CADx-assisted cases, the odds of making a correct diagnosis significantly increased by 3.4 % each month (OR:1.034, 95 % CI: [1.020-1.049], $p < 0.001$), whilst for unassisted cases, accuracy did not significantly increase over time (1.1 % each month, OR:1.011, 95 % CI: [0.997-1.025], $p = 0.118$). Similarly, the odds of correctly identifying a non-adenoma as such (diagnostic specificity) increased by 2.3 % each month for CADx-assisted diagnoses (OR: 1.023, 95 % CI: [1.001-1.046], $p = 0.036$) but did not increase for unassisted diagnoses. All diagnostics metrics trended higher over time for CADx-assisted optical diagnosis, although monthly increases in sensitivity and PPV were not statistically significant.

Conclusions This cohort represents, to our knowledge, the first longitudinal evaluation of endoscopist optical diagnosis performance evolution, with and without CADx use, in an implementation setting. Over a study period of four years, optical diagnosis performance increased at a higher rate over time in CADx-assisted cases compared to unassisted cases, supporting that CADx use may enable endoscopist upskilling. These findings highlight the need for further evaluation of human-computer interactions, notably what happens to endoscopist diagnostic performance if CADx support is withdrawn after extended use. OP144 Training and Early Adoption of Optical Diagnosis for Diminutive Polyps in the English Bowel Cancer Screening Programme

Authors Ahmad A[1, 2, 3], Hearing S[4], Stebbing J[5], Adams L[3], Peploe A[3], Emery-Downing K[3], Maclean R[3], Saunders BP[1, 2]

Institutes **1** St Mark's National Bowel Hospital, London, United Kingdom; **2** Imperial College London, London, United Kingdom; **3** NHS England, London, United Kingdom; **4** Royal Derby Hospital, Derby, United Kingdom; **5** Royal Surrey NHS Foundation Trust, Guildford, United Kingdom

DOI 10.1055/s-0046-1820799

Aims Optical diagnosis (OD) with a resect-and-discard strategy for diminutive polyps enables real-time endoscopic characterisation, photo-documentation, and immediate resection without histopathology. This approach supports more sustainable, efficient, and cost-effective practice while maintaining diagnostic quality. In 2023, the NHS Bowel Cancer Screening Programme (NHSBCSP) formally approved OD for implementation, with national roll-out commencing in 2024. This study provides an early evaluation of the first 18 months of implementation, examining training uptake, accreditation outcomes, establishment of local quality-assurance structures, and early estimates of time and cost savings.

Methods All 520 screening colonoscopists were invited to complete a two-stage national OD accreditation pathway.

Part 1 consisted of a national training day covering classification systems, high-confidence criteria, and photo-documentation standards. Participants completed pre- and post-course assessments involving optical diagnosis of 120 polyp images. Accreditation required ≥ 85 % accuracy for high-confidence calls and ≥ 50 % of all calls made with high confidence.

Part 2 involved supervised OD assessment at each colonoscopist's base hospital, requiring 20 consecutive high-confidence in-vivo OD cases. Assessment included evaluation of photo-documentation using the 3C score (clean, complete, correctly focussed) and accuracy against histology. A pass required ≥ 90 % adequate photo quality and ≥ 85 % diagnostic accuracy.

Successful candidates became fully accredited to perform OD with resect-and-discard in screening practice. Re-accreditation is required every two years via an online assessment of 120 images. Each screening centre was asked to appoint an Optical Diagnosis Champion responsible for ongoing performance monitoring, quality assurance, and supporting colleagues through the accreditation process.

Results Between March 2024 and October 2025, six national training days were delivered. A total of 501 attendees (501/520, 96 %) have completed Part 1, and 451 of 501 (90 %) passed the post-course assessment. By October 2025, 276 of 501 (55 %) had completed both stages and were fully accredited.

Optical Diagnosis Champions were appointed at 62 of 64 screening centres (97 %), providing near-universal local leadership.

As of 31 October 2025, 32,919 diminutive polyps had been resected and discarded without histopathology, generating an estimated cost saving of £1,218,003, based on a £37 cost per specimen. This corresponds to an estimated 10,973 hours of histopathology reporting time saved (assuming 20

minutes per polyp). Additional gains are anticipated as more colonoscopists achieve accreditation.

A further national training day is planned for February 2026, after which Part 1 training will transition to an eLearning format to support flexible access and enable completion of national roll-out.

Conclusions The first 18 months of implementation show high engagement with OD training across the NHSBCSP, with approximately half of trained colonoscopists already accredited and delivering OD in practice. Early outcomes demonstrate substantial cost and workforce efficiencies. With strong local QA infrastructure established through Optical Diagnosis Champions and continued expansion of training access, full national implementation is expected by 2027, offering a scalable model for integrating OD within population-based screening.

DOI 10.1055/s-0046-1820800

Aims Endoscopist optical diagnosis (OD) in real-time during colonoscopy could replace histopathological examination for diminutive (≤ 5mm) colorectal polyps. Computer-Aided Diagnosis (CADx) may help improve and standardize OD. However, data evaluating CADx-assisted OD primarily originates from controlled experimental study designs, limiting its external validity. This study aimed to evaluate diagnostic performance of CADx-assisted OD versus CADx-unassisted OD for diminutive polyps encountered in routine clinical practice by a diverse cohort of endoscopists at a tertiary care center [1–3].

Methods We conducted a large prospective, IRB-approved, pragmatic implementation study (NCT06822816) at the Montreal University Hospital Center between January 2021 and July 2025. Consecutive patients ≥ 40 years old undergoing elective colonoscopies with ≥ 1 diminutive polyp identified were included. Polyp characteristics, including endoscopist optical diagnosis, were consistently documented during each procedure by a research assistant. All diminutive polyps with available optical diagnosis and histopathology diagnosis were included in this analysis. Procedures were performed with or without CADx assistance depending on CADx availability in the endoscopy suite and endoscopist choice. A diverse cohort of endoscopists, including trainees, with varying degrees of optical diagnosis and CADx experience participated. Our primary outcome was the sensitivity for adenoma diagnosis of CADx-assisted OD versus CADx-unassisted OD, using polyp histopathology diagnosis as ground truth. Secondary outcomes were the accuracy, and adenoma specificity, positive predictive value (PPV) and negative predictive value (NPV) of each method. Implications for the resect-and-discard and diagnose-and-leave strategies were also evaluated.

Results A total of 1827 diminutive polyps, 860 with CADx diagnosis (of which 709 with CADx-assisted OD) and 979 without CADx use (unassisted OD), found in 966 patients (mean age 66 years, 46.8 % female) were included. The polyp cohort consisted of 1120 (61.3 %) adenomas, 421 (23.0 %) hyperplastic polyps, 57 (3.1 %) sessile serrated lesions, and 212 (12.3 %) polyps with other histologies. 30 endoscopists, including 17 trainees, participated in the study. Adenoma sensitivity of CADx-assisted OD (85.6 %, 95 %CI:[81.9-88.7]) did not differ compared to unassisted OD (83.8 %, 95 %CI:[80.7-86.5], p = 0.416). However, adenoma sensitivity of the CADx output itself was significantly lower (76.1 % [72.2-79.6]), p = 0.001). Adenoma specificity of CADx-assisted and unassisted OD was also similar, (62.4 %(57.1-67.4) vs 58.9 %(53.9-63.7);p = 0.319), ▶ **Table 1**. The rate of high confidence diagnoses was similar with or without CADx assistance, 84.9 % (602/709) and 81.1 % (794/979), respectively, and had similar diagnostic performance. In a simulated diagnose-and-leave strategy, among diminutive rectosigmoid polyps diagnosed with high confidence, there was no statistically significant difference in the NPV for adenomas between unassisted and CADx-assisted predictions (94.4 %[87.1-97.6] vs 94.4 %[86.0-97.9], p = 0.987)

▶ **Table 1** Diagnostic performance metrics (%(95 % CI), p-value)

	CADx-Unassisted	CADx-Assisted	CADx Output
Accuracy	66.1 % (63.1-68.9)	63.7 % (60.2-66.9) 0.271	61.4 % (58.1-64.5) 0.029
Specificity	58.9 % (53.9-63.7)	62.4 % (57.1-67.4) 0.319	64.6 % (59.6-69.3) 0.096
PPV	77.6 % (74.4-80.5)	74.6 % (71.1-77.8) 0.180	74.6 % (71.1-77.8) 0.172
NPV	67.6 % (62.8-72)	66.4 % (62-70.6) 0.671	64.8 % (60.3-69.1) 0.330

Conclusions In this implementation study reflecting routine clinical practice with CADx availability, CADx-assisted OD did not significantly outperform unassisted OD for diminutive colorectal polyps. Both CADx-assisted and unassisted high-confidence diagnoses for rectosigmoid polyps met the ≥ 90 % NPV benchmark for implementation of diagnose-and-leave strategies.

OP146 Optical Polyp Diagnosis in Inflammatory Bowel Disease: A Pilot Study of AI-Assisted and Conventional Approaches

Authors Ouizzane C[1], Battat R[1], Djinbachian R[1], Michal V[2], Oleksiw M[1], Daoud DC[1], Bernard EJ[1], Orlicka K[1], Leduc R[1], D'aoust L[1], Liu Chen Kiow J[1], Deslandres E[1], Bouin M[1], Panzini B[1], Bouchard S[1], von Renteln D[1]

Institutes **1** CHUM – Centre hospitalier de l'Université de Montréal, Montréal, Canada; **2** Research Center Du Chum ., Montréal, Canada

DOI 10.1055/s-0046-1820801

Aims Artificial intelligence (AI)–supported optical diagnosis (OD) underpins "resect-and-discard" and "diagnose-and-leave" strategies in non-IBD screening cohorts, but its performance in IBD cohorts is poorly defined. We evaluated computer-aided assisted diagnosis (CADx) and non-assisted OD of diminutive and small polyps in patients with inflammatory bowel disease (IBD).

Methods We conducted a prospective, pragmatic implementation study with a secondary analysis of adult IBD patients undergoing colonoscopy at a tertiary center. Only diminutive and small polyps were included. Endoscopists freely chose OD modality in real time; each polyp could generate CADx-unassisted OD, CADx-unassisted image-enhanced endoscopy (IEE) OD, standalone CADx prediction, and/or CADx-assisted OD. Histopathology served as the reference standard.

Results Of 280 screened patients, 138 with 256 polyps (345 ODs) were analyzed (mean age 54.7 years; balanced Crohn's colitis and ulcerative colitis). Most polyps were diminutive (80.9 %) and polypoid (89.3 %). Across all polyp types, accuracy was 59.4 % (95 % CI 52.9–65.5) for CADx-unassisted OD and 60.3 % (53.6–66.7) for CADx-unassisted IEE OD. Standalone CADx achieved 36.8 % (18.6–59.8) accuracy, while CADx-assisted OD reached 52.6 % (31.0–73.3), with wide confidence intervals due to few evaluable cases. For adenomas, CADx-unassisted and CADx-unassisted IEE OD showed comparable sensitivity (83.0 % and 86.8 %) and specificity (78.1 % and 78.0 %), with negative predictive values ≥ 90 %. Performance for hyperplastic and inflammatory polyps was similarly modest and only marginally improved by IEE.

Conclusions In IBD surveillance, OD performance, even with IEE and off-the-shelf CADx, falls short of performance obtained in non-IBD cohorts and compared to guideline thresholds. Chronic architectural and vascular distortion in IBD patients likely makes OD more challenging underscoring the need for IBD-specific training of CADx systems.

OP147 Predictive accuracy of optical evaluation for high-risk serrated lesions and the impact of a brief educational intervention

Authors Kim J[1], Gupta V[2], Pellise M[3, 4], Gupta S[5], Kerrison C[1], Lam B[1], Hasib A[1], Kim YS[1], Eitan M[6, 1], Lee EYT[1], Burgess N[1], Michael J B[1]

Institutes **1** Westmead Hospital, Westmead, Australia; **2** Post Graduate Institute of Medical Education & Research, Chandigarh, Chandigarh, India; **3** Institut de Malalties Digestives i Metabòliques, Barcelona, Spain; **4** Hospital Clínic de Barcelona, Barcelona, Spain; **5** St. Michael's Hospital, Toronto, Canada; **6** meir medical center, Kefar Sava, Israel, Kefar Sava, Israel

DOI 10.1055/s-0046-1820802

Aims Real-time characterisation of advanced lesions during colonoscopy informs the therapeutic approach. Sessile serrated lesions with dysplasia are a subgroup of advanced lesions that are difficult to recognise and accurately characterise. The ability of expert endoscopists to recognise these lesions is unknown; moreover, the impact of a simple training module on subsequent performance is of interest. This study aimed to assess the baseline accuracy of experts and trainees in recognising SSL-D and to evaluate whether a brief educational module could improve their diagnostic performance.

Methods Seventy high-quality images were selected from a database of large sessile and flat polyps. Histopathology was used as the gold standard. The images were presented in randomised order to expert endoscopists and trainees. The focus was on identifying areas of demarcation amongst homogenous lesions.Participants were then asked to predict the underlying histology. Subsequently, an educational module was delivered, and participants were asked to repeat the test using the same images in a different randomised order.

Results Thirty-seven participants were included: 16 trainees and 21 experts. Baseline predictive accuracy for SSL-D was only 24.0 % across the group; 18.3 % for trainees and 28.2 % for experts. This improved significantly, regardless of experience level, after the educational module to 69.7 % ($p < 0.001$) for the whole cohort; 67.5 % for trainees and 71.4 % for experts. Before training, SSL-D was incorrectly identified as TA or TVA in 40 %. Post-training, this reduced significantly to 7.6 % ($p < 0.001$) for all participants. For experts, this decreased to 7.0 % ($p < 0.001$) and trainees to 8.3 % ($p < 0.001$).

Conclusions SSL-D lesions are underdiagnosed by both expert and trainee endoscopists. The simple principle of identifying a demarcated area within an otherwise homogenous lesion can significantly improve the predictive accuracy and performance of experts and trainees.

DOI 10.1055/s-0046-1820803

Aims Accurate identification of submucosal invasive cancer (SMIC) in large non-pedunculated colorectal polyps (LNPCPs) is critical for selecting appropriate treatment—endoscopic resection for benign lesions versus surgery for deeply invasive cancer. Video assessment may facilitate expert review and multidisciplinary triage without repeat examinations, but whether diagnostic performance differs from live assessment remains unclear. This multicentre prospective study compared live versus video assessment for SMIC detection by expert and optically trained endoscopists.

Methods Consecutive LNPCPs referred for endoscopic resection at four tertiary centres were assessed in real time by expert endoscopists or optically trained interventional fellows. Before resection, the performing endoscopist recorded their SMIC assessment, and a high-definition video was obtained. Subsequently, assessors not involved in the original procedure independently reviewed videos via a web-based platform and classified lesions for SMIC.

The primary outcome was SMIC detection accuracy comparing live versus video assessment. Secondary outcomes were sensitivity and specificity stratified by expertise. Metrics were summarised with exact binomial 95 % confidence intervals (CI), and live–video differences compared using χ^2 tests. Multivariate modelling analyses respected the hierarchical data structure, retaining one live assessment per lesion and clustering video assessments by lesion and rater.

▶ Table 1

Comparison	Metric	Live (95% CI)	Video (95% CI)	P-Value
All assessors	Sensitivity	79.2% (65.0–89.5)	70.1% (61.3–77.9)	>0.05
	Specificity	87.4% (81.9–91.7)	82.7% (79.2–85.9)	>0.05
	Accuracy	85.8% (80.8–89.9)	80.2% (76.9–83.2)	>0.05
Experts	Sensitivity	88.9% (70.8–97.6)	74.4% (58.8–86.5)	>0.05
	Specificity	88.1% (80.5–93.5)	78.3% (72.3–83.6)	**0.047**
	Accuracy	88.2% (81.6–93.1)	77.7% (72.1–82.6)	**0.016**
Fellows	Sensitivity	66.7% (43.0–85.4)	67.9% (56.8–77.6)	>0.05
	Specificity	86.5% (77.6–92.8)	86.0% (81.5–89.8)	>0.05
	Accuracy	82.7% (74.3–89.3)	82.0% (77.7–85.7)	>0.05

Results Overall, 246 LNPCPs underwent live assessment by 9 assessors (136 expert, 110 fellow), generating 637 video assessments (260 expert, 377 fellow). SMIC was present in 49 lesions (19.9%), high-grade dysplasia in 71 (28.9%), and low-grade dysplasia in 118 (48.0%).

For all assessors combined, sensitivity for SMIC was 79.2% (95%CI 65.0–89.5) live versus 70.1% (95%CI 61.3–77.9) video (P>0.05); specificity was 87.4% (95%CI 81.9–91.7) versus 82.7% (95%CI 79.2–85.9) (P>0.05); accuracy was 85.8% (95%CI 80.8–89.9) versus 80.2% (95%CI 76.9–83.2) (P>0.05) (▶ **Table 1**).

Among experts, sensitivity was 88.9% (95%CI 70.8–97.6) live versus 74.4% (95%CI 58.8–86.5) video (P>0.05); specificity 88.1% (95%CI 80.5–93.5) versus 78.3% (95%CI 72.3–83.6) (P=0.047); accuracy 88.2% (95%CI 81.6–93.1) versus 77.7% (95%CI 72.1–82.6) (P=0.016).

Among fellows, no significant differences were observed: sensitivity 66.7% (95%CI 43.0–85.4) versus 67.9% (95%CI 56.8–77.6) (P>0.05); specificity 86.5% (95%CI 77.6–92.8) versus 86.0% (95%CI 81.5–89.8) (P>0.05); accuracy 82.7% (95%CI 74.3–89.3) versus 82.0% (95%CI 77.7–85.7) (P>0.05).

Conclusions Expert endoscopists ruled out SMIC more accurately during live assessment than video review, driven by approximately 10% higher specificity—likely reflecting real-time control of visualisation and targeted interrogation. For centres employing selective ESD strategies, live expert assessment remains the most reliable approach for excluding invasive cancer and ensuring patients receive appropriate treatment. Video assessment offers a practical alternative for expert triage when live assessment is unavailable and enables multidisciplinary and training case discussion.

Aims Although several cohort studies [1–3] have reported that EUS-guided hepaticogastromy with antegrade placement (EUS-HGAS) prolongs time to recurrent biliary obstruction (TRBO) compared with EUS-HGS alone, prospective evidence remains unavailable. We conducted a multicenter prospective study to evaluate the outcomes of EUS-HGAS for unresectable malignant biliary obstruction (MBO) and further compared the results with historical data of EUS-HGS.

Methods This present study involved 24 referral centers in Japan. Patients scheduled to undergo EUS-HGAS for unresectable malignant biliary obstruction (MBO) after failed endoscopic retrograde cholangiopancreatography (ERCP)

Endoscopy 2026; 58: S1–S1041

between October 2022 and February 2025 were prospectively enrolled. In this procedure, an uncovered metal stent (MS) was used as the antegrade stent, and either a plastic stent or a covered MS was placed at the EUS-guided access route. Clinical assessments and blood tests were performed on postoperative days 1, 3, 30, 90, and 180, and additional imaging studies, such as CT scans, were obtained when clinically indicated. For comparison, historical data on EUS-HGS using a covered MS for unresectable MBO after failed ERCP were collected from the participating institutions for the period between April 2018 and March 2022. A matched cohort with balanced baseline characteristics was created using 1:2 propensity score matching to compare the EUS-HGAS and EUS-HGS groups. The primary endpoint was TRBO, while secondary endpoints included technical success, clinical success, adverse events (AEs), recurrent biliary obstruction (RBO), procedure time, length of hospital stay, and overall survival.

Results A total of 49 patients were prospectively enrolled in the EUS-HGAS group. Baseline characteristics were as follows: 57 % male, median age 76 years, ECOG performance status 0 in 24 %, pancreatic cancer as the primary malignancy in 55 %, distal biliary obstruction in 86 %, surgically altered anatomy in 35 %, duodenal obstruction in 59 %, preprocedural cholangitis in 18 %, and ascites in 16 %. The technical and clinical success rates were 73 % (36/49) and 92 % (33/36), respectively. Early and late adverse event (AE) rates were 12 % (6/49; three cases of acute pancreatitis and three of bile peritonitis) and 2 % (1/49; acute cholecystitis), respectively. The RBO rate was 6 % (2/36). The median procedure time was 40 minutes (interquartile range [IQR], 26–50), and the median length of hospital stay was 13 days (IQR, 8–18).

In the EUS-HGS group, 414 patients were identified. In the prematched cohort, significant differences were observed between the two groups in primary cancer site, site of biliary obstruction, surgically altered anatomy, preprocedural cholangitis, and the presence of ascites. After matching, no significant differences in baseline characteristics were observed between the two groups. Ultimately, 44 patients in the EUS-HGAS group and 88 in the EUS-HGS group were included in the matched cohort.

The technical success rate was significantly lower in the EUS-HGAS group (70 % vs. 95 %, $P < 0.001$). Conversely, the RBO rate was significantly lower in the EUS-HGAS group (3 % vs. 21 %, $P = 0.022$). TRBO was significantly longer in the EUS-HGAS group (median not reached vs. 230 days; $P < 0.001$), whereas overall survival did not differ between the groups (196 days vs. 97 days; $P = 0.481$). No significant differences were observed in clinical success, AEs, procedure time, or length of hospital stay.

Conclusions Although EUS-HGAS had a lower technical success rate compared with EUS-HGS, it demonstrated a longer TRBO. In contrast, no differences were observed in AEs or overall survival between the two groups. The prolonged TRBO associated with EUS-HGAS may provide clinical benefits for patients with a longer life expectancy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP150 Clinical Outcomes of EUS-Guided Hepaticogastrostomy Plus Antegrade Stenting: Impact of Stent Type Used for HGS

Authors Ishiwatari H[1], Sakamoto H[2], Doi T[2], Ohba A[2]

Institutes 1 Shizuoka Cancer Center, Nagaizumi, Japan; 2 Nagaizumi, Japan

DOI 10.1055/s-0046-1820805

Aims Endoscopic ultrasound-guided biliary drainage (EUS-BD) has been developed as an alternative when endoscopic retrograde cholangiopancreatography fails in patients with malignant biliary obstruction. Several EUS-BD approaches exist; however, in patients with surgically altered anatomy or duodenal obstruction, EUS-guided hepaticogastrostomy (EUS-HGS) is often the only feasible option. EUS-HGS combined with antegrade stenting (EUS-HGAS) has been reported to improve stent patency and reduce the risk of peritonitis in patients requiring biliary drainage. However, the influence of stent type used for the HGS—either plastic stents (PS) or metal stents (MS)—on clinical outcomes has not been fully evaluated. This study aimed to compare clinical outcomes of EUS-HGS and EUS-HGAS according to the type of stent used for HGS.

Methods This single-center retrospective study included patients with malignant biliary obstruction who underwent EUS-HGS or EUS-HGAS between 2016 and 2025. Patients with Bismuth type II or higher hilar obstruction were excluded. The outcomes assessed were adverse event (AE) rates, stent patency, and overall survival (OS). Patients were categorized into four groups based on the stent type used for HGS: HGS-MS, HGS-PS, HGAS-MS, and HGAS-PS. Metal stents were used for antegrade stenting in all EUS-HGAS procedures. Variables that differed among groups—surgically altered anatomy, prior transpapillary stenting, and metastasis—were included in a multivariable Cox proportional hazards model to identify factors associated with stent patency.

Results During the study period, 306 patients underwent EUS-HGS or EUS-HGAS, and 242 met the inclusion criteria after excluding 64 patients with hilar obstruction (132 HGS-MS, 31 HGS-PS, 52 HGAS-MS, and 27 HGAS-PS). Baseline characteristics differed significantly between groups regarding surgically altered anatomy, previous transpapillary stenting, and the presence of metastasis. Overall AE rates were similar among groups (19 %, 13 %, 14 %, and 19 %; $p = 0.79$), as were severe AE rates (≥ grade III: 7 %, 6 %, 4 %, and 7 %; $p = 0.07$). Median stent patency differed significantly, with durations of 338 days (HGS-MS), 159 days (HGS-PS), and not reached in both HGAS groups ($p < 0.05$). Overall survival also varied significantly among groups (123, 497, 201, and 142 days; $p < 0.05$). In multivariable analysis, using the HGS-MS group as the reference, the hazard ratios (HRs) for stent dysfunction were 0.29 (95 %CI: 0.11–0.72; $p < 0.01$) for HGAS-MS, 0.37 (95 %CI: 0.11–1.26; $p = 0.11$) for HGAS-PS, and 3.31 (95 %CI: 1.47–7.46; $p < 0.01$) for HGS-PS.

Conclusions EUS-HGAS using an MS for HGS placement significantly prolonged stent patency compared with EUS-HGS. The benefit of EUS-HGAS was diminished when a plastic stent was used for HGS. Among all groups, HGS-PS showed the shortest stent patency. These findings highlight the importance of selecting an appropriate stent type for HGS when performing EUS-guided biliary drainage [1].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820806

Aims Learning curve of EUS-guided Hepaticogastrostomy (EUS-HGS) has been explored through retrospective studies involving few elite senior endoscopists, with procedural time as the main surrogate outcome. This study aims to evaluate the learning curve of a junior endoscopist (JE) covering also clinically relevant patient outcomes.

Methods From a prospective single-center registry of EUS-HGS (PROTECT, ClinicalTrials.gov NCT04813055) using a dedicated, partially covered stent (Giobor, Taewoong), the learning curve of one JE, with advanced experience in pancreatobiliary endoscopy (PBE), was analyzed to identify changing points ("knots") applying linear and spline regression and cumulative sum control chart (CUSUM) on several continuous and dichotomic variables.

Results 71 EUS-HGS performed by one JE between April-2021 and October-2025 were included (median age 67 [60-74], males 62 %, pancreatic cancer 49 %, metastatic 79 %). Technical (97.2 %) and Clinical (71 %) success and Procedure-related Adverse Events (27.9 %) remained stable throughout the learning curve.

Adaptive regression showed a significant knot of procedural time (min), fluoroscopy time (sec) and radiation dose (Gy) after 9 procedures. CUSUM showed a significant improvement in the same outcomes after 31, 22 and 27 procedures respectively. Mean procedural time constantly decreased from 83 minutes in the first 9 cases to 39 minutes in the last twenty ($p = .0005$), as well as radiation doses from 1674 to 146 Gys ($p < .0001$). 89 % of the first 9 procedures were supervised by a senior endoscopist compared to 9.5 % of the last twenty ($p = .0002$).

Conclusions From a prospective registry, the learning curve of a JE in EUS-HGS showed a significant improvement after ≈ 10 cases, with stabilization after approximately 25 cases, while efficacy and safety remained constant. With adequate baseline PBE expertise and structured training in high-volume institutions, operators can achieve and maintain high safety and efficacy from the outset, with a relatively rapid learning curve thereafter.

Conflicts of Interest G. Vanella has received lecture and consultancy fees from Boston Scientific.

OP152 Long-term outcomes of EUS-guided hepaticogastrostomy with a novel partially covered metal stent featuring an anchoring flange in malignant biliary obstruction

Authors Shin IS[1], Moon JH[1], Lee YN[1], Park JW[1], Lee TH[2], Yang JK[2], Chung KH[3], Cho YD[3], Park SH[2]

Institutes **1** Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea; **2** Soonchunhyang University Cheonan Hospital, cheonan, Republic of Korea; **3** Soonchunhyang University Seoul Hospital, Seoul, Republic of Korea

DOI 10.1055/s-0046-1820807

Aims Endoscopic ultrasound-guided hepaticogastrostomy (EUS-HGS) has emerged as a reliable option for biliary drainage after failed ERCP. A partially covered self-expandable metal stent (PCSEMS) with an anchoring flange may further improve its technical stability and clinical outcomes. We evaluated the long-term outcomes of EUS-HGS using the dedicated stent in an expanded patient cohort.

Methods Consecutive patients who underwent EUS-HGS with a long PCSEMS with an anchoring flange were enrolled. The stent was designed with a 1.5-cm uncovered intrahepatic portion and a fold-back distal flange measuring 2.0 cm in diameter. The primary outcome was technical and clinical success, and secondary outcomes were adverse events (AEs), recurrent biliary obstruction (RBO), and time to RBO.

Results A total of 41 patients with unresectable malignant biliary obstruction underwent EUS-HGS. Technical and clinical success rates were 100 % (41/41) and 92.7 % (38/41), respectively. AEs occurred in 4.9 % of patients (2/41, both cholangitis), with no severe AEs observed during follow-up. RBO developed in 31.7 % (13/41), with a median time to RBO of 6.5 months. Causes of RBO included aggravated malignant stricture (n = 4), food impaction (n = 4), sludge formation (n = 3), and tissue hyperplasia at the uncovered portion (n = 2). All cases of RBO were successfully managed with re-intervention via the established EUS-HGS route.

Conclusions EUS-HGS using the novel partially covered metal stent with an anchoring flange is effective and safe, ensuring durable long-term outcomes with stable re-intervention and without severe AEs such as stent migration.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP153 Textbook outcomes of EUS-guided HepatiCoGastrostomy according to indication and presenting anatomy: a prospective cohort study

Authors Vanella G[1], Stasio RC[2, 3], Bara R[2, 1], Marzocca G[2, 1], Palumbo D[4, 1], Frigo F[3, 2], Casadei-Gardini A[5, 1], De Cobelli F[4, 1], Reni M[5, 1], Falconi M[6, 1], Capurso G[1, 2], Arcidiacono P[2, 1]

Institutes **1** Vita-Salute San Raffaele University, Milano, Italy; **2** Pancreatobiliary Endoscopy and Endosonography Division, IRCCS San Raffaele Scientific Institute, Milan, Italy; **3** University of Turin, Torino, Italy; **4** Radiology Department, IRCCS San Raffaele Scientific Institute, Milan, Italy; **5** Medical Oncology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; **6** Pancreatic Surgery Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy

DOI 10.1055/s-0046-1820808

Aims Endoscopic Ultrasound-Guided HepaticoGastrostomy (EUS-HGS) has emerged as a valuable complement to retrograde biliary drainage. However current evidence is focused on technical success and constrained by small sample sizes, retrospective design, heterogeneous techniques and indications.

Methods Single center prospective study conducted between April-2021 and October-2025. All consecutive patients undergoing EUS-HGS with a dedicated partially covered metal stent (Giobor, Taewoong) for a malignant indication were enrolled in a prospective registry of Therapeutic EUS (PROTECT; ClinicalTrials.gov NCT04813055) with prospective scheduled bimonthly assessment of outcomes. 30-days Net Clinical Benefit (NCB30) was defined as Clinical Success (CS) without recurrent biliary obstruction (RBO) or 30-days mortality, while Textbook Outcome (TBO30) was defined as NCB30 plus no 30-days procedure-related adverse events (AEs).

Results 83 patients were included (median age 67 [60-74], female 61.4 %, pancreatic adenocarcinoma 50.6 %, cholangiocarcinoma 20.5 %, metastatic diseases 78.3 %, ascites 41 %).

Indication for EUS-HGS were: 1) distal malignant biliary obstruction (MBO) with duodenal invasion (43.4 %); 2) drainage completion of hilar MBO (39.8 %); 3) surgically-altered anatomy (16.9 %).

Technical success and CS rate were 95.2 % and 70.9 % respectively. AEs were registered in 43.4 % of patients (mild/moderate 19.5 %, severe/fatal 25.6 %) and were deemed procedure-related in 28.4 %. 30-days mortality was 21.8 % (cancer-related in 83 %). After a median follow-up of 63 [32-113] days, RBO was registered in 6.8 %.

Endoscopy 2026; 58: S1–S1041

NCB30 and TBO30 were 54.2 % and 45.8 % respectively. Best Supportive Care (BSC) was advised in 60.9 % of patients.

CS was significantly lower when the stenosis was hilar versus distal/anastomotic (p = 0.001). Accordingly, the NCB30 was significantly lower when EUS-HGS drained only one segment versus the left hemiliver versus the whole liver (36.4 % versus 45.5 % versus 73.5 %, p = 0.02). Since the AEs were also higher in patients undergoing partial versus complete liver drainage (p = 0.001), the TBO30 was accordingly different, being 9.1 % versus 39.4 % and 67.6 % respectively (p = 0.002) as well as advice for BSC (p = 0.0008).

Conclusions Despite excellent technical success, only ≈ 50 % of patients experience a net clinical benefit or a textbook outcome after EUS-HGS, whilst the rest receive a recommendation for BSC. Outcomes are deeply influenced by the level of the stenosis and actual liver drainage, claiming for personalized imaging-guided patients' selection.

Conflicts of Interest G. Vanella has received lecture and consultancy fees from Boston Scientific.

OP154 Endoscopic retrograde cholangiopancreatography with and without Endoscopic ultrasound guided hepaticogastrostomy for bilateral biliary decompression in malignant hilar biliary obstruction: a preliminary results

Authors Saad M[1], Abo Elhassan M[1], Hakim H[1], Altonbary A[1]
Institute 1 Mansoura University, Mansoura, Egypt
DOI 10.1055/s-0046-1820809

Aims Bilateral Endoscopic retrograde cholangiopancreatography (ERCP) stenting in advanced malignant hilar biliary obstruction (MHBO) is challenging and technically difficult, particularly in Bismuth type III and IV. The combination of Endoscopic ultrasound-guided hepaticogastrostomy (EUS-HGS) and ERCP for advanced MHBO could provide a chance of higher technical success, longer stent patency, and less events of stent clogging. The aim of this study is to evaluate efficacy and safety of combined EUS-HGS and ERCP compared to ERCP for bilateral biliary decompression in advanced MHBO.

Methods A prospective randomized controlled study conducted on patients with advanced MHBO. A sample size of 72 patient achieved 90 % power. Enrolled patients were randomized to ERCP or combined EUS-HGS and ERCP. Technical success was defined as bilateral transpapillary metallic stenting in ERCP group or unilateral transpapillary metallic stenting in right side and EUS-guided transgastric stenting in the left side in the combined group. Clinical success was defined as reduction of total serum bilirubin levels to less than half of the pre-treatment level within 2 weeks. Patients were hospitalized and observed for early complications in the first 2 days. Laboratory investigation were repeated in regular out patients visits at 2, 4, 12 and 24 weeks or until death.

Results From May 2024 to August 2025, a total of 31 patients were enrolled. There were 25 males and 6 females with median age of 64 years. Technical success rates were 86.3 % (19/22) in ERCP group with 3 patients crossed-over to the other group due to failure to opacify the left biliary system compared to 100 % (12/12) in combined EUS-HGS/ERCP group with no statistically significant difference (P = 0.116). Clinical success rates were higher in combined EUS-HGS/ERCP group 83.3 % (10/12) compared to 52.6 % (10/19) in ERCP group with no statistically significant difference (P = 0.08). There was statistically significant difference in the median procedure time between ERCP group (22 mins) and combined EUS-HGS/ERCP group (43.5 mins) (P = 0.004). The rate of overall adverse events was not statistically significant between both groups (ERCP 15.8 %, combined EUS-HGS/ERCP 16.5 %; P = 0.387). In ERCP group, 3 patients had cholangitis that improved with adequate antibiotics. In combined EUS-HGS/ERCP, one patient had cholangitis, and one patient had melena that improved with conservative management. For late adverse events, stent patency was similar, and none required reintervention in both groups.

Conclusions Combined EUS-HGS/ERCP seems to have better technical and clinical success rates for bilateral biliary decompression of advanced MHBO compared to ERCP alone with significantly higher median procedure time and comparable overall adverse events.

DOI 10.1055/s-0046-1820810

Aims Guidelines recommend endoscopic eradication therapy (EET) for Barrett's esophagus (BE) with early neoplasia. [1] Visible lesions are resected, followed by ablation of residual flat BE, or primary ablation when no lesion is visible. Cryoballoon Focal Ablation (CbFA; C2 Merit Medical) is a well-tolerated and effective treatment for ETT for Barrett's esophagus (BE) with early neoplasia. [2] Prior experience has largely been limited to BE segments of ≤ C2M5, with few long-term durability data, and earlier studies using a 10-second (s) dose per ablation. [3] We report outcomes from a prospective UK multicentre registry using a refined approach of 8s per ablation with adjunct mucosal protective medication and including patients with a longer BE segments.

Methods Consecutive patients from three UK tertiary centres were prospectively enrolled. Inclusion criteria were BE ≤ C5M5 with an indication for ablation therapy, such as BE with early neoplasia (BE-D: low-grade dysplasia (LGD), high-grade dysplasia (HGD), intramucosal adenocarcinoma) without a visible lesion or residual BE following endoscopic resection of early neoplasia. CbFA was repeated at 3-monthly intervals until eradication or a maximum of five sessions, using a focal catheter with an 8s dose per application. In between each treatment, patients received high-dose proton pump inhibitor twice daily and 14 days of sucralfate (2 g, three times daily). Adjunct argon plasma coagulation (APC) was permitted after two CbFA sessions for residual islands < 5 mm. Post treatment surveillance and biopsies followed ESGE guidance.[2] Primary endpoints were histologically confirmed eradication of intestinal metaplasia (CE-IM), and dysplasia (CE-D) at the end of treatment. Secondary outcomes included number of ablation sessions, adverse events, device malfunction, and stricture rate.

Results From January 2020 to November 2025, 67 patients were recruited (80.6 % male; mean age 71), and underwent 138 CbFA sessions. Median pre-ablation BE length was C0M2 (maximum C5M5). Worst baseline histology was LGD in 41.8 %, HGD in 31.3 %, early cancer in 19.4 %, and intestinal metaplasia in 7.5 % (including RFA-refractory). Most patients (92.5 %) were ablation treatment-naïve; 7.5 % had RFA-refractory BE. Among treatment-naïve patients, 43 underwent prior endoscopic resection (39 EMR, 4 ESD).

In those patients completing CbFA treatment to date (n = 22), CE-D was achieved in 100 % and CE-IM 90.9 %, after a median of two CbFA sessions, with 31.8 % receiving adjunct APC. No device malfunctions or intraprocedural adverse events occurred. Strictures developed in 9 % and resolved with balloon dilatation. Durability data were available for 10 patients (mean follow-up 31.3 months, range 14.2–53.2), with CE-D 100 % and CE-IM 90.0 %.

Conclusions Interim real-world registry results, including medium-term durability, align with the larger Euro-Coldplay study,[1] supporting CbFA as a safe and effective EET option for BE-D in segments up to ≤ C5M5, with a lower stricture rate using our refinement approach. Ongoing enrolment will further define long-term efficacy and safety in routine UK practice.

DOI 10.1055/s-0046-1820811

Aims The optimal follow-up (FU) after successful endoscopic eradication therapy (EET) for Barrett's esophagus (BE) with dysplasia or early cancer is uncertain. We previously developed an externally validated prediction model for recurrence using data from the Dutch Barrett Expert Center (BEC) registry, a nationwide database capturing all patients treated with EET for BE neoplasia in the Netherlands [1, 2]. Since our earlier publication, continued prospective data collection has yielded an expanded cohort with longer FU. In the present study, we aimed to reassess risk factors for recurrent dysplasia/cancer and to identify predictors specifically associated with progression to advanced cancer.

Methods We included all BE patients with successful EET from the BEC registry [1]. Primary objectives were to identify independent predictors of recurrent HGD/cancer, and predictors of recurrent advanced cancer. Advanced cancer was defined as cancer exceeding the criteria for curative endoscopic therapy. Data were analyzed using Cox proportional hazards regression, with variables first assessed in univariate analysis and subsequently entered into a multivariable model using backward elimination. We selected patient and treatment characteristics that would be known at completion of EET and that were plausible predictors of recurrence. Selected variables were age, gender, BE-length, baseline pathology, poor healing after RFA with treatment delay, persisting esophagitis at the end of the treatment phase, number of endoscopic resection (ER) treatment sessions, new visible lesion(s) (VL) that occurred during ablation. Additionally, we evaluated whether endoscopic FU performed in a non-BEC versus in a BEC, was associated with an increased risk of advanced cancer recurrence.

Results In total, 1269 patients (1038 male, median age 66 yrs, median BE of C2M4) were included with baseline LGD in 27 % and HGD/EAC in 73 %. During a median endoscopic FU of 65 months (IQR 42-93), 53/1269 (4 %, annual risk 0.8 %) developed recurrent HGD or cancer. Of these, 15/53 patients (annual risk 0.2 %) had progressed to advanced cancer.

In univariate analysis, we found a significant association with risk for progression to HGD or cancer for the following variables: increasing baseline BE length (HR 1.1 [95 % CI 1.0-1.2]), new VL during the ablation phase (HR 5.8 [95 % CI 3.1-10.8]), increasing number of ER treatment sessions (HR 1.8 [95 % CI 1.4-2.4]).

The following were independently associated with recurrent HGD or cancer: new a VL during the ablation phase (HR 3.8 [95 % CI 1.8-7.8], present in 5 % vs 25 %), a higher number of ER treatment sessions (HR 1.4 [95 % CI 1.0-1.9], median 1 (IQR 1-1) vs 1 (IQR 1-2)), and increasing baseline BE length (HR 1.1 [95 % CI 1.0-1.2] , median M4 vs M6).

In univariate analysis, we found a significant association with risk for progression to advanced cancer for the following variables: increasing baseline BE length (HR 1.2 [95 % CI 1.0-1.3]); persisting esophagitis at the end of the treatment phase (HR 3.2 [95 % CI 1.0-10.0]), new VL during the ablation phase (HR 4.5 [95 % CI 1.3-15.8]), increasing number of ER treatment sessions (HR 1.8 [95 % CI 1.1-3.1]), FU endoscopies performed in a non-expert hospital (HR 0.6 [95 % CI 0.2-1.9]).

The following characteristics were independently associated with recurrence of advanced cancer: an increasing number of ER treatment sessions (HR 1.7 [95 % CI 1.0-2.9], median 1 (IQR 1-1) vs 1 (IQR 1-2)) and longer BE length at baseline (HR 1.2 [95 % CI 1.0-1.3], median M4 vs M7).

We found that FU endoscopies performed in non-BECs versus in BECs, were not associated with an increased risk of progression to advanced cancer. Notably, baseline histology did not independently predict either outcome.

Conclusions In this large, nationwide cohort, recurrent HGD or cancer after successful EET was uncommon, and progression to advanced cancer was rare. Despite the addition of new patients and extended FU, the predictors of recurrent HGD or cancer were consistent with those identified in our previous model. Although numbers were limited and external validation is still required, both increasing baseline BE length and multiple ER treatment sessions were independent risk factors for progression to advanced cancer. These findings further refine the evidence base for individualized, risk-adapted post-EET FU strategies.

DOI 10.1055/s-0046-1820812

Aims Endoscopic submucosal dissection (ESD) is increasingly used for Barrett's esophagus–associated neoplasia due to superior en bloc and R0 resection rates compared with endoscopic mucosal resection (EMR). However, its cost-effectiveness in the United States remains uncertain due to a lack of standardized reimbursement codes for ESD. We evaluated the cost-effectiveness of ESD versus EMR using pooled clinical outcomes and contemporary U.S. Medicare payment data.

Methods A decision-analytic model was developed from a U.S. Medicare perspective over a two-year horizon. Clinical probabilities were extracted from two meta-analyses (*Fujiyoshi 2024*, *Radadiya 2024*). Key pooled inputs included R0 resection (ESD 78 % vs EMR 67 %), recurrence (ESD 2 % vs EMR 6 %), perforation (1 % vs 0.1 %), delayed bleeding (10 % vs 8 %), and esophagectomy rates (ESD 8 % vs EMR 5 %). Costs were derived from 2024 Medicare national average payments and standardized inpatient cost benchmarks. QALYs incorporated decrements for recurrence, complications, strictures, and esophagectomy. Outcomes included total cost, QALYs, ICER, and net monetary benefit (NMB) at a $100,000/QALY threshold. One-way sensitivity analysis was performed.

Results ESD costs $9,761.92 per patient versus $5,826.76 for EMR. QALYs were slightly lower with ESD (1.87180 vs 1.87638). ESD remained **dominant,** more costly, and less effective with an incremental cost of $3,935 and incremental QALY of –0.00458. Incremental NMB favored EMR by $4,393. Sensitivity analysis identified the ESD index procedure cost and ESD esophagectomy probability as the most influential parameters; however, ESD did not become cost-effective under any plausible range.

Conclusions Despite superior en bloc and R0 resection, ESD is not cost-effective compared with EMR for Barrett's-associated neoplasia under current U.S. Medicare reimbursement. Our limitations include a shorter follow-up period of 2 years and the absence of comprehensive prospective studies reporting the use of adjunctive therapies post-EMR, like cryoablation, radiofrequency ablation, or repeat EMR, which could increase the costs associated with the procedure and reduce its cost-effectiveness. Furthermore, higher esophagectomy rates post-ESD might be associated with advanced lesions to start with compared to EMR. ESD may become cost-effective with standardized reimbursement codes and lower esophagectomy in future large prospective studies.

OP158 Outcomes of Selective Laparoscopic Lymph Node Sampling After Complete Endoscopic Resection of High-Risk Early Esophageal Cancer

Authors Mann O[1], Rösch T[2], Dupree A[1], Von Kroge P[2], Guido S[1], Dautel P[1], Younis F[3], Till C[1], Möller K[2], Hackert T[2], Zimmerman-Fraedrich K[2]

Institutes **1** University Medical Center Hamburg-Eppendorf, Hamburg, Germany; **2** UKE, Hamburg, Germany; **3** Tel Aviv Sourasky Medical Center – Ichilov, Tel Aviv-Yafo, Israel

DOI 10.1055/s-0046-1820813

Aims Curative endoscopic resection for T1 oesophageal cancer is increasingly accepted, yet in high-risk cases with possible lymph node metastases (LNM), nodal status and the need for further therapy remain unclear. We report outcomes of selective laparoscopic lymph node sampling (LLS) after endoscopic resection to improve risk stratification.

Methods High-risk T1 carcinomas treated with this combined approach (2012–2024) were retrospectively analyzed. The primary outcome was tumour-free survival; secondary outcomes were lymph node (LN) yield and LLS-related adverse events (AEs).

Results Fifty-five patients (mean age 68.2years; 41 men) underwent LLS (48 adenocarcinomas, 7 squamous). Mean LN yield was 27.4 nodes (excluding one failed procedure). Eight patients had positive LNs, with no clear histologic differences compared with LN-negative patients. Seven of the eight LN-positive patients, plus two with local recurrence only, proceeded to surgery. Surgical mortality was 22.2 % (2/9); all survivors remained tumour-free. Among 45 LN-negative, non-operated patients (mean follow-up 45.6 months), two non-curable recurrences (4.5 %) occurred after 2–3 years. Seven patients developed other neoplasias, and one died of unrelated causes. Overall, with endoscopic resection plus LLS, 50/54 patients (92.6 %) remained tumour-free at a mean follow-up of 44.6 months. Major LLS-related AEs occurred in two patients; delayed gastric emptying in 16.7 % (3/9 severe).

Conclusions Resection specimen histology poorly predicts LNM in early oesophageal cancer. Selective LLS after endoscopic resection is feasible, supporting organ preservation in most high-risk patients. Only LN-positive cases appear to require surgery—or alternative treatment—while LN-negative patients show low late-recurrence rates.

DOI 10.1055/s-0046-1820814

Aims Endoscopic submucosal dissection (ESD) for Barrett's esophageal neoplasia (BEN) remains limited due to its technical complexity and concerns regarding adverse events, particularly the risk of stricture formation. This study aims to evaluate the safety of BEN-ESD and identify risk factors for adverse events, with a focus on post-ESD stricture and the effects of different preventive strategies.

Methods This multicenter retrospective study included all consecutive BEN-ESDs from eight tertiary centers. Demographic, endoscopic, procedural, and histologic characteristics- including lesions' size and circumferential involvement (LCI), prior treatment, and stricture-prevention methods were collected. Preventive strategies were categorized as none, topical budesonide, oral prednisolone or steroid injection. The primary endpoint was post-ESD stricture, defined as luminal narrowing requiring endoscopic dilation. Secondary endpoints included risk factors for stricture, the effects of each preventive strategy, and the incidence of other adverse events. To reduce treatment-selection bias and to estimate marginal causal effects of each preventive strategy, propensi-

ty scores were calculated. Inverse probability of treatment weighting (IPTW) was applied to logistic regression models, and these models were used to obtain predicted stricture risks across treatment groups.

Results Among 706 eligible cases from across participating centers, 18 were excluded due to insufficient follow-up, leaving 688 patients for the final analysis (85 % male; median age 69 years [IQR 61–76]; median Body Mass Index (BMI) 27 kg/m² [IQR 24–30]). The length of Barrett's esophagus was characterized using the Prague classification, with a median circumferential (C) length of 2 cm (IQR 0–6) and a median maximal (M) length of 4 cm (IQR 2–7). Lesions were predominantly located in the lower thoracic esophagus (82 %), followed by the abdominal (11 %), middle (6.5 %), and upper thoracic (0.5 %) part. Prior treatment had been performed in 20.2 % of patients, including EMR (9.1 %), ESD (6.4 %), RFA (8.7 %), other ablative therapies (2.3 %), surgery (1.4 %) and radiation or chemoradiotherapy (1.0 %). Histology at resection corresponded to adenocarcinoma in 71 %, high-grade dysplasia in 17 %, and low-grade dysplasia in 8.6 %. LCI was < 50 % in 35 %, 50-74 % in 46 %, 75–99 % in 14 %, and 100 % in 5 % of the cases. Stricture-preventive strategies were implemented in 25 % of ESDs, with application rates increasing by circumferential involvement: 8 % for LCI < 50 %, 19 % for LCI 50–75 %, and 67 % for LCI > 75 %. The stricture-preventive approaches employed were topical budesonide in 14 % of procedures, oral prednisolone in 11 %, and local steroid injection in 4 %. Overall, post-ESD stricture occurred in 14.8 % of patients and increased with circumferential involvement (7.2 % for LCI < 50 %, 10.4 % for 50–74 %, and 39.4 % for ≥ 75 %; p < 0.0001). Stricture risk was primarily driven by circumferential extent and prior endoscopic treatment. Using propensity score–based IPTW to estimate marginal causal effects, the predicted standardized risks for post-ESD stricture were 11.2 % (95 % CI 8.5-14.9) with no preventive therapy, 11.2 % (95 % CI 3.0-26.7) with oral prednisolone, 3.7 % (95 % CI 1.1-21.1) with steroid injection and 3.1 % (95 % CI 0.5–7.2) with topical budesonide. Topical budesonide was the only strategy that demonstrated a statistically significant reduction in standardized predicted stricture risk. Perforation occurred in 0.3 % and bleeding in 3.9 % of cases, all managed endoscopically. No severe adverse events resulted from preventive therapies.

Conclusions BEN-ESD is safe, with stricture occurring in 15 % of patients. Circumferential extent ≥ 75 % and prior treatment are the major risk factors for post-ESD stricture. Our results show that topical budesonide is the only preventative strategy with a meaningful reduction in predicted stricture risk.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP160 Longterm outcome of endoscopic management in elderly patients with Barrett's oesophagus-associated dysplasia and cancer predicted by Charlson Comorbidity index

Authors Biswas S[1, 2], Jie X[3], Hey MA[2], Hosack T[2], Braden B[4, 5]
Institutes **1** Oxford NIHR Biomedical Research Centre, Oxford, United Kingdom; **2** Translational Gastroenterology Unit, Oxford, United Kingdom; **3** Oxford University Medical School, Oxford, United Kingdom; **4** Münster University Hospital, Münster, Germany; **5** Medical Dept B, University Hospital Münster, Münster, Germany
DOI 10.1055/s-0046-1820815

Aims The risk of dysplasia and cancer increases with age in Barrett's oesophagus. Advanced endoscopic therapy such as endoscopic resection and radiofrequency ablation (RFA) is indicated in dysplasia and intramucosal cancer, but is associated with higher risks in older patients with severe comorbidities. Little guidance is available as to when to stop endoscopic therapy and follow-up. Therefore, we analysed the outcomes of endoscopic therapy in elderly patients (> 75 years) in a tertiary centre over the last 15 years in relation to their Charlson Comorbidity score (CSI).

Methods All patients aged > 75 years who underwent endoscopic therapy since 2008 were selected from the prospectively maintained database. Their Electronic Patient Record (EPR) was searched to establish patient details and outcomes.

Results Since 2008, 109 patients aged > 75 years with dysplasia or early Barrett's cancer underwent advanced endoscopic therapy. The median age was 80 years with a range from 75 to 90 years. Only 19/109 (17 %) of patients were female. The majority of patients pre-therapy had high-grade dysplasia (59 %) at the time of referral. The median Barrett's length was C3M5.

80/109 (73 %) underwent EMR first, 10/109 underwent RFA first (9 %) and 19/109 (17 %) had APC only. 27 % were on anticoagulation with warfarin or a DOAC (direct oral anticoagulant). 19 % were on an antiplatelet. In terms of complications following therapy, there were 2 delayed haemorrhages, 1 stricture formation and no perforations.

72/109 patients (66 %) achieved complete resolution of intestinal metaplasia (CR-IM) and 87/109 (80 %) achieved complete resolution of dysplasia (CR-D) in the intention to treat analysis. Of the 4 patients with invasive adenocarcinoma (2 identified pre-therapy and 2 identified post-therapy), 2 patients achieved complete resolution of dysplasia. 31/109 patients died during the 15 years follow-up, with a median survival of 5 years after the start of treatment. Only 2 patients died from oesophageal cancer [1].

The overall all cause mortality was higher in patients with higher Charlson Comorbidity Index score (p = 0.04).

Conclusions Older patients were able to tolerate advanced endotherapy and endoscopic follow-up for Barrett's oesophagus well, with good resolution of metaplasia and/or dysplasia, similar to the UK HALO registry results in which the mean age was 67 years. In elderly patients over 75 years with advanced Barrett's dysplasia or early cancer, advanced endotherapy and follow-up is safe and should be considered in the context of patient's fitness and CCI reflecting life expectancy as well as individual risk of progression to invasive cancer.

OP161 Endoscopic Ultrasound-Guided Biomarker Evaluation of Pancreatic Cancer After Exposure to Therapy

Authors Lee SE[1], Kim D[1], Rolston V[1], Vakiani E[1], Sigel C[1], O'reilly EM[1], Yu K[1], Capanu M[1], Chou JF[1], Jarnagin W[1], Soares K[1], Schattner M[1]
Institute **1** Memorial Sloan Kettering Cancer Center New York – Main Hospital, New York, United States of America
DOI 10.1055/s-0046-1820816

Aims Comprehensive molecular profiling by next-generation sequencing (NGS) of pancreatic adenocarcinoma (PDAC) can identify both prognostic and therapeutic biomarkers. Endoscopic ultrasound (EUS)-guided biopsy of PDAC is generally adequate for NGS testing. However, the impact of prior chemotherapy and radiotherapy on sample adequacy and NGS success from EUS-guided biopsies of the pancreas is not well described.

Methods All EUS-guided tissue acquisition by fine needle aspiration or core needle biopsy specimens diagnostic for PDAC at Memorial Sloan Kettering Cancer Center were retrospectively identified between 2014 and 2025. Comprehensive molecular profiling was performed using the institution's paired

tumor-normal, large panel, hybridization-capture based, NGS assay known as Memorial Sloan Kettering Integrated Mutation Profiling of Actionable Cancer Targets (MSK-IMPACT). NGS testing results were analyzed. Relevant clinical and pathologic data were obtained from the electronic medical record. The following methods of statistical analyses were utilized: Fisher's exact test for comparing categorical data between two groups, Chi-squared test for more than two categorical groups, and the Wilcoxon rank sum test for comparing groups of continuous data.

Results NGS testing was requested on 601 EUS-guided biopsies of PDAC and was successful on 468 (78 %) specimens. NGS success rates have significantly improved over time (68 % in 2015-2020 vs 86 % in 2021-2025, $p < 0.001$) with improvements in sequencing and DNA extraction. Most samples that failed testing were due to a low DNA concentration and low tissue cellularity. Of 591 specimens, 78 (13 %) were exposed to therapy preceding EUS-guided biopsy – 60 (77 %) with chemotherapy alone and 18 (23 %) with radiotherapy. All specimens exposed to radiation received concurrent chemotherapy. There was no statistically significant difference in NGS success with or without exposure to any therapy (74 % vs 80 %, $p = 0.3$). Sub-group analyses of NGS performance based on exposure to chemotherapy alone vs no prior therapy (77 % vs 79 %, $p = 0.6$) and to radiation vs no prior therapy (67 % vs 79 %, $p = 0.2$) confirm that prior treatment does not significantly affect the feasibility of NGS testing from EUS-guided biopsies of the pancreas. Further supporting this, the DNA concentration of specimens did not significantly differ comparing exposure to any therapy vs no prior therapy (2.2ng/uL vs 2.6ng/uL, $p = 0.3$), chemotherapy alone vs no prior therapy (2.4ng/uL vs 2.5ng/uL, $p = 0.7$), and radiation vs no prior therapy (2.0ng/uL vs 2.5ng/uL, $p = 0.2$). Of the successful cases, 95 % of them identified a significant hotspot mutation – a potential prognostic or therapeutic biomarker for matched targeted therapy.

Conclusions This is the largest series to date confirming the feasibility of EUS-guided biopsies of PDAC for NGS testing. It is also the first to evaluate whether therapy exposure prior to biopsy affects NGS performance. Although chemotherapy and radiotherapy can alter the tumor microenvironment, the analyses herein suggest that specimen adequacy for NGS is feasible in pre-treated PDAC. This emphasizes the clinical utility of EUS-guided biomarker evaluation of PDAC after initial therapy or at disease progression to identify potential new actionable targets. EUS-guided biopsies of PDAC is a valuable tool for obtaining tissue for NGS pre-, during, and after completion of therapy.

Aims Differentiating benign from malignant biliary strictures in patients with suspected perihilar cholangiocarcinoma (pCCA) remains a major clinical challenge. The current diagnostic standard for pCCA is brush cytology which offers high specificity (95-100 %) but limited sensitivity (41-67 %). As a result, diagnosis is often delayed and additional invasive procedures are required, highlighting the need for more sensitive diagnostic tools. Liquid biopsy approaches are increasingly used in oncology, with plasma derived cell-free DNA (cfDNA) being the most widely investigated. However, plasma cfDNA performs poorly in early-stage or small tumors. Bile, in contrast, can contain up to 20-fold higher cfDNA concentrations than plasma, providing a potentially richer source of tumor-derived DNA for biliary tumors (1). Since bile can be collected during routine endoscopic retrograde cholangiopancreatography (ERCP), analysis of bile-derived cfDNA may enhance diagnostic sensitivity without additional procedural burden. The primary aim of this study was to evaluate the feasibility and accuracy of Next-Generation Sequencing (NGS) on bile-derived cfDNA for mutation-based diagnosis of pCCA [1].

Methods In this prospective cohort study, bile samples were collected during ERCP from consecutive patients with suspected pCCA from June 2023 onwards. Bile cfDNA was extracted using the QIAamp MinElute circulating cell free DNA Mini Kit. NGS was performed using Ion Torrent with the Oncomine Pan-Cancer Cell-Free assay. Final diagnosis was established by histological evaluation of surgical or biopsy specimens and clinical follow-up consistent with malignant disease. Primary outcome was correct diagnosis of pCCA on cfDNA. Secondary outcome was correct diagnosis of pCCA based on bile cfDNA combined with brush cytology.

Results Between June 2023 and October 2025, bile samples were obtained from 60 patients with suspected pCCA. At the time of sample collection, 20 patients had metastatic disease, 20 were considered resectable, and 20 had locally advanced disease. High-quality cfDNA was successfully extracted from all samples, and NGS mutation analysis has thus far been completed in 43 patients. Among these, one or more (likely) pathogenic mutation(s) were detected in 37 patients, yielding a sensitivity of 86 % (37/43, 95 %CI 72-95 %). The most frequently detected mutations were KRAS (32 %), TP53 (23 %), BRAF (8 %), PIK3CA (8 %) and ERBB2/3 (5 %/4 %). Brush cytology was performed in 42 patients and was positive for malignancy in 31 cases (74 %, 95 %CI 58-86 %). When combining brush cytology with NGS of bile-derived cfDNA, a definitive diagnosis of pCCA was established in 41 cases, yielding a sensitivity of 95 % (95 %CI 84-99 %). NGS analysis of tissue (cytology or biopsy specimens) obtained during routine diagnostic work-up was available for 31 of 43 patients using standard-of-care panels. In 21 patients, mutation profiles matched those detected in bile cfDNA, and in two patients no mutations were detected in bile and tissue. Thus, in 23 out of 31 patients (74 %, 95 %CI 55-88 %), bile cfDNA mutation profiling was fully concordant. In five patients, mutations were identified in bile cfDNA but not in tissue, most commonly due to low DNA quality in the tissue samples. In three patients, mutations were detected in tissue but not in bile; in all three cases the tissue-detected mutations were not included in the Oncomine panel used for bile cfDNA analysis.

Conclusions In the first results of this prospective proof-of-concept study, mutational analysis on bile-derived cfDNA was shown possible and substantially improved the detection of pCCA at the initial diagnostic stage. NGS on cfDNA in bile achieved a sensitivity of 86 %. When combined with brush cytology the sensitivity even increased to 95 %. These results may have major impact on diagnosis of pCCA. Moreover, identifying actionable mutations through cfDNA analysis may not only enhance detection but could also play an important role in guiding future targeted therapeutic strategies. Future studies should focus on developing a cholangiocarcinoma specific gene panel, considering the number of patients with mutations outside the current panel and thereby potentially improving diagnostic sensitivity even further.

DOI 10.1055/s-0046-1820818

Aims Lymph node (LN) metastases are a poor prognostic factor in intrahepatic cholangiocarcinoma (iCCA) and perihilar cholangiocarcinoma (pCCA). Extraregional LN metastases (LNM) preclude surgical exploration. Knowledge pertaining to the presence of regional LNM can guide decision-making weighing the risks and benefits of surgical resection. When diagnosing suspicious lymph nodes, endoscopic ultrasound (EUS) offers the possibility of direct tissue acquisition (TA) for pathological confirmation. While the European Association for the Study of the Liver (EASL) Clinical Practice Guideline on the management of extrahepatic CCA already recommends preoperative EUS [1], the European Society of Gastrointestinal Endoscopy (ESGE) guideline on bile duct strictures makes no specific recommendations [2]. This prospective study aims to assess the yield of preoperative systematic EUS for LN staging for resectable iCCA and pCCA.

Methods We conducted a prospective, multi-center, international trial enrolling patients from seven tertiary referral centers in the Netherlands and Belgium. All presumed resectable iCCA and pCCA patients, without intra-pancreatic tumor ingrowth on cross-sectional imaging, were eligible. All patients, regardless of the LN findings on cross-sectional imaging, underwent a systematic EUS with extensive regional and extraregional LN sampling: attempting to biopsy all LN with ≥ 5 millimeter short-axis diameter. Abdominal LN stations 8 up to 18 are systematically checked according to the Japanese classification [3]. The primary outcome was the yield of EUS and its impact on clinical decision making, defined as the number of patients who were precluded from surgery due to EUS findings (identification of regional or extraregional LNM and other findings) or had altered surgery strategy/approach. Secondary outcomes included EUS related adverse events defined according to the AGREE classification [4], and the 'miss' rate of LNM defined as LNM identified during surgical exploration not detected by EUS-TA.

Results A total of 254 patients were included (59 % male, median age of 68 years [IQR: 61 – 74]), consisting of 62 iCCA and 192 pCCA patients. LNs were identified on cross-sectional imaging in 72 % of patients. A total of 284 EUS procedures were performed, during which 1262 LN were identified in 243 patients (96 %). EUS-TA was carried out for 418 LN (33 %), yielding malignancy in 73 LN (58 regional and 15 extraregional) across 45 patients. In 13 patients (5 %), pancreatic ingrowth was identified. At cross-sectional imaging performed before EUS, 43 (59 %) of these EUS-TA proven LNM were described as pathological, 10 (14 %) were described as non-pathological, and 20 (27 %) were not mentioned.

EUS yielded clinically relevant findings in 50 of the 254 patients (20 %): EUS precluded surgery in 43 patients (regional LNM: 21, extraregional LNM: 10, pancreatic ingrowth: 8, other reasons such as IgG4 cholangitis or adrenal metastasis diagnosis: 4), and altered the surgical plan in 7 patients (pancreatic ingrowth). In twelve patients regional LNM were identified but surgery was not precluded.

Among the 150 patients who finally underwent surgical exploration without EUS-TA sampled LNM, 'missed' LNM were identified in 106 of the 809 retrieved LN (13.1 %), in 51 patients. Of the 106 LNM, 91 were regional and 15 extraregional. These 'missed' extraregional LNM were identified in 8 patients, regional LNM in 43 patients. EUS related complications occurred in 3 procedures (1 %): bleeding requiring embolization (AGREE III) and hypotension (2x: AGREE I).

Conclusions EUS with systematic evaluation of regional and extraregional LN is safe and should be offered to all presumed resectable iCCA and pCCA patients. It provides information for clinical decision making in 20 % of patients including identifying malignant extraregional lymph nodes precluding resection. (ClinicalTrials.gov, Number: NCT05678218).

OP164 Outcomes of a novel biliary hybrid metal stent composed of an inner-covered and an outer-uncovered stent for unresectable distal malignant biliary obstruction

Authors Yang MJ[1], Choi CY[1], Hwang JC[1], Yoo BM[1], Kim JH[2]
Institutes **1** Ajou University School of Medicine, Suwon, Republic of Korea; **2** Asan Chungmu Hospital, Asan, Republic of Korea
DOI 10.1055/s-0046-1820819

Aims Uncovered self-expandable metal stents (SEMS) are prone to tumor ingrowth, whereas covered SEMS carry the risk of migration. We evaluated the feasibility of a newly developed biliary hybrid SEMS, designed to prevent both issues, for patients with unresectable distal malignant biliary obstruction (MBO).

Methods Eighty patients with unresectable distal MBO underwent endoscopic placement of the hybrid SEMS (Two-in-One stent; Taewoong Corp., Goyang, Korea). This stent consists of an inner silicone-covered SEMS and an outer-uncovered SEMS. In cases of inner-covered SEMS dysfunction, it can be endoscopically removed while leaving the uncovered SEMS in place.

Results Stent placement was successful in all patients (80/80), with clinical success in 98.8 % (79/80). Inner-covered stent dysfunction occurred in 28.9 % (22/76), primarily due to biliary sludge (90.9 %, 20/22). No stent migration or bile duct kinking occurred. Mean cumulative patency of the inner-covered and the Two-in-One stents were 537.5 days (95 % confidence interval (CI), 433.8–641.2) and 778.7 days (95 % CI, 709.6–847.8), respectively. The 6-, 12-month, and lifetime patency rates of the Two-in-One stent were 94.0 %, 86.4 %, and 78.9 %, respectively. Early and late adverse events were observed in six patients (four with pancreatitis and two with cholecystitis) and 27 patients (22 with recurrent biliary obstruction [RBO] and five with non-RBO) patients, respectively [1–18].

Conclusions The Two-in-One stent demonstrates a high lifetime patency rate in patients with unresectable distal MBO, initially functioning as a non-migrating, partially covered SEMS and later transforming into an uncovered SEMS after removal of the clogged inner-covered SEMS.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820820

Aims Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive disease with a poor prognosis. A deeper molecular characterization of PDAC could be useful to find new therapeutic options. By using a targeted NGS-based approach, we analyzed gene variants in time-matched solid and liquid biopsies to evaluate concordance rate and potential correlations with clinicopathological features.

Methods A prospective cohort of 30 PDAC patients was enrolled. Inclusion criteria were: age of pts ≥ 18 years, histological diagnosis of PDAC at all stages, availability of a formalin-fixed paraffin-embedded (FFPE) tumor sample obtained by EUS-FNB and availability of a time-matched blood sample. Cell-free DNA (cfDNA) was extracted from the plasma. For NGS analysis, a custom panel including 39 genes more frequently altered in PDAC according to literature was used. Fisher's exact test was applied to evaluate the association between gene variants and patients features [1–6].

Results Most of mutations were found in cancer driver genes, such as KRAS and TP53, in solid as well as in liquid biopsies. 24 out of 30 tumor biopsies were successfully analyzed by NGS, confirming EUS-FNB ability to provide adequate DNA for sequencing. In 5 patients, cfDNA analysis was able to detect variants undetectable in the time-matched solid biopsy. No statistically significant differences were found in different patient phenotypes.

Conclusions Assessment of PDAC mutational profile by a targeted NGS approach suggests the importance to characterize solid biopsies as well as liquid biopsies to improve the diagnostic typing. Future studies with larger patients

cohorts and longitudinal sampling are needed to elucidate the role of cfDNA in PDAC prognosis and treatment monitoring.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Patients with pancreatic ductal adenocarcinoma (PDAC) are increasingly being treated with chemotherapy, either as (neo-)adjuvant or palliative treatment. Histological confirmation is often required prior to treatment, with fine needle biopsy (FNB) being the preferred diagnostic approach. However, current FNB-needles achieve a diagnostic accuracy ranging from only 67 to 87 %. Furthermore, the guidelines of the European Society of Gastrointestinal Endoscopy do not provide specific recommendations regarding the optimal number of passes during a FNB procedure with a three-prong asymmetric tip FNB-needle. The aim of this study was to investigate the diagnostic accuracy of a novel three-prong asymmetric tip FNB needle (Micro-Tech, Nanjing, China) and to determine after how many passes PDAC was diagnosed. Additionally, the study evaluated the added value of rapid on-site evaluation (ROSE).

Methods We performed an investigator-initiated prospective cohort study in three hospitals in The Netherlands. Patients with suspected PDAC and an indication for EUS-FNB were included. During each procedure, three biopsies were obtained and placed in separate formalin containers. ROSE was performed until ROSE was representative.

Results In 125 of 138 included patients the diagnosis PDAC could be confirmed by using the three-prong asymmetric tip FNB needle (diagnostic accuracy of 90.6 %). Following the second and third pass, the diagnostic confirmation rate was 92.0 % and 96.8 %, respectively. Although ROSE was not representative after the first pass in 48 patients, a positive histological result was still obtained in 30 of these cases (62.5 %). A total of 14 complications were seen; 10 patients developed an acute pancreatitis; two patients after only EUS-FNB, and eight after a combination of EUS-FNB with Endoscopic Retrograde Cholangiopancreatography (ERCP).

Conclusions The three-prong asymmetric tip FNB needle demonstrated a high diagnostic accuracy, with a diagnostic confirmation rate of 92.0 % after two passes. However, ROSE had no additional diagnostic value in this group with high-likelihood PDAC, it can be considered in atypical difficult cases.

OP167 Efficacy of addition of oral simethicone emulsion on the quality of bowel preparation for colonoscopy– An open-label randomized controlled trial

Authors Maheshwari S[1], Giri S[1], Anand AC[1], Sahu MK[1], Panigrahi SC[1], Nath P[1], Mallick B[1], Praharaj D[1], Sahu SK[1]

Institute **1** Kalinga Institute of Medical Sciences (KIMS), Bhubaneswar, India

DOI 10.1055/s-0046-1820822

Aims High-quality bowel preparation is essential for optimal mucosal visualization, adenoma detection, and overall colonoscopy effectiveness. Simethicone, an antifoaming agent, has been studied as an adjunct to PEG regimens to reduce intraluminal bubbles, though most prior trials used tablet formulations. This study aims to assess whether adding simethicone emulsion to PEG-electrolyte solution improves the quality of bowel cleansing and other colonoscopic preparation parameters.

Methods Consecutive adult patients undergoing colonoscopy were screened between April 2024 to October 2025 and randomized into two groups: 2 L PEG-ELS split dose + 300 mg simethicone emulsion per liter of PEG-ELS (Group A) and 2 L PEG (Group B). The primary endpoint was the effectiveness of bowel cleansing, as assessed by the Boston Bowel Preparation Scale (BBPS). Secondary endpoints included bubble score, cecal intubation time, polyp detection rate (PDR), and adverse events (▶ **Table 1**).

▶ **Table 1** Comparison of outcomes between the patients in each group

Parameters	Group A (n = 72)	Group B (n = 72)	p-value
Boston Bowel Preparation Scale: Total	7.36 ± 1.33	7.19 ± 1.58	0.495
Adequate bowel preparation	63 (87.5 %)	59 (81.9 %)	0.354
Bubble score: Total	0.49 ± 0.80	2.67 ± 2.92	< 0.001
Cecal intubation time (SD), in min	4.62 ± 1.54	5.96 ± 2.72	< 0.001
Colon withdrawal time (SD), in min	6.54 ± 1.02	6.97 ± 1.19	0.027
Polyp detection rate, n (%)	8 (11.1 %)	8 (11.1 %)	1.000
Adverse events: Bloating, n (%)	1 (1.4 %)	4 (19.4 %)	0.001
Willing to undergo a repeat colonoscopy if indicated	64 (88.9 %)	54 (75.0 %)	0.030

Results After exclusion, 150 patients were randomized, out of which 3 did not complete the preparation, and 3 patients had luminal obstruction precluding completion of the procedure. A total of 144 patients were included in the analysis, with 72 in each group. There was no difference in age (48.33 ± 15.14 vs. 47.00 ± 14.78 years), body mass index (23.38 ± 3.57 vs. 22.58 ± 3.79 kg/m^2), or the proportion of patients with comorbidities. Mean total BBPS scores did not differ significantly (7.36 ± 1.33 vs 7.19 ± 1.58; p = 0.495), nor did segmental scores for the right, transverse, or left colon (p = NS for all). Adequate bowel preparation (BBPS ≥ 6 with neither segmental score < 2) was achieved in 87.5 % of Group A and 81.9 % of Group B (p = 0.354), indicating similar cleansing effectiveness. In contrast, bubble burden differed markedly between groups. Group A demonstrated significantly lower bubble scores across all colonic segments, including cecum (p < 0.001), ascending colon (p < 0.001), transverse colon (p = 0.001), descending colon (p = 0.005), and rectosigmoid (p = 0.006). The total bubble score was significantly lower in Group A compared with Group B (0.49 ± 0.80 vs. 2.67 ± 2.92; p < 0.001), indicating substantially clearer mucosal visualization. Cecal intubation time was significantly shorter in Group A (4.62 ± 1.54 min) compared with Group B (5.96 ± 2.72 min; p < 0.001). Colon withdrawal time was also marginally but significantly shorter in Group A (6.54 ± 1.02 vs 6.97 ± 1.19 min; p = 0.027). Despite these differences in visualization and procedure times, polyp detection rates were identical (11.1 % in both groups; p = 1.000). Adverse event profiles favored Group A. Bloating was significantly less frequent (1.4 % vs 19.4 %; p = 0.001). Rates of nausea/vomiting, abdominal cramps, and sleep disturbances did not differ significantly. Patient acceptability was higher in Group A, with more patients willing to undergo repeat colonoscopy if required (88.9 % vs 75.0 %; p = 0.030).

Conclusions The addition of simethicone emulsion to PEG-ELS demonstrated a significantly reduced bubble burden, shorter cecal intubation and withdrawal times, fewer adverse symptoms, and greater patient acceptability, despite similar BBPS scores and polyp detection rates. These findings support the added value of simethicone-based preparation in enhancing mucosal visibility and improving overall procedural quality and patient comfort.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP168 Optimal Timing of Simethicone and N-Acetylcysteine Premedication to Improve Gastric Mucosal Visibility: A Randomized Controlled Trial

Authors Nabi Z[1], Inavolu P[1], Rughwani H[1], Pratap Singh A[1], Reddy DN[2]
Institutes 1 AIG Hospitals, Hyderabad, India; 2 Asian Institute of Gastroenterology (AIG Hospitals), Department of Medical Gastroenterology, Hyderabad, India
DOI 10.1055/s-0046-1820823

Aims Adequate gastric mucosal visibility (GMV) is essential for high-quality upper gastrointestinal (GI) endoscopy. This study aimed to evaluate the optimal timing of premedication with simethicone and N-acetylcysteine (NAC) in improving GMV.

Methods In this single-center, randomized controlled trial, 1,200 adult patients undergoing elective upper GI endoscopy were randomized into four groups: placebo, simethicone + NAC with endoscopy performed after 10–20 minutes, 20–30 minutes, and > 30 minutes. The primary outcome was the proportion of patients achieving adequate gastric mucosal visibility (GMV), defined as a score of < 7 on a validated visibility scale. A pre-specified subgroup analysis of the > 30 minute group was performed by stratifying patients into 20-minute intervals (31–50, 51–70, and 71–90 minutes) to assess the durability of mucosal clarity over time (▶ **Table 1**).

▶ **Table 1**

Characteristic	Group 1 (Placebo)	Group 2 (10–20 min)	Group 3 (20–30 min)	Group 4 (> 30 min)	Overall p-value	Significant Differences (Post hoc)
Adequate GMV (%)	8 (2.7)[a]	75 (25.0)[b]	194 (64.7)[c]	200 (66.7)[c]	< 0.0001	1 ≠ 2, 1 ≠ 3, 1 ≠ 4, 2 ≠ 3, 2 ≠ 4; 3 = 4
Mean Gastric Score	10.3[a]	8.5[b]	6.4[c]	6.2[c]	< 0.0001	All pairs except 3 vs 4
Lesion Detection (%)	43.7	46.7	48.7	47.3	0.655	NS (Not Significant)

Results Adequate GMV was significantly higher in all preparation groups compared to placebo (p < 0.001). The 20–30 minute and > 30 minute groups demonstrated the highest rates of adequate visibility (64.7 % and 67 %, respectively), both significantly superior to the 10–20 minute group (25 %) and placebo (2.7 %). In the > 30 minute subgroup analysis, the 31–50 minute interval demonstrated the highest adequacy (73.5 %). The 51–70 minute group showed moderate adequacy (52.1 %), which was not significantly different from the 20–30 minute group (p = 0.207). However, the 71–90 minute group (n = 16) had reduced adequacy (43.8 %) and did not differ significantly from the 10–20 minute group (p = 0.145). No adverse events were reported across study arms.

Conclusions Endoscopy performed between 20 and 50 minutes after mucosal preparation yields optimal gastric mucosal visibility. A decline in visibility beyond 50 minutes suggests a practical upper limit for endoscopy timing following preparation. These findings support structured, time-sensitive scheduling following mucosal cleansing to enhance procedural quality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP169 Prospective Evaluation of Ketamine and Midazolam Sedation for ERCP: A Safe Strategy with Superior Respiratory Stability and Faster Recovery Compared to Opioid-Based Regimens

Authors Cominardi A[1], Prati GM[1], Corso RM[2], Aragona G[1]
Institutes **1** Gastroenterology and Digestive Endoscopy Unit, Guglielmo da Saliceto Hospital, Piacenza, Italy; **2** Reanimation and Intensive Therapy Unit, Guglielmo da Saliceto Hospital, Piacenza, Italy
DOI 10.1055/s-0046-1820824

Aims Sedation for endoscopic procedures often risks respiratory and cardiovascular depression, particularly in elderly and frail patients. In endoscopic retrograde cholangiopancreatography (ERCP), frequently performed in the prone position, maintaining cardiorespiratory stability is essential. Ketamine, when combined with low-dose midazolam, may offer safer hemodynamic and respiratory profiles than traditional opioid-based regimens. Our primary aim was to evaluate the safety and efficacy of sedation with ketamine combined with low doses of midazolam for ERCP. The secondary aim was to compare its tolerability and adverse event (AE) profile with opioid-based sedation (pethidine, fentanyl or propofol) combined with midazolam.

Methods All patients undergoing ERCP with ketamine and midazolam sedation in our Digestive Endoscopy Unit from September 2023 to November 2025 were prospectively collected (Group A). For comparison, all patients who underwent ERCP with opioid-based sedation plus midazolam (Group B) from September 2022 to November 2025 were retrospectively and prospectively included. Group B was subdivided into: B1 (pethidine + midazolam), B2 (fentanyl + midazolam), and B3 (propofol + midazolam). Outcomes included procedure duration, recovery time, pain (measured before and after ERCP using the Visual Analogue Scale [VAS]), technical and clinical success rates, and sedation-related adverse events (AEs). Statistical analysis was performed using chi-square test, Student's t-test, Mann–Whitney U test, logistic regression, with significance set at p < 0.05.

Results A total of 940 patients were included: 417 received ketamine + midazolam (Group A; 227 males, median age 78 [21–98]) and 523 received opioid-based sedation (Group B; 257 males, median age 79 [34–98]).

Within Group B, 402 patients (76.8 %) received pethidine + midazolam (Group B1), 72 (13.8 %) fentanyl + midazolam (Group B2), and 49 (9.4 %) propofol + midazolam (Group B3).

In Group A, median doses were ketamine 40 mg [10–130] and midazolam 2.5 mg [1–7.5].

In Group B, median doses were: pethidine 45 mg [10–100] + midazolam 3.5 mg [1–9]; fentanyl 50 mcg [25–125] + midazolam 3 mg [1–6]; propofol 160 mg [50–450] + midazolam 2.5 mg [1–6].

Technical success was 96 %in Group A and 95.6 % in Group B; clinical success was 99.5 % and 99 %, respectively.

Sedation-related AEs occurred in 4.1 % (17/417) of Group A (2.2 % hallucinations, 1.4 % sialorrhea with mild desaturation, 0.5 % vomiting) and in 9.4 % (49/523) of Group B (Group B1: 7.7 %; Group B2: 13.9 %; Group B3: 16.3 %). Reported AEs in Group B included hypoxemia, bradycardia, and hypotension. Respiratory insufficiency was more frequent in Group B (14/31 in Group B1, 7/10 in Group B2, 7/8 in Group B3), whereas Group A showed only two cases of mild desaturation. No severe AEs occurred in either group. The most severe hypoxemia occurred in Group B3, requiring temporary interruption of ERCP in four cases.

Pain control was excellent in Group A, with only one patient (0.4 %) reporting a one-point increase in VAS after ERCP.

Median recovery time was significantly shorter with ketamine (16.8 ± 3.1 minutes) compared with opioids (26.6 ± 4.3 minutes).

No statistically significant differences were found between groups in ERCP duration (p = 0.33), pain control (p = 0.63), technical success (p = 0.82) or clinical success (p = 0.56).

AEs were significantly more frequent in Group B2 vs Group A (p = 0.04) and in Group B3 vs Group A (p = 0.03), particularly regarding respiratory insufficiency.

Conclusions Ketamine combined with low-dose midazolam is a safe and effective sedation strategy for ERCP, providing excellent pain control and a significantly lower incidence of respiratory events compared with opioid-based regimens. Given its favorable respiratory and hemodynamic profile and comparable procedural success, ketamine–midazolam represents a valuable alternative, especially for patients at increased risk of respiratory compromise during ERCP.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP170 Remimazolam versus midazolam for sedation during diagnostic gastroscopy: a multicenter, double-blind, randomized controlled trial

Authors Munters K[1], Alvarez Herrero L[1], Van Heel NC[2], Burger JP[3], Oort FA[3], Van Munster SN[1], Weusten BL[1]
Institutes **1** St. Antonius Hospital, Nieuwegein, Netherlands; **2** Gelre Hospitals, Apeldoorn, Netherlands; **3** Rijnstate, Arnhem, Netherlands
DOI 10.1055/s-0046-1820825

Aims Midazolam is widely used for procedural sedation during gastrointestinal (GI) endoscopy, but its limitations include prolonged recovery and impaired post-procedural memory. Remimazolam, a novel sedative, may enable faster recovery with improved preservation of cognition. Although both agents have been extensively studied, head-to-head comparisons in a Western population are limited. We therefore aimed to compare remimazolam to midazolam for diagnostic upper GI endoscopy in a multicenter, double-blind, randomized controlled trial.

Methods This trial is being performed in three Dutch community hospitals involving five experienced endoscopists. Adult patients scheduled for diagnostic upper GI endoscopy with procedural sedation were eligible; anticipated use of fentanyl or other opioids was an exclusion criterium. Patients were randomized 1:1 for sedation with either remimazolam or midazolam, with both patients and observers blinded for allocation. Vital signs, the validated Modified Observer's Assessment of Alertness/Sedation (MOAA/S) scores, and the validated Aldrete recovery scores were monitored at pre-defined time intervals during one hour post-procedure. In a follow-up phone call one day after the procedure, a memory test and patient questionnaire were completed. Primary endpoint was time to full alertness, defined as the interval between the latest sedative dose and the first of three consecutive MOAA/S scores ≥ 5. Secondary endpoints included sedation success rate, memory performance, the proportion of patients ready for discharge home at the time of leaving the endoscopy room, and adverse events. Sedation success was defined as completion of the procedure as intended, using ≤ 5 boluses of the sedative during endoscopy, and without the need for any additional sedative agents. Memory was evaluated by recall of a playing card shown after full alertness. Readiness for discharge was defined as the first Aldrete score ≥ 9, according to current guidelines. We report interim outcomes of our study in the intention-to-treat analysis.

Results In this interim analysis, 141/148 (95 %) patients were enrolled, with 71/141 (50 %) patients receiving remimazolam and 70/141 (50 %) patients midazolam. Baseline characteristics were similar between groups (66 % male; mean age 68 ± 11 years). The most common indication for the endoscopy was Barrett surveillance (98/141 patients; 70 %).

Median total doses were 8mg (IQR 7-9) for remimazolam and 5mg (IQR 4-7) for midazolam. Median procedure times were similar: 6 minutes (IQR 4-8) in both groups ($p < 0.005$). Sedation success rate was 96 % (68/71, 95 % CI 88-99) with remimazolam and 97 % (68/70, 95 % CI 90-99) with midazolam ($p = 0.718$). Procedure failure occurred due to ongoing agitation (remimazolam, n = 2; midazolam, n = 1) and food in the stomach (n = 1 in both groups).

Time to full alertness was significantly shorter with remimazolam: median 10 minutes (IQR 8-13) versus 22 minutes (IQR 13-33) with midazolam ($p < 0.005$). Setback in full alertness occurred in 1 % (95 % CI 0-8) after remimazolam versus 19 % (95 % CI 11-29) after midazolam ($p < 0.005$).

At the time of leaving the endoscopy room, 93 % (95 %CI 85-97) of remimazolam patients were ready for discharge home, versus 30 % (95 %CI 21-42) of midazolam patients ($p < 0.005$). Successful memory testing was observed in 65 % (95 % CI 53-75) versus 17 % (95 % CI 10-28) for remimazolam and midazolam, respectively ($p < 0.005$). Endoscopist and patient satisfaction were high in both groups. No serious adverse events occurred.

Conclusions Remimazolam for diagnostic upper GI endoscopy, enables faster recovery than midazolam, allowing most patients to meet discharge criteria directly after leaving the endoscopy room. Together with superior post-procedural memory, and high satisfaction, these preliminary results may support the potential for safe, recovery-room-free discharge following remimazolam monotherapy in routine clinical practice.

DOI 10.1055/s-0046-1820826

Aims Remimazolam, an ultrashort-acting benzodiazepine, is a promising sedative in the armamentarium for healthcare professionals who do not have access to non-anesthesiologist-administered propofol sedation. We aimed to evaluate the efficacy and safety of remimazolam compared to propofol as monotherapy for sedation in adults undergoing gastrointestinal endoscopic procedures.

Methods A systematic review across MEDLINE and Cochrane Central Register for RCTs was performed, evaluating the efficacy and safety of sedation with monotherapy remimazolam compared to propofol for sedation in GI endoscopic procedures, from 01.01.2019 to 31.07.2024. The primary outcome was the total adverse events rate, while sedation induction time, overall procedural time, sedation success, and patient satisfaction comprised the secondary outcomes. Pairwise meta-analyses were undertaken to present the effect size on study outcomes as either Risk Ratio (RR) or Mean Difference (MD) with 95 % confidence interval (CI). We also performed sensitivity analyses by type of adverse event rate (hypotension, bradycardia, respiratory). The quality of evidence was assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

Results Fourteen RCTs involving 3158 patients (remimazolam 1587, propofol 1571) were included. Compared to propofol, monotherapy with remimazolam was associated with a significantly lower total adverse event rate [RR 0.66, 95 % CI (0.56 – 0.78), $I^2 = 73$ %]. This effect was consistent for hypotension [RR 0.40, 95 % CI (0.29 – 0.54), $I^2 = 75$ %], bradycardia episodes [RR 0.46 95 % CI (0.32 – 0.67, $I^2 = 0$ %] as well as respiratory adverse events rate [RR 0.44, 95 % CI (0.27-0.74), $I^2 = 42$ %]; there was low confidence in estimates. Remimazolam administration resulted also in a shorter sedation induction time [MD -0.41, 95 % CI (-0.70 – 0.12), $I^2 = 97$ %]. On further analysis, procedural time, sedation success, and patient satisfaction were similar between the two medication treatments [MD 0.69, 95 % CI (-0.74-2.13); $I^2 = 54$ %; RR 0.99, 95 % CI (0.90-1.09), $I^2 = 98$ % and MD 0.77, 95 % CI (-0.22-1.76), $I^2 = 55$ %, respectively]. Certainty of evidence was low.

Conclusions Remimazolam monotherapy displays better safety profile with clinically similar efficacy when compared to propofol monotherapy for sedation in gastrointestinal endoscopic procedures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP172 Comparative Evaluation of Propofol-Based Sedation Strategies in Endoscopy: Safety, Recovery, and Satisfaction in Non-Anesthesiologist Administration

Authors Abu Baker F[1], Heba M[1], Natour R[1], Nicola D[1], Ovadia B[1], Oren G[1]

Institute **1** Hillel Yaffe Medical Center, Hadera, Israel

DOI 10.1055/s-0046-1820827

Aims Propofol has become the cornerstone sedative in gastrointestinal (GI) endoscopy because of its rapid onset, short half-life, and predictable recovery profile. With the growing global adoption of nonanesthesiologist-administered propofol (NAAP), optimizing its delivery strategy is of increasing clinical relevance. While combining propofol with benzodiazepines has been proposed to achieve a dose-sparing effect and enhance sedation stability, the clinical benefit of this approach over propofol monotherapy remains uncertain. This study prospectively compared the safety, performance, satisfaction, and cost profiles of propofol monotherapy versus propofol–midazolam combination under standardized NAAP protocols.

Methods In this randomized, single-center trial, 330 adult patients undergoing elective upper, lower, or bidirectional endoscopy were assigned to receive either propofol alone or propofol combined with midazolam (1:1 ratio). Sedation was administered by trained gastroenterology teams following structured NAAP protocols. The primary endpoints were sedation-related complications and total propofol dosage. Secondary endpoints included procedure completion, recovery quality, patient and endoscopist satisfaction, and per-procedure sedation cost. Logistic regression identified independent predictors of compli-

cations, and receiver operating characteristic (ROC) analysis assessed the discriminatory capacity of propofol dosage.

Results Both sedation regimens were safe and effective, with no differences in overall (30.3 % vs. 33.3 %) or severe complications (1.8 % vs. 2.4 %). Propofol monotherapy required a higher total dose (197 ± 90 mg vs. 174 ± 75 mg, $P = 0.013$) but achieved significantly smoother and faster recovery ($P < 0.001$). Patient satisfaction exceeded 95 % in both groups, and endoscopist ratings of procedural comfort and sedation adequacy were uniformly high. Multivariable analysis identified bidirectional endoscopy (aOR = 2.49, 95 % CI: 1.57–3.97) and BMI > 30 (aOR = 1.69, 95 % CI: 1.02–2.78) as independent predictors of sedation-related events, while the propofol regimen itself was not associated with higher risk (aOR = 0.83, 95 % CI: 0.50–1.31). Propofol dose alone demonstrated limited predictive accuracy for adverse events (AUC = 0.64 monotherapy; AUC = 0.59 combination). Sedation costs were slightly lower for monotherapy (median 1.04 € vs. 1.29 €, $P < 0.001$).

Conclusions Propofol-based sedation administered by trained gastroenterology personnel is safe and efficient for routine endoscopic practice. Monotherapy, while requiring higher propofol doses, offers faster recovery, simplified administration, and marginal cost savings without compromising safety or satisfaction. The addition of midazolam does not confer measurable clinical benefit in standard elective cases but may be selectively advantageous for anxious or complex patients. These findings support the broader implementation of propofol monotherapy as a primary NAAP regimen and highlight the need for multicenter studies to further refine risk-adapted sedation algorithms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Cholangioscopy: From stones to cancer

DOI 10.1055/s-0046-1820828

Aims Intraductal papillary neoplasms of the bile duct (IPN-Bs), recognized as potential precursors of invasive cholangiocarcinoma, present diagnostic challenges due to their variable imaging characteristics, mucin production, and frequent tumor multiplicity. Conventional imaging modalities may be limited in accurately characterizing these lesions. We assessed the clinical utility of peroral cholangioscopy (POC) in the diagnosis and management of IPN-Bs.

Methods IPN-Bs were diagnosed in consecutive patients who underwent POC, based on a comprehensive assessment of clinical presentation, laboratory findings, imaging studies, and POC results. The primary outcome was the detection rate of IPN-Bs. The secondary outcomes were the technical success of POC and POC-guided forceps biopsy (POC-FB), procedure-related adverse events (AEs), detection rate of IPN-Bs missed on prior imaging, and management modification rate after POC.

Results POC was completed in 599 of 621 patients (94.9 %). Mild procedure-related AEs occurred in nine patients (1.4 %) and were managed conservatively. IPN-Bs were identified in 84 patients (13.3 %), including 25 (29.8 %) that had not been detected on prior imaging. Among the 81 of 84 patients in whom POC-FB was successful, histopathologic diagnoses included indefinite for dysplasia (17.3 %), low-grade dysplasia (53.1 %), high-grade dysplasia (13.6 %), and invasive carcinoma (16.0 %). Among 59 patients with suspected IPNBs on conventional imaging, POC findings led to management modifications in 17 cases (20.2 %).

Conclusions POC is a useful diagnostic modality for the detection of IPN-Bs and facilitates accurate decision-making for subsequent management planning.

DOI 10.1055/s-0046-1820829

Aims Differentiating between main duct intraductal papillary mucinous neoplasm (IPMN) with the presence of segmental irregular wall thickening and/or millimetric mural nodules and chronic pancreatitis (CP) is a significant challenge. When the diagnosis is unclear, endoscopic ultrasound (EUS) is indicated. The Rosemont criteria, including main duct morphology, hyperechoic foci, calcifications in the pancreatic duct (MPD), pancreatic parenchymal changes, MPD irregular contour or dilation are essential for diagnosing CP but are not always conclusive. Instead IPMN-MD diagnosis depends on imaging techniques like MRI and EUS, revealing an MPD diameter > 5 mm and often the presence of wall thickening or mural nodules. In cases where chronic pancreatitis is considered definite or possible according to the Rosemont criteria, and there is dilation of MPD accompanied by segmental irregular wall thickening, the differential diagnosis becomes particularly challenging. In such cases, peroral pancreatoscopy could be reliable for identifying IPMN and provide useful information. An accurate diagnosis is crucial because patients may need a total pancreatectomy, which is associated with both short-term complications (e.g., infections, organ failure) and long-term issues (e.g., diabetes, malabsorption syndrome). The 5-year survival rate for these patients ranges from 25 % to 60 %.

Methods In this case series 5 patients who underwent EUS for differential diagnosis between CP and IPMN- MD with the presence of segmentary irregular wall thickening or millimetric mural hyperechoic nodule < 5 mm from January 2023 to November 2024 were included. All patients had EUS evidence of MPD dilation > 10 mm, with irregular contour e/o mural nodules not clearly suggestive of plugs, calcifications, or intraluminal growth. Contrast-enhanced EUS (CH-EUS) were performed, showed the presence of MPD nodules. Because definitive diagnosis of IPMN- MD could be challenging in advanced chronic pancreatitis cases, we scheduled a peroral pancreatoscopy (POPS) using the Spyglass DS system. Pancreatoscopy allowed direct high-definition visualization of the pancreatic ducts and targeted biopsy on abnormal-appearing mucosal lesions for histological confirmation [1–11].

Results The cohort had a mean age of 60 years (3 male, 2 female), with a median follow-up of 84 days. MPD dilation was 17.2 mm (SD 7.5mm). In 2 cases, pancreatoscopy revealed an MPD covered by regular epithelium with raised areas of hyperemia, where spybite biopsies confirmed nonspecific inflammation. In 1 case, the MPD was covered by fish-egg-like protrusions without vascular structures (type 2, Hara et al.), while in 2 cases, it showed villous-type protrusions (type 4, Hara et al.) (figure1) with histology confirming low-grade IPMN in one patient and high-grade IPMN in two. The three IPMN patients underwent surgery, with histology confirming low-grade dysplasia in one and high-grade dysplasia in two.

Conclusions These preliminary findings suggest that pancreatoscopy is a valuable tool in resolving the differential diagnosis between CP and IPMN-MD with irregular wall thickening. It can help avoid unnecessary invasive procedures in CP patients and provide a more accurate assessment of IPMN-MD severity. Further prospective studies with larger cohorts are needed to confirm these

results and explore the potential of pancreatoscopy as a standard practice in differentiating these two conditions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP175 Cholangioscopy guided electrohydraulic lithotripsy for large common bile duct stones- safety and feasibility evaluation of a large 1.5mm EHL probe (CRAC-Stones study) under direct vision. An interim analysis

Authors Chaouachi R[1], Ellrichmann M[2,3], Rahe G[4], Dollhopf M[5], Schramm C[4], Beyna T[6], Dechene A[7], Kandulski A[8], Dormann A[9], Heinrich H[10], Gerges C[11]

DOI 10.1055/s-0046-1820830

Aims Cholangioscopy-guided electrohydraulic lithotripsy (EHL) is an established therapy for difficult bile duct stones [1]. However, small-diameter probes have limited its effectiveness [1]. With the introduction of digital cholangioscopes featuring 2.0-mm working channels, larger and potentially more efficient probes can now be used. The CRAC-STONE trial is the first prospective multicenter cohort study evaluating the safety and efficacy of a **1.5-mm EHL probe** used in digital single-operator cholangioscopy for large bile duct stones.

Methods This ongoing study includes patients with large or difficult bile duct stones from seven high-volume German centers.

Inclusion criteria: Common bile duct stone ≥ 10mm and/or lumen occluding Indication for endoscopic retrograde cholangiography with cholangioscopy and electrohydraulic lithotripsy

Primary endpoint: Technical Success rate defined as stone clearance or ability to pass a stent if previously not possible

Secondary endpoints: Rate of interventions with ability to advance the 4.5FR/1.5mm EHL probe at the stone and apply electrohydraulic lithotripsy. Rate of AE within 30 days after the procedure, Number of 4.5FR/1.5mm EHL probes used to achieve primary endpoint (PE)

Results (interim analysis, n = 24):

Mean stone size was 16,3mm. Technical success was achieved in **21/24 cases (87,5 %)**. Probe advancement to the target stone was successful in **22** cases (**91,6 %**). Mean procedure duration was **57 min**. A mean of **1.4 probes** were required per procedure. No severe adverse events occurred. Minor adverse events included transient abdominal discomfort and two cases of mild post-ERCP pancreatitis, all resolving with conservative management. At 30-day follow-up, **21/24 patients (87,5 %)** demonstrated sustained clinical success, and re-intervention was required in **2 cases**.

Conclusions Use of a 1.5-mm EHL probe via digital single-operator cholangioscopy appears highly feasible, safe, and effective for treating large bile duct stones. This larger-diameter probe may enhance fragmentation efficiency and overall procedural performance. Final results from the full cohort are awaited.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820831

Aims Indeterminate biliary strictures remain diagnostically challenging, with conventional ERCP tissue sampling offering low sensitivity (21-66 % [1]). Single operator cholangioscopy (SOC) allows direct intraductal visualization and targeted biopsies, potentially improving diagnostic accuracy. However, real-world, long-term data on its diagnostic yield and safety remain limited.

Methods We performed a retrospective observational cohort study of all adults undergoing SOC between January 2020 and December 2024 at a tertiary referral centre. The aim was to identify the diagnostic yield for malignancy of SOC visual assessment and targeted biopsies (▶ **Table 1**).

▶ **Table 1** Diagnostic Yield of Cholangioscopy

		95 % CI (lower, upper)
Prevalence	0.33	0.20, 0.49
Sensitivity	0.87	0.60, 0.98
Specificity	0.80	0.61, 0.92
Positive predictive value	0.68	0.43, 0.87
Negative predictive value	0.92	0.75, 0.99
Positive likelihood ratio	4.33	2.06, 9.11
Negative likelihood ratio	0.17	0.05, 0.61

Statistical analysis included descriptive summaries, group comparisons using chi-square and t-tests, and diagnostic accuracy evaluation with sensitivity, specificity, predictive values, likelihood ratios, and AUC. Group comparisons between benign and malignant final diagnoses were performed using chi-square tests for categorical variables and t-tests for continuous variables, with significance set at $p < 0.05$.

Results Among 433 SOC procedures, 330 were performed for stone management and 10 with incomplete data were excluded, leaving 93 patients for analysis. Most patients were male (62.4 %) with a mean age of 57 years. SOC visual impression and histology were strongly associated with final diagnosis ($p < 0.001$), whereas other clinical and procedural factors did not reach statistical significance. 70 (75.3 %) had benign and 23 (24.7 %) had malignant strictures as their final diagnosis. Based on visual impression and biopsy confirmed histological diagnosis, sensitivity for malignancy was 0.87 (95 % CI 0.60–0.98) and specificity was 0.80 (95 % CI 0.61–0.92). The positive predictive value was 0.68 (95 % CI 0.43–0.87), while the negative predictive value was 0.92 (95 % CI 0.75–0.99). Two patients (2.2 %) experienced adverse events in the form of cholangitis.

The Area under the Curve was calculated at 0.83, suggesting that the model reliably aids in ruling out malignancy in strictures. After adjusting for indication and stricture location, the model's discriminative ability decreased substantially (with an AUC of 0.7247), highlighting their importance in the diagnostic yield of SOC.

Conclusions SOC demonstrated high negative predictive value, supporting its clinical utility in the differentiation of benign and malignant biliary strictures when compared to reported performance of conventional ERCP tissue sampling. Prospective, multicentre studies with larger sample sizes are needed to validate these findings, refine SOC-based diagnostic criteria, and better define when to include SOC in the diagnostic algorithm for biliary strictures.

OP177 Pancreatoscopy-guided laser lithotripsy to treat symptomatic chronic pancreatitis-related stone disease

Authors Bracken L[1], Huang D[1], Craig P[1]
Institute 1 St George Hospital, Kogarah, Australia
DOI 10.1055/s-0046-1820832

Aims Chronic pancreatitis often leads to debilitating pain, malnutrition, and steatorrhea, with pain driving poor quality of life, opioid dependence, and frequent emergency department (ED) presentations.

Obstructing main pancreatic duct (PD) stones are postulated to contribute to pain through ductal hypertension. Endoscopic stone clearance with ERCP is technically challenging and frequently unsuccessful. Pancreatoscopy-guided lithotripsy (PL) using Holmium laser (HL) is a novel therapeutic adjunct, but both short- and long term outcome data are limited.

We aimed to evaluate the safety, effectiveness, and long-term outcomes of PL-HL for symptomatic obstructing main PD stones.

Methods Patients with symptomatic PD stones were prospectively enrolled. After ERCP with sphincterotomy and stricture dilatation, PL-HL was performed for stone fragmentation using a 10FG Boston Scientific Spyglass pancreatoscope advanced over an 0.025inch guidewire and Lumenis Verapulse Holmium YAG laser with a 272µm fibre. The primary outcome was reduction in pain-related ED presentations. Secondary outcomes included total stone clearance, weight gain, changes in Izbicki pain score, opioid use, and adverse events.

Results Over a nine year period, 22 patients referred for treatment underwent PL-HL (median age 68 [IQR 55-78], 46 % female). Baseline main pancreatic duct (MPD) diameter was 7mm [IQR 7-10] and 10 (65 %) patients had more than one PD stone.

17 (77 %) patients had chronic pain with 11 (50 %) requiring regular opioids. The median Izbicki Pain Score was 38.8 [IQR 19.5-43.8].

Overall 31 pancreatoscopy procedures were performed in the 22 patients with 5 (23 %) of patients requiring multiple PL-HL sessions. Total stone clearance was achieved in 91 % of cases. The median laser settings were 1.4 J, 15 Hz with median total energy delivered 2.6 kJ [IQR 0.7-5.0].

Post-procedural complications occurred in 9 % of procedures, this was predominantly short-lasting pain in 2 cases (6 %) with only 1 (3 %) case of mild pancreatitis.

Median follow up was 13 months [IQR 7-40]. Full results are shown in the Table. There was a significant reduction in ED presentations following PL-HL treatment ($p = 0.018$). Similarly, Izbicki Pain Scores, median patient weights, and MPD diameters also improved significantly with a trend to improvement in steatorrhoea (▶ **Table 1**).

▶ **Table 1** Patient outcomes post laser lithotripsy in 22 patients

Outcome	Pre-Treatment (%)	Post-Treatment (%)	P value
MPD diameter (mm)^	7 [7-9]	5 [4-7]	0.002
Weight (kg)^	61 [54-89]	73 [58-90]	0.002
ED presentations^	1 [0-3]	0 [0-1]	0.018
Izbicki Pain Score^	39 [20-44]	0 [0-21]	<0.001
Opioid use			
Any	11 (50)	10 (46)	1.000
Daily	5 (23)	3 (14)	0.500
Steatorrhea	11 (52)	2 (10)	0.008

Conclusions In a single tertiary endoscopy centre, PL-HL achieved total main PD stone clearance in 91 % of cases. Stone clearance was associated with significant improvements in Izbicki pain scores, subsequent ED presentations, weight, and MPD diameter. Therefore, among symptomatic chronic pancreatitis patients with main PD stones: PL-HL appears safe and is associated with clinically meaningful improvements in patient quality of life and reduced healthcare utilisation.

OP178 The significance of cholangioscopic atypia in indeterminate biliary stricture specimens in patients with or without primary sclerosing cholangitis

Authors Hope A[1], Craig P[2]
Institutes 1 St George Hospital, Kogarah, Australia, Sydney, Australia; 2 St George Hospital, Kogarah, Australia
DOI 10.1055/s-0046-1820833

Aims Indeterminate biliary strictures (IBS) are those with an uncertain diagnosis following investigation including cross-sectional imaging, endoscopic ultrasound, and endoscopic retrograde cholangiopancreatogram. Digital cholangioscopy (DC) has emerged as a valuable tool to assess IBS allowing direct visualization and targeted biopsies, most centres do not use aspiration cytology. The clinical significance of finding histological or cytological atypia in IBS

Endoscopy 2026; 58: S1–S1041

remains uncertain. Atypia may reflect inflammation or herald malignancy, with prior studies suggesting malignancy rates of 50 % in non primary sclerosing cholangitis (PSC) cohorts. Clarifying the prognostic implications of atypia is essential to guide clinical decision-making and avoid delays in diagnosis and treatment. This study aimed to assess the long-term outcomes of patients with IBS undergoing DC in whom histological or cytological atypia was identified, stratified by PSC status.

Methods We analysed a prospectively collected cohort of 45 patients between 2017-2024 from a tertiary referral centre in Sydney, Australia with indeterminate strictures and atypia. Patients were stratified into PSC (n = 13) and non-PSC (n = 32) groups. Clinical variables included age, gender, serum bilirubin and Ca19.9 levels, stricture location, preceding stent placement and time to final diagnosis (FD). At cholangioscopy IBS were visually assessed and then specimens obtained for histology and aspiration cytology. Sampling modality with atypia was categorised as biopsy alone, cytology alone, or both. FD malignancy was determined by DC specimens, surgical pathology, or multidisciplinary team consensus based on imaging and clinical progress after at least 6 months follow-up post DC. Statistical analyses included odds ratios for malignancy and Fisher's exact test for atypia severity.

Results The median age was 66 years, with PSC patients younger (52) than non-PSC patients (70); 64 % male. Median follow-up was 49 (8-87) months. Atypia was identified by aspiration cytology in 20 (45 %) patients, histology in 6 (13 %), and both modalities in 19 (42 %). Overall, 29/45 patients (64 %) were malignant: 22 cholangiocarcinoma, 7 other malignancies.

Non-PSC patients had malignancy identified in 27/32 (84 %) versus PSC patients 2/13 (15 %) with odds ratio for malignancy 0.01 (95 % CI 0.0–0.3, p = 0.009). Finding atypia on both biopsy and cytology specimens trended toward increased malignancy risk (OR 17.0, p = 0.058). Serum bilirubin and Ca19.9 levels, gender, stricture location and previous stenting were not predictive. "Highly atypical" cytology or histology was identified in 14 (31 %), all had FD malignancy (Fisher's exact p < 0.001).

Conclusions In patients with IBS with atypia identified on DC:

1. The diagnostic yield is increased with additional aspiration cytology
2. Highly atypical findings suggest malignancy
3. Non-PSC patients usually harbour malignancy and should be considered for further intensive investigations and early treatment
4. The presence of atypia in PSC although concerning, is usually associated with a benign course

Conflicts of Interest Authors do not have any conflict of interest to disclose.

The Role of Endoscopy in liver transplantation

15/05/2026, 14:30–15:30 **Aqua 1 + 2**

OP179 Biliary anastomotic strictures after liver transplantation: performance of multiple plastic stents and intraductal metal stents

Authors Togliani T[1], Granato A[1], Massella A[1], Mastromauro M[1], Tebaldi M[1], Tomba F[1], Carraro A[1], Borin A[1], Bortolasi L[1], Bosio C[1], Bronzoni C[1], Violi P[1], Lisotti A[2], Mirante VG[1]

Institutes 1 Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy; 2 Imola Hospital S. Maria della Scaletta, Imola, Italy

DOI 10.1055/s-0046-1820834

Aims Biliary anastomotic strictures (AS) occur in 10-25 % of cases after liver transplantation (LT) and ERCP with multiple plastic stenting (MPS) is the mainstay of treatment. The aim of this study was to assess the performance of three different endoscopic strategies: 1) only MPS, 2) combination of MPS and double-flared intra-ductal covered metal stents (IDS), 3) only IDS [1].

Methods This is a retrospective single center study on patients affected by AS treated with MPS, MPS + IDS or IDS. Exclusion criteria were: 1) previous or intervening treatment with percutaneous techniques or with traditional transpapillary fully covered metal stents (SEMS), 2) presence of concomitant non-anastomotic biliary strictures. In case of AS, MPS or IDS were placed, then removed and possibly replaced in case of AS persistence; the procedures were scheduled according to symptoms, biochemistry and imaging; changing from one type of stent to the other was up to the endoscopist. After the treatment period or during the follow-up, based on the ERCP or MRCP results, we defined: 1) healing, when the AS disappeared after stent removal and it did not recur in the follow-up; 2) relapse, when the AS recurred after resolution; 3) failure, if the AS persisted or if the stricture extended upwards to the hilum. We recorded these outcomes according to the type of stents used, the duration of treatment (DOT), the number of procedures done (NOP) (▶ **Table 1**).

▶ **Table 1**

	MPS (16 pts)	MPS + IDS (17 pts)	IDS (16 pts)
Healing	9 pts (56.3 %)	14 pts (77.8 %)	14 pts (87.4 %)
	DOT = 11.7 months	DOT = 15.6 months	DOT = 6.9 months
	NOP = 12.2	NOP = 5.2	NOP = 2.6
Relapse	3 pts (18.7 %)	2 pts (11.1 %)	1 pt (6.3 %)
	DOT = 19.7 months	DOT = 5.5 months	DOT = 10 months
	NOP = 8.7	NOP = 7.0	NOP = 6
Failure	4 pts (25.0 %)	1 pt (5.6 %)	1 pt (6.3 %)
	DOT = 15.8 months	DOT = 22 months	DOT = 5 months
	NOP = 7.7	NOP = 15	NOP = 4

Results In the period 2015-2025 562 patients underwent LT; 81 (14.4 %) developed an AS after a mean of 13.2 months; 49 of them entered the study. Overall, 37 patients (75.5 %) healed (current mean FU: 15.9 months), the others relapsed or failed. MPS obtained a lower healing rate and required a higher NOP compared to MPS + IDS or IDS (p < 0.05); to get AS resolution IDS needed for a shorter DOT compared to MPS or MPS + IDS (p < 0.05). Overall, 6 patients relapsed after a mean of 18.2 months; 5 healed after further endoscopic stenting, 1 underwent LT. The 6 patients who experienced endoscopic failure were treated transcutaneously or underwent LT.

Conclusions Compared to the MPS alone, the use of IDS, alone or in combination with MPS, was associated with better outcomes in terms of AS resolution, NOP or DOT. Future studies should compare the performance of IDS and SEMS in this setting.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP180 Biliary complications following liver transplantation: a long-term follow-up in a high-volume tertiary center

Authors Hujova A[1], Mares J[1], Jarosova J[1], Macinga P[1], Taimr P[1], Fronek J[1], Hucl T[1]

Institute 1 Institute for Clinical and Experimental Medicine, Prague, Czech Republic

DOI 10.1055/s-0046-1820835

Aims Biliary complications following liver transplantation are among the most common complications affecting graft function and patient morbidity after transplantation. Several risk factors have been identified, and continuous improvements in surgical techniques and perioperative care have been made. While insufficient data exists to draw conclusions, internal biliary stents have been reported to decrease the rate of biliary complications [1–3].

Methods We retrospectively analyzed prospectively collected data with long-term follow-up from a high-volume tertiary center. The study included all adult patients who underwent deceased-donor liver transplantation (DDLT) or living-donor liver transplantation (LDLT) between 2005 and 2023, with a minimum follow-up period of one year. The aim of the study was to assess the incidence and trends of biliary complications during those years, determine the risk factors, and evaluate the prophylactic effect of internal biliary stents on the development of biliary complications.

Results This study included 1,775 liver transplant recipients (1,804 transplants), predominantly male (59.1 %), with a median age at transplantation of 55.9 years. Of these patients, 326 patients (18, 2 %) received an internal biliary stent perioperatively due to a bile duct diameter of less than 6 mm or mismatched bile duct sizes. Overall, biliary complications occurred in 23.7 % of patients, with a statistically significantly higher incidence among LDLT recipients (52,6 %; p = 0.006). The incidence of biliary complications with a stent was higher (29,4 % v.s. 22,4 %; p = 0.009). The year of liver transplantation (OR = 0.96; p = 0.0001), the presence of a hepaticojejunoanastomosis (OR = 0.56; p = 0.0019), and split liver grafts (OR = 1.77; p = 0.0062) were significant risk factors for the development of biliary complications.

Conclusions Biliary complications remain a significant issue following liver transplantation, particularly in LDLR. Several risk factors have been identified, including the type of biliary anastomosis and the type of liver graft. Biliary stenting in liver transplant recipients hasn't proved its prophylactic effect.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820836

Aims This systematic review aims to evaluate and compare the effectiveness, safety, and long-term outcomes of Endoscopic Retrograde Cholangiopancreatography (ERCP) versus Percutaneous Transhepatic Radiological Procedures (PTRPs) in managing biliary complications following liver transplantation (LT). The study addresses the clinical challenge of selecting the optimal intervention for complications such as anastomotic strictures (AS), non-anastomotic strictures (NAS), bile leaks, and biliary stones [1].

Methods A systematic review was conducted according to PRISMA 2020 guidelines, analyzing 31 studies published between 1997 and 2023. Data were sourced from six electronic databases including PubMed/MEDLINE, Embase, and Cochrane Library. Eligible studies included adult and pediatric LT recipients experiencing post-transplant biliary complications treated with ERCP or PTRPs (PTBD, PTCD, PTC). Outcomes assessed were technical and clinical success, adverse events, recurrence rates, and retreatment needs. Quality was appraised using the Newcastle-Ottawa Scale. Due to heterogeneity, a narrative synthesis was performed.

Results ERCP demonstrated high clinical success rates for bile leaks (71–100 %) and anastomotic strictures (65–96 %), but lower efficacy for non-anastomotic strictures (12–42 %). PTRPs showed superior efficacy in complex strictures, with success rates between 70 % and 90.6 %, and achieved 100 % success in pediatric cohorts. Comparative studies revealed ERCP technical success rates ranging from 65 % to 94.9 %, while PTRP technical success reached up to 90.6 %. Safety profiles differed: ERCP was associated with pancreatitis incidence of 4–10 %, bleeding in 2.6–16 %, and cholangitis in 1.3–10.6 %; PTRPs carried hemorrhage risks of 1.4–11.1 %, sepsis rates of 5–22 %, and catheter-related complications including dislodgement (9.1 %) and occlusion (27.1 %). Long-term outcomes favored ERCP for AS, with recurrence rates between 0 % and 32 %, particularly lower (7.7 %) with plastic stents versus 30.3 % with covered self-expandable metal stents (cSEMS). NAS recurrence after ERCP was higher (33–50 %), often requiring additional interventions. PTRP maintained approximately 70 % patency at 3.5 years but required repeat interventions in 43–53 % of cases. Hybrid ERCP-PTRP approaches achieved over 90 % success in complex cases, reducing surgical revision rates by 38–62 %.

Conclusions ERCP remains the preferred first-line intervention for bile leaks and accessible anastomotic strictures due to its minimally invasive nature and favorable safety profile. PTRPs are valuable for complex or ERCP-refractory strictures, especially in pediatric patients, despite higher complication rates. Hybrid strategies combining ERCP and PTRP optimize outcomes in anatomically challenging cases. Future research should focus on randomized controlled trials comparing these modalities, development of predictive models for individualized treatment, and innovations in stent technology and procedural guidance. Standardized outcome definitions and multidisciplinary collaboration will enhance clinical decision-making and patient care in post-LT biliary complication management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Biliary complications including anastomotic strictures and bile leak occur in approximately 14 %-20 % of patients post-orthotopic liver transplantation (post-OLT). Endoscopic retrograde cholangiopancreatography (ERCP) and insertion of plastic stents represent the standard treatment for these biliary complications, however, there is limited data on the rate of resolution of stricture or bile leak, stricture or leak recurrence and long-term outcomes of ERCP in liver transplant patients with these biliary complications

Methods We reviewed clinical records of 3590 consecutive patients who underwent OLT between January 2011 to January 2023. For the patients who developed anastomotic biliary strictures (ABS) or bile leak (BL), specific data including the demographics, indication of OLT, graft type, configuration of bile ducts, number of biliary anastomosis, and procedure-related data including number of ERCP sessions required and requirement of per-cutaneous transhepatic biliary drainage (PTBD) were extracted. Primary outcome was rate of stricture or bile leak resolution and secondary outcomes were to estimate the rate of stricture or leak recurrence and identify predictive factors for recurrence of biliary complications [1].

Results Of total 3590 patients who underwent liver transplant, 540 (15 %) patients (male = 465, 86.1 %; mean age- 49.3 ± 10.6 years) developed biliary complications [ABS – 469 (86.9 %) patients; BL – 60 (11.1 %) patients; stricture with bile leak – 11 (2 %) patients]. The median time to stricture formation after OLT was 6 (IQR: 3- 10) months, and the median time from OLT to bile leak was 29.5 (IQR:15- 51.5) days. The technical success for ERCP was 89.1 % (481/540); 59 (10.9 %) patients required a combination of ERCP and PTBD (followed by rendezvous ERCP) for biliary drainage and one patient required surgery. Of 480 patients with ABS, 409 (85.2 %) patients achieved stricture resolution after a median 3 (IQR:2- 4) ERCP sessions and median 6 (IQR:4-9) months. Rest required surgery. Stricture recurrence occurred in 20.5 % (84/409) patients after median 5 (IQR: 3-12) months of stent free trial; 90 % (76/84) patients were subsequently managed by ERCP successfully, and 8 patients required surgery. Of 60 patients with BL, rate of resolution was 95 % (57/60) after median 1 (IQR: 1-2) ERCP session and median 3 (IQR: 3-4) months; none of these patients developed recurrence. On multivariate analysis, requirement of more than 3 ERCP sessions (aOR: 1.6, 95 % CI: 1.1-1.8; p = 0.004)and multiple duct-to-duct anastomosis (aOR: 1.7, 95 % CI: 1.2-2.7; p = 0.02)predicted recurrence of strictures.

Conclusions ERCP is an effective for post-OLT biliary anastomotic strictures and bile leaks. The number of ERCP procedures and multiple duct-to-duct anastomosis were predictors of stricture recurrence.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP183 Per-Oral Cholangioscopy-Guided Tissue Sampling Reveals Fibrogenic Signaling Activation in Biliary Anastomotic Strictures after Liver Transplantation

Authors Bofill A[1], Ribera J[1], Fernandez-Simon A[1], Ruiz P[1], Fundora Y[1], Montironi C[1], Morales-Ruiz M[1, 2], Cardenas A[1, 2]

Institutes **1** Hospital Clínic de Barcelona, Barcelona, Spain; **2** Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain

DOI 10.1055/s-0046-1820838

Aims Biliary anastomotic strictures (BAS) are the most common biliary complication in liver transplant (LT) recipients. BAS are associated with significant morbidity leading to higher rates of graft failure and retransplantation. The underlying mechanisms involved in the development of fibrosis of BAS are not well understood; however, animal studies suggest that overexpression of transforming growth factor beta (TGF-B) can play an important role. Per-oral digital cholangioscopy (POCS) allows clear visualization of the common bile duct and adequate sampling of the biliary epithelium in order to evaluate factors associated with local fibrosis. This prospective study aims to investigate the underlying pathophysiology of BAS, with direct visualization using POCS to allow biopsy sampling, and support the identification of novel therapeutic targets to block fibrogenic and reparative pathways [1–3].

Methods We conducted a prospective, controlled, single-center study including LT recipients with BAS that underwent cholangioscopy with biopsy, as well as patients undergoing surgery for BAS. RNA was extracted from bile duct samples of LT patients with BAS (experimental group) and without BAS (control group). Analyses included quantification of TGF-B and its membrane receptors, interleukin-6 (IL-6), and evaluation of downstream intracellular signaling mediators (phosphorylated SMADs and STATs) using real-time quantitative reverse transcription PCR (RT-qPCR). Normal bile duct tissue from liver donors (distal common bile duct) served as controls.

Results Thirty-two LT recipients with BAS underwent POCS or surgery; 24 of these provided adequate RNA for molecular analysis. These samples were compared with 8 controls. RT-qPCR showed significant differences in SMAD1, SMAD2, and α-SMA mRNA expression between BAS and control tissues ($p < 0.05$). Although TGF-B, its membrane receptors, IL-6, and STAT3 levels were higher in BAS samples, these differences did not reach complete statistical significance.

Conclusions This study provides molecular evidence of activation of TGF-B-related fibrogenic pathways in BAS after LT, as reflected by significant increases in SMAD1, SMAD2 and α-SMA expression. Overall, the findings highlight downstream fibrotic signaling as a potential therapeutic target and emphasize the value of POCS-guided tissue sampling in understanding the pathophysiology of BAS.

DOI 10.1055/s-0046-1820839

Aims Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease and a major indication for orthotopic liver transplantation (OLT). Post-transplant biliary complications, including bile leaks and anastomotic strictures, remain common and significantly impact graft function and patient outcomes. Pre-transplant endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy is frequently performed in PSC patients with dominant strictures, but its potential protective effect on post-OLT biliary outcomes has not been clearly established.

The aim was to evaluate whether ERCP with sphincterotomy performed before OLT is associated with a reduction in post-transplant biliary complications in patients with PSC.

Methods A retrospective analysis was conducted on 45 patients with PSC who underwent OLT at the S.Orsola University Hospital. Patients were divided into two groups: those who underwent ERCP with sphincterotomy prior to OLT (n = 30) and those who did not (n = 15). Baseline characteristics, ERCP features, and post-OLT outcomes were assessed. Post-transplant biliary complications were categorized as early (< 30 days) or delayed (> 30 days).

Results Among 45 PSC patients (M:F 33:12; mean age 47 years), 24 had associated inflammatory bowel disease. Of the 30 patients in the sphincterotomy group, 22 underwent more than one ERCP procedure, totaling 54 ERCPs. Presence of dominant strictures was the main indication for ERCP (n = 25/30), with plastic biliary stents placed in 14 patients. Post-ERCP adverse events occurred in 4/54 (7 %) procedures, all mild pancreatitis managed conservatively [1–3].

Post-OLT biliary complications occurred in 2/30 patients (6.7 %) in the sphincterotomy group, 1 early bile leak and 1 delayed anastomotic stricture. In the no-sphincterotomy group 6 complications occurred in 5/15 patients (33.3 %): 3 early (2 bile leaks and 1 acute stricture) and 3 delayed anastomotic strictures. The difference in overall complication rates between the two groups was statistically significant (p = 0.032).

Conclusions ERCP with sphincterotomy prior to OLT in PSC patients is associated with a significantly lower rate of post-transplant biliary complications. These findings suggest that pre-transplant endoscopic sphincterotomy may have a protective effect on the biliary anastomosis and should be considered as part of the pre-OLT evaluation strategy in selected PSC patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP185 Establishing a Structured Barrett's Esophagus Care Program to Enhance Patient Engagement and Care Continuity in a High-Volume Tertiary Center: A Quality Improvement Framework

Authors Brownie T[1], Khalaf K[1], Clancy J[1], Mahjoob M[1], Gupta S[1], Calo N[1], Mosko J[2], Teshima C[1], May G[1]

Institutes **1** St. Michael's Hospital, Toronto, Canada; **2** Division of Gastroenterology, St. Michael's Hospital, Toronto, Canada

DOI 10.1055/s-0046-1820840

Aims Patients referred for dysplastic Barrett's Esophagus (BE) often travel long distances for specialized endoscopic therapy, frequently arriving without understanding their diagnosis, treatment options, or cancer risk. This information gap contributes to patient anxiety, missed appointments, loss to follow-up and worse outcomes, while placing additional administrative and educational burden on physicians. To design, implement, and evaluate a structured care program aimed at improving patient education, engagement, and continuity of care for individuals with dysplastic BE referred to a high-volume tertiary endoscopy center.

Methods The program introduced a standardized workflow for pre- and post-procedure patient engagement. Educational resources covering BE pathophysiology, endoscopic therapies and lifestyle modification were developed and approved by the institutional Patient Education Committee. An EDC platform was used to document intake, disseminate materials, and track patient progress.

Results Over a three month initial implementation period, 305 patients were enrolled in the Barrett Care Program. Pre-procedure engagement improved markedly, with 93 % of patients contacted prior to their visit to address questions, review expectations, and clarify logistics. Detailed medical histories and medication reviews were completed for 64 % of patients, facilitating earlier identification of comorbidities and potential procedural risks. Appointment preparation and counselling were successfully completed for all contacted patients, 34 % required additional outreach for individualized issues. Educational reach was broad among all enrolled patients receiving targeted information regarding EMR, ESD, cryotherapy and RFA prior to their procedures. With regards to home monitoring post procedure at days 3, 7, and 14; 70 % of patients were followed-up, allowing timely assessment of symptoms, early detection of complications, and direct patient-initiated communication with the care team, including any necessary escalations to emergent care (3 %). A total of 783 pathology reports were entered into the program database, ensuring complete documentation to support timely case escalation, multidisciplinary review, and coordinated discharge back to community care. The program enhanced patient understanding, reduced procedural anxiety, and improved satisfaction with communication and follow-up. Physicians reported smoother coordination and fewer administrative delays, highlighting improved integration across the care program's framework.

Conclusions By embedding structured education, proactive outreach, and centralized tracking into BE care, the program improved patient engagement, adherence, and continuity in a high-volume tertiary setting. This scalable QI model demonstrates that structured navigation frameworks can enhance both patient-centered and system-level outcomes in specialized endoscopic practice.

OP186 Optical diagnosis of diminutive colorectal polyps performed by endoscopy nurses using virtual chormoendoscopy or Computer-aided diagnosis (CADx) system: preliminary results of a prospective single-center study

Authors Calabria L[1], Prandi F[1], Treppete L[1], Busnelli A[1], Orsingher L[1], Gatti A[1], Carcangiu F[1], Cassinari L[1], Carpani E[1]
Institute **1** Ospedale Valduce – Como, Como, Italy
DOI 10.1055/s-0046-1820841

Aims Virtual chromoendoscopy and AI-based computer aided characterization systems (CADXs) have been investigated for optical diagnosis (OD) of diminutive (≤5mm) colorectal polyps. However available clinical trials on OD mostly involved expert endoscopists from tertiary referral centres. While limited evidence on less experienced endoscopists (e.g., trainees) exists, there are no data on diagnostic performances of chrompendoscopy-based and CADEx-assisted OD performed by endoscopy nurses. The present study was aimed at comparing diagnostic performances of endoscopy nurses in OD of diminutive colonic polyps either with virtual chromoendoscopy or with CADx assistance.

Methods The study involved two steps (Phase 1 and Phase 2). In Phase 1, endoscopy nurses from a single endoscopy center (O.V.) performed OD of consecutive diminutive colorectal polyps by using virtual chromoendoscopy with Blue Light Imaging (BLI, Fujifilm Co. Tokyo, Japan). In Phase 2, the OD was performed with the assistence of a CADx system (CADEYE; Fujifilm Co., Tokyo, Japan). For each colonic polyp evaluated in both study phases the OD (dichotomized as adenoma or non-adenoma) was recorded, along with the level of confidence (high or low). All diminutive polyps were resected and sent for histopathological evaluation (reference standard). Overall diagnostic accuracy of high confidence ODs, as well as rate of polyps evaluated with high confidence were compared across the two study phases. While performing OD nurses were blinded to the endoscopist's evaluation. In both study phases all participating nurses were asked to evaluate at least 50 consecutive diminutive polyp each.

Results Seven endoscopy nurses participated in both study phases. In Phase 1 (from April 1st to June 30th 2025) a total of 525 diminutive polyps were evaluated. Of them 460 were assessed with high confidence (high-confidence rate: 88 %, 95 % CI: 84–90 %). The mean number of polyps analyzed with high confidence per nurse was 65 (SD 9.77, range 54–79). The overall high confidence diagnostic accuracy was 83 % (95 % CI: 80–87 %, range 78–91 %). From July 1st 2025 to August 31st 2025 (Phase 2) a total of 179 polyps were evaluated. One hundred forty-nine polyps were assessed with high confidence (high-confidence rate: 83 %, 95 % CI: 77–88 %). The mean number of polyps analyzed per nurse was 21 (SD 5, range 15–31). In Phase 2 the overall high confidence diagnostic accuracy was 78 % (95 % CI: 70–84 %, range 65-94 %). Both the overall high confidence accuracy and high-confidence rate were comparable across the two study phases (chi-square: 2.42, p = 0.13 and chi-square: 2.19, p = 0.13, respectively).

Conclusions According to our preliminary results, no statistically significant differences were disclosed in both diagnostic high confidence accuracy and high-confidence rate for the OD of diminutive colorectal polyps when performed using chromoendoscopy alone or with the assistance of a CADx system by a group of endoscopy nurses.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP187 Establishing Recommendations to Develop a Standardized Curricula for Nursing Education and Training in ERCP: a Modified Delphi Consensus

DOI 10.1055/s-0046-1820842

Aims Endoscopic Retrograde Cholangiopancreatography (ERCP) is a technically complex therapeutic endoscopic procedure that requires highly skilled nurses trained to assist physicians who are performing, not only basic ERCPs, but also the most complex advanced practice procedures. An exceptional level of coordination and communication is required between endoscopists and nurses to optimize patient care and outcomes. Despite the procedure's widespread use, there are currently no standardized global guidelines or curricula to guide nursing education and training in ERCP. Following an international survey [1] conducted in 2024 that revealed substantial variability and gaps in ERCP nursing education, our objective was to develop consensus-based recommendations to inform a standardized ERCP nursing curriculum.

Methods A steering committee established a modified Delphi process involving 19 international experts representing diverse geographical regions (all 5 continents) and clinical settings. The expert panel was comprised of experienced endoscopy nursing professionals, 80 % of whom worked in academic centres. Most (90 %) held a Bachelor's degree or higher credentials in nursing. Participants had long clinical tenure (median 20 years in nursing; 16 years in endoscopy) and substantial ERCP exposure (median 10 years assisting in ERCP; median 25 ERCP cases per month). Experts reviewed and rated draft statements derived from the global needs assessment, literature review, and existing perioperative and gastroenterology nursing guidelines. Consensus was defined a priori as ≥ 80 % agreement across panelists.

Results A total of 19 international experts from North and South America, Europe, Africa, Asia, and Oceania participated in the study, representing both academic and high-volume community ERCP centers. Consensus was achieved across all proposed domains, with agreement levels ranging from 88 % to 100 %. The highest consensus was observed for statements emphasizing structured, competency-based learning, mentorship, and progressive skill acquisition. Eg: Statement: Training should ensure progressive mastery, moving from observation of live cases to guided assistance and eventually to independent technical support under supervision. Experts strongly supported incorporating both didactic and hands-on components, including simulation, case-based discussions, and real-time procedural exposure. Domains rated as most essential included patient safety, infection control, scope and equipment handling, fluoroscopy principles, and post-procedural care. Eg: Statement: Infection prevention training should ensure that nurses are competent in duodenoscope reprocessing, equipment labelling, and compliance with institutional and regulatory safety alerts. The panel also emphasized the importance of competency assessment tools and periodic revalidation to maintain standards. In the second round, six statements reached perfect consensus with a median score of 10 and no variability (range 10–10), indicating universal agreement among experts on core ERCP nursing competencies. These top-ranked priorities centered on procedural literacy, safe and proficient handling of ERCP accessories, guidewire and cannulation support, structured error analysis, and alignment

of training content with procedural indications and real-world clinical demands (▶ **Table 1** below).

▶ **Table 1**

ERCP nursing education must integrate knowledge of procedural indications with practical competency in equipment handling and anticipation of accessory requirements.
Nurses must be proficient in the preparation and safe handling of key ERCP accessories (sphincterotomes, guidewires, balloons, baskets, and stents) and understand their indications and limitations.
Nurses must be competent in supporting cannulation by preparing, exchanging, and managing guidewires under fluoroscopic guidance, preventing wire displacement.
Errors and complications should be analyzed constructively, emphasizing learning and system improvement.

Conclusions This Delphi study establishes international consensus that no standardized ERCP nursing curriculum currently exists and confirms the need for a structured, competency-based program. The proposed framework emphasizes theoretical knowledge, supervised hands-on training, clear learning objectives, and continuous evaluation. Implementation of these recommendations may enhance the safety, efficiency, and quality of ERCP practice worldwide.

OP188 Analysis of the quality of endoscopic reports for screening colonoscopy using the human error rate prediction (THERP) technique. A retrospective analysis at the Endoscopy Clinic of Senigallia (Central Italy)

Authors Palma E[1], Kostandini A[1], Di Sario A[1]
Institute 1 Senigallia Hospital, Senigallia, Italy
DOI 10.1055/s-0046-1820843

Aims An adequate documentation is considered a quality marker in endoscopy. The Medical Reporting SW used at the Endoscopy Clinic in Senigallia (Central Italy) cannot be updated to meet current quality standards, so in 2024 the nursing staff implemented a nursing record, which is archived with the endoscopic clinical record but not delivered to the patient [1].
IT engineers are implementing a new health documentation digital system for the local health company (AST Ancona), that will feed the Electronic Health Record (EHR). In particular, it should contain mandatory fields referring to quality standards for endoscopic procedures, in order to create a digital health record that improves the coordination and accessibility of care by consolidating patient information.

Methods Retrospective analysis of all medical/nursing records of screening colonoscopies performed in the period September 2024 – September 2025.
The authors applied the THERP technique (Technique for Human Error Rate Prediction) applying the Hierarchical Task Analysis to a screening colonoscopy procedure and identifying incomplete/missing data in the medical reporting software and in the nursing chart and nursing documentation.
Data was analyzed using Chi square statistics.

Results In the observation period we performed 407 screening colonoscopies, the sample included 187 females aged 63,9 ± 11,3 y. (IQR = Q3-Q1 = 71 – 58 = 13) and 220 males aged 64,6 ± 10,4 y. (IQR = Q3-Q1 = 72 – 58 = 14).
All patients were assessed in the pre-procedure step (informed consent, correct bowel preparation, time-out).
The Cecal Intubation Rate (CIR) was 97.33 %. In 5 female patients (2.77 %) the colonoscopy was postponed due to the presence of solid feces.
The assigned BBPS score was statistically different between males and females only in scores ≥ 6 [($< .05$).
Biopsies of mucosal lesions or polypectomies were performed in 67.27 % males and in 52.94 % females ($p < .05$).
The BBPS was inadequate (< 6) in 66 patients (31.26 %); 40 men and 26 women.
Twenty patients were rescheduled for a repeat procedure due to failure to discontinue antiplatelet/anticoagulant medications.
The BBPS was not indicated in 27 patients (13.08 %), respectively 17 males and 10 females.

Conclusions The current SW does not help endoscopic staff to comply with recommendations on correct colonoscopy reporting, because it lacks information on pre-procedure assessment (only in nursing documentation) and sometimes lacks data on cecal intubation, retraction times, and BBPS assessment.
Also post procedure surveillance data are currently recorded in nursing documentation, which is archived and not given to the patient. This information can help software engineers create more suitable software that includes both nursing and medical information and complies with ESGE recommendations (e.g., calculating the ADR score for each endoscopist).
Specifically, mandatory fields include: type of bowel preparation (PEG/ELS, volume, same day/fractionated dose), BBPS score, and post-procedure recommendations (i.e. resuming antiplatelet or anticoagulant therapy or dietary recommendations).

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP189 Nursing consultation for biofeedback. Improving the quality of life of our patients

Authors Torres Zamora YC[1], Gonzalez Gonzalez M[2], Hernández Ponce L[3]
Institutes 1 Complejo Hospitalario Insular, Las Palmas De Gran Canaria, Spain; 2 Hospital Insular, Las Palmas de Gran Canaria, Spain; 3 Registered Nurse, Las Palmas de Gran Canaria, Spain
DOI 10.1055/s-0046-1820844

Aims Anorectal biofeedback is a learning method in which physiological activity is monitored. Through visual or auditory means, the patient receives information about this activity, which helps them to modify and control it. It is a non-invasive behavioural therapy with no known adverse effects.It is the first-line therapy for patients with dyssynergic defecation or faecal incontinence who have not responded to pharmacological and behavioural treatment. It can also be used less frequently in patients with levator ani syndrome and solitary rectal ulcer syndrome.
In 2025, our unit initiated the Biofeedback Nursing Consultation, where nurses are responsible for managing and conducting as many sessions as necessary, as well as discharging patients.
The main objective of this consultation is to improve patients' quality of life by providing them with tools to reduce and control faecal incontinence events.
Once an anal manometry test has identified that a patient is a candidate for biofeedback, they are referred to the Nursing Consultation Service.Nurses are fully responsible for scheduling and conducting any necessary sessions. They can also suggest any additional tests that may be required.

Endoscopy 2026; 58: S1–S1041

Methods The first session lasts 45 minutes, while subsequent sessions last 30 minutes. The number of sessions depends on the patient's progress, with appointments every two weeks and weekly telephone follow-ups.

During the first visit, a personalised interview is conducted to assess the impact of incontinence on the patient's daily life. An initial biofeedback session is then carried out according to the patient's specific needs. Recommendations for home practice are provided, and health education on healthy lifestyle habits is reinforced [1–3].

Each scheduled session begins with a brief interview to assess the patient's ongoing condition.A biofeedback session is then conducted, adapted to the individual's needs.

The patient should lie on their left side and face the monitor while performing contraction/relaxation exercises under observation. A balloon may be inflated if needed, in order to create a sensation of fullness in the anus.

Continence should be improved as soon as the slightest sensation of rectal fullness is felt, by contracting the anal sphincter muscles voluntarily for as long as possible and with sufficient intensity to prevent leakage. If dyssynergia is present, the aim is to achieve coordinated bowel movements and re-establish a regular bowel rhythm.

A discharge report is prepared once treatment is complete.

Results Patients have been pleased with the establishment of this clinic, as they see it as a way to receive treatment for a condition that affects not only their physical health, but above all their psychological and social well-being.

Up to now, 15 patients have been taken home, all of whom are female with an average age of 70. They were diagnosed with mixed faecal incontinence (hypotonia and hyposensitivity) and required an average of three to four sessions before being discharged.

Conclusions Biofeedback is an easy and effective method of improving faecal incontinence.Nurses provide patients with the necessary tools to take responsibility for the entire process.Proper health education is essential for the success of this therapy.Supporting patients is essential to ensure they adhere to the established guidelines at home.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP190 My worst case scenario: Voluntary ingestion of foreign bodies by an teenage psychiatric patient

Authors Torres Zamora YC[1], Hernández Ponce L[2], Gonzalez Gonzalez M[3]

Institutes **1** Complejo Hospitalario Insular, Las Palmas De Gran Canaria, Spain; **2** Registered Nurse, Las Palmas de Gran Canaria, Spain; **3** Hospital Insular, Las Palmas de Gran Canaria, Spain

DOI 10.1055/s-0046-1820845

Aims Report an endoscopic case in which multiple emergency endoscopies were performed on a psychiatric patient due to foreign body ingestion.

Deliberately ingesting foreign objects is a relatively common phenomenon among people with substance use disorders or psychiatric conditions. When this behaviour is repeated, it may indicate a pattern of self-harm or a way of seeking relief. These patients are difficult to treat, so a coordinated multidisciplinary team must examine the biological, social and psychological needs.

Patients with suspected or diagnosed foreign bodies in the upper digestive tract should undergo endoscopy to confirm the diagnosis and and establish the optimal treatment. The therapeutic approach to removing ingested objects varies depending on their location, nature and any associated complications. If endoscopy fails, surgery should be performed.

Methods 17-year-old female patient with a history of attachment disorder, personality disorder (cluster B) and eating disorder without substance abuse is presented. Several healthcare visits were made by the patient due to voluntary ingestion of foreign bodies.

The first upper gastrointestinal endoscopy was performed, with the last documented procedure. In total, 34 emergency endoscopies were performed due to foreign body ingestion [1–3].

Of these, 19 were performed in the Digestive Endoscopy Unit itself. Due to the potential risk posed by the ingested foreign body, 12 endoscopies were performed in the operating theatre and one in the resuscitation room of the Emergency Department.

All endoscopies were performed under sedation and/or general anaesthesia depending on the procedure location, with only one performed while the patient was conscious.

In only 16 out of the total number of endoscopies carried out, foreign objects were observed. These objects included plastic (5) or medical supplies such as an identification bracelet or a peripheral venous extension tube and others, as well as batteries (3), a carabiner, a chess piece, a screw, and pieces of glass (3).

The procedure has not been without complications. On two occasions, ulcers were observed as a result of the presence of batteries, as well as one tear and two lacerations.

There was an irregular frequency pattern, with some dates showing repeat endoscopies on the same day or consecutive days, and others showing breaks of weeks or even months.

Results The nursing staff care for the patient throughout the emergency endoscopy. However, our work ends once the foreign body has been removed.

The large number of endoscopies we have performed over the years has made us feel impotent, as we are unable to provide a lasting solution to the problem.

The patient is still undergoing psychiatric and psychological treatment, which is essential for her recovery.

Conclusions Endoscopic treatment is only a solution for removing foreign bodies that could lead to complications. Psychological therapy, combined with medication, can help to reduce the number of voluntary ingestions by providing an explanation and treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820846

Aims Stricture formation is a recognised complication after oesophageal endoscopic submucosal dissection (ESD), particularly following extensive resections, and frequently necessitates repeated therapeutic intervention. Oesophageal self-dilatation (SD) is an established approach for managing refractory benign strictures but has not previously been evaluated as a prophylactic strategy after ESD. This study reports our initial clinical experience with prophylactic SD in patients undergoing oesophageal ESD.

Methods A retrospective analysis of all oesophageal ESDs performed at a single centre between July 2023 and September 2025. Since July 2024, early SD was offered to patients undergoing large-circumference oesophageal ESD (LC-ESD) defined as those involving > 75 % circumferential extent. Patients treated before SD introduction, and those treated thereafter who did not undertake SD for any reason, formed the real-world comparator cohort. Collected variables included demographic data, lesion characteristics and procedural factors. The primary outcome was stricture requiring therapeutic endoscopic intervention (SRT). Secondary outcomes included number of dilatations at 2, 4, and 6 months and at last follow-up; change in dysphagia grade; and clinically important events (stenting, non-oral feeding, stricture-related perforation).Between-group comparisons used chi-square or Fisher's exact tests for categorical variables and Mann–Whitney U tests for continuous variables. An exploratory logistic regression model was used to evaluate the independent association between SD and SRT, adjusting for resection-risk category, selected on the basis of observed group differences and clinical relevance.

Results Twenty-two LC-ESD were included (SD n = 7 vs non-SD n = 15). The technical success rate of SD was 7/8 (87.5 %). Baseline characteristics were broadly comparable. Median circumferential extent was 100 % in both groups, median age was 79 vs 73 years, and median lesion location was 27 cm vs 30 cm. Small numerical differences were noted in sex distribution (57 % vs 86 % male), median lesion length (50 mm vs 70 mm), and the proportion of T1b lesions (14 % vs 46 %), although none were statistically significant (all p > 0.20). The main numerical imbalance was resection-risk category, with a higher proportion of "high-risk" resections in the non-SD group (53 % vs 14 %; p = 0.07). SRT occurred in 3/7 (42.9 %) SD patients compared with 12/15 (80.0 %) non-SD patients (p = 0.14). The crude odds ratio for SD was 0.19, corresponding to an approximate 80 % relative reduction in the odds of SRT. After adjusting for resection-risk category, SD continued to show a protective association (adjusted OR 0.20, 95 % CI 0.02–1.67), although this did not reach statistical significance (p = 0.14) and the confidence interval remained wide due to small sample size. The number of endoscopic dilatations was consistently lower among SD patients across all timepoints: at 8 weeks (median 0 vs 2; p = 0.30), 4 months (0 vs 2.5; p = 0.28), 6 months (0 vs 2.5; p = 0.26), and last follow-up (0 vs 4; p = 0.11). Time to first endoscopic dilatation was similar, with a median of 35 days (IQR 35–35.5) in the SD group and 28 days (15–41) in the non-SD group. Peak dysphagia grade compared with pre-ESD was lower in the SD group (median 1, IQR 0–2) than in the non-SD group (median 2, IQR 1–3.5; p = 0.26). Dysphagia at last follow-up was low in both groups (median 0).No SD-related perforations occurred. Stenting was required in 1/7 (14.3 %) SD vs 4/15 (26.7 %) non-SD patients, and non-oral feeding was needed in 0/7 vs 2/15 (13.3 %) respectively. All perforations (1 SD vs 2 non-SD) occurred during endoscopic dilatation rather than during SD.

Conclusions Prophylactic self-dilatation after LC-ESD appears feasible, safe, and may be associated with lower stricture rates and dilatation burden. Although the observed differences were not statistically significant, the magnitude and consistency of the findings suggest a potential clinical benefit. These early real-world data provide initial support for SD as a useful patient-directed prophylactic strategy, warranting confirmation in larger prospective studies.

OP192 Self-bougienage for the management of post Endoscopic Submucosal Dissection refractory oesophageal strictures

Authors Gazelakis K[1], Jones F[1], Macisaac M[1], Tsoi E[1], Cameron G[1], Yang L[1], He T[1], Chen R[1], Taylor A[1], Holt B[1]

Institute **1** St. Vincent's Hospital Melbourne, Fitzroy, Australia

DOI 10.1055/s-0046-1820847

Aims Oesophageal strictures occur in up to 90 % of patients post Endoscopic Submucosal Dissection (ESD) involving > 75 % of the oesophageal circumference. Despite prophylactic measures, up to 40 % of patients develop refractory strictures. Oesophageal self-bougienage therapy (OSBT) is an alternative for refractory strictures and may reduce procedural risk and cost and improve patient satisfaction. The study aims to describe the impact of introducing OSBT in the management of post-ESD refractory oesophageal strictures.

Methods High stricture risk (> 75 % circumferential) ESD patients received prophylactic treatment in the form of systemic (8 weeks) and topical (6 weeks) steroid and planned endoscopic oesophageal dilations commencing at 2 weeks post-ESD. Patients were eligible for OSBT if they required frequent endoscopic dilation with a stable endoscopic dilation diameter of > 10mm. Patients underwent supervised introductory sessions with their gastroenterologist, and periodic planned endoscopic dilation for home bougie up-sizing. Demographics, clinical characteristics, stricture and procedural data, and complications were recorded.

Results There were 43 high stricture risk oesophageal ESD patients between May 2022- May 2025. Of these, 6 (13.3 %) were enrolled from May 2024 onward and 5/6 (83 %) successfully initiated OSBT and were included in the final analysis. Three (60 %) were female with a median (IQR) age of 77 years (65.0-83.0). All patients underwent 100 % circumferential ESD for squamous cell high grade dysplasia or pT1a carcinoma, with a median (IQR) ESD length of 10cm (8.0-13.0). Two (40 %) had undergone triamcinolone injection. Median (IQR) time to enrolment from ESD was 6.0 (4.0-18.0) months. Over a median (IQR) follow-up of 5.0 months (4.0-7.5), patients required a median (IQR) of 2 (2.0-2.0) educational sessions prior to initiating self-bougienage. There were no adverse events. OSBT significantly reduced the median (IQR) number of endoscopic dilations required, from 10 (8.0-12.5) in the 6-months pre-enrolment to 4 (2.5-6.0) in the 6-months post-enrolment (p = 0.02). All patients had improved stricture diameter, with an increase in median (IQR) bougie diameter of 11 (10.5-13) to 14mm (13-16) at last follow-up (p = 0.04).

Conclusions OSBT resulted in significant reduction in endoscopic dilation frequency and improved stricture diameter, with a reduction in health service utilization, and potential cost implication and improved patient satisfaction.

DOI 10.1055/s-0046-1820848

Aims Gastrointestinal (GI) tract leaks and fistulae represent serious clinical challenges with substantial morbidity and mortality. Self-expanding metal stents (SEMS) have long been the standard endoscopic intervention. More recently, endoscopic vacuum therapy (EVT) has emerged as a promising endoscopic alternative. This multicenter analysis compares the efficacy and safety of EVT and SEMS for managing GI tract leaks and fistulae.

Methods A total of 90 patients were included: 58 treated with SEMS between 2014 and 2024 and 32 treated with EVT from 2022 onward (27 with Eso/Endo-SPONGE© [Boston Scientific, Marlborough, Massachusetts, USA] and 5 with VacStent Glä [Micro-Tech Europe GmbH, Düsseldorf, Germany]). Demographic variables, clinical characteristics, and therapeutic outcomes were analyzed. Primary outcome was successful leak/fistula closure, confirmed through both endoscopic and radiologic assessment. Secondary outcomes included need for additional endoscopic therapy, and complication, readmission, and mortality rates.

Results Baseline characteristics—including age, gender, etiology (benign vs malignant), timing of endoscopic intervention, and leak size—were comparable across treatment groups ($p > 0.05$). EVT demonstrated a significantly higher closure rate compared to SEMS (84.2 % vs. 65.5 %, $p = 0.044$). Despite requiring more treatment sessions (median 4.5 vs. 1[MS1] [MOU2] , $p < 0.001$), EVT required fewer adjuvant endoscopic interventions (5.3 % vs. 36.2 %, $p = 0.001$) and was associated with significantly fewer technique-related complications (5.3 % vs. 62.1 %, $p < 0.001$), as well as lower readmission rates (13.5 % vs. 47.3 %, $p = 0.016$). Mortality was not significantly different between two groups.

Conclusions In this multicenter study, EVT proved to be a highly effective and safe modality for managing spontaneous and postoperative GI tract leaks/fistulae. With superior closure rates and fewer complications compared to SEMS—even when analyzed against a decade of retrospective stent experience—EVT shows strong potential to become the preferred endoscopic therapy for these complex clinical scenarios.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP194 VAC-Stent versus EsoSponge for Anastomotic Leak Management after Gastroesophageal Surgery: A Multicenter Pilot Study

Authors Li Cavoli TV[1], Pigò F[1], Zito FP[2], Mirante VG[3], Mangiafico S[4], Manta R[5], Cocca S[1], Grande G[1], Conigliaro R[1], Bertani H[1]

Institutes **1** Azienda Ospedaliero Universitaria di Modena – Gastroenterology and Endoscopy, Modena, Italy; **2** Azienda Ospedaliera Universitaria "Antonio Cardarelli" – Gastroenterology and Endoscopy, Napoli, Italy; **3** Azienda Ospedaliera Universitaria Integrata Verona – Gastroenterology Unit, Verona, Italy; **4** Azienda Ospedaliero-Universitaria Policlinico G.Rodolico – San Marco, Catania, Italy; **5** United Hospitals of Livorno, Livorno, Italy

DOI 10.1055/s-0046-1820849

Aims Anastomotic leak (AL) after gastroesophageal surgery is a potentially life-threatening condition and the complex management still remains non-standardized.

Endoscopic vacuum therapy (EVT) has emerged as an effective therapeutic option, facilitating rapid clearance of the leak and promoting granulation tissue formation.

Two EVT systems are currently available: a polyurethane sponge attached to a 10 Fr tube, featuring an intraluminal or intracavitary treatment, and a self-expandable metal stent (SEMS) with an embedded polyurethane sponge (VAC-Stent). Both systems have shown promising results; however, comparative evidence remain limited.

The aim of the study was to compare the efficacy and safety of treating upper GI AL using the VAC-Stent or the sponge (EsoSponge).

Methods We conducted a retrospective multicenter comparative study across five Italian tertiary referral centers, including patients treated for benign or malignant upper GI anastomotic leaks, using either the VAC-Stent or the EsoSponge system.

The primary endpoint was clinical success, defined as complete healing of the transmural defect with coverage by granulation tissue. Therapy was considered ineffective in cases of defect persistence or progression during treatment (▶ **Table 1**).

▶ **Table 1**

	VAC-stent	Esos-ponge	p-value
Clinical Success			**0,04**
- Yes	35; 81 %	14; 56 %	
-No	8; 19 %	11; 44 %	
30-day mortality			1
- Yes	6; 14 %	3; 12 %	
-No	37; 86 %	22; 88 %	
N ° of procedures (Mean ± SD)	2,4 ± 1	4,4 ± 3,8	**0,001**
PCR T0 mg/dl (Mean ± SD)	10 ± 8	13 ± 13	**0,03**
PCR T24 mg/dl (Mean ± SD)	6 ± 9	16 ± 14	**0,003**
PCR T5 mg/dl (Mean ± SD)	4 ± 6	10 ± 8	**0,007**

Secondary endpoints included trends in inflammatory biomarkers, complication rates, use of additional therapeutic treatments, number of endoscopic sessions, and mortality during follow-up.

Results 68 patients were treated (43 VAC-Stent, 25 EsoSponge) with comparable demographics, including mean age (61.6 years in both groups) and sex distribution. Malignant disease was predominant (72 % vs 56 %) and Ivory-Lewis esophagogastric resection accounted for 37 % and 48 % of procedures, respectively.

Clinical success was significantly higher with VAC-Stent (81 % vs 56 %, **$p = 0.04$**), while 30-day mortality was similar (14 % vs 12 %).

VAC-Stent achieved better inflammatory control (C reactive protein 6.3 vs 16.1 mg/dL at 24 h, **$p = 0.003$**; 4.0 vs 9.9 mg/dL at day 5, **$p = 0.007$**) and required fewer procedures (median 2 vs 4, **$p = 0.001$**). The VAC-Stent group required fewer additional interventions than the EsoSponge group (35 % vs 52 %, $p = 0.07$). Additional treatments included stent placement (33 % vs 30 %), pigtail drainage (7 % vs 31 %), and other endoscopic or surgical procedures (33 % vs 23 %).

Conclusions Both VAC-Stent and EsoSponge proved effective in managing AL after gastroesophageal surgery. VAC-Stent provided faster inflammatory control, fewer device replacements, and a shorter therapeutic course, resulting in

higher clinical success rates. Prospective randomized studies are warranted to confirm these findings.

DOI 10.1055/s-0046-1820850

Aims Transoral Incisionless Fundoplication (TIF2.0) is an endoscopic procedure for gastroesophageal reflux disease (GERD), which aims to recreate the oesophageal flap valve using the EsophyX device. TIF2.0 is currently endorsed by the American Society of Gastrointestinal Endoscopy as a mechanical option for patients with proven GERD. We report on the largest dataset outside North America on the safety and efficacy of TIF2.0 conducted within the European TIF registry (EURO-TIF).

Methods A prospective, multi-centre registry conducted across seven European centres and registered at Cleveland Clinic London (CCL-2021-TIF). All prospectively collected data among patients undergoing TIF2.0 for GERD since 2021 were eligible for inclusion. The primary outcomes were change in reflux-specific quality of life questionnaire (GERD-HRQL) and acid suppression use from baseline to 24-months follow-up. Secondary outcomes included procedural outcomes, changes in oesophageal physiological parameters, and adverse events (AGREE classification). Within-patient changes were analysed using paired t-tests and a linear mixed-effects model. Univariable logistic regression explored predictors of anti-acid discontinuation and AET normalisation.

Results In total, 261 patients have undergone TIF2.0 with data available on 192. The average age was 47 years (IQR 36-56), 38.5 % were female (n = 74), and the median Charleson Co-morbidity Index was 0 (IQR 0-1). Most were treatment naïve (97.4 %, n = 187) and 91.1 % (n = 175) were on regular anti-acid therapy. A hiatus hernia (HH) was observed in 51.9 % (n = 97) with an average size of 1 cm (IQR 1-2). Baseline physiological testing was conducted in 161 patients (wireless capsule in 52.5 % [n = 85]), which showed an average acid exposure time (AET) of 10.1 % (IQR 6.8-15.3), total reflux episodes of 86.3 (SD 52.8; catheter-based), and average daily reflux episodes of 58.2 (SD 21.7; wireless). The average GERD-HRQL score at baseline was 19.2 (SD 11.7; n = 171) with a dissatisfaction score in 81.4 % (n = 140). Technical success was 99.5 % (n = 191), the average procedure time was 39.0 minutes (SD 11.5), an average 14 pairs of plications were used (IQR 10-14), and median inpatient stay was 1 day (IQR 1). Over 30-days, there were 18 adverse events including 12 AGREE grade I, 3 AGREE grade II, and 3 AGREE grade IIIa (bleeding at the fundoplication). At 6-, 12-, and 24-months post-procedure, 78.6 % (n = 151), 53.6 % (n = 103), and 18.2 % (n = 35) were available for follow-up. The average GERD-HRQL was 3.9 (95 % CI; 2.7-5.1; p < 0.001), 4.0 (95 % CI 2.8-5.3; p < 0.001), and 3.5 (95 % CI 0.7-6.2; p = 0.01), which corresponded to a mean within patient reduction of -13.5 (SD 10.0; p < 0.001), -14.2 (SD 10.5; p < 0.001), and -23.1 (SD 14.5; p < 0.01), respectively. The total number of patients able to discontinue anti-acid therapy was 84.5 % (n = 87/103), 85.3 % (n = 70/82), and 84.6 % (n = 11/13). Finally, among patients undergoing physiological testing with or without recurrent symptoms, the average AET was significantly lower at both 6-months (2.3 %; SD 3.3; n = 24; p < 0.001) and 12-months (4.5 %; SD 4.2; n = 21; p = 0.01) follow-up. No baseline variable predicted anti-acid discontinuation or AET normalisation at 12 months in univariable analysis.

Conclusions We present the largest worldwide dataset on patients undergoing TIF2.0 demonstrating a safe and effective mechanical intervention for GORD with significant symptomatic and physiological improvements.

OP196 Stretta Improves Extraesophageal Reflux Symptoms: 12-Month Interim Results From a Randomized Trial

Authors Kostalova K[1], Kuzko I[1], Suchanek S[1]

Institute **1** Military University Hospital Prague, Prague, Czech Republic

DOI 10.1055/s-0046-1820851

Aims Extraesophageal reflux (EER) is a challenging GERD phenotype with limited response to pharmacological therapy. The mechanism of Stretta remains uncertain, with proposed neuromodulatory and esophagogastric junction–related effects. High-quality evidence in EER is lacking. This study aimed to evaluate the clinical effectiveness of Stretta in patients with objectively confirmed GERD, with a prespecified 12-month interim subgroup analysis focused on patients with clinically significant extraesophageal reflux.

Methods Adults with symptomatic GERD and abnormal esophageal acid exposure were randomized 1:1 to Stretta or conservative therapy. Outcomes included daily PPI dose and two validated symptom scores — the GERD-HRQL (GERD Health-Related Quality of Life) and RSI (Reflux Symptom Index) — as well as esophageal acid exposure time (AET). A complete-case analysis was performed at 12 months. A responder was defined as ≥ 50 % improvement in the respective parameter. A predefined subgroup analysis was conducted for patients with clinically significant extraesophageal reflux (RSI ≥ 13).

Results Fifty-three patients were randomized. Complete 12-month data were available for PPI (n = 28), GERD-HRQL (n = 31), RSI (n = 31), and AET (n = 29). At 12 months, Stretta achieved significantly greater improvement than conservative therapy in daily PPI use (median 0 vs 20 mg/day; p = 0.003), GERD-HRQL (11 vs 32; p = 0.02), and RSI (7.5 vs 21; p = 0.02), while AET remained comparable between groups (p = 0.20).

Within the Stretta arm, RSI (p = 0.01) and daily PPI use (p = 0.02) improved significantly from baseline, whereas GERD-HRQL showed a non-significant trend toward improvement (p = 0.06). No significant within-group changes occurred in the conservative arm.

Stretta achieved higher ≥ 50 % responder rates across all primary outcomes compared with conservative therapy (PPI 100 % vs 56.2 %; RSI 46.2 % vs 11.8 %; GERD-HRQL 53.8 % vs 17.6 %).

In the predefined EER subgroup (RSI ≥ 13), treatment separation further increased, with responder rates of 100 % vs 50 % for PPI, 54.5 % vs 9.1 % for RSI, and 70 % vs 9.1 % for GERD-HRQL. Between-group comparisons confirmed significant advantages of Stretta for PPI (p = 0.007), GERD-HRQL (p = 0.006), and RSI (p = 0.01), with moderate-to-large effect sizes, while AET changes remained non-significant (p = 0.48).

Conclusions This interim analysis of a randomized controlled trial in patients with objectively confirmed GERD provides the first prospective randomized evidence evaluating Stretta in extraesophageal reflux. Stretta resulted in clinically meaningful improvement in EER symptoms and marked PPI reduction, with the greatest benefit in patients with clinically significant EER. These findings support Stretta as a promising endoscopic option for this difficult-to-treat GERD phenotype. Final RCT outcomes are forthcoming.

Endoscopy 2026; 58: S1–S1041

Conflicts of Interest KK has received honoraria for lectures and workshops from Imedex, a distributor of Stretta in the Czech Republic.

Quality matters: Colonoscopy in Colorectal Cancer

Aims Colorectal cancer (CRC) is the third most common malignancy worldwide, and screening colonoscopy in selected high-risk population plays a pivotal role in the early detection and removal of precancerous lesions [1]. The effectiveness of screening program depends on achieving and maintaining high-quality performance standards, including the cecal intubation rate, the bowel preparation adequacy, and the adenoma detection rate (ADR) [2]. Furthermore, with the recognition of the serrated pathway of colorectal carcinogenesis, accounting for approximately one-third of CRC cases, the detection of sessile serrated lesions has recently emerged as an additional key quality indicator [3].

This study evaluated temporal trends in key quality indicators over a 20-year period within a CRC screening program.

Methods This was an observational study that included all patients aged 50–69 years who participated in fecal immunochemical test (FIT)-based CRC screening program between 2006 and 2024

Only high-quality index colonoscopies performed after a positive FIT result, with adequate bowel preparation (Boston Bowel Preparation Score ≥ 2 in each segment), and complete procedures (reaching the cecum) were included in the analysis.

The primary endpoints were ADR, advanced ADR (AADR), serrated detection rate (SDR), proximal SDR (PSDR) and PSDR ≥ 10mm. The secondary endpoint was to evaluate possible risk factors associated with the primary outcomes.

Results Overall, 30118 high-quality index colonoscopies were analyzed. Of these, 46.8 % were performed in females; 25.1 % of patients were aged 50–54 years, 21.6 % were 55–59 years, 24.5 % were 60–64 years, and 28.8 % were 65–69 years. The mean ADR, AADR, SDR, PSDR and PSDR ≥ 10 mm was 46.4 %, 30.4 %, 11.2 %, 4.1 % and 0.9 %, respectively.

We observed a substantial increase in PSDR, rising from 4.7 % in 2006 to 6.6 % in 2024, as well as in PSDR ≥ 10 mm, which increased from 0.3 % to 1.5 %. Conversely, ADR, AADR, and SDR showed an initial decline over time, followed by subsequent stabilization.

Univariate and multivariate analyses indicated that male sex and older age were associated with a higher ADR (RR 1.41, 95 % CI [1.38-1.45]; RR 1.29, 95 % CI [1.25-1.35] age 65-69; p < 0.001), AADR (RR 1.40 [1.35-1.45]; RR 1.27 [1.20-1.34] age 65-69; p < 0.001), and SDR (RR 1.40 [1.31-1.49] p < 0.001; RR 1.12 [1.01-1.23] age 65-69, p = 0.034), whereas only older age was associated with PSDR (RR 1.33 [1.11-1.60] age 65-69, p = 0.002). Conversely, female sex was associated with a higher PSDR ≥ 10 mm (male vs female RR 0.72 [0.57-0.93], p = 0.010).

Finally, we evaluated how the interval between the FIT invitation and the subsequent colonoscopy influenced detection outcomes. Compared with patients undergoing their index colonoscopy after prior negative FIT results, progressively higher ADRs were observed in those receiving colonoscopy after their first FIT invitation (RR 1.09, 95 % CI 1.05–1.14, p < 0.001), in those who had never previously accepted a FIT invitation (RR 1.26, 95 % CI 1.22–1.31, p < 0.001), and in patients with a history of screening colonoscopies in which cancer or adenomas were detected (cancer/advanced adenomas: RR 1.27, 95 % CI 1.02–1.58, p = 0.033; initial adenomas: RR 1.22, 95 % CI 1.06–1.41, p = 0.007). Conversely, lower detection rates were observed among participants with previously negative colonoscopies (RR 0.75, 95 % CI 0.67–0.83, p < 0.001). A similar pattern was noted for AADR. Interestingly, this association was not evident for SDR, PSDR, or PSDR ≥ 10 mm.

Conclusions Over two decades of FIT-based CRC screening, a notable increase was observed in the detection of proximal serrated lesions, particularly those measuring ≥ 10mm. This upward trend likely reflects improved endoscopic awareness, advancements in imaging technology, and growing recognition of the serrated pathway as an independent contributor to colorectal carcinogenesis. Moreover, unlike ADR and AADR, which were influenced by sex, age and proper adherence to the screening program, serrated lesion detection showed a distinct epidemiologic pattern. Our findings highlight the essential role of serrated lesion detection in effective CRC prevention and reinforce the need to standardize serrated-specific quality indicators within screening programs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP198 Individual risk factors and comorbidities are linked to risk for post-colonoscopy colorectal cancer in high-quality screening colonoscopies

Authors Zessner-Spitzenberg J[1], Waldmann E[1], Klinger A[1], Penz D[2], Bognar F[1], Unger S[1], Selinger T[1], Demschik A[1], Trauner M[1], Ferlitsch M[3]

DOI 10.1055/s-0046-1820853

Aims While many post-colonoscopy colorectal cancers (PCCRC) occur due to poor procedure quality, little is known about the PCCRC risk in persons with adequate colonoscopy quality. The aim of this study was to identify risk factors for PCCRC in colonoscopies with adequate bowel preparation, cecal intubation, and an endoscopist ADR > 25.

Methods Screening colonoscopy baseline data were extracted from the Austrian screening colonoscopy registry and linked to nation-wide insurance claims data and electronic health record databases. PCCRC was defined as a CRC occurring > 6 months after a negative index colonoscopy, in line with the World Endoscopy Organization terminology. A multivariable time-to-event analysis was performed to evaluate risk factors for PCCRC.

Results We analyzed records from 54,559 screening participants who developed 73 PCCRCs. The detection of high-risk polyps (HR 2.21, 95 % CI 1.52, 3.23) was associated with PCCRC, compared to persons with a negative screening colonoscopy. Strong associations for PCCRC were observed for plasma GGT levels (HR per unit increase 1.003, 95 % CI 1.0004-1.0056), type 2 diabetes mellitus (HR 2.66, 95 % CI 1.48, 4.77) and low physical activity level (HR 1.73, 95 % CI 1.02, 2.94).

Conclusions individual risk factors provide the missing link to PCCRC risk in otherwise adequate screening colonoscopies. Patient characteristics should be included into tailored surveillance recommendations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP199 Incidence and mortality from PCCRC due to inadequate bowel preparation differs by sex

Authors Zessner-Spitzenberg J[1], Waldmann E[1], Penz D[2], Klinger A[1], Demschik A[1], Bognar F[1], Unger S[1], Selinger T[1], Trauner M[1], Ferlitsch M[1]

Institutes **1** Medical University of Vienna, Wien, Austria; **2** Klinik Floridsdorf, Vienna, Austria

DOI 10.1055/s-0046-1820854

Aims Adequate bowel preparation is one of the key quality parameters in screening colonoscopy. Although men tend to have worse bowel preparation scores than women, it is unknown whether male sex is an independent risk factor for post-colonoscopy colorectal cancer (PCCRC) when bowel preparation is inadequate (▶ **Table 1**).

▶ **Table 1**

	HR for PCCRC	95 % CI	HR for PCCRC death	95 % CI
Female and adequate preparation	—	—	—	—
Female and indequate preparation	1.59	1.09, 2.33	1.14	0.41, 3.15
Male and adequate preparation	1.35	1.20, 1.51	1.91	1.51, 2.41
Male and indequate preparation	3.02	2.30, 3.98	6.02	3.80, 9.52

Methods The Austrian screening colonoscopy quality assurance registry was used for the analyses. Data on PCCRC mortality were obtained through the Austrian death registry, and incident PCCRC > 6 months after screening colonoscopy were obtained through insurance claims data from the Austrian Social Insurance Institution. Cox proportional hazards model adjusted for age and sex was used to investigate the association of bowel preparation quality and the outcomes of interest. Adequate bowel preparation was defined as a score of either “excellent”, “good”or “fair” on the Aronchick scale, according to the current guidelines.

Results A total of 381,069 patient were analyzed. We investigated 1213 incident PCCRC and 242 PCCRC deaths. When women with adequate bowel preparation were considered the reference, men with adequate bowel preparation had higher hazards for PCCRC (HR 1.35, 95 % CI 1.20, 1.51) and PCCRC death (HR 1.91, 95 % CI 1.51, 2.41). While women with inadequate bowel preparation had 1.59 times higher hazards for PCCRC (95 % CI 1.09, 2.33) and PCCRC death (HR 1.14, 95 % CI 0.41, 3.15), the risk was highest for men with inadequate bowel preparation (HR for PCCRC 3.02, 95 % CI 2.30, 3.98, HR for PCCRC death 6.02, 95 % CI 3.80, 9.52)

Conclusions Men have a disproportionally higher risk for PCCRC and associated mortality when bowel preparation standards are not met. Intensive efforts should be made to ensure repeat colonoscopy in male patients with inadequate bowel preparation is performed.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP200 Comparison of 1 L, 2 L, and 4 L polyethylene glycol solutions for colonoscopy preparation in hospitalised patients: a multicentre, randomised controlled trial

DOI 10.1055/s-0046-1820855

Aims Adequate bowel preparation is essential for high-quality colonoscopy, yet remains particularly challenging among hospitalised patients, who frequently present multiple risk factors for poor cleansing. Current European guidelines provide no specific recommendations, while US guidelines favour high-volume (4 L) polyethylene glycol (PEG) regimens despite low-quality evidence. We conducted a multicentre, randomised, endoscopist-blinded trial to compare the efficacy, safety, tolerability, and patient acceptability of 1 L PEG–ascorbate, 2 L PEG–ascorbate, and 4 L PEG in inpatients. We tested the hypothesis that 1 L PEG–ascorbate would be non-inferior to higher volumes in achieving adequate bowel cleansing [1–3].

Methods This investigator-initiated phase IV trial was conducted in seven Italian hospitals (June 2021–January 2025). Hospitalised adults scheduled for elective colonoscopy were randomised (1:1:1) to receive 1 L PEG–ascorbate (PLENVU), 2 L PEG–ascorbate (MOVIPREP), or 4 L PEG (SELG-ESSE), all in split-dose regimen. Endoscopists were blinded to allocation. The primary endpoint was adequate cleansing, defined as Boston Bowel Preparation Scale (BBPS) ≥ 6 with all segments ≥ 2. Secondary outcomes included high-quality cleansing (BBPS 8–9), right-colon cleansing, tolerability, willingness to repeat, adverse events, and compliance (≥ 75 % intake). Analyses were performed on the modified full analysis set (mFAS), excluding incomplete colonoscopies due to strictures, previous colectomy, or therapeutic procedures. Non-inferiority was concluded if the lower bound of the two-sided 95 % CI for 1 L versus comparator was above –10 %. Missing data were conservatively imputed as failures.

Results Overall, 665 patients were randomised (1 L = 228; 2 L = 218; 4 L = 219); 624 constituted the mFAS (1 L = 210; 2 L = 204; 4 L = 210). Baseline characteristics were balanced across arms. Adequate cleansing was achieved in 84.8 % with 1 L PEG–ascorbate, 79.5 % with 2 L PEG–ascorbate, and 79.1 % with 4 L PEG. The absolute difference versus 2 L PEG–ascorbate was + 5.3 % (95 % CI –2.2 to + 12.8) and versus 4 L PEG + 5.7 % (95 % CI –1.7 to + 13.1), meeting non-inferiority criteria. High-quality cleansing (BBPS 8–9) was superior with 1 L (50.0 %) compared with 2 L (36.6 %) and 4 L (39.1 %): absolute difference + 13.4 % (95 % CI + 3.9 to + 22.7) and + 10.9 % (95 % CI + 1.4 to + 20.3), respectively. Right-colon high-quality cleansing (BBPS = 3) was achieved in 41.9 %, 28.8 %, and 31.9 % ($p < 0.05$), translating to numbers-needed-to-treat of 7.6 (1 L vs 2 L) and 10 (1 L vs 4 L). Compliance (≥ 75 % intake) was 95.6 %, 94.5 %, and 93.6 % across groups ($p = 0.643$). Despite more vomiting (14.9 % vs 7.3 % vs 11.4 %) and thirst (27.6 % vs 14.2 % vs 14.2 %), willingness to repeat was highest with 1 L (84.2 %) versus 2 L (82.1 %) and 4 L (68.0 %; $p < 0.001$). Serious adverse events were rare: one bowel perforation (in 1 L group) and one hypertensive crisis (4 L), both judged unrelated to treatment. No clinically relevant electrolyte disturbances or renal impairment were observed.

Endoscopy 2026; 58: S1–S1041 |

Conclusions Among hospitalised patients, 1 L PEG–ascorbate achieved non-inferior adequate cleansing and superior high-quality and right-colon cleansing compared with 2 L and 4 L PEG regimens. Despite higher transient symptoms (i.e., vomiting, thirst), patient acceptability was significantly greater, suggesting easier intake and reduced procedural burden. These findings support the use of a low-volume regimen as an effective, safe, and patient-centred alternative for inpatient bowel preparation. Adoption of 1 L PEG–ascorbate in real-world practice may streamline preparation, improve adherence, and reduce the need for repeated colonoscopies—challenging current US guideline assumptions, and addressing a gap in European recommendations.

DOI 10.1055/s-0046-1820856

Aims Given their well-established inverse association with the risk of post-colonoscopy colorectal cancer (CRC), polyp detection metrics such as the adenoma detection rate (ADR) are considered key quality indicators for colonoscopy. However, the widespread monitoring of these metrics is hindered by the need to link endoscopy and pathology data. This study evaluated the feasibility of an infrastructure for automated linking of data from the Dutch national endoscopy and pathology databases to enable nationwide, continuous, and low-effort monitoring of pathology-dependent polyp detection metrics [1].

Methods Structurally reported data from the Dutch Gastrointestinal Endoscopy Audit (DGEA) and Automated National Pathological Anatomy Archive (PALGA) were linked using an automated stepwise protocol. The adequacy of linking was assessed per endoscopy unit and colonoscopy indication category. Included categories involved colonoscopies after a positive fecal immunochemical test (FIT) for the CRC screening program (i.e. 'FIT positive colonoscopies') and colonoscopies for post-polypectomy and CRC surveillance, familial CRC risk, or evaluation of symptoms (collectively referred to as 'diagnostic colonoscopies'). Units for which adequate linkage was established were included to evaluate polyp detection metrics across the different categorized colonoscopy indications, as well as inter-unit variability in various polyp detection metrics. Included metrics were the ADR, advanced ADR (AADR), adenomas per colonoscopy (APC), proximal serrated polyp detection rate (PSPDR), and sessile serrated lesion detection rate (SSLDR). Additionally, the extent to which units met the recently proposed polyp detection performance targets of the American Society for Gastrointestinal Endoscopy was evaluated: for FIT-positive colonoscopies an ADR > 50 % is recommended, while for diagnostic colonoscopies in individuals aged > 45 years an ADR > 35 %, APC > 0.6, and SSLDR > 6 % are recommended [1].

Results In total, 182,539 colonoscopies from 36 units were included. Adequate linkage was achieved for 30/32 (94 %) units for FIT-positive colonoscopies, for 22/35 (63 %) units for post-polypectomy and CRC surveillance colonoscopies, for 14/25 (56 %) units for colonoscopies for familial CRC risk, and for 17/36 (47 %) units for colonoscopies for evaluation of symptoms. The main cause of inadequate linkage involved the absence of structurally recorded histopathology results in the PALGA pathology database. Median polyp detection rates for categorized colonoscopy indications are reported in ▶ **Table 1**. Detection rates varied considerably across units, with observed differences between units ranging up to 21 % (ADR), 11 % (AADR), 0.7 (APC), 15 % (PSPDR) and 17 % (SSLDR). The ADR performance target for FIT-positive colonoscopies was achieved by 28/30 (93 %) units. The ADR, APC and SSLDR performance targets for diagnostic colonoscopies were achieved by 15/21 (71 %), 19/21 (90 %) and 18/21 (86 %) units, respectively.

Conclusions This is the first study to describe an infrastructure for automated linking of data from national endoscopy and pathology databases. It demonstrates that if both endoscopy and pathology data are consistently recorded using standardized templates, as was done for FIT-positive colonoscopies, automated calculation of histopathology-dependent polyp detection metrics is possible for almost all endoscopy units. As such, the described linking protocol could allow for scalable, resource-efficient, nationwide and continuous monitoring of polyp detection metrics. Linked data revealed that most units achieve established polyp detection performance targets, though substantial inter-unit variability exists. To further leverage the potential of the described infrastructure, efforts to improve availability of structured endoscopy and pathology data for all units and colonoscopy indications are warranted.

OP202 Evaluating COLOFIT for triage of urgent colorectal cancer referrals: a multi-centre validation study

Authors Gerard P[1], Morrison M[1], Mccartney S[1], Ahmad OF[1], Myers A[2], El Khatib M[2], Thakkar R[2], Cusack M[3], Wawszczak A[4], Ziprin P[5], Bansal S[6], Artezula J[6], Padua K[6], Humes D[7], Seward E[1]

DOI 10.1055/s-0046-1820857

Aims Colorectal cancer (CRC) is a major cause of cancer-related morbidity and mortality. In the UK, a faecal immunochemical test (FIT) threshold of ≥ 10 µg/g is used to determine the need for urgent investigation. However, as in many other healthcare systems, the demand for colonoscopy or computed tomography colonography (CT-C) exceeds capacity. For example, within London there are 70,000 patients a year who are referred to the urgent suspected cancer service. The COLOFIT model, incorporating FIT, age, sex and routine blood parameters, was recently developed to improve CRC risk stratification and therefore prioritisation of patients for urgent investigation. We aimed to externally validate the COLOFIT model in a multicentre secondary care setting among patients referred under an urgent suspected cancer pathway, comparing its diagnostic performance to FIT alone and assessing its potential to reduce the number of urgent referrals.

Methods We performed a retrospective multicentre cohort study of patients referred under urgent suspected cancer pathways to eight London hospitals between 2023 and 2025. Patients with all available COLOFIT variables (FIT, age, sex, platelet count and mean cell volume) and a confirmed CRC outcome were included. We evaluated the diagnostic performance of COLOFIT across a range of thresholds and compared it with FIT ≥ 10 µg/g. Discrimination and calibration were assessed using the area under the receiver operating characteristic curve (AUC) and the observed-to-expected (O/E) ratio, respectively [1].

Results 2512 patients were included (median age 63 years and 47 % male). 117 (4.7 %) were diagnosed with CRC. Using FIT ≥ 10 µg/g, sensitivity for CRC was 94.0 % (95 % CI:88.2– 97.1 %) with a specificity of 19.5 % (CI:18.0–21.1 %). We identified that a COLOFIT threshold of 0.75 % 1-year CRC risk captured the same number of cancers as FIT ≥ 10 µg/g and would have led to a reduction in urgent referrals by 303 (12 %). This COLOFIT threshold had a sensitivity of 94.0 % (CI:88.2–97.1 %) and a specificity of 32.2 % (CI:30.4–34.1 %). The COLOFIT model demonstrated higher discriminatory performance with AUC 0.76 (CI: 0.71–0.80) compared to AUC 0.73 (CI:0.68–0.77) for FIT alone. COLOFIT was overall well calibrated but slightly underestimated CRC risk with observed cases being approximately 8 % higher than expected (O/E ratio 1.08, CI 0.89–1.28).

Conclusions Our study externally validates the COLOFIT model in patients urgently referred for suspected cancer. The COLOFIT model would lead to a reduction in urgent referrals by 12 %. In London, this could lead to a reduction in 8700 referrals per year to the urgent suspected cancer pathway. The COLOFIT model is a potential tool to lower urgent referral volume without compromising diagnostic performance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820858

Aims Endoscopic ultrasound–guided portosystemic pressure gradient (EUS-PPG) is an alternative method of assessing portal hypertension by directly obtaining portal and hepatic venous pressure measurements. Transjugular hepatic venous portal gradient (HVPG) has been the gold standard for measuring portal hypertension, with measurements ≥ 10 mm Hg defined as clinically significant portal hypertension. Previous studies have shown that EUS-PPG correlates with HVPG along with clinical parameters of portal hypertension, FIB-4 and histologic fibrosis staging; however, downstream clinical outcomes such as hepatic decompensation have yet to be elucidated. In this study, we aim to evaluate the utility of EUS-PPG in predicting new hepatic decompensation in patients with compensated cirrhosis (▶ **Table 1**).

Methods This was a retrospective study at two tertiary academic hospitals of patients with compensated cirrhosis who underwent EUS-PPG from 2014 to 2025. Clinical, laboratory, procedural, and follow-up data including development of decompensation event (variceal hemorrhage, new ascites, hepatic encephalopathy, and jaundice) were collected. Baseline demographics were compared between patients with and without new decompensation. Univariate and multivariate logistic regression were performed to determine predictors of new decompensation. Receiver operating characteristic curve was analyzed to further assess the ability of EUS-PPG in predicting decompensation. Post-hoc-analysis was performed to establish optimal PPG cutoff with maximal negative predictive value [1].

Results A total of 134 patients with cirrhosis who underwent EUS-PPG between 2014 to 2025 were identified. 44 patients had previous history of decompensation while 90 were well compensated at time of EUS-PPG. For the compensated cohort of cirrhotic patients, the mean age was 60.8 (SD = 10.79) and 60 % were female. Mean MELD-Na was 10 (SD = 34.05) and mean Child-Pugh score was 5.3 (SD = 0.62). Most common liver disease etiology was MASLD (54 %). Within the follow-up interval up to 36 months after EUS-PPG, new decompensation occurred in 13.3 % (12/90) of patients. The mean PPG in the group of patients who developed decompensation was 10.5 mmHg compared to 7.14 mmHg in the group who remained compensated (p = 0.040).

▶ **Table 1**

	Univariate Analysis			Multivariate Analysis		
	OR	**95 % CI**	**p-value**	**OR**	**95 % CI**	**p-value**
Age	**1.08**	**0.99-1.16**	**0.06**	**1.14**	**1.01-1.29**	**0.048**
Sex	1.083	0.32-3.72	0.899	4.15	0.68-25.24	0.681
BMI	1.04	0.97-1.11	0.259	1.09	0.98-1.21	0.106
NSBB	1.53	0.29-8.14	0.616	0.65	0.08-5.61	0.697
MELD	1.04	0.90-1.20	0.601	0.73	0.51-1.04	0.084
CP	**2.33**	**1.13-4.82**	**0.022**	**6.34**	**1.46-27.56**	**0.014**
PPG	**1.11**	**1.01-1.24**	**0.049**	**1.21**	**1.04-1.42**	**0.016**

42 % of the decompensated group had PPG ≥ 10 mmHg, compared to 28 % in the compensated group (p = 0.024). In multivariate analysis, PPG, Child-Pugh scores and age were found to be significant predictors of decompensation. ROC curve for diagnostic capacity of EUS-PPG showed C-statistic of 0.660. In post-hoc analysis, a PPG ≤ 6 yielded a 97 % negative predictive value for the absence of new decompensation.

Conclusions Higher EUS-PPG values were linked with increased risk of first hepatic decompensation in this multicenter cohort. These findings highlight the potential of EUS-PPG to support risk stratification in compensated cirrhosis and to complement existing tools to anticipate clinical progression.

DOI 10.1055/s-0046-1820859

Aims Clinically significant portal hypertension (CSPH) is the strongest predictor of hepaticdecompensation. The hepatic venous pressure gradient (HVPG) is the gold standard for diagnosingCSPH, but it provides only an indirect estimate of portal pressure and may underestimatepresinusoidal or mixed forms of portal hypertension (PH), particularly in porto-sinusoidal vasculardisorder (PSVD) and metabolic-associated steatotic liver disease (MASLD).

Endoscopic ultrasound (EUS)-guided portal pressure gradient (PPG) measurement enables direct recording of portal and hepatic vein pressures, potentially offering a more comprehensivehemodynamic assessment. This study evaluated the concordance between EUS-PPG and HVPG and assessed their prognostic value in predicting hepatic decompensation.

Methods In this prospective single-center study, consecutive patients with suspected CSPH of variousetiologies underwent both EUS-PPG and HVPG measurement. Baseline demographic, biochemical, and clinical data were collected. EUS-PPG was obtained using the EchoTip Insight system, and HVPG was measured according to Baveno VII recommendations. Correlation between EUS-PPG and HVPG was assessed using Pearson's coefficient, while agreement was evaluated with Bland–Altman analysis. Predictors of hepatic decompensation (ascites, variceal bleeding, or hepaticencephalopathy) were explored using univariate and multivariate logistic regression analyses [1–5].

Results Ninety patients were enrolled (45.6 % male; mean age 60 years). Liver disease etiologies includedPSVD (35.6 %), MASLD (31.1 %), autoimmune liver diseases (14.4 %), metabolic/alcohol-relatedliver disease (7.8 %), viral hepatitis (7.8 %), and alcohol-related liver disease (3.3 %). All procedureswere technically successful without severe adverse events.

Mean EUS-PPG and HVPG values were 14 ± 6 mmHg and 9 ± 5 mmHg, respectively. Seventypatients (77.8 %) had PPG > 10 mmHg, while only 41 (45.6 %) had HVPG > 10 mmHg. Concordancebetween methods was modest, with a mean PPG–HVPG difference of + 4.7 mmHg (95 % limits of agreement ranging from − 9.6 to + 18.9 mmHg) and a weak linear correlation (r = 0.036, p = 0.73).

During a median follow-up of 12 months, 17 patients (18.9 %) developed hepatic decompensation. At univariate analysis, PPG (OR 1.27; 95 % CI 1.11–1.44; $p = 0.0003$) and platelet count (OR 0.97; 95 % CI 0.95–0.99; $p = 0.001$ were significantly associated with the occurrence of hepaticdecompensation .

In the multivariate logistic regression model including significant variables, EUS-PPG (OR 1.40; 95 % CI 1.11–1.76; $p = 0.004$), together with platelet count (OR 0.97; 95 % CI 0.95–1.00; $p = 0.037$)remained independent predictors of hepatic decompensation.

Conclusions EUS-PPG is a feasible, safe, and informative method for assessing portal hypertension acrossheterogeneous liver disease etiologies. It independently predicts hepatic decompensation, suggesting potential advantages over HVPG especially in presinusoidal or mixed forms of portalhypertension such as PSVD and MASLD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP205 Same session validation of a custom-built 22G with the commercial 25G system for EUS-guided portal pressure gradient measurement

Authors Praktiknjo M[1], Farouk N[1], Wang Z[1], Stadtmann J[1], Van De Loo DJ[1], Kimmann M[1], Gunia C[1], Meier JA[1], Uschner FE[1], Peiffer KH[1], Laleman W[2], Trebicka J[1], Braden B[1]

Institutes 1 Münster University Hospital, Münster, Germany; 2 Department of Gastroenterology and Hepatology, University Hospitals Leuven, KU Leuven, Leuven, Belgium

DOI 10.1055/s-0046-1820860

Aims Endoscopic ultrasound-guided portal pressure gradient (EUS-PPG) measurement is a promising alternative to hepatic venous pressure gradient (HVPG) assessment, especially in settings where HVPG is unavailable or limited. The commercial 25-gauge (25G) system showed good correlation against hepatic venous pressure gradient (HVPG). However, the 25G has drawbacks due to its small calibre and the proprietary pressure transducer. The aim of this study is to validate a custom-built 22G conventional intravascular pressure transducer system (22G EUS-PPG).

Methods In this prospective study, 26 patients underwent EUS-PPG measurement using both systems during the same session. The primary outcome was the correlation of PPG values. Secondary outcomes included the correlation and variability of portal vein pressure (PVP) and hepatic vein pressure (HVP) measured by both systems.

Results PPG values showed excellent correlation of both systems ($r = 0.901$, $p < 0.001$). 25G EUS-PPG correctly identified clinically significant portal hypertension (CSPH, defined as PPG ≥ 10mmHg) in 25 of 26 (96.2 %) cases. Portal vein and hepatic vein pressures also correlated significantly ($r = 0.776$ and $r = 0.673$, respectively) between both systems. Variability within both systems was very low to low.

Conclusions EUS-PPG measurements obtained with the commercial 25G and custom-built 22G EUS-PPG systems are validated. The custom-built 22G system excels due to pressure-tracing quality control, availability and cost-efficiency.

OP206 Echo-Endoscopic Shear-Wave Elastography of the Spleen: A Cohort Study Measuring Splenic Stiffness with Liver Elastography

Authors Ghita-Adrian B[1], Miutescu B[2], Gadour E[3], Burciu C[4], Brasovan A[5], Moga T[6], Ratiu I[1], Ghiuchici AM[5], Popescu A[1]

Institutes 1 Victor Babeș University of Medicine and Pharmacy, Timișoara, Romania; 2 Department of Gastroenterology and Hepatology, "Victor Babes" , Timișoara, Romania; 3 Liver Transplantation Department, King Fahad Specialist Hospital , Dammam, Saudi Arabia; 4 Department of Gastroenterology, Faculty of Medicine, West University "Vasile Goldis", Arad, Romania; 5 University of Medicine and Pharmacy Timisoara, Romania, Timisoara, Romania; 6 Advanced Regional Research Center in Gastroenterology and Hepatology, Timisoara, Romania

DOI 10.1055/s-0046-1820861

Aims Splenic stiffness is influenced by portal venous pressure, yet its behaviour when assessed by endoscopic ultrasound point shear-wave elastography (EUS-pSWE) and its relationship with liver elastography across common clinical phenotypes remain insufficiently described. This study aimed to characterise splenic stiffness measured by EUS-pSWE, determine its agreement with splenic shear-wave speed, compare it with concurrent liver elastography, and evaluate potential threshold values for excluding or confirming advanced fibrosis.

Methods In this prospective cohort from a single centre, 59 adults undergoing clinically indicated EUS received standardized EUS-pSWE of the spleen along with same-day liver vibration-controlled transient elastography (VCTE). Reliable exams required ≥ 10 valid measurements and an IQR/median ratio < 30 %. Non-parametric testing was used for group analyses, and associations were assessed using Spearman correlation. Two predefined splenic-stiffness thresholds (~25 and ~32 kPa) were examined for their diagnostic ability to identify advanced fibrosis (F ≥ 3) defined by VCTE.

Results Twelve participants met criteria for obesity; this subgroup was younger (49.6 ± 13.5 vs 70.2 ± 27.2 years, $p = 0.0073$) and predominantly male (50 % vs 14.9 %, $p = 0.0258$). Splenic and hepatic stiffness values were comparable (all $p \geq 0.4456$). Liver stiffness rose steadily with fibrosis severity (from 5.12 kPa at F0–1 to 19.36 kPa at F4), whereas splenic stiffness did not demonstrate a monotonic trend across fibrosis stages (24.34 kPa at F0–1, 33.03 kPa at F3, 26.98 kPa at F4; Kruskal–Wallis $p = 0.18$), consistent with its hemodynamic dependency. Splenic stiffness showed strong internal agreement with splenic shear-wave speed ($\rho = 0.955$, $p < 0.001$). No significant correlations were observed between splenic parameters and either liver stiffness ($\rho = 0.124$, $p = 0.357$) or CAP ($\rho = 0.199$, $p = 0.14$).

A splenic-stiffness cut-off near 25 kPa provided high negative predictive value (93.8 %) with moderate sensitivity (77.8 %), specificity (60.0 %), and LR– of 0.37 (χ^2 $p = 0.0362$). A threshold around 32 kPa offered strong rule-in performance (specificity 88.0 %, sensitivity 44.4 %, LR + 3.7, NPV 89.8 %; χ^2 $p = 0.0169$).

Conclusions Splenic stiffness measured via EUS-pSWE demonstrates excellent internal consistency, appears largely independent of liver stiffness, and yields clinically practical thresholds for excluding (~25 kPa) and confirming (~32 kPa) advanced fibrosis. These findings support the incremental diagnostic value of splenic EUS-pSWE during routine endoscopic assessment.

DOI 10.1055/s-0046-1820862

Aims This study aimed to determine the optimal needle type for endoscopic ultrasound-guided liver biopsy (EUS-LB) by comparing the diagnostic accuracy and specimen adequacy of various 19G and 22G fine-needle aspiration (FNA) and fine-needle biopsy (FNB) needles through a systematic review and network meta-analysis of randomized controlled trials (RCTs).

Methods We conducted a network meta-analysis of five RCTs published between 2016 and 2022 in the USA, including 251 adult patients undergoing EUS-LB for parenchymal liver disease. The needles compared were 19G FNA, 19G Franseen FNB, 19G Fork-tip FNB, 22G Franseen FNB, and 22G Fork-tip FNB. Primary outcomes were total specimen length (mm) and number of complete portal tracts (CPTs).

Results Both 19G Fork-tip and 19G Franseen FNB needles yielded significantly longer specimens compared to 22G Franseen FNB (MD 2.76 mm [95 % CI 1.43 to 4.10] and 3.19 mm [2.07 to 4.31], respectively) and 22G Fork-tip FNB (MD 4.78 mm [0.95 to 8.62] and 5.21 mm [1.45 to 8.97], respectively). They also outperformed 19G FNA (MD 3.92 mm [0.51 to 7.33] and 3.49 mm [0.01 to 6.98], respectively). No significant difference was found between 19G FNA and 22G Franseen or Fork-tip needles. SUCRA rankings for specimen length favored 19G Franseen (0.91) and 19G Fork-tip (0.83). Regarding CPT count, 19G Franseen and 19G Fork-tip FNB significantly exceeded 22G Fork-tip FNB (MD 23.62 [5.25 to 41.98] and 22.80 [5.92 to 39.68], respectively) and 19G FNA (MD 21.50 [7.98 to 35.02] and 22.32 [6.98 to 37.65], respectively), with no significant difference compared to 22G Franseen FNB. SUCRA rankings for CPTs were 0.85 for 19G Fork-tip and 0.82 for 19G Franseen (Table 1). Diagnostic adequacy was higher with 19G Fork-tip (RR 6.61 [1.08 to 40.53]) and 19G Franseen (RR 8.50 [1.76 to 41.09]) compared to 22G Franseen FNB. Adverse events were rare, with only one gastric hematoma and mild abdominal pain episodes reported [1, 2].

Conclusions The 19G end-cutting FNB needles (Franseen and Fork-tip) provide superior specimen length and portal tract yield compared to smaller gauge or FNA needles, supporting their preferential use in EUS-LB. These findings suggest larger caliber needles improve diagnostic quality without compromising safety. However, low evidence quality warrants further high-powered RCTs to confirm these results and guide clinical practice guidelines.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820863

Aims Endoscopic ultrasound (EUS)-guided liver biopsy is gaining rapid interest, but there is still debate over biopsy site, the types and diameters of needles and the biopsy technique. We performed a prospective, head-to-head trial to compare the diagnostic efficacy and the sample quality of a 19-gauge fine-needle biopsy (FNB) needle and a 22-gauge FNB needle.

Methods Between July 1st, 2024, and March 1st, 2025, we performed EUS-guided liver biopsies on forty consecutive patients. We took two biopsies from each patient's left lobe; one with a 19-gauge FNB needle and the other with a 22-gauge needle, both performed by the same endoscopist at the same session. The biopsy technique was wet-suction with heparin-primed needles, without a stylet, performed as one pass with five actuations. We recorded demographic factors, assessed specimen quality, and followed up on adverse events [1–3].

Results All patients had a diagnosis, but four patients undergoing sampling with the 22-gauge FNB needle had microscopically inadequate specimens. The diagnosis was made based on biopsy findings from the 19-gauge FNB needle in these patients. Mean preprocessing total length and the longest length of the tissue core were significantly higher with 19-gauge needles [58 (25 – 142, min-max)mm and 15.1 (4 – 31, min-max) mm] vs. [45 (6 – 67) and 12.2 (3 – 28) mm, respectively; $p < 0.001$]. The number of complete portal tracts was significantly higher with the 19-gauge needle [35 (17-110) (min-max) vs 20 (5-65) (min-max), respectively; $p < 0.001$]. The only adverse event was hepatic abscess in one patient, which resolved with EUS-guided internal drainage using a lumen-apposing metal stent. The abscess culture showed Streptococcus anginosus, a bacterium associated with poor dental hygiene and the spontaneous development of hepatic abscesses after dental procedures.

Conclusions EUS-guided liver biopsy with a 19-gauge FNB needle is superior to a 22-gauge FNB needle.(Clinicaltrials.gov identifier;NCT06643520)

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims The Sydney EMR recurrence tool was developed nearly a decade ago [1]; since then, EMR technique and best practices has evolved. We aimed to reassess predictors of residual or recurrent neoplasia after EMR of large colorectal polyps and to evaluate risk stratification performance.

Methods This study used data from three large international multicenter prospective studies enrolling patients undergoing EMR of large (≥ 20 mm), non-pedunculated colorectal polyps between 2013 and 2025. Patients with complete initial resection who underwent at least one surveillance colonoscopy with identification of the EMR resection site were included. Recurrence was defined as biopsy-proven residual or recurrent neoplasia at the first surveillance colonoscopy. The primary outcomes of interest were patient-, polyp-, and procedure-level characteristics associated with recurrence following EMR. Analyses were additionally stratified by resection approach (hot vs cold EMR). Associations were evaluated using multivariable logistic regression. Risk estimates from multivariable models were used to derive additive risk scores, and predictive performance was assessed using receiver operating characteristic curves. All analyses were performed using R.

Results A total of 1,629 patients with 1,718 non-pedunculated colorectal polyps ≥ 20 mm underwent EMR (76 % hot EMR, 24 % cold EMR). Recurrence at first surveillance colonoscopy (median 6.0 months) occurred in 19.0 % of polyps. Recurrence was independently associated with larger polyp size (≥ 40 mm; OR 2.31), sessile morphology with any Paris 1s component (OR 1.38), intraprocedural bleeding (IPB, OR 1.74), incomplete submucosal lifting (OR 1.58), nonuse of a distal attachment cap (OR 1.58), incomplete or absent margin ablation (OR 2.02), and cold EMR compared with hot EMR (OR 2.95) (all p ≤ 0.024). Serrated histology, dysplasia, colonic location, visible fibrosis, and perceived ease of resection were not associated with recurrence. For hot EMR only, most factors remained associated with recurrence except sessile morphology. For cold EMR, recurrence was associated with larger size, IPB, and high-grade dysplasia (HGD). Across all EMR, absence of any identified risk factor defined a low-risk group with a negative predictive value of 95 %, while presence of at least one risk factor accounted for 93 % of recurrent lesions (sensitivity 93 %); however, prediction models demonstrated limited discrimination (AUC 0.64–0.66).

Conclusions This large multicenter analysis confirms established risk factors for recurrence after EMR (polyp size and IPB) and identifies additional factors (sessile morphology, submucosal lifting, margin ablation, cold resection, and cap use). Risk factor profiles differed between hot and cold EMR, and the modest discriminatory performance of prediction tools suggests a meaningful contribution of operator-related factors beyond measured polyp and procedural characteristics.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Institutes 1 Department of Medicine, 1st Faculty of Medicine, Military University Hospital, Prague, Czech Republic; 2 Department of Gastrointestinal Oncology, 1st Faculty of Medicine, Military University Hospital, Prague, Czech Republic

DOI 10.1055/s-0046-1820865

Aims Recurrence after piecemeal endoscopic mucosal resection (pEMR) of large nonpedunculated colonic polyps (LNPCPs) remains a major limitation of this technique. Margin thermal ablation (MTA) has been shown in randomized trials to reduce recurrence neoplasia, but evidence of its effectiveness and predictors of recurrence in routine clinical practice is still limited. This study evaluated the recurrence rates after pEMR of LNPCPs (≥ 20 mm) before and after implementation of MTA in a single high-volume endoscopy center. Secondary aims were to identify independent risk factors for local recurrence and to compare adverse events between two cohorts.

Methods This single-center retrospective comparative cohort study included consecutive patients undergoing pEMR for LNPCPs ≥ 20 mm during two time periods: 2013–2015 (without MTA) and 2022–2024 (with systematic MTA). Patients treated with standard pEMR without MTA between January 2013 and December 2015 were used as a historical control cohort, as complete endoscopic and surveillance data were available for this period and MTA had not yet been implemented in our unit. These outcomes were compared with a contemporary cohort of patients treated with pEMR and systematic MTA between 2022 and 2024. The primary endpoint was local recurrence at the first surveillance colonoscopy (SC1), performed 4–6 months after resection. Secondary outcomes included risk factors for recurrence and adverse event rates. Recurrence was defined as endoscopic and/or histological evidence of adenomatous tissue at SC1. All surveillance examinations were performed using high-definition white light and virtual chromoendoscopy.

Results Data from 359 patients with 384 LNPCPs were analyzed. Of these, 232 LNPCPs were resected by pEMR. During 2013–2015, a total of 108 LNPCPs were treated with standard pEMR without MTA (S-pEMR), whereas during 2022–2024, 124 LNPCPs were resected with pEMR and systematic margin thermal ablation using snare-tip soft coagulation (T-pEMR). Baseline characteristics of patients undergoing SC1 were similar between groups. Local recurrence at SC1 was detected in 11 lesions (9 %) in the T-pEMR group compared with 28 lesions (26 %) in the S-pEMR group (p = 0.0005; RR = 0.34; 95 % CI, 0.18–0.65). Local recurrence decreased by 17 %, corresponding to a 66 % relative risk reduction. Local recurrence was significantly associated with lesions ≥ 30 mm (p = 0.005) and high-grade dysplasia (p = 0.005). Adverse events were comparable between groups, with no significant differences.

Conclusions Margin thermal ablation following piecemeal EMR significantly reduced local recurrence in routine clinical practice, resulting in a 17 % absolute and 66 % relative reduction in recurrence without an increase in adverse events. High-grade dysplasia, and lesion size ≥ 30 mm were independent predictors of recurrence. Recognition of these risk factors may help guide more tailored surveillance strategies.

OP211 Optimizing Endoscopic Mucosal Resection Outcomes through Adjunctive Techniques for Complex Colorectal Polyp Resection: a Retrospective Observational Cohort Study

Authors Khalaf K[1], Li H[1], Bucheeri MAGA[1], Jugnundan S[1], Nishimura T[1], Hanna Y[1], Devloo R[1], Abu Shawish W[1], Brar G[1], Gupta S[1], He T[1], Zhang L[1], Harb M[1], Fujiyoshi Y[1], Clancy J[1], Calo N[1], May G[1], Teshima C[1], Mosko J[1]

Institute 1 St. Michael's Hospital, Toronto, Canada

DOI 10.1055/s-0046-1820866

Aims Endoscopic mucosal resection (EMR) remains the cornerstone for managing complex colorectal polyps, yet local recurrence after piecemeal resection remains a major limitation. To mitigate this, adjunctive methods, including cold avulsion with snare-tip soft coagulation (CAST), hot avulsion and snare-tip submucosal release have been introduced to improve histologic completeness and long-term durability.

Methods This retrospective observational cohort study included all consecutive patients who underwent EMR for complex colorectal polyps between 2019 and 2025 at St. Michael's Hospital, Toronto, Canada. Adjunctive methods were applied at the discretion of the endoscopist according to lesion morphology, completeness of and/or predicted success of snare resection, and recurrence risk. In our practice, distal-cap assisted EMR (EMR-DC) is not considered an adjunctive technique. Primary outcomes were technical success, procedure-related adverse events, and recurrence at first surveillance colonoscopy (▶ **Table 1**).

▶ **Table 1**

	CAST (n = 453)	Hot Avulsion (n = 111)	Submucosal release (n = 123)
Technical success	437 (96.47); p = 0.74	107 (96.4); p = 0.92	113 (91.87); p = 0.007
Intra-procedural Perforation (DMI 4-5)	3 (0.66); p = 0.48	1 (0.9); p = 0.23	4 (3.3); p = 0.49
Delayed Bleeding	8 (1.77); p = 0.28	3 (2.7); p = 0.81	1 (0.8); p = 0.23
Delayed Perforation	0 (0); p = 0.18	0 (0); p = 0.58	1 (0.8); p = 0.18
Recurrence at first surveillance	36 (7.95); p = 0.02	6 (5.4); p = 0.78	8 (6.5); p = 0.49

Results Among 1,364 lesions resected by EMR, adjunctive techniques were frequently applied to optimize resection outcomes. CAST was used in 453, hot avulsion in 111, and submucosal release in 123 resections. Technical success was high across all adjunctive methods, with CAST achieving 96.47 % (437/453; p = 0.74), hot avulsion 96.40 % (107/111; p = 0.92), and submucosal release 91.87 % (113/123; p = 0.007). Clinically significant intra-procedural perforation (DMI 4–5) was uncommon across techniques. CAST was associated with 3 such events (0.66 %; p = 0.48), hot avulsion with 1 event (0.9 %; p = 0.23), and submucosal release with 4 events (3.3 %; p = 0.49), with no statistically significant differences between groups. Delayed bleeding occurred in 1.77 % of CAST (8/453; p = 0.28), 2.7 % of hot avulsion (3/111; p = 0.81), and 0.8 % of submucosal release cases (1/123; p = 0.23). Delayed perforation was rare, occurring in none of the CAST or hot avulsion cases and in 1 patient (0.8 %; p = 0.18) following submucosal release. Recurrence at first surveillance colonoscopy was lowest for hot avulsion (5.4 %; 6/111; p = 0.78) and submucosal release (6.5 %; 8/123; p = 0.49). CAST demonstrated a significantly higher recurrence rate at surveillance 7.95 % (36/453; p = 0.02), despite its high technical success rates. In multivariable analysis, none of the adjunctive techniques were independently associated with recurrence: CAST (OR 0.75, 95 % CI [0.39–1.46]; p = 0.401), hot avulsion (OR 1.82, 95 % CI [0.64–5.13]; p = 0.260), and submucosal release (OR 1.06, 95 % CI [0.39–2.86]; p = 0.906). Lesion characteristics such as Paris morphologies (e.g., Ip vs IIa: OR 0.26, 95 % CI [0.08–0.90], p = 0.033; Ip vs IIa + Ic: OR 0.09, 95 % CI [0.02–0.42], p = 0.002) and size (e.g., > 50 mm vs 20–29 mm: OR 0.20, 95 % CI [0.06–0.68], p = 0.010; > 50 mm vs 30–50 mm: OR 0.39, 95 % CI [0.20–0.75], p = 0.005) remained significant predictors of recurrence.

Conclusions Our analysis suggests that recurrence is driven primarily by intrinsic lesion characteristics, such as size and morphology, rather than the specific adjunctive technique employed. Thus, the choice of adjunct should be tailored to the lesion characteristics and procedural goals. Snare-tip submucosal release offers a valuable rescue option for fibrotic, non-lifting, or recurrent lesions despite its greater procedural complexity, whereas CAST and hot avulsion remain effective, lower-risk tools. A selective, lesion-tailored adjunctive strategy can maximize EMR curative yield, maintain safety, and may reduce the need for escalation to ESD in complex colorectal lesions.

Orsola-Malpighi Hospital, bologna, Italy; 4 Azienda Ospedaliero Universitaria di Modena – Gastroenterology and Endoscopy, Modena, Italy; 5 Gastroenterology and Gastrointestinal Endoscopy, IRCCS San Raffaele Hospital, Milan, Italy

DOI 10.1055/s-0046-1820867

Aims Complete resection of polypoid colorectal lesions is essential to prevent local recurrence and progression to colorectal cancer. Laterally spreading tumors of granular type (LST-G) represent a common indication for advanced endoscopic resection. Our aim was to compare efficacy and safety of EMR versus ESD for the treatment of colorectal LST-G.

Methods This is an interim analysis of an ongoing multicenter randomized controlled trial involving five Italian centers. Consecutive patients aged > 18 years, with life expectancy > 10 years, and presenting with colorectal LST-G > 20 mm referred for endoscopic resection were included. Exclusion criteria were non-granular LST, presence of depressed areas, lesions on scars or anastomoses, polyps in inflammatory bowel desease, patients with familial adenomatous polyposis and Lynch syndrome, and Kudo V pattern. Patients were randomized to EMR or ESD. The primary outcome was local recurrence at 6 and 12 months. Secondary outcomes included R0 resection, en bloc resection, procedure time, and early adverse events.

Results A total of 269 patients (134 ESD, 135 EMR) were analyzed after exclusion of 25 patients with incomplete data. Baseline age, sex and lesion size were comparable between groups. Lesion distribution differed significantly, with a higher prevalence of rectal lesions in the ESD group (p < 0.001).En bloc resection rate was significantly higher in the ESD group (96.7 % [117/121] vs 30.9 % [38/123]; p < 0.001). Procedure speed was higher with EMR (median 314 [179;440] mm²/min) compared with ESD (median 200 [131;273] mm²/min;

p < 0.001).Early bleeding (3/121 ESD vs 1/123 EMR; p = 0.105) and perforation (9/121 ESD vs 3/123 EMR; p = 0.172) were comparable in the two groups.Recurrence at 6 and 12 months tended to be lower in ESD group (6 months: 1.4 % vs 5.4 %; 12 months: 0 % vs 6 %) however, these differences were not statistically significant (p = 0.063), as follow-up is still ongoing.

Conclusions In this interim analysis, ESD showed safety comparable to EMR for treating colorectal LST-G, with similar rates of early adverse events. However, ESD achieved a significantly higher en bloc resection rate at the expense of a lower resection speed and longer procedure time. A trend towards reduced recurrence was observed after ESD, which was not yet statistically significant pending full completion of follow-up.

DOI 10.1055/s-0046-1820868

Aims Hot endoscopic mucosal resection (HEMR) and endoscopic submucosal dissection (ESD) are established approaches for large colorectal lesions. Several alternative strategies, including cold EMR (CEMR), HEMR with margin ablation (HEMR-A), underwater EMR (UEMR), and endoscopic full-thickness resection (EFTR), have recently emerged, but their comparative efficacy and safety remain uncertain.

Methods A systematic search of PubMed/MEDLINE, Embase, and Scopus identified randomized controlled trials (RCTs) comparing endoscopic resection techniques for large non-pedunculated colorectal polyps. Primary outcomes were local recurrence and adverse events (AEs). Both direct and indirect comparisons were performed, and results were expressed as odds ratios (ORs) with 95 % confidence intervals (CIs). Heterogeneity, network inconsistency, risk of bias, and certainty of evidence were assessed using a frequentist random-effects network meta-analysis (NMA) and GRADE methodology.

Results Nine RCTs comprising 2,379 procedures and six resection strategies were included. Regarding recurrence, ESD demonstrated superior efficacy, significantly outperforming HEMR (OR 0.10; 95 %CI 0.01–0.85) and HEMR-A (OR 0.12; 95 % CI 0.01–0.94). Conversely, CEMR ranked lowest, showed the highest recurrence rate, proving inferior to HEMR (OR 2.18; 95 % CI 1.43–3.32), HEMR-A (OR 2.63; 95 % CI 1.75–3.95), UEMR (OR 3.64; 95 % CI 1.79–7.40), and ESD (OR 22.58; 95 % CI 2.68–189.97). In terms of safety, CEMR ranked highest, with fewer AEs than HEMR (OR 0.37; 95 % CI 0.18–0.74), HEMR-A (OR 0.38; 95 % CI 0.16–0.88), and ESD (OR 0.16; 95 % CI 0.06–0.45). In contrast, ESD presented the poorest safety profile, showing higher AEs versus HEMR-A (OR 2.31; 95 % CI 1.34–3.99).

Conclusions ESD offers the greatest efficacy in reducing recurrence but at the cost of increased procedural risk, whereas CEMR provides the most favorable safety profile with lower efficacy. HEMR, HEMR-A, and UEMR demonstrate intermediate performance, underscoring inherent trade-offs between efficacy and safety. These findings support an individualized, lesion and patient-specific approach to technique selection and highlight the need for further high-quality trials evaluating emerging modalities, such as EFTR.

OP214 Longitudinal Outcomes and Prevalence of Sessile Serrated Lesions (SSL) in an Australian population cohort

Authors Shibu R[1], Nguyen P[1], Mikhail-Gouda P[1], Subhaharan D[1], John S[1]

Institute **1** Gold Coast University Hospital, Southport, Australia

DOI 10.1055/s-0046-1820869

Aims Sessile serrated lesions (SSLs) are premalignant lesions that account for 15-30 % of all colorectal cancers (CRC). A rising incidence of CRC in younger adults has been noted in Australia. The contribution of SSLs in this regard is uncertain. We aimed to evaluate the prevalence and characteristics of SSLs in our population. Specifically, we assessed disease burden in the younger cohort (< 50 years). Data regarding ideal surveillance strategies after initial resection of SSLs is limited. We assessed longitudinal outcomes of patients with at least 1 SSL on index colonoscopy with their follow up findings.

Methods We conducted a retrospective single-centre study of index colonoscopies performed between 2015 and 2021. The analysis included review of electronic medical records and endoscopy reports for patient demographics, number of SSLs, size, location, presence of dysplasia/cancer and serrated polyposis syndrome (SPS). We used these records to subsequently track and analyse follow up colonoscopy findings.

Results Data from 18,728 colonoscopy procedures were collected and analysed. Indications for colonoscopies included screening (49.2 %), surveillance (19.3 %) and symptoms (31.5 %). The prevalence of SSLs was 21.5 % (4029 patients). Overall, 54.4 % of affected patients were female and those aged between 50-75 had the highest prevalence (63.6 %). 20.6 % (830 patients) had advanced SSLs (> 10mm, presence of dysplasia or cancer) on index colonoscopy. 27.2 % of patients with SSLs were young adults (< 50) and females were affected more commonly than males in this subgroup (59.3 %), particularly in those < 40 years (63.5 %).

A large proportion of SSLs (82.5 %) were small (< 10mm) and 69.5 % were in the proximal colon. 58 % (2,339 patients) had a follow-up colonoscopy with a mean follow up time of 2.72 years. 30.7 % had > 1 SSL on follow-up colonoscopy and 20.9 % of these patients had advanced SSLs. Dysplasia was present in 4.1 % of patients on index colonoscopy and more prevalent with larger SSLs (> 10mm) and age > 75. Dysplasia was infrequent on follow-up colonoscopy (3.3 %) and 1 patient developed adenocarcinoma. Patients with dysplasia in the index colonoscopy had a higher risk of dysplastic SSLs (5.20 %) on follow-up compared to those without dysplasia (0.80 %).

Conclusions This study suggests a high prevalence of SSLs in Australia. Young adults (< 50) accounted for 27.2 % of the disease burden. Currently, we offer CRC screening with biennial faecal occult blood tests from the age of 45 years. Thus, a large population at risk may not currently be receiving screening. Aetiological factors and the burden of SSLs in colorectal cancer in young adults require further investigation to develop cost-effective management pathways. Our follow up data analysis, which is ongoing, suggests that those with dysplastic lesions or advanced lesions are more likely to have advanced pathology in subsequent procedures. Further data is required to determine ideal surveillance strategies in the future.

OP215 A study on the relationship between histological malignancy and mucin phenotype in superficial non-ampullary duodenal epithelial tumors and a novel endoscopic diagnosis for predicting mucin phenotype

Authors Nakayama A[1], Mizobe R[2, 3], Katsumi A[2, 3], Kubo Y[2, 3], Ishizawa M[2, 3], Oowada M[2, 3], Imura Y[2, 3], Murata S[2, 3], Miyazaki K[3], Kirita K[1], Masunaga T[1], Mizutani M[3], Akimoto T[1], Takatori Y[3], Kawasaki S[3], Matsuura N[1], Takabayashi K[3], Yahagi N[1], Kato M[3]

Institutes **1** Cancer Center, Keio University, School of Medicine, Tokyo, Japan; **2** Gastroenterology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan; **3** Center for Diagnostic and Therapeutic Endoscopy, Keio University School of Medicine, Tokyo, Japan

DOI 10.1055/s-0046-1820870

Aims In the endoscopic diagnosis of superficial non-ampullary duodenal epithelial tumors (SNADETs), distinguishing cancer from adenoma is not straightforward, unlike with other gastrointestinal tumors. Meanwhile, SNADETs are classified into gastric phenotype and intestinal phenotype as mucin phenotypes, with duodenal cancers with gastric phenotype specifically reported to have poor prognosis. We hypothesized that predicting mucin phenotype based on endoscopic findings could potentially estimate the biological malignancy of SNADETs. Focusing on this as a novel endoscopic diagnostic approach, we conducted the following study.

Methods We prospectively enrolled 500 cases suspected of SNADET at our hospital from August 2018 to April 2021. Among them, we analyzed 401 cases (401 lesions) that underwent endoscopic treatment and received a pathological diagnosis of SNADET. Two pathologists specializing in gastrointestinal pathology performed histological diagnosis using the Vienna Classification (VCL) and evaluated mucin phenotypes via immunostaining (CD10, MUC2, MUC5AC, and MUC6), with endoscopic diagnoses completely blinded. Two expert endoscopists evaluated the lesion location, size, macroscopic type, and presence of erythema using white light imaging. Furthermore, image-enhanced endoscopy with magnifying endoscopy (IEE-ME) were evaluated for superficial structure and white opaque substance (WOS). Superficial structure was classified as closed-loop structure (CLS) or open-loop structure (OLS). CLS was defined as a closed structure resembling the background duodenal villi structure. OLS was defined as a linear or open structure. WOS was classified as present or absent. All endoscopic findings were evaluated completely blinded to the SNADET pathological diagnosis. In this study, gastric phenotype, predominantly gastric phenotype, and mixed phenotype were classified as G-type, while predominantly intestinal phenotype and intestinal phenotype were classified as I-type. Each endoscopic finding was compared between the two types, and multivariate analysis was performed using a logistic regression model.

Results Mucin phenotypes were gastric phenotype in 34 cases, gastric phenotype predominant in 11 cases, mixed phenotype in 18 cases, intestinal phenotype predominant in 158 cases, and intestinal type in 180 cases. The proportions of VCL categories 4/5 were 63.6 %, 54.5 %, 38.9 %, 36.1 %, and 23.9 %, respectively ($P < 0.0001$, Cochran-Armitage trend test). Additionally, VCL C5.2 was observed in 10 cases, 8 of which were gastric phenotype. Compared to I-type, G-type showed higher proportions in location (bulb to the proximal site of descending part: 68.2 % vs 45.3 %, $P < 0.0001$), lesion size (23.3 mm vs 18.6 mm, $P = 0.0226$), macroscopic type (Type 0-I: 49.4 % vs 14.3 %, $P < 0.0001$), erythema (present: 60.3 % vs 32.8 %, $P < 0.0001$), superficial structure (CLS: 76.2 % vs 29.6 %, $P < 0.0001$), and WOS (negative: 44.4 % vs 11.0 %, $P < 0.0001$). Multivariate analysis showed SNADET was associated with superficial structure (CLS: OR 3.6782, 95 % CI 1.8105-7.4725), WOS (negative: OR 3.2691, 95 % CI 1.6232-6.5841), and macroscopic type (Type 0-I: OR 2.5117, 95 % CI 1.2763-4.9429) were independently and significantly associated with being G-type.

Conclusions The higher the proportion of gastric phenotype in SNADET, the higher the proportion of histological malignancy, demonstrating the importance of mucin phenotype in SNADET. Furthermore, this study revealed that SNADET with gastric phenotype, representing a high-risk group, can be predicted based on only endoscopic findings including IEE-ME.

DOI 10.1055/s-0046-1820871

Aims Cold snare polypectomy (CSP) minimizes the risk of adverse events and has become a standard treatment for subcentimeter-sized colorectal polyps. CSP may also be suitable for small superficial non-ampullary duodenal epithelial tumors (SNADETs). We conducted this multicenter single-arm confirmatory trial (D-COP trial) to evaluate the safety and efficacy of CSP for SNADETs (UMIN000030876).

Methods The major indication criteria were endoscopically diagnosed SNADET ≤ 10 mm and ≤ 3 target lesions. Patients with suspected submucosal invasive cancer or familial adenomatous polyposis were excluded. CSP was performed using an electrosurgical snare without electrocautery. Follow-up endoscopy was performed at 3, 12, and 36 months after CSP, and a biopsy from the CSP scar was planned at 12 months regardless of recurrent suspicion. The primary endpoint was the local recurrence rate within 12 months. The estimated sample size was 363 patients, assuming a 12-month local recurrence rate of ≤ 7 %, based on EMR data (3.4 %), with $\alpha = 5$ % and power 80 %.

Results A total of 408 patients (430 lesions) were enrolled from 86 institutions (January 2018–February 2019). CSP was attempted for 413 lesions in 395 patients. The median tumor size was 5 mm (range 2–10 mm). Approximately 84 % of lesions were located in the second part of the duodenum, and the most common macroscopic type was 0-IIa (67 %). Preoperative biopsy was performed in 291 lesions (70 %). Thirty-seven lesions could not be resected by CSP and were removed with electrocautery (9 %), and CSP was discontinued due to arrhythmia in one patient. The en-bloc resection rate was 90 %, and no endoscopic residual tumor was observed after CSP. Bleeding requiring endoscopic hemostasis immediately after CSP occurred in 15 lesions (3.6 %), and delayed bleeding occurred in three cases (0.7 %). All bleeding events were controlled endoscopically without transfusion or surgery. There was no intraoperative or delayed perforation.

Histopathology revealed 349 adenomas, 45 cancers (43 intramucosal, 2 submucosal invasion), and 17 non-neoplastic lesions. Among neoplastic lesions, horizontal margins were negative/positive/undetermined in 242/24/128 lesions, and vertical margins were 343/4/47.

At 3 months, 375 patients (389 lesions) underwent follow-up endoscopy, and four local recurrences were detected; all were completely removed with cold biopsy. At 12 months, 367 patients (381 lesions) underwent follow-up endoscopy, and 11 local recurrences were detected. All were treated endoscopically (7 cold biopsy, 1 CSP, 2 underwater EMR, 1 EMR), and none required surgery. The 12-month local recurrence rate was 3.8 % (95 % CI: 2.11 %–6.33 %), and the upper limit of the 95 % CI was lower than the predefined threshold (6.33 % < 7 %). At 36 months, endoscopic examinations were performed in 89.5 % of patients, and local recurrence was identified in 9 cases. The cumulative local recurrence rate at 3 years after CSP was 5.3 %. Metachronous SNADET lesions were detected in 11 cases (2.9 %) during the 3-year follow-up period.

Conclusions CSP was a safe and effective treatment for subcentimeter SNADETs, with favorable mid-term local control and low adverse event rates.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP217 Endoscopic and Long-term Outcomes of Endoscopic Submucosal Dissection (ESD) for Non-Ampullary Duodenal Neuroendocrine Tumors (NADNETs): a Western Single-Center Retrospective Cohort Study

Authors Tagliamonte G[1], Ravizza D[1], Bravi I[1], Galtieri A[1], Giunta M[1], Maregatti M[1], Soru P[1], Trovato C[1], De Roberto G[1]

Institute 1 Division of Endoscopy, European Institute of Oncology, IRCCS, Milan, Italy

DOI 10.1055/s-0046-1820872

Aims Non-ampullary duodenal neuroendocrine tumors (NADNETs) optimal treatment is still debated1. Data on performance and outcomes of endoscopic submucosal dissection (ESD) is lacking especially in Western countries. We evaluated efficacy, safety and long-term outcomes of ESD to manage NADNETs in an Italian tertiary referral center [1].

Methods Consecutive patients treated with ESD for non-functioning NADNETs between 2012 and 2025 at IRCCS Istituto Europeo di Oncologia of Milan were included. Data was obtained from hospital records and analysed retrospectively. All procedures were performed under general anaesthesia and patients were admitted for post-procedural observation.

Results Overall, 17 NADNETs in 17 patients underwent ESD. Fifteen NADNETs were localized in the duodenal bulb (88 %) and 2 in the second duodenal portion (D2). Median lesions' size was 10 mm (IQR 7-11 mm). Fourteen NADNETs (82 %) were G2and 3 were G1.

All the lesions were resected en bloc, R0 resection was obtained in 7/17 cases (41 %). All R1 resection had positive vertical margins (VM). At histology one lymph-vascular invasion (LVI) was observed (▶ **Table 1**).

Mucosal defect closure was obtained with TTS clips in 16/17 cases (94 %). Median hospital stay after endoscopic treatment was of 4 days (IQR 3-5 days). No cases of intraprocedural bleeding, delayed perforation or delayed bleeding occurred. We observed 3 cases of intraprocedural perforation (18 %). All the defects were closed during the procedure and the patients managed by withholding per os feeding plus intravenous antibiotics for 3 to 5 days (▶ **Table 2**).

At univariate analysis no baseline variables (age, sex, tumor size, location, grade or Ki67) were significantly associated with R1 resection. At univariate analysis a significant association between tumor location in D2 and intraprocedural perforation was observed (OR 48.4, 95 % CI 1.50-1554, p = 0.028). Median hospital stay did differ between patients with (7 days, [IQR 6–8.5]) or without intraprocedural perforation (4 days [IQR 3–4]) (p = 0.003).

Median follow-up time was 56 months (IQR 28-80.5 months). No local nor distant recurrence was observed. No death occurred. We observed only 1 case (6 %) of disease progression. Among the ten patients with R1 resection one patient underwent additional surgical treatment without any residual tumor or lymph node involvement at histological analysis of the surgical specimen. The remaining nine patients underwent follow-up only. No local or distant recurrence occurred in the ten cases of R1 resection.

▶ **Table 1** Results of univariable logistic regression models to assess the association of demographic and clinical variables with resection status (R1 vs R0)

Variable	Level/ Unit	OR (95 % CI)	p value
Age, years	+ 1 Year	1.04 (0.94-1.15)	0.485
Sex, female	Male vs Female	1.67 (0.25-10.99)	0.596
DNET size, mm	+ 1 mm	1.26 (0.88-1.80)	0.204
DNET size group	≥ 10 mm vs ≤ 10 mm	8.14 (0.89-74.77)	0.064
DNET location	D2 vs duodenal bulb	0.68 (0.05-8.11)	0.764
Grade	G2 vs G1	0.78 (0.08-7.57)	0.834
Ki67 index	+ 1 %	1.08 (0.82-1.34)	0.697

▶ **Table 2** Results of univariable logistic regression models to assess the association of demographic and clinical variables with intraprocedural perforation (yes vs no)

Variable	Level/Unit	OR (95 % CI)	p value
Age	+ 1 year	0.81 (0.65-1.01)	0.062
Sex	Male vs Female	0.96 (0.10-9.44)	0.976
DNET size, mm	+ 1 mm	0.93 (0,67-1.28)	0.638
DNET size group	≥ 10 mm vs ≤ 10 mm	0.71 (0.07-7.17)	0.774
DNET location	D2 vs Duodenal bulb	**48.4 (1.5-1554)**	**0.028**
Grade	G1 vs G2	0.33 (0.03-3.81)	0.376
Ki67 index	+ 1 %	1.24 (0.95-1.61)	0.117

Conclusions This study represents the largest European cohort of NADNETs treated by ESD to date. Our experience supports the careful use of ESD for non-functioning NADNETs to achieve en-bloc resection. The technique holds potential risks of AEs that can be managed conservatively. Extra caution is required when approaching lesions in D2.

In our experience R1 resection was not uncommon but it did not affect local or distant recurrence during follow-up. Further studies are needed to determine how to manage patients with R1 resection.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP218 Safety, technical efficacy and long-term clinical outcomes of endoscopic therapy for duodenal Neuroendocrine Tumors (NETs)

Authors Bhagwat S[1], Chandrashekar A[1], Kanani Y[1], Khatri P[1], Yewale R[1], Pujari R[1], Palnitkar S[1], Gadhikar H[1], Bapaye A[1]

Institute 1 Deenanath Mangeshkar Hospital and Research Center, Pune, India

DOI 10.1055/s-0046-1820873

Aims Current recommendations support endoscopic resection (ER) for duodenal submucosal (SM) NETs (d-NETs) measuring < 10 mm without any nodal involvement,however there is no consensus on ER for lesions measuring > 15 mm. With evolving ER & closure techniques, ER can be considered for lesions beyond D1, larger lesions &/or involving the muscularis propria (MP). Oor objective was to evaluate success, techniques, outcomes & recurrence after endotherapy for d-NETs.

Methods Single centre, retrospective analysis of prospectively maintained database – undergoing ER and band ligation and leave (BLnL) strategy for histologically proven d-NETs – 13 years (January 2013 – October 2025). Prior hi-definition EGD, radial EUS & DOTATATE scan. Demography, lesion characteristics, number, resection modality, adverse events (AEs), histology recorded. Treatment protocol – single lesions – ER, multiple – ER for largest lesion followed by BLnL for remaining. Follow-up (F/u) at 1 month (m), 6 m, then annually. Recurrence & its management recorded.

Results N = 80 pts; n = 142 d-NETs, 25 pts (31.25 %) had > 1 lesion; mean age (y) – 59.16 [SD 11.39], Males – 59 (73.75 %). Presentation –– Incidental – 69/80 (86.25 %), GI bleed – 7/80 (8.75 %), diarrhoea– 4/80 (5 %). Macroscopic appearance – Yamada Type I/II – 140/142 (98.5 %) III/IV – 2(1.4 %); Location – D1 -119 (83.8 %); D2 – 22 (15.4 %), D3 – 1 (0.7 %); Mean size (mm) – 11.5 [SD 5.63]; Largest – 50 mm; Size > 15mm – 32/142 (22.5 %) [15-20mm – 16; > 20mm – 16]. EUS – layer of involvement – SM – 120/142 (84.5 %); MP – 12/142 (8.45 %); 10 – too small for EUS evaluation. DOTA positive – 64/80 (80 %).

Index ER – N = 80/80 (100 %), n = 80/142 (56.33 %); ER type – ESD – 54/80 (67.5 %), EMR – 9/80 (11.25 %), freehand EFTR (f-EFTR)– 13/80 (16.25 %), device assisted EFTR (d-EFTR) – 4/80 (5 %). Location wise = D1 = ESD – 50/73 (68.49 %), EMR – 7/73 (9.5 %), f-EFTR 13/73 (17.8 %), d-EFTR- 3/73 (4.1 %); D2 = ESD – 4/6 (66.6 %), EMR 2/6 (33.3 %); D3 = d-EFTR – 1/1 respectively. Primary closure – ESD – 43/54 (79.6 %), no closure – 10/54 (20.3 %); f-EFTR 13/13 (100 %); d-EFTR – 5/5 (100 %). Location wise – D1 – closure = 63/73 (86.3 %), D2 = 6/6 (100 %), D3 = 1/1 (100 %). Closure techniques – D1 = Endoclips – 36, Endoloop + clips – 7, Rotatable over line method (ROLM) – (n = 2), OTSC – 4, Endosuture – 1, Helix tacking system – 2, Advanced TTS clips – 6; D2 = Endoclips – 4, post EMR – No closure. Technical success (TS) – 100 %; AEs – muscle defect during ESD = 7 (primary closure), delayed bleeding = 1 (hemoclip), asymptomatic GB entrapment in d-EFTR clip – 1. Resection – Enbloc = 100 %; R0 – D1 = 56/73 (70 %), D2 – 2 (7.5 %); Histology = WHO G1 = 65/80 (82.5 %), G2 = 14/80 (17.5 %), G3 = 0. 2ndsession – n = 62, D1 = 46, D2 = 16. ER = 14/62 (22.6 %) [D1 = 12/46 (26.1 %), D2 = 2/16 (12.5 %)]; BL&L = 48/62 (77.4 %) [D1 34/46 (73.9 %), D2 = 14/16 (87.5 %)]. ER type – D1 – ESD = 8, hybrid ESD = 2, EMR = 2; D2 – EMR = 2. Primary closure = 7/14 (50 %). Closure techniques – endoclips – 5, endoloop + clips – 1, advanced TTS clips – 1. TS – 100 %; AE – nil. Additional therapy in 1 patient – DOTA + ve periportal LN – EUS RFA. Recurrence/new lesions – 5/80 (6.25 %). Median time to recurrence – 6 m (IQR 5); Surgery = 1, unresectable = 1 – PRRT; ER = 3 – in 2 of 3 = 2nd recurrence – repeat ER = 1, surgery = 1. Mean F/u (m) 6.7 ± 10.5; Max F/u – 60 m. Multivariable regression analysis – no clearly identifiable risk factors for non-R0 resection – non-significant trends for larger lesion size (p-value – 0.6) & MP invasion (p-value – 0.095); Number of lesions, location in D1 or D2, G1/G2 hd no significance. Similarly for recurrence rates – unable to reach statistical significance on multivariable regression analysis due to very low overall recurrence rates.

Conclusions ER for d-NETs using ESD and / or EFTR is safe & effective with high R0 resection rates. Recurrences were rare during long term follow-up & could mostly be treated endoscopically.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP219 Endoscopic full-thickness resection (EFTR) versus endoscopic submucosal dissection (ESD) in the management of duodenal, non-metastatic and non-ampullary neuroendocrine tumours (NETs) sized between 1-2cm: a meta-analysis

Authors Manti M[1], Tsioufis P[2], Kamperidis N[1], Toskas A[1], Laskaratos FM[1], Arebi N[1]

Institutes 1 St Mark's National Bowel Hospital, London, United Kingdom; 2 North Middlesex University Hospital, London, United Kingdom

DOI 10.1055/s-0046-1820874

Aims Duodenal, non-metastatic, non-ampullary neuroendocrine tumours (DNMA-NET) measured between 1-2cm should be referred to tertiary centres for individualised management [1]. The resection techniques may include endoscopic full-thickness resection (EFTR) and endoscopic submucosal dissection (ESD). However, specific guidance on technique efficacy remains limited.

Methods We conducted a literature systematic review and meta-analysis between September 2025-October 2025 of original studies published in English language to compare the technical success rates (primary outcome) of G1-G2, DNMA-NET 1-2cm among PubMed and Cochrane databases. Technical success was defined by complete lesion resection confirmed by inspection. We included studies published after 2014, ensuring both techniques were widely available. The secondary outcomes were: en-block and R0 resection rates, peri-procedural adverse events and recurrence rates at 6 months. R0 resection was confirmed by histopathology. Analysis was performed using the R statistical software and the study followed the PRISMA checklist. The effect size on study outcomes was calculated using random effect model and it is shown as RR (95 %CI).

Results We identified 9 studies (4 including EFTR [2–5] and 5 about ESD [6–10]) with 156 lesions (99 in EFTR and 57 in ESD). 2 EFTR studies used the full-thickness-resection device (FTRD) [4, 5]. No randomised controlled trials were identified. 3 [4, 6, 8] of the studies were multi-centre while the remainder were single-centre. EFTR had a pooled technical success of 93 % (95 % CI, 84–99 %), and ESD had 95 % (95 % CI, 85–100 %). There was no significant difference between groups (p = 0.27), with no heterogeneity detected (I^2 = 0 %). En-block resection rates were similarly high across techniques. EFTR demonstrated a pooled en-bloc rate of 100 % (95 % CI, 77–100 %), while ESD achieved 76 % (95 % CI, 48–97 %). Although the common-effects model suggested a difference (p = 0.02), this was not significant under random-effects (p = 0.18). Heterogeneity within the ESD subgroup was substantial (I^2 = 67.7 %). Pooled R0 resection was 93 % (95 % CI, 87–98 %) for EFTR and 95 % (95 % CI, 85–100 %) for ESD, with no significant subgroup difference (p = 0.27). Heterogeneity was minimal (I^2 = 0 %). Adverse event rates, including perforation and major bleeding, were low overall. EFTR demonstrated a pooled adverse event rate of 1 % (95 % CI, 0–1 %), while ESD showed 3 % (95 % CI, 0–46 %). There was no significant subgroup difference (p = 0.40), though ESD studies displayed moderate heterogeneity (I^2 = 73 %). Recurrence rates at 6 months following resection were similarly low. EFTR recurrence was 0 % (95 % CI, 0–9 %), compared with 10 % (95 % CI, 2–22 %) after ESD. The difference was not statistically significant (p = 0.27), though heterogeneity for ESD was moderate (I^2 = 57 %).

Conclusions EFTR and ESD showed **comparable performance** across all outcomes. R0 resection rates were similarly high (EFTR 93 %, ESD 95 %) with no subgroup difference.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820875

Aims Superficial non-ampullary duodenal epithelial tumors (SNADET) are rare but have been increasingly reported in recent years. Phenotypes of SNADET are classified into gastric-type, intestinal-type, and mixed-type. Among these, gastric-type is less common and remains poorly understood. It is also considered to have a higher histological malignancy, making preoperative diagnosis highly significant. The aim of this study was to clarify the histopathological features of gastric-type SNADETs and to explore the feasibility of endoscopic diagnosis for gastric-type SNADETs using endoscopy.

Methods Cases of gastric-type SNADETs resected endoscopically or surgically at four high-volume centers in Japan between Jan 1997 and Dec 2023 were retrospectively collected. Endoscopic images (white light and magnified-image enhanced endoscopy (M-IEE)) were re-evaluated by four endoscopic specialists at each institution. Histopathological evaluation involved re-performing HE and immunohistochemical staining, with central pathology review. Histological grade was made based on WHO criteria, and immunohistochemical positivity was defined as a staining rate of ≥ 10 %.

Results From the 164 cases, we excluded recurrent lesions, non-neoplastic lesions, lesions with intestinal-type, and cases without M-IEE observation. This left 90 pure gastric-type SNADETs for analysis. The predominant cell type was pyloric-gland type in 50 cases and foveolar type in 40 cases. Histological grade was low-grade adenoma in 33 cases, high-grade adenoma in 49 cases, and carcinoma in 8 cases. Submucosal invasion was observed in 3 cases. The pyloric-gland type showed a higher proportion of males ($P = 0.04$), a greater prevalence of macroscopic type 0-I ($P = 0.03$), and a tendency toward lower nuclear atypia ($P = 0.009$). Conversely, the foveolar type had a higher proportion of macroscopic type 0-IIa ($P = 0.02$) and higher tumor malignancy ($P = 0.04$). Vascular visibility under M-IEE was significantly higher in the foveolar-type ($P = 0.007$). No differences were observed in tumor location or tumor size. However, this study could not identify endoscopic findings predictive of tumor malignancy.

Conclusions It is difficult to diagnose the malignancy grade of gastric-type SNADET based solely on M-IEE endoscopic findings. Establishing new endoscopic diagnostic criteria, including qualitative assessment, is required.

DOI 10.1055/s-0046-1820876

Aims Unresectable Malignant Hilar Biliary Obstruction (UMHBO) requires effective drainage of both liver lobes to reduce recurrent biliary obstruction (RBO). The CERES technique—ERCP for right-sided drainage combined with EUS-guided hepaticogastrostomy (EUS-HGS) for the left duct—may provide more durable drainage than bilateral ERCP alone. This preliminary analysis evaluates early outcomes of the ongoing randomized CERES-BILAT trial (▶ **Table 1**).

▶ **Table 1** Preliminary Outcomes of CERES vs Bilateral ERCP in the CERES-BILAT Randomized Trial

Outcome	CERES (n = 9)	Bilateral ERCP (n = 10)	p-value
Clinical success at 2 weeks (%)	88.9 %	60.0 %	0.153
Total bilirubin at 2–4 weeks (mg/dL)	3.29 (2–8)	3.03 (1–18)	0.129
Procedure time (min)	127.2 ± 61.7	66.3 ± 42.1	**0.021**
Cholangitis (%)	12.5 %	33.3 %	0.466
Stent occlusion (%)	0 %	16.7 %	0.375
6-month RBO (%)	11.1 %	20.0 %	0.466
Time to RBO (days)	60 ± 46.9	35 ± 46.9	0.660
Hospital days	2.4 ± 0.5	4.2 ± 2.3	0.124

Methods Patients with Bismuth III–IV UMHBO were randomized 1:1 to CERES or bilateral ERCP. The primary endpoint is 6-month RBO. Secondary endpoints include technical and clinical success, bilirubin reduction, procedure time, ad-

verse events, time to RBO, and hospital stay. This interim analysis includes 19 patients (CERES n = 9; Bilateral ERCP n = 10)

Results Baseline characteristics were similar between groups. Technical success was 100 % in both arms. Clinical success at 2 weeks was higher with CERES (88.9 % vs 60.0 %; p = 0.153), though not statistically significant. Procedure time was significantly longer in CERES (127.2 ± 61.7 vs 66.3 ± 42.1 min; p = 0.021). Adverse events were infrequent. Cholangitis occurred in 1 CERES patient versus 2 bilateral ERCP patients. Stent occlusion occurred only in the bilateral ERCP group. No severe complications (perforation, bile leak, peritonitis) were observed. RBO occurred later in CERES (mean 60 vs 35 days). Six-month RBO rate was 11.1 % vs 20.0 % (p = 0.466). CERES showed a trend toward shorter hospitalization (2.4 vs 4.2 days)

Conclusions Both CERES and bilateral ERCP demonstrated excellent technical success and acceptable safety. CERES showed favorable trends toward improved clinical success, fewer complications, longer time to RBO, and shorter hospitalization. Although not statistically significant due to limited sample size, these early findings suggest potential clinical advantages of CERES pending full trial completion

DOI 10.1055/s-0046-1820877

Problem to solve Ineffective glucagon-like peptide 1 (GLP-1) signaling within pancreatic islets is a root cause of β-cell dysfunction and a fundamental driver of type 2 diabetes (T2D) pathogenesis and progression. GLP-1 receptor agonists have become cornerstone therapies for the management of metabolic diseases such as T2D. However, their efficacy depends on chronic, supraphysiologic GLP-1 exposure, and systemic tolerability constraints prevent achieving therapeutically effective concentrations in the pancreas. There remains an urgent unmet need for durable, well-tolerated therapies that directly target pancreatic β-cell dysfunction and restore physiologic GLP-1 signaling.

Innovation We have developed a novel endoscopic ultrasound (EUS)-guided delivery system and single-dose adeno-associated virus (AAV) pancreatic gene therapy platform which enables durable, nutrient-responsive incretin production directly from β-cells. The delivery device includes a custom echogenic 27-gauge conical-tip needle with a lateral side port for improved EUS visualization and atraumatic fluid delivery, paired with a pressure-regulated infusion system for controlled administration. AAV9.INS.GLP1, an AAV9 gene therapy for T2D, encodes a human GLP-1 sequence driven by an engineered human insulin promotor to restrict GLP-1 expression to β-cells. We have previously shown in diabetic mice that a single intraperitoneal dose of AAV9.INS.GLP1 can durably improve fasting blood glucose to a greater extent than chronic daily administration of semaglutide. Here, we aim to evaluate the feasibility and safety of the clinical route-of-administration by targeting AAV9.INS.GLP1 directly to the pancreas via EUS-guided delivery in Yucatan pigs.

Results Animals received vehicle (n = 2) or AAV9.INS.GLP1 (n = 6) via EUS-guided intrapancreatic infusion, and histology, systemic markers of tissue toxicity, biodistribution, and transgene expression were evaluated over 6 weeks post-procedure. All procedures were successfully performed. Lipase, amylase, and troponin I levels remained in the normal range with only a transient, mild aspartate aminotransferase (AST) elevation resolving by day 3 post-procedure. AAV9.INS.GLP1 EUS-guided targeting resulted in enriched pancreatic lobe transgene AAV9 transduction, GLP-1 transgene RNA expression and a subsequent 9.5-fold increase in active GLP-1 protein levels (0.19 pg/µg total protein) compared to vehicle controls (0.02 pg/µg total protein). Clinical, laboratory, and histologic evaluation revealed no toxicity findings. Dual pancreatic immunofluorescence analyses confirmed β-cell-restricted GLP-1 expression, with co-localization of GLP-1 and insulin in islets (~5 % insulin$^+$/GLP-1$^+$cells across ~25 % of islets) and no staining in exocrine tissue.

Conclusions These findings demonstrate that AAV9.INS.GLP1 can be safely and reproducibly targeted to the pancreas using a custom EUS-guided delivery system to achieve β-cell-specific GLP-1 expression without local or systemic toxicity. Single-dose GLP-1 pancreatic gene therapy represents a paradigm shift toward a durable, well-tolerated therapy that addresses β-cell dysfunction as a root cause of T2D. A first-in-human trial of AAV9.INS.GLP1 is planned for 2026.

OP223V EUS-guided removal of fishbone: a potentially secure and scalable approach

Authors Hu S[1], Deliang L[1], Liu D[1], Liu B[1]

Institute **1** The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

DOI 10.1055/s-0046-1820878

Abstract Text A 57 years old man presented to our hospital due to abdominal pain. Computed Tomography of the abdomen revealed a linear dense shadow in the gastric antrum region and it extends to the head of the pancreas, with inflammatory exudation in the abdominal cavity, suggestive of a foreign body. After a multidisciplinary consultation, it was decided to perform endoscopic removal of the foreign body.

After the endoscope was inserted, the gastric wall was smooth and no puncture point was observed. Then, Endoscopic ultrasound (EUS) was performed to search the foreign body. Luckly, the foreign body was positioned and marked. Subsequently, the gastric wall was incised with a Dual knife and an IT knife. After thorough irrigation, A fishbone was found and removed. Finally, the incision was tightly closed with clips.

OP224 Impact of a dedicated advanced biliary cannulation course on difficult cannulation strategies – outcomes of a UK-wide advanced cannulation masterclass

Authors Jivanjee S[1], Durkin D[1], Bekkali NL[2], Mahmood S[3], Basavaraju U[4], Mitra V[5], Reed O[6], Brooklyn T[7], Hebbar S[1]

Institutes **1** Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom; **2** John Radcliffe Hospital, Oxford University Hospitals, Oxford, United Kingdom; **3** Manchester University NHS Foundation Trust, Wythenshawe, United Kingdom; **4** Aberdeen Royal Infirmary, Aberdeen, United Kingdom; **5** University Hospital of North Tees, Hardwick Road, Stockton-on-tees, United Kingdom; **6** Southern Health, Belfast, United Kingdom; **7** Gloucestershire hospital, Bath, United Kingdom

DOI 10.1055/s-0046-1820879

Aims Needle-knife fistulotomy (NKF) is an advanced cannulation strategy for difficult biliary access, yet formal training is inconsistent and many ERCPists report low confidence in performing and teaching it. We aimed to describe UK consultant ERCPists' baseline NKF experience, training and teaching confidence, and to evaluate the impact of a national series of advanced biliary cannulation masterclasses on NKF knowledge and intended use within a structured difficult-cannulation algorithm

Methods We delivered ten one-day advanced biliary cannulation masterclasses across the UK for 152 consultant ERCPists. Before the course, delegates completed an online questionnaire on NKF use, prior formal NKF training, and experience and comfort in training trainees (1–10 scale, 1 = not at all comfortable, 10 = very comfortable); NKF knowledge was scored on the same scale.

Each masterclass combined didactic teaching, video-based discussion of varied ampullary morphology and group discussion of escalation pathways when standard cannulation fails. Core sessions covered NKF, double guidewire technique, transpancreatic septotomy and cannulation of papillae in diverticula. Using a stepwise ESGE-based framework, the technical steps of NKF were deconstructed and reinforced with hands-on model training, emphasising when to escalate and how to teach NKF within an algorithmic approach.

After each course, delegates completed a post-course questionnaire capturing retrospective "before" and "after" NKF knowledge scores, intention to use NKF more frequently and to consider primary fistulotomy in selected cases. Self-rated knowledge of double guidewire, transpancreatic septotomy and diverticular cannulation were also collected. Descriptive statistics are reported (▶ **Table 1**).

▶ **Table 1**

Measure	Value
NKF knowledge before course (mean, 1–10)	5.4 (median 5)
NKF knowledge after course (mean, 1–10)	8.6 (median 9)
Will use NKF more often	94.3 % (115/122)
Will consider primary fistulotomy in select cases	79.5 % (97/122)

Results Of the 152 participants, 126 filled out the pre-course and 122 the post-course questionnaire. At baseline, 82.5 % (104/126) had used NKF for ductal access and 42.1 % (53/126) had performed primary fistulotomy; only 33.3 % (42/126) reported prior formal NKF training and 27.0 % (34/126) had ever trained trainees in NKF. Mean NKF knowledge was 5.8/10 (median 6). Comfort training trainees was 3.7/10 (median 3), with 14 % (18/126) rating their comfort ≥ 7/10.

Post-course, mean NKF knowledge increased from 5.4 (median 5) to 8.6 (median 9) (n = 122), a mean gain of + 3.2 points; 84 % (102/122) improved by ≥ 2 points and 66 % (81/122) by ≥ 3 points. Overall, 94.3 % (115/122) stated they would use NKF more often (68.9 % slightly more, 25.4 % significantly more), and 79.5 % (97/122) would consider primary fistulotomy in selected cases. Knowledge scores for double guidewire, transpancreatic septotomy and diverticular cannulation also improved across the series.

Conclusions Among UK consultant ERCPists, NKF is used but formal training and teaching are limited. A national series of ten focused masterclasses, incorporating video-based discussion, model training and an explicit escalation algorithm, was associated with substantial gains in NKF knowledge and a clear shift towards greater and earlier use, including primary fistulotomy in selected cases. Structured, morphology-based training that also reinforces other advanced cannulation strategies may help close the gap between everyday practice and teaching confidence, supporting safer dissemination of advanced biliary access techniques.

OP225 Correlating EUS-guided Portosystemic Pressure Gradient measurement (EUS-PPG) with Shear Wave Elastography (SWE) and liver fibrosis to improve portal hypertension diagnosis

Authors Lariño Noia J[1], Dominguez-Novoa Y[1], Molina-Perez E[1], Vallejo-Senra N[1], Fernández-Castroagudín J[1], Iglesias-Garcia J[1], Nieto-Garcia L[1], Porto-Silva MDS[1], Dominguez-Munoz JE[1]

Institute 1 University Hospital of Santiago. Foundation Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain

DOI 10.1055/s-0046-1820880

Aims Aim of our study was to evaluate the correlation between EUS–guided portosystemic pressure gradient measurement (EUS-PPG) and EUS-guided shear wave elastography (EUS-SWE) with histological liver fibrosis (LF) in patients with suspected clinically significant portal hypertension (CSPH).

Methods This prospective, descriptive, single-centre cohort study included patients with suspected CSPH. Baseline assessment comprised transient elastography of the liver and spleen (FibroScan) and laboratory testing for FIB-4 score calculation. Endoscopic evaluation consisted of upper gastrointestinal endoscopy to assess signs of portal hypertension, followed by EUS using a linear echoendoscope (FujiFilm 740UT) connected to an Arietta-850 ultrasound system, under deep sedation. EUS-SWE was performed and liver stiffness recorded in kilopascals (kPa). EUS-PPG was measured using a standard 22G needle, with the gradient defined as the difference between mean portal venous and hepatic venous pressures. LF was determined histologically after EUS-guided liver biopsy with a 19G needle. The primary outcome was the correlation among EUS-PPG, EUS-SWE, and histological LF. Secondary outcomes included technical success, correlations with other clinical parameters, and adverse events. Correlation analyses were performed using Spearman's test and biserial correlation. Data are reported as mean values and percentages.

Results Nineteen patients were included (mean age 58.9 ± 11.5 years; 17 males, 85 %). Technical success was achieved in 18/19 cases (94.7 %), and no adverse events occurred. Mean PPG was 5.9 ± 4.5 mmHg (range 0–17), mean EUS-SWE was 18.6 ± 9.9 kPa (8.1–40.3), and mean liver FibroScan was 12.4 ± 11.2 kPa (4.1–54.7). Oesophageal varices were detected in 2 patients (10.5 %) and gastric varices in 1 patient (5.3 %). Histological fibrosis (METAVIR) was as follows: F0 (n = 5, 29.4 %), F1 (n = 1, 5.9 %), F2 (n = 1, 5.9 %), F3 (n = 6, 35.3 %), and F4 (n = 4, 23.5 %). Correlation between EUS-PPG and LF, liver FibroScan, and EUS-SWE was 0.548 (p = 0.028), 0.679 (p = 0.003), and 0.288 (p = 0.247), respectively. Correlation between EUS-SWE and liver FibroScan and LF was 0.579 (p = 0.012) and 0.699 (p = 0.002), respectively.

Conclusions EUS-PPG is a safe and feasible technique that correlates well with liver FibroScan and histological fibrosis. EUS-SWE appears to be a promising surrogate marker of liver fibrosis in patients with suspected portal hypertension.

OP226 3D visualization enhances cannulation performance in ERCP simulation among novice trainees – simulator study

Authors Finta A[1], Németh B[1, 2], Göbl J[1], Szalai M[1], Katona M[1], Bélafi D[1], Novák P[3, 1], Tupcsia F[1], Szombath R[1], Maróti Z[1], Sziklási T[1], Tőgl K[1], Madácsy L[1]

Institutes 1 Endo – Kapszula Magánorvosi Centrum, Székesfehérvár, Hungary; 2 Petz Aladár County Teaching Hospital, Győr, Hungary; 3 Kiskun County Hospital, Kecskemét, Hungary

DOI 10.1055/s-0046-1820881

Aims Selective biliary cannulation during ERCP is technically challenging, especially for beginners. Successful cannulation within 15 minutes can significantly reduce the risk of post-ERCP pancreatitis. While 3D visualization is used

in various medical fields, its role in ERCP training is unclear. This study aimed to evaluate the effect of 3D technology on cannulation performance and learning curve in novice endoscopists.

Methods Forty physicians without ERCP experience were enrolled: 20 gastroenterologists (with gastroscopy and colonoscopy experience) and 20 surgeons (with laparoscopic experience). Participants were randomized to 2D or 3D groups (wearing 3D glasses and using 3D processor, Medicaltek Taiwan) and performed biliary cannulation on ERCP simulator with haptic feedback (Accutouch, USA) replicating six different Vater papilla morphologies. Experts positioned the duodenoscope with the papilla in an en face view before each attempt. Time to successful cannulation was recorded across several trials per participant, with a limit of 15 mins. Five ERCP experts also tested the model under both conditions and provided subjective feedback.

Results Participants trained with 3D visualization demonstrated significantly faster skill acquisition compared with the 2D group. The 3D group reached the 90 % competency threshold by attempts 5–6, whereas the 2D group achieved this level only around attempts 9–10, with several participants failing to reach full competency within the training window. Individual learning-curve plots showed lower variance and a steeper improvement trajectory in the 3D group, also greater heterogenity and slower progression in the 2D group, indicating a higher cognitive load and less efficient depth perception during micro-manipulation tasks.

Conclusions This is the first randomised study to show that 3D visualization improves biliary cannulation performance and accelerates learning in novice ERCP trainees. Given its accessibility, 3D technology may be a valuable tool in early endoscopic training especially in difficult endoscopy procedures, such as ERCP or ESD. Further studies are warranted to evaluate its potential to improve real-life ERCP cannulation outcomes and reduce complication rates.

DOI 10.1055/s-0046-1820882

Aims Although ESD is preferred for rectal adenomatous lesions larger than 20 mm, there is less agreement related similar lesions located in the colon. There is current inconsistent evidence coming from both Eastern and Western centres, with different rates of submucosal invasive cancer (SMIC) in the colon and the rectum, with studies based on pEMR reporting lower rates especially in the right colon (5 %), and studies based on ESD reporting higher rates (8-27 %) [1–5]. We set up a European multicenter retrospective study to assess the prevalence of SMIC and high-grade dysplasia (HGD) in a cohort of colorectal LST treated by ESD.

Methods European centers were invited to fill in a database of consecutive patients. Clinical variables related to patients and procedures as well as the center's resection strategy for colorectal LST dissection (selective or universal colorectal ESD) were recorded. The prevalence of HGD and SMIC in the left colon (LC – splenic flexure to sigmoid) and right colon (RC – caecum to transverse colon) and rectum (RE) were recorded, and a logistic regression analysis was performed to test the data.

Results 19 European centers provided data on 3321 lesions, 824 in the RC, 496 in the LC and 2001 in RE. 1055 lesions were resected with an universal colorectal ESD approach, 2063 with a universal rectal – selective ESD colon approach, 205 with a selective colorectal ESD approach. There were statistically significant differences in the case mix of RC, LC and RE, with smaller lesions in the RC and LC when compared to RE (RC 40.8mm ± 16.4; LC 40.5mm ± 18.6; RE 51.3 ± 28.2mm $p < 0.001$). RE had higher prevalence of LST-G-M (57.0 %; RC 38.2 %; LC 35.7 %, $p < 0.001$). LST-NG-FE and LST-NG-PD prevalence was higher in the colon (respectively, RC 21.1 %; LC 17.1 %; RE 5.6 %, $p < 0.001$; RC 15.0 %, LC 14.1 %, vs RE 4.2 % $p < 0.001$). Sessile lesions were more common in LC (16.1 %) and RE (16.8 %) than RC (6.9 %, $p < 0.001$). The LC and RE had higher prevalence of SMIC when compared to the RC (RC 11.6 %; LC 22.4 %; RE 19.8 % $p \leq 0.001$). A multivariate analysis was carried out on the overall cohort and separately on the RC, LC and RE cohorts to find risk factors associated with SMIC (variables considered: age, gender, dimensions, resection strategy, nodular component, morphology – LST classification). On the overall cohort, right colon location and morphology LST-G-H are protective factors against the risk of SMIC. In RC, LST-G-M and LST-NG-PD are risks factor for SMIC. In LC, LST-NG-PD, sessile and semipeduncolated lesions are risk factors for SMIC. Male gender and morphology other than LST-G-H (a part semi-peduncolated) were risks factor for increased SMIC in RE.

Conclusions Our current data suggest that ESD could be potentially adopted as universal strategy in the left colon and rectum, a selection strategy is advised on the right colon to achieve cost-effectiveness. Different odds ratio are associated with polyp morphology depending on the location. Right colon is a protective factor against the risk of SMIC, whereas left colon has similar rates to rectum.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820883

Aims The primary objective of the "intERsection" trial is to evaluate the need for surgery by comparing endoscopic submucosal dissection (ESD) and endoscopic mucosal resection (EMR) for laterally spreading colorectal lesions (LST) without signs suggestive of deep submucosal invasion. This analysis presents the histological and clinical outcomes during the first 30 days after the procedure.

Methods Multicenter, prospective, randomized non-inferiority clinical trial including LST-Non Granular Flat-Elevated lesions ≥ 20 mm and LST-G Mixed-type lesions ≥ 30 mm without signs suggestive of deep submucosal invasion. A non-inferiority margin of < 5 % excess surgeries for ESD versus EMR was established.

Results A total of 277 patients were considered eligible between December 2020 and February 2025. 47 patients had screening failures or met exclusion criteria. Ultimately, 121 patients (50.4 %) were randomized to ESD and 119 (49.6 %) to EMR.

In the ITT analysis, en-bloc resection rates were 76.7 % in the ESD group vs 17 % in the EMR group; RR 4.27 (95 % CI 2.86 – 6.38; p < 0.001). Conversion from ESD to EMR occurred in 21.5 % of cases vs 6 % conversions from EMR to ESD; RR 3.32 (95 % CI 1.57 – 7; p < 0.001). Among all included lesions, only 4.2 % showed submucosal invasion, with no histological differences between groups. Delayed bleeding was more frequent in the EMR group: 16 % vs 4 %; RR 4.67 (95 % CI 1.64 – 13.31; p < 0.001). Intraprocedural perforation was higher in the ESD arm: 13.3 % vs 3.3 %; RR 3.93 (95 % CI 1.35 – 11.42; p = 0.009), with no differences in delayed perforation (2.5 % in ESD vs 0 % in EMR; RR 6.03 [95 % CI 0.31 – 118.99; p = 0.08]).

The need for surgery for any cause was 4.1 % (5 out of 121) in the ESD group vs 0 % (0 out of 119) in the EMR group; therefore, so far, non-inferiority of ESD cannot be concluded (Δ = 4.1 %; 95 % CI -3.09 % – 11.00 %).

Conclusions For the moment, we cannot conclude that ESD is non-inferior to EMR regarding the need for surgery for any cause at 30 days after the procedure. ESD achieves a higher rate of en-bloc resection at the cost of a higher intraprocedural perforation rate and a trend towards increased need for surgery due to complications, while EMR was associated with a higher frequency of delayed bleeding.

DOI 10.1055/s-0046-1820884

Aims Early rectal cancers with features suggesting deep submucosal invasion pose a therapeutic dilemma: radical surgery provides oncologic safety but at the cost of organ loss and substantial functional impairment. Endoscopic intermuscular dissection (EID) offers a deeper plane of resection while preserving rectal wall integrity and may expand organ-preserving treatment options. However, real-world data on its effectiveness and safety remain limited, particularly outside of the Netherlands. This study provides the first multicenter Polish analysis of outcomes following EID for early rectal cancer [1].

Methods This retrospective multicenter cohort study included consecutive patients treated with EID for rectal invasive cancer across three tertiary centers in Poland. All procedures with at least partial, intentional EID performed between 2022 and 2025 were reviewed. Demographic characteristics, lesion features, procedural data, and histopathology were collected.Primary outcomes were technical success, R0 resection, and curative resection. Technical success was defined as successful intermuscular dissection with en-bloc resection. Curative resection was defined as R0 resection without histopathological high-risk features for lymph node metastasis (excluding sm2 and sm3 invasion).

Results Sixty-eight patients (mean age 66.4 years; 52.9 % men) with 68 lesions were included. Median lesion size was 34 mm (IQR 20–40 mm), and the mean distance from the dentate line was 49 mm. Paris classification types were sessile (Is) in 33 lesions (48.5 %), depressed (IIc/IIs) in 32 (47.0 %), and flat/elevated (IIa/IIb) in 3 (4.4 %). JNET classification was 2B in 43 lesions (63.2 %) and 3 in 19 (27.9 %); and 6 unclassified. Ulceration was present in 20 lesions (29.4 %). Mean procedure time was 54 minutes; defect closure was performed in 27 patients (39.7 %). Technical success was reached in 65 of 68 cases (95.6 %; 95 %

CI 88.8–98.4). An R0 resection was achieved in 59 patients (86.8 %; 95 % CI 76.9–92.9). Final pathology showed T1 cancer in 46 patients (67.6 %), T2 in 19 (27.9 %), and T3 in 3 (4.4 %). Histological high-risk features included lymphovascular invasion in 12 patients (17.6 %), high tumor budding in 7 (10.3 %), and poor differentiation in 1 (1.5 %). Overall, curative resection criteria were met in 39 (57.4 %; 95 % CI 45.2–69.0). Adverse events occurred in 8 patients (11.8 %; 95 % CI 6.1–21.5 %), with the highest severity graded Clavien–Dindo IV.

Outcomes by T stage

In T1 cancers (n = 46), R0 resection was achieved in 45 patients (97.8 %) and curative resection in 39 patients (57.4 %; 95 % CI 45.2–69.0). In T2 cancers (n = 19), R0 resection was achieved in 14 patients (73.7 %). Potential curative resection in T2 cancers defined as R0 resection without additional high-risk histological features (excluding depth of invasion) was achieved in 10 patients (52.6 %).

Conclusions EID achieves high technical and curative resection rates in early rectal cancer and expands the potential for organ-sparing, multimodal strategies in higher-risk cases.

Aims Colorectal endoscopic submucosal dissection (ESD) is widely established in Eastern countries, whereas its diffusion in Western settings has been slower, partly due to concerns regarding feasibility, safety, and reproducibility [1–4]. This study aimed to assess real-world outcomes of colorectal ESD performed in high-expertise European centers and to compare these results with existing Asian and Western data.

Methods This retrospective multicenter study included consecutive patients undergoing colorectal ESD in 19 European referral centers (2010–2025). Demographic, procedural, and histopathological variables were collected. Outcomes (en bloc, R0, perforation, bleeding, delayed bleeding, delayed perforation, surgery for complication) were analyzed and compared with available Asian and Western literature (chi-square test) [5, 6].

Results A total of 3504 colorectal ESDs were analyzed. Median age was 69 years (Male 57.2 %;Female 42.8 %), and median lesion size was 40 mm. Median procedure time was 100 minutes, and CO_2 was used in 90.2 % of procedures. Overall procedural success was 89.6 %, with en-bloc resection in 89.1 % and R0 resection in 77.4 %. The overall complication rate was 9.13 % (perforation 4.25 %, bleeding 2.57 %, delayed bleeding 2.05 %, delayed perforation 0.46 %); surgery for complications was required in only 0.43 %.Compared with recent Western data (Singh 2023) [2], en bloc resection rates (89.1 % vs 84.6 %) were significantly higher in our cohort ($p < 0.001$), while perforation (4.25 vs 5.5 %), bleeding (2.57 % vs 4.1 %), and need for surgery due to complications (0.43 % vs 1.8 %) were significantly lower ($p < 0.01$). These findings indicate a substantial improvement over previously reported Western performance, approaching outcomes observed in Asian cohorts, although intraprocedural bleeding and perforation remained higher than in Kobayashi et al. (0.7 % and 2.6 %) [3, 4]. Differences in adverse-event definitions across studies must, however, be acknowledged. Importantly, the need for surgery due to complications in our series was comparable to that reported in Asian cohorts (0.43 % vs 0.5 %/0.8 %). En bloc resection rates in our study were significantly lower than the highest rates reported in the large Japanese cohort by Kobayashi (96.9 %) and in the Asian reference series by Fuccio (93 %) ($p < 0.001$) [3, 4]. R0 resection rates remained significantly lower than those reported by Fuccio (85.6 %; $p < 0.001$) but did not significantly differ from those in the Kobayashi cohort (77.4 %; $p = 0.21$), while still aligning with the upper range of previously published Western outcomes (77 %) [2].

Conclusions In high-volume European centers, colorectal ESD now achieves safety outcomes comparable to leading Asian series, with a markedly lower need for surgery than previously reported in Western cohorts. R0 resection rates mirror those of the large Japanese Kobayashi cohort, though en bloc rates remain slightly lower than long-established Asian programs. These results support wider European adoption of colorectal ESD, alongside continued development of structured training pathways. Prospective studies are needed to standardize outcome measures and enable robust international comparisons.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820886

Aims Recurrent rectal lesions pose a significant therapeutic challenge due to scarring and local fibrosis. These changes often necessitate endoscopic dissection at a deeper level than the submucosa to achieve complete resection. This study aims to assess whether the depth of resection for recurrent rectal lesions is dependent on the type of index therapy (endoscopic vs. surgical) and the technical success of endoscopic therapy for recurrent lesions according to the depth of resection.

Methods This multicentre retrospective study included 199 rectal recurrent lesions from eight UK centres. The primary outcome was comparison of the deepest resection level between previous endoscopic therapy (P-E) and previous transanal surgery (P-S) cases. Secondary outcomes included technical success (R0 rate), adverse events and recurrence rates according to resection depth and technique (knife assisted-EMR, ESD, and deeper dissection: intermuscular**,** subserosa and full thickness resection).

Results Out of the 199 cases, 133 cases (67 %) had P-E and 61 (31 %) P-S; data was not available for five cases. Deep dissection was required in 36 % of P-S recurrences compared with 20 % of P-E recurrences (**p = 0.04**). (▶ **Table 1**)

▶ **Table 1**

Depth of Dissection	P-E (n = 118)	P-S (n = 45)	Total
Submucosal dissection	94 (80 %)	29 (64 %)	123
Deeper dissection – total	24 (20 %)	16 (36 %)	40
• *Intermuscular*	*20*	*9*	*29*
• *Subserosa*	*0*	*1*	*1*
• *Full thickness*	*4*	*6*	*10*
Total (available data)	**118**	**45**	**163**

p = .04

Lesions were treated with Hybrid (n = 31, mean lesion size 58.8mm, IQR = 30 – 70), ESD (n = 96, 40.2mm, IQR 21- 50) or Deeper dissection (n = 41, 52.3mm, IQR 38 – 70).

R0 resection was achieved in 66 % of ESD cases and 83 % of deeper dissections. Only 2 knife-assisted EMR resections (4 %) were R0; the remaining cases were either Rx (85 %) or R1 (11 %).

Among the 141 patients with follow up data, recurrence was observed in 16/47 (34 %) knife assisted-EMR cases, 5/69 (6 %) ESD and 2/25 (8 %) deeper dissection group.

Adverse events were rare and included two cases (4.9 %) of post polypectomy syndrome (PPS), both in the deeper dissection group, and five (4.7 %) post polypectomy bleeding (PPB) cases, all post ESD.

Conclusions The recurrences from prior transanal surgery were significantly associated with the need for deeper dissection when compared with prior endoscopic therapy. Resections extending beyond the intermuscular level were associated with higher R0 rates, suggesting potential benefit in selected recurrent cases with significant fibrosis. All knife-based endoscopic approaches were safe treatment options**;** however, ESD and Deeper dissection achieved superior clearance of rectal recurrences, while knife-assisted EMR was associated with the highest recurrence rate.

Aims The extent of variation between endoscopists and its impact on recurrence remains poorly defined. We aimed to quantify endoscopist-level variation in EMR recurrence and to identify endoscopist characteristics associated with this variation (▶ **Table 1**).

Endoscopy 2026; 58: S1–S1041

▶ **Table 1**

Risk factor	OR	95 % CI
Endoscopist recurrence rate		
Q4 (highest) vs Q1 (lowest)	3.05	2.05-4.53
Polyp		
Size ≥ 40 mm (vs 20-39 mm)	2.24	1.66-3.02
Procedure		
Cold (vs hot EMR)	2.17	1.57-2.99
Margin ablation (no/incomplete vs complete)	1.99	1.44-2.75
Intraprocedural bleeding (yes vs no)	1.59	1.06-2.37
Submucosal lift (no/partial vs complete)	1.54	1.10-2.15

Methods We analyzed data from three prospective studies enrolling patients who underwent EMR of ≥ 20-mm non-pedunculated colorectal polyps and subsequently completed at least one surveillance colonoscopy with identification of the resection site. Participating endoscopists completed a structured survey describing their resection practices and experience. The primary outcome was residual or recurrent neoplasia at first surveillance colonoscopy (hereafter termed recurrence). Endoscopist-specific recurrence rates were estimated using shrinkage-adjusted predictions from mixed-effects multivariable logistic regression models, incorporating endoscopist case volume and adjusting for polyp complexity and procedural factors (including size, histology, intraprocedural bleeding, and resection technique).

Results A total of 1,629 patients with 1,718 large polyps met the inclusion criteria. EMR was performed by 79 endoscopists, with corresponding survey data available for 1,450 EMRs (84.4 %). Among endoscopists performing at least 20 EMRs, crude recurrence rates varied widely from 0 % to 38.3 % (Figure 1). After shrinkage adjustment, endoscopist-level incomplete resection rates ranged from 7.5 % to 35.9 % across all EMRs. Recurrence was nearly three-fold higher among endoscopists in the highest versus lowest recurrence quartile (odds ratio [OR] 2.99, 95 % confidence interval [CI] 2.01–4.45), an effect that exceeded the magnitude of association observed for large polyp size (≥ 40 mm; OR 1.99) or resection method (cold vs hot EMR; OR 2.06, 95 % CI 1.63–2.61), the next two strongest predictors. Differences across endoscopist quartiles were more pronounced for cold EMR than for hot EMR (OR 3.40, 95 % CI 2.11–5.49 vs OR 4.59, 95 % CI 1.84–11.41). In contrast, years since training, advanced endoscopy training, lifetime colonoscopy volume, and EMR volume (hot or cold) were not associated with recurrence after EMR.

Conclusions This first formal assessment of endoscopist effects on recurrence after large polyp EMR demonstrates substantial variation across endoscopists. The effect of variation on recurrence was greater than traditional polyp or procedure risk factors, including polyp size and resection technique (cold vs hot EMR). Prior training or procedural volume was not associated with this variation, highlighting operator skill as a critical determinant of EMR quality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP233 Implementation of ESGE Recommendations on Margin Thermal Ablation After EMR: Preliminary results from the TABLE Multicentre Real-World Study

Aims Margin thermal ablation (MTA) following endoscopic mucosal resection (EMR) of large non-pedunculated colorectal lesions has been shown to markedly reduce recurrence in studies conducted in tertiary referral centres after dedicated training in the ablation technique, and is now recommended by ESGE (2024). However, data on real-life implementation across centres with variable case volumes and expertise, including referral units, are limited. This study aimed to evaluate the feasibility, safety and early outcomes of MTA in a multicentre routine-practice setting.

Methods This was a prospective multicentre observational study conducted across 14 Italian endoscopy units performing therapeutic colonoscopy. Consecutive patients undergoing EMR for colorectal lesions ≥ 20 mm were included. Demographic, lesion and procedural characteristics, completeness of MTA, and peri- and post-procedural adverse events were collected. Surveillance was planned according to European guidelines and local recurrence was assessed endoscopically. The primary endpoint was the feasibility of MTA in routine practice, while secondary endpoints included local recurrence and the occurrence of adverse events.

Results A total of 498 patients with 517 lesions were included (mean age 70.0 ± 10.4 years; 54.9 % male). Most lesions were proximal (76.1 %) and classified as level 3–4, according to the Size–Morphology–Site–Access scoring system (SMSA).Piecemeal EMR was performed in 80.1 % of cases, yielding 98.2 % of complete resections, while en-bloc resection was achieved in 19.9 %. Overall, MTA was applied in 66.9 % of lesions, including 50 %, 72.6 %, and 96.2 % of en-bloc, piecemeal, and complete piecemeal EMR, respectively. Complete MTA was achieved in 91.4 % of complete piecemeal resections. Adverse events occurred in 12.4 % (intraprocedural bleeding 8.9 %, intraprocedural perforation 1.0 %, delayed bleeding 2.3 %, delayed perforation 0.2 %), consistent with expected EMR risks. Follow-up was available for 332 lesions (64.2 %). Overall recurrence was 15.7 %, with substantial inter-centre heterogeneity (0–35 %). Recurrence after complete piecemeal EMR with complete MTA was 14.5 % (0–24.2 % across centres) versus 26.4 % (0–45.5 %) following incomplete or omitted MTA (p = 0.02). Incomplete/omitted MTA was more frequent in SMSA 4, lesions ≥ 40 mm, and proximal locations [1–4].

Conclusions MTA was feasible and widely adopted across centres with different procedural volumes and expertise. Nonetheless, its effectiveness varied according to lesion complexity. The marked inter-centre heterogeneity in both adoption and outcomes highlights the impact of operator experience and local workflows, reinforcing the need for harmonised protocols, competency-based training and standardised ablation techniques to ensure consistent performance and optimise recurrence reduction across different practice settings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820889

Aims Endoscopic Mucosal Resection (EMR) is established as the standard of care for large (> = 20mm) nonpedunculated colonic polyps. However, similar lesions in the rectum are at greater risk of submucosal invasive cancer. Therefore selective use of Endoscopic Submucosal Dissection (ESD) to achieve en bloc resection offers therapeutic advantages in the management of large (> = 20mm) Non-Pedunculated Rectal Polyps (LNPRPs) A rectum-specific selective resection algorithm (SRA) has been proposed as a means of achieving cure of early cancer, but multicentre data is absent. We evaluated the effectiveness of an SRA for LNPRPs in a large, multinational, prospective cohort (▶ **Table 1**).

▶ **Table 1** Oncological outcomes

	EMR (n = 7)	ESD (n = 52)	P Value
SMIC	7	52	< 0.001
No high risk features	2	10	0.622
En bloc resection	4	44	0.071
R0 resection	4	36	0.415

Table 4: Values are nLesions with no high risk features determined eligible for endoscopic cure

Methods LNPRPs at four tertiary centres were enrolled over 44 months. LNPRPs with endoscopic features of SMIC [Kudo pit pattern Vi; JNET 2B], or increased risk of covert SMIC based on morphology [Paris 0-Is or 0-IIa + Is nongranular, 0-IIa + Is granular with a dominant nodule ≥ 10 mm] underwent ESD. Remaining LNPRPs underwent EMR. Outcomes included en bloc with R0 resection rates for SMIC, detection of SMIC following EMR, and adverse events.
Results A total of 404 LNPRPs (median size 40 mm IQR 30-50mm) were referred: 234 (58 %) underwent ESD, 166 (41 %) EMR, and 4 (1 %) were referred directly to surgery. ESD and EMR cohorts were comparable for patient age and comorbidity and lesion size. No significant adverse events occurred.
In the ESD group, en bloc resection was achieved in 221 (94 %) cases. Rates of SMIC (22.2 % vs 4.2 %, p < 0.001) and high-grade dysplasia (49.1 % vs 28.3 %, p < 0.001) were significantly higher in the ESD group. Among LNPRPs with low-risk SMIC treated by ESD, 100 % were cured. Two of seven SMIC in the EMR group were low risk and were removed en bloc with R0 resection.
Conclusions In a multicentre setting, a rectum specific SRA based upon optical evaluation effectively identified high-risk lesions requiring ESD, without resulting in overtreatment of benign lesions. Among polyps with SMIC, 20 % were low-risk and amenable to cure by endoscopic resection. All low-risk cases in this cohort were removed en bloc with R0 resection.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP235 Advances in colorectal endoscopic resection have altered incidence and risk factors for recurrence: a comparative study over two time periods

Authors Ayubi H[1], Eqbal A[1], Olaolu O[1], Judge C[1], Noreillie MA[1], Lim A[1], Campion J[1], Thrumurthy S[1], Gulati S[1], Hayee B[1], Haji A[1], Emmanuel A[1]
Institute **1** King's College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1820890

Aims EMR remains the primary therapeutic option for LNPCP in western practice, but new procedures and techniques are increasingly employed. Large published series previously defined expected rates of, and risk factors for, residual/recurrent adenoma after endoscopic resection (ER). However, these may no longer be relevant. We aimed to identify independent risk factors for recurrent/residual adenoma in a contemporary cohort of LNPCP treated by ER compared to a historical cohort.
Methods Patients with LNPCP treated by ER at a tertiary referral centre between January 2011 and September 2023 who had completed 6 month surveillance (SC1) were included. Patients were divided into contemporary (January 2018 – September 2023) and historical (January 2011 – December 2017) cohorts. Post-ER scars were examined using with magnification chromoendoscopy and NBI/BLI. Clinicopathological features significantly associated with recurrent/residual adenoma on univariate analysis were subjected to multiple logistic regression to identify independent risk factors.
Results 1517 ER were performed over the study period of which 946 met the inclusion criteria and had undergone SC1: 483 in the contemporary cohort and 463 in the historical cohort. In the contemporary cohort 313 (65 %) were treated using ESD compared to 117 (25 %) in the historical cohort (p < 0.001). En bloc resection was more frequently achieved in the contemporary cohort compared to the historical cohort (70 % *versus* 33 %, p < 0.001). Recurrent/residual adenoma at SC1 was detected in 2.5 % in the contemporary cohort compared to 8.9 % in the historical cohort (p < 0.001). For the historical cohort, multivariate analysis revealed that previous failed attempt at resection (OR 2.80, 95 % CI 1.14-6.88, p = 0.25); piecemeal resection (OR 5.21, 95 % CI 1.18-23.02, p = 0.03) and involvement of > 75 % of the circumference of the lumen (OR 5.80, 95 % CI 2.07-16.25, p < 0.001) were independently associated with recurrent/residual adenoma: However, for the contemporary cohort, only difficult access to the lesion (OR 4.24, 95 % CI 1.21-14.78) was independently associated with recurrent residual adenoma at SC1.
Conclusions Significant changes have taken place in ER practice over the last decade. This study demonstrates this has led to a marked alteration in previously established expected outcomes and risk factors for recurrence. Furthermore, the increasing use of adjunctive measures and techniques such as ESD throughout the colorectum may help drive down recurrence rates with the advantage of producing high quality histopathological specimens and accurate diagnosis, leading to a reduction in surveillance requirements. These data should help define performance standards for advanced resection units as well as guide informed consent and decision making for patients.

OP236 Risk factors for delayed perforation or sepsis following endoscopic resection of large non pedunculated colorectal polyps

Authors Ayubi H[1], Judge C[1], Olaolu O[1], Eqbal A[1], Lim A[1], Campion J[1], Adeyeye A[1], Thrumurthy S[1], Gulati S[1], Hayee B[1], Haji A[1], Emmanuel A[1]
Institute 1 King's College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1820891

Aims The safety and efficacy of endoscopic resection (ER) as a first-line treatment for large non-pedunculated colorectal polyps (LNPCP) is well established. Significant complications are infrequent. Risk factors for immediate perforation have been described although it is frequently amenable to endoscopic closure and rarely results in significant deleterious sequelae. Delayed perforation or sepsis is a rare complication with potentially devastating consequences. Emergent surgery may be necessary with its attendant major complications. Risk factors for delayed perforation/sepsis after ER of LNPCP are not well established. We analysed a large series of advanced ER of LNPCP to identify factors associated with delayed perforation.

Methods Consecutive patients with LNPCP treated by ER at a tertiary referral centre between September 2011 and September 2023 were included. Lesions were resected using EMR, piecemeal EMR and ESD. Univariate analysis was used to examine clinicopathological factors potentially associated with delayed perforation.

Results 1883 ER for LNPCP were performed over the study period with a mean size of 46.4mm + /- 26.4mm (median 40mm, range 20-210mm). ESD was used for 890. Delayed perforation or sepsis occurred in 24 (1.3 %) patients of which 8 (0.4 %) required emergent surgery and 1 required CT guided drainage of an abscess. 3 patients developed sepsis after ESD of rectal lesions without evidence of perforation on CT with luminal contrast and required intensive care unit (ICU) management. There was no mortality. In patients who suffered a delayed perforation or sepsis, 54 % of LNPCP were in the right colon, 8 % in the left colon and 38 % in the rectum. Delayed perforation/sepsis was significantly associated with extreme size (OR 3.02, 95 % CI 1.35-6.76, $p < 0.001$); difficult access (OR 2.63, 95 % CI 1.16-5.97, $p = 0.02$); ESD (OR 4.08, 95 % CI 1.52-10.98, $p = 0.003$) and long procedure time over 240 min (OR 5.20, 95 % CI 2.02-13.36, $p < 0.001$) but not location, F2 fibrosis, or age.

Conclusions Delayed perforation/sepsis after ER of LNPCP is rare, and a requirement for surgery extremely rare, but varies according to lesion and procedure characteristics. The consequences can be severe and include surgery, guided drainage or ICU admission. Delayed perforation/sepsis can affect patients with LNPCP in any location including the rectum. Given the risk factors identified in this study, these data could help realistically counsel patients with LNPCP of extreme size, difficult access and requiring complex prolonged procedures regarding the risks of delayed perforation and sepsis.

DOI 10.1055/s-0046-1820892

Aims Few studies have evaluated quality-of-life outcomes in patients undergoing endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR) for laterally spreading colorectal lesions (LST). We aim to compare quality of life before and after the procedure, and to assess differences in outcomes between the two techniques.

Methods Multicenter, prospective, randomized non-inferiority clinical trial included LST-Non Granular Flat-Elevated lesions ≥ 20 mm and LST-Granular mixed-type lesions ≥ 30 mm without signs of deep submucosal invasion. Quality-of-life assessment was performed using the EQ-5D questionnaire before the procedure and 30 days afterwards.

Results A total of 277 patients were considered eligible between December 2020 and February 2025. Screening failures or exclusion criteria applied in 47 patients. Ultimately, 121 patients (50.4 %) were randomized to ESD and 119 (49.6 %) to EMR. Both EQ-5D questionnaires were completed by 224 patients: 111 in the ESD arm and 113 in the EMR arm.

Overall, no statistically significant differences were observed in mobility ($Z = -0.94$; $p = 0.346$), self-care ($Z = -1.667$; $p = 0.09$), usual activities ($Z = -1.291$; $p = 0.297$), pain/discomfort ($Z = -1.177$; $p = 0.239$), or anxiety/depression ($Z = -0.943$; $p = 0.34$). However, the global visual analogue scale showed a significant improvement at 30 days following either procedure ($Z = -1.63$; 95 % CI −3.1 to −2.42; $p < 0.01$).

When comparing techniques (ESD n = 111 vs EMR n = 113), no significant differences were found in mobility ($Z = -0.004$; $p = 0.99$), self-care ($Z = -0.99$; $p = 0.32$), pain ($Z = -1.04$; $p = 0.29$), anxiety/depression ($Z = -1.264$; $p = 0.206$), or in the change in visual analogue scale scores (ESD: + 1.61 vs EMR: + 1.75; 95 % CI −3.02 to + 2.75; $p = 0.462$). The only significant difference was observed in the perception of usual activities, which improved more in the EMR group ($Z = -2.307$; $p = 0.021$).

Conclusions Overall, patients showed improvement in the global visual analogue scale 30 days after either procedure. Between techniques, patients in the EMR arm experienced a significantly greater improvement in their perception of usual daily activities.

DOI 10.1055/s-0046-1820893

Aims Endoscopic Ultrasound-Directed Transgastric ERCP (EDGE) has emerged as a minimally invasive alternative for patients with Roux-en-Y gastric bypass (RYGB) anatomy who require biliary or pancreatic intervention. EDGE procedure consists of EUS-guided gastrogastromy or jejunogastromy creation (step 1) followed by transgastric ERCP (step 2). The two steps can be performed during the same or separate endoscopic sessions. Single-session EDGE allows for expedited therapeutic treatment and reduces resource utilization but risks perforation with dislodgement of lumen apposing metal stent (LAMS). Here we describe our single center experience of performing single session EDGE with fixation.

Methods This is a single center retrospective study of patients with RYGB anatomy who underwent EDGE procedure at the University of California Irvine from March 2021 to November 2025. The primary outcome was stent migration. Secondary outcomes included technical and clinical success of procedure, rate of adverse events, size of LAMS, indwelling stent duration and choice of LAMS fixation.

Results A total of 37 patients (81.1 % female) were identified with RYGB anatomy who underwent EDGE procedure between 2021 to 2025. Indications for EDGE procedure included stone disease (n = 25, 67.5 %), malignancy (n = 8, 21.6 %) or bile leak (n = 4, 10.8 %). Single-session EDGE procedure was performed in 31 (83.7 %) of patients while dual-session EDGE was performed in 6 (16.2 %) with use of 20x10 mm size LAMS in 35 (94.5 %) cases. Technical success rate of EDGE procedure was 36 out of 37 cases (97.3 %), with 1 misdeployment of LAMS, salvaged with an over the scope clip. Clinical success as defined by success of ERCP for indication was 36 out of 37 cases (97.3 %). Within our initial experience of EDGE procedures during the first two years, 12 (32.4 %) cases were performed without LAMS fixation. From those cases, there was one reported case of LAMS migration in a patient who underwent single session EDGE using a 15 x 10 mm LAMS. The migration was seen following ERCP and treated with 20mm x 6 cm covered metal stent secured with an over the scope clip. For subsequent single-EDGE procedures, LAMS was fixed either with 3 clips in Trident formation in 14 cases (35.1 %) or an over the scope clip in 10 cases (26.4 %) with no incidence of stent migration. Rates of adverse events were low with 1 LAMS misdeployment (2.9 %), 2 cases (5.8 %) of post-ERCP pancreatitis managed with supportive therapy and 1 case (2.9 %) of post-sphincterotomy bleeding. The median length of indwelling stent was 38 days with 12 (32.4 %) patients who did not return to follow-up for removal of LAMS. Fistula closure after LAMS removal was performed in 22 (59.4 %) of cases using over-the-scope clip while 1 case (2.9 %) closed naturally and 1 (2.9 % case no fistula closure was performed at the request of the patient to help gain weight.

Conclusions Our single center retrospective experience demonstrates that single-session EDGE demonstrates high rates of procedural efficacy with low rates of adverse events and minimal events of stent migration, thus supporting it as a practical, safe and cost-effective alternative to two-staged approaches.

Aims Endoscopic ultrasound (EUS)-directed transenteric endoscopic retrograde cholangiography (ERCP, EDEE) using a lumen-apposing metal stent (LAMS) is a novel biliary drainage technique for patients with surgically altered anatomy. To evaluate the feasibility, safety and effectiveness of EDEE.

Methods A multicenter, retrospective study. We included consecutive patients with altered anatomy who underwent an EDEE. Surgical anatomy configuration, prior biliary drainage and ERCP indications were collected. The EUS-guided anastomosis technique was assessed. The primary outcome was the technical success of the EDEE. The secondary outcomes were the clinical success and the adverse events (AE).

Results Ninety-four ERCPs were performed in 55 patients (60 ± 16.2 years-old, 56.4 % male). The most frequent surgical anatomy was Roux-en-Y hepaticojejunostomy (n = 23, 41.8 %) and a prior biliary drainage was performed in 28 patients (50.9 %). Benign strictures were the most frequent indication (58.2 %). The most frequent techniques to identify the biliary limb were EUS imaging alone (n = 14, 25.5 %) and EUS-guided puncture of the biliary limb with retrograde opacification of the surgical hepaticojejunostomy (n = 14, 25.5 %). The procedure was performed using a direct freehand approach (n = 49, 89.1 %). Technical and clinical success rates of EDEE were 87.3 % and 93.8 %, respectively. The overall AE rate was 20 % (9.1 % LAMS-related). The rate of persistent fistula was 30.6 % with a median follow-up period of 3 months.

Conclusions The EDEE technique offers a new and effective approach for biliary drainage in patients with surgically altered anatomy, particularly in benign indications and/or when several ERCPs are expected.

DOI 10.1055/s-0046-1820895

Aims Malignant gastric outlet obstruction (MGOO) is a debilitating complication of peri-ampullary cancers. [1, 2] Treatment options include endoscopic ultrasound-guided gastroenterostomy (EUS-GE), enteral stenting (ES), and surgical gastrojejunostomy (SGJ). Recent, high quality randomized controlled trials (RCTs) [3–5] have emerged comparing these modalities. We aim to provide a comprehensive comparative assessment of EUS-GE, ES, and SGJ in MGOO.

Methods We performed a systematic review and network meta-analysis (NMA) of RCTs and observational cohort studies with causal adjustment analysis comparing EUS-GE to ES, EUS-GE to SGJ, or SGJ to ES for MGOO (PROSPERO: CRD420251133918). We searched PubMed, Embase, and Web of Science databases. The outcome measurements were rate of reintervention, rate of clinical success, rate of adverse events, post procedure length of hospitalization, and time to oral intake. Analyses were conducted in R software using the *gemtc* and *netmeta* package interfacing with JAGS for Bayesian random-effects NMA and MetaInsight. We evaluated outcomes using a Bayesian random-effects NMA model and summarized findings with network plots, surface under the cumulative ranking curve (SUCRA), and forest plots. Transitivity was assessed by comparing key effect modifiers across studies. Consistency between direct and indirect evidence was examined through Bayesian node-splitting analyses. Sensitivity analysis was also performed by restricting the modeling to only RCTs (▶ **Table 1**).

Results We included 6 RCTs and 10 causally adjusted cohort studies encompassing 1585 patients (376 EUS-GE, 726 ES, and 483 SGJ). All trials exclusively enrolled patients with MGOO, comparable tumor stage and baseline physical status. Assessment of the transitivity assumption showed comparable patient characteristics across treatment groups. EUS-GE ranked as the optimal approach in terms of lowest reintervention rate (SUCRA, 99.87 %), highest clinical success (SUCRA, 93.00 %), lowest adverse events (SUCRA, 90.13 %), shortest length of hospitalization (SUCRA, 95.00 %), and shortest time to oral intake (SUCRA, 82.99 %). Regarding the reintervention rate, EUS-GE significantly reduced the risk of reintervention compared with ES in the direct pairwise meta-analysis [risk ratio (RR) 0.19, 95 % confidence interval (CI) 0.10–0.36]. The NMA demonstrated that the reintervention rate remained significantly higher in SGJ group versus EUS-GE group [RR 4.1, 95 % credible intervals (CrI) 1.75-9.75], and in ES group versus EUS-GE group (RR 5.55, 95 % CrI 2.85-14.26). Bayesian node-splitting analyses revealed no inconsistencies. Sensitivity analyses restricted to RCTs were consistent with the primary analysis.

Conclusions Our network meta-analysis demonstrates that EUS-GE is superior to ES and SGJ in the management of MGOO. Large scale data on EUS-GE are now needed to monitor its safety as it disseminates outside expert centers.

Aims This multicentre study assessed the Traffic Light System in routine EDGE practice, focusing on efficiency, success, and safety.

Methods Prospectively recorded registry data from three tertiary HPB centres (Jan 2023–Dec 2024) were retrospectively analysed. Adults with RYGB undergoing EDGE for biliary or pancreatic indications were included; exclusions were prior sleeve gastrectomy, incomplete records, or non-standard stents [1–3].

▶ **Table 1**

Treatment	Reintervention	Length of hospitalization	Adverse events	Time to oral intake	Clinical success
EUS-GE	99.87 % (1st)	96.91 % (1st)	90.13 % (1st)	82.99 % (1st)	93.00 % (1st)
ES	7.53 % (3rd)	52.53 % (2nd)	49.33 % (2nd)	65.34 % (2nd)	9.60 % (3rd)
SGJ	42.60 % (2nd)	0.56 % (3rd)	10.54 % (3rd)	1.67 % (3rd)	40.40 % (2nd)

Five blinded reviewers reassessed imaging and fluoroscopy to classify access sites using TLS criteria. The primary aim was to assess TLS predictive validity for technical and clinical success and adverse events (▶ **Table 1**).

▶ **Table 1**

Parameter	Green (n = 25)	Amber (n = 4)	Red (n = 2)	p-value
Age (median)	61	58	66	–
Sex	17F/8M	3F/1M	2F	–
Stent size	20 x 10 mm	20 x 10 mm	20 x 10 mm	–
Aetiology	Stones (21) Pancreatic CA (2) Indeterminate stricture (2)	Stones (2) Pancreatic CA(1)	Biliary Stones (2)	–
Two-stage procedures (n)	25	4	2	
Technical success	100 %	100 %	0	–
ERCP success 1st attempt	100	100	0	0.03
Repeat EDGE required (%)	0	0	100	< 0.01
Procedure time (minutes)	48 ± 12	62 ± 15	78 ± 21	0.02
Adverse events (%)/LAMS migration (%)	0/0	0/0	0/0	–

Collected variables included demographics, indication, LAMS size, access site, procedure stage, technical and ERCP success, clinical success, procedure duration, and AEs. ANOVA was used for continuous data and Chi-square/Fisher's exact tests for categorical variables ($p < 0.05$).

Results Thirty-four EDGE procedures were performed, including 31 two-stage cases, all by highly experienced endoscopists (> 1,000 ERCPs and > 1,000 EUS). Patients were categorised as Green (n = 28), Amber (n = 4), and Red (n = 2), with similar median ages (61–66 years) and sex distribution. All received a 20 × 10 mm stent. Choledocholithiasis predominated across groups.

Two-stage procedures were used in thirty-one patients, who were appropriate for the subgroup analysis. Technical success was 100 % in Green and Amber groups but not achieved in the Red group. First-attempt ERCP success was 100 % in Green and Amber but 0 % in Red ($p = 0.03$). Repeat EDGE was required only in the Red group ($p < 0.01$). Mean procedure time increased from Green to Red (48 ± 12 vs 62 ± 15 vs 78 ± 21 min; $p = 0.02$).

No LAMS migration, adverse events, or clinical failures occurred in any group.

Conclusions The Traffic Light System (TLS) effectively predicted procedural performance during EDGE. Green and Amber sites consistently showed high technical success, shorter procedure times, and no adverse events, confirming them as safe and favourable access points. In contrast, Red Zone access was linked to technical failure, absent first-attempt ERCP success, longer procedures, and a universal need for repeat EDGE. Overall, the TLS offers a clear, practical framework for assessing technical difficulty, guiding LAMS site selection, and improving planning and outcomes in EDGE.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP242 Development of a Novel Anchor Device for EUS-guided Gastrojejunostomy

Authors Okuzono T[1], Satoshi I[1]

Institute 1 Sendai Kousei Hospital, Sendai, Japan

DOI 10.1055/s-0046-1820897

Aims EUS-guided gastrojejunostomy (EUS-GJ) using a lumen-apposing metal stent (LAMS) has been increasingly performed; however, misdeployment and dislocation remain as major complications. Misdeployment may occur when the jejunum separates from the gastric wall after puncture, whereas dislocation may occur when either the gastric or jejunal flange becomes dislodged after stent deployment. As a preprocedural step for EUS-GJ, techniques using a 19-gauge needle to place an anchor have been reported; however, these approaches are technically complicated and time-consuming. Shortening the procedural time is essential for the success of EUS-GJ. Therefore, we developed a novel anchoring device that can be deployed in a single step using a 19G needle. Using this new device, we performed EUS-GJ in living pigs. This product is an investigational, non-approved medical device. The aim of this study is to evaluate the feasibility of a newly developed anchor device designed for EUS-GJ [1].

Methods Between May and November 2025, EUS-GJ using the novel anchor device was performed in five live pigs (30-36kg). Necropsy was performed immediately in four pigs, whereas one pig underwent necropsy approximately one month later. First, an ENBD tube was advanced beyond the ligament of Treitz, and the jejunum was distended with saline. Using a GF-UCT 260 scope, the stomach and jejunum were fixed with a 20mm anchor device prior to deployment of an electrocautery-enhanced metal stent. The novel anchor was preloaded at the tip of a dedicated 19G needle. After puncturing the saline-distended jejunum from the stomach, the distal flap of the anchor was deployed by pushing the stylet, and withdrawing the needle enabled fixation of the gastric and jejunal walls. We evaluated the success rate of anchor placement, the time required from 19G needle puncture to anchor deployment, and the presence of retained anchors between the stomach and jejunum at necropsy.

Results Anchor deployment was successful in all cases, and retention between the gastric and jejunal walls was confirmed at necropsy in all pigs. The mean deployment time was 57 seconds (34-85 seconds).

Conclusions The novel anchor device enabled simple and rapid wall fixation during EUS-GJ. This device may have the potential to reduce adverse events such as misdeployment or dislocation and improve the safety of EUS-GJ procedures.

Conflicts of Interest Stock ownership: KOEDA Inc.

OP243 Unplanned Procedural Events (UPE) during EUS-guided Gastrointestinal and Enteroenteric Anastomoses (EUS-GEA) using Lumen-Apposing Metal Stents (LAMS): Treatment Approaches and Outcomes

Authors Sanjosé Crespo A[1], Marcos-Carrasco N[1], Ortiz Chimbo DS[1], Martinez-Ortega A[2], Martínez-Moreno B[3], Alvarez-Delgado A[2], Arrubla A[4], Dura Gil M[5], Aparicio JR[3], Subtil Iñigo JC[6], Cobreros del Caz M[1], Marquina V[7], Perez-Miranda M[1]

DOI 10.1055/s-0046-1820898

Aims UPEs during LAMS anastomoses (Teoh et al; PMID: 31367676) include stent misdeployment (SMD) and dislocation (SDL), which may or may not result in adverse events (AEs). Compared to other LAMS anastomoes, the potential for UPEs is greater with EUS-GEA. The incidence of SMD is highest during the initial 40 EUS-GEs (Ghandour et al PMID: 34352256), whereas SDL is associated with through-the-LAMS procedures. As EUS-GEA disseminates and novice operators adopt it, filling knowledge gaps about UPE management becomes paramount.

Main study aim: to describe treatment approaches and outcomes used to manage UPEs during EUS-GEA, including technical and clinical success rates. As secondary study aims, time to hospital discharge, and adverse AE rates were also analyzed.

Methods Retrospective, observational, multicenter study on consecutive patients who underwent EUS-GEA with LAMS and experienced SMD or SDL between 2015 and 2025 at 6 Spanish Hospitals. Technical success was defined as resolution of the UPE by endoscopy. Clinical success was defined as the absence of need for any subsequent reintervention to manage UPE-related AEs. The AGREE scale was used to grade AEs.

Results From a total of 860 EUS-GE performed for gastric outlet obstruction (GOO), biliary access in altered anatomy (BAAA), or lower intestinal obstruction (LIO), 73 patients (median: 52.1 % women; mean age 70.85 years; ASA III; Charlson Comorbidity Index 5) were identified with any UPE. Among the UPE cohort GOO (41.1 %) and BAAA (34.2 %) were the dominant clinical scenarios. Overall, 40 % of patients had postoperative anatomy. SMD represented 79.5 % of UPEs, with Type I SMD as the most frequent (56 %). Most UPEs (91.8 %) were diagnosed intraprocedurally. Endoscopic management was attempted in 86.3 % of patients, with successful salvage of EUS-GEA achieved in 31.5 %. NOTES techniques were used in 37.1 %. Overall, technical success was 83.1 %, and clinical success 70.4 %. AEs occurred in 42.5 % of patients, with post-procedural pain as the most common AE. Five patients (6.8 %) experienced AGREE Grade V AEs (bronchoaspiration, intra-abdominal infection, and bleeding). An additional 3 patients died following surgical treatment or due to inability to tolerate oral intake. Six patients were never able to tolerate oral

diet, although most patients (78 %) achieved tolerance within < 24 hours of the UPE. Surgery was required in 13.7 % of cases, typically between 3 and 24 hours after the UPE. Intensive care unit admission occurred in 11.3 % overall. Among surgically managed patients, 50 % required ICU admission, compared with 6.6 % of those treated endoscopically (p = 0.002). Mean hospital stay was 10.92 days for endoscopically treated patients and 22.5 days for surgically treated patients.

Conclusions When UPEs are identified during the procedure, endoscopic intervention can salvage most instances of SMD/SDL, preventing AEs and minimizing negative clinical outcomes. Endoscopists performing EUS-GEA should be trained to promptly recognize and manage these uncommon yet potentially severe incidents

DOI 10.1055/s-0046-1820899

Aims Hirschsprung's disease (HSCR) is a congenital disorder characterized by the absence of intrinsic ganglion cells and myenteric plexuses of the hindgut**.** Per-rectal endoscopic myotomy (PREM) is a minimally invasive third-space endoscopic procedure used in the management of Hirschsprung's disease.

To evaluate the technical outcomes and clinical success of PREM, assessed by improvement in stool frequency, reduction in laxative requirement and Wexner constipation score pre- and post-procedure.

Methods Retrospective analysis of 52 consecutive patients undergoing PREM across 12 tertiary centres (2015–2025). Demographic, procedural, postoperative recovery and functional outcome data (stool frequency, laxative requirement and Wexner score) were compared pre- and post-procedure using paired statistical testing.

Results Fifty-two patients underwent PREM with a mean age of 16.38 ± 17.9 years; 29 (55.8 %) were male. Congenital Hirschsprung disease was the indication in 82.5 % (33/52), acquired Hirschsprung in 26.9 % (14/52) and post-surgical recurrence in 9.6 % (5/52). Mean duration of symptoms was 94.80 ± 136.22 months. The recto-anal inhibitory reflex was absent in 80.8 % (42/52), a dilated colonic segment was present in all patients (100 %), and barium enema findings were confirmatory for Hirschsprung disease in 65 % (26/40) and suspicious in 32.5 % (13/40). The mean length of the aganglionic or hypo ganglionic segment was 7.38 ± 2.85 cm. Procedurally, the mean tunnel length was 13.4 ± 5.1 cm, mean myotomy length 10.9 ± 4.1 cm, and mean procedure duration 90 ± 33 minutes, with 100 % technical success. Median of first bowel sounds: 12 hours (IQR 12–12), passage of flatus: 12 hours (IQR 12–24), first bowel movement: 48 hours (IQR 24–48), and resumption of oral liquids: 24 hours (IQR 24–24). Median hospital stay was 5 days (IQR 12– 24 hours). Major adverse events occurred in 9.6 % (5/52), consisting of perforation (n = 1), clip dislodgement requiring surgical closure (n = 1), large tunnel entry defect requiring surgical repair (n = 1), surgical emphysema (n = 1), and localized perirectal collection (n = 1); all were managed successfully without mortality. Median follow-up was 14 months (IQR 3–46.5). Functional outcomes improved significantly with laxative usage decreasing from 4.3 ± 2.488 units to 1.6 ± 0.9 ($p < 0.0001$), stool

frequency increasing from once every 7.1 ± 4.29 days to once every 1.31 ± 0.55 days (p < 0.0001), Wexner constipation score decreasing from 23.76 ± 3.98 to 8.13 ± 1.19 (p < 0.0001).

Conclusions PREM is a safe and effective minimally invasive treatment for Hirschsprung's disease, offering sustained symptom improvement with very low complication rates.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP245 Real-World Practices and Barriers in ESD training: a Worldwide Comprehensive Survey

Aims Endoscopic submucosal dissection (ESD) requires advanced expertise and technical skills. Japan provides the benchmark model through high case volumes and structured supervision, while Western curricula (ESGE/ASGE) emphasise supervised training and stepwise progression [1, 2]. Adherence to these frameworks and access to resources remain inconsistent globally.

Methods We aimed to explore real-world ESD training conditions, barriers, and adherence to curricula across diverse geographic and institutional contexts, from the perspectives of both trainees and trainers. A cross-sectional, anonymous web-based survey (April–July 2025) was conducted across 39 countries using a 55-item questionnaire on ESD training opportunities, barriers, and curriculum adherence. The survey was disseminated in English through national endoscopy society representatives. Trainees were defined as endoscopists proficient in basic endoscopy who had begun supervised ESD training, while trainers were experienced ESD endoscopists (> 100 procedures) involved in teaching. Institutional ESD volume was classified as low (< 50/year), medium (50–100/year), or high (> 100/year) [3].

Results Among 288 respondents from 39 countries (137 trainees, 151 trainers), most worked in academic or tertiary hospitals, with 43 % from low-, 30 % medium-, and 27 % high-volume centres. Overall, males were predominant (n = 226, 78.5 %). Structured training was reported by 47 %, more frequently in medium and high-volume centres (P < 0.001), while adherence to ESGE/ASGE curricula reached 46 %, ranging from 27 % in low- to 70 % in high-volume centres (P < 0.001) and varying across regions (highest in North-West Europe, lowest in South-East Europe; P < 0.001). Access to simulators was absent in nearly half, particularly in low-volume centres (P < 0.001). In vivo human training, animal models, and observerships were rated as the most valuable modalities, whereas lack of simulators, limited cases, and high costs were key barriers, without significant differences between trainees and trainers. Conversely, limited available time was perceived as a more impactful barrier for trainees compared to trainers (P = 0.018). Regarding training modalities, trainees rated traction (P = 0.002) and underwater (P = 0.005) techniques higher than trainers, whereas no significant differences were found for pocket creation, closure-first strategies, or stepwise lesion difficulty. Quality indicators were tracked in 63 % of institutions, with R0 and en bloc resection rates most valued, while dissection speed was de-emphasised. No substantial differences were observed between trainers and trainees. Thresholds for independent practice varied widely, with 42.7 % indicating 10–25 and 32.6 % 26–50 supervised cases. Geographic disparities emerged, with North-West Europe and Asia-Pacific hosting more high-volume centres, while Africa, the Middle East, and South-East Europe reported limited curriculum fulfilment, model access, and higher cost-related barriers (▶ **Table 1**).

▶ **Table 1**

Item, rating > = 4	Overall (n = 288)	Trainee (n = 137)	Trainer (n = 151)	p
Impact of Hands-on simulator	74.3 %	71.5 %	76.8 %	0.840
Barrier: Limited time for training	40.3 %	35.0 %	45.0 %	0.018
Training modality: traction	71.2 %	78.1 %	64.9 %	0.002
Training modality: underwater	50.7 %	56.2 %	45.7 %	0.005
Training modality: Start with whole easy lesions	83.0 %	86.9 %	79.5 %	0.03

Conclusions Global ESD training remains highly heterogeneous, with gaps in resources, curriculum implementation, and equitable access across regions and centre volumes. Limited trainer–trainee differences were observed; however, the marked male predominance underscores the need to address gender imbalance, together with strengthening structured programs and training resources worldwide.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP246 Role of endoscopic enteral contrast instillation in the management of iatrogenic colonic perforations

Authors Tapias Solis L[1], Romito R[1], Moscardo Ribes A[1], Gracia Carlos A[2], Pedregal Pascual P[3], Blanco Nodal I[1], Escude Torrella L, Gordillo Abalos J[1], Gomez Oliva C[1], Concepción Martin M[1], Murzi Pulgar M[1], Guarner-Argente C[4]

DOI 10.1055/s-0046-1820901

Aims Management of iatrogenic perforations is not yet standardized, with therapeutic options including endoscopic closure, surgery, or conservative treatment. Endoscopic therapy using conventional or OTSC clips can reduce the need for surgery, and enteral contrast instillation after closure may help confirm successful sealing on subsequent CT imaging. This study aimed to evaluate the efficacy and clinical outcomes of endoscopic closure for iatrogenic colonic perforations, and to assess the potential benefit of enteral contrast instillation in confirming defect closure and optimizing patient management

Methods A retrospective analysis was performed of all iatrogenic perforations detected during colonoscopy at our center between 2013 and 2025. Endoscopic closure was attempted whenever feasible. Clinical success was defined as complete resolution without surgical intervention. The use and effect of enteral contrast instillation were analyzed regarding its capacity to detect leaks, avoid unnecessary surgery, and shorten the time to oral diet resumption in successfully treated patients. Statistical analyses compared etiologies, techniques, and clinical variables

Results A total of 72 patients were included, 43 (59.7 %) of whom were female, with a mean age of 70 ± 12 years. Endoscopic management was attempted in 60 cases (83.3 %), encompassing all thermally induced perforations (44/44, 100 %) and 16 of 28 traction-related perforations (57 %; p < 0.01). Overall clinical success was achieved in 56/72 patients (77.8 %), with a significantly higher rate for thermal perforations (42/44, 95.5 %) compared to traction-related lesions (14/28, 50 %; p < 0.01). Among those treated endoscopically, success was achieved in 56/60 (93.3 %), with comparable outcomes between etiologies once closure was attempted (87.5 % for traction-related vs. 95.5 % for thermal; p = 0.29).

Closure was attempted using conventional clips in 48 cases (80 %), OTSC clips in 11 (18.3 %), and endoscopic suturing (Apollo) in 1 (1.7 %). Enteral contrast was considered unnecessary in 12/60 (20 %) cases due to confident complete closure with immediate discharge. Among the remaining 48 patients, contrast was instilled in 39 (81 %) and omitted in 9. In one case with suspected incomplete closure, CT imaging revealed no leak, allowing conservative management and avoidance of surgery. Contrast leakage was reported in three patients (7.7 %), all managed non-surgically (two minimal leakage and one retroperitoneal). Among successfully treated patients, the use of contrast instillation significantly shortened the time to diet reintroduction (2.1 ± 2.2 vs. 4.7 ± 3.5 days; p = 0.02), although leak detection understandably delayed refeeding (5.0 ± 3.6 vs. 1.9 ± 1.9 days; p = 0.017).

Conclusions Endoscopic treatment of iatrogenic colonic perforations is safe and highly effective, especially for thermic induced injuries. The adjunctive use of enteral contrast instillation appears to be a valuable tool to verify complete closure, guide management, and enable earlier and safer reintroduction of diet. This approach may help avoid unnecessary surgical interventions and optimize recovery in selected patients.

OP247 Risk factors for appendicitis recurrence after ERAT in patients with acute appendicitis: a multicenter cohort study with long-term follow-up

Authors Zhang J[1], Liu B[1], Liu D[1]

Institute **1** The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

DOI 10.1055/s-0046-1820902

Aims Endoscopic retrograde appendicitis therapy (ERAT) has emerged as a minimally invasive approach to treating appendicitis. This study aimed to assess the long-term safety and efficacy of ERAT and to develop a model predicting 1-year appendicitis recurrence in patients with acute appendicitis, to guide clinical decision-making (▶ **Table 1**).

Methods A retrospective analysis was conducted on clinical data from 435 patients with acute appendicitis who underwent ERAT at three hospitals between October 2017 and October 2024. 24 clinical variables were screened, and Spearman correlation analysis revealed correlation coefficients exceeding 0.6 between some variables. To address multicollinearity, LASSO regression was employed to identify key predictive factors in the training set. A predictive model was constructed using multivariate logistic regression, and a nomogram was developed.

Results All ERAT procedures were technically successful, and a clinical success rate of 92.4 % was achieved. The median follow-up period was 37 months, and the overall recurrence rate was 16.1 %; most recurrences (13 %) were observed in the first year. Based on LASSO regression analysis, the final predictors identified were: age > 60 years (OR = 0.240, 95 % CI: 0.069–0.838, *P* = 0.025), Alvarado score > 6 (OR = 6.874, 95 % CI: 3.024–15.626, *P* < 0.001), appendicitis with fecalith (OR = 3.937, 95 % CI: 1.749–8.866, *P* = 0.001), inexperienced operator (OR = 2.082, 95 % CI: 1.089–3.982, *P* = 0.027), procedure time > 40 minutes (OR = 2.180, 95 % CI: 1.067–4.456, *P* = 0.033), tapered transparent cap used (OR = 0.380, 95 % CI: 0.170–0.847, *P* = 0.018), and appendix lumen distortion (OR = 12.331, 95 % CI: 2.496–60.927, *P* = 0.002). Based on these seven predictive factors, a nomogram model was constructed to predict recurrence risk within one year after ERAT.

Conclusions ERAT is a safe and effective treatment for acute appendicitis. The risk of recurrence is highest within the first year. Seven independent risk factors for recurrence within one year after ERAT were identified, and a recurrence risk prediction model based on these predictive factors can assist in future clinical decision-making for ERAT.

▶ **Table 1** Analysis of risk factors for appendicitis recurrence after ERAT

	B	Standard error	Wald	*P*	OR (95%CI)
Age>60 years old	-1.425	0.637	5.007	0.025	0.240 (0.069~0.838)

OP248 Safety and efficacy of a novel traction-band-assisted endoscopic closure technique for large defects after gastric endoscopic full-thickness resection: a pilot study

Authors Deliang L[1], Liu D[1], Liu B[1]
Institute 1 The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China
DOI 10.1055/s-0046-1820903

Aims Background and aims: Endoscopic full-thickness resection (EFTR) has gradually become the main choice for large gastric submucosal tumors. However, endoscopic closure after EFTR often leads to inversion of the mucosal layer and poor alignment of the muscularis propria, making secure closure challenging. Herein, we developed a novel "traction-band-assisted endoscopic closure (TBAEC)" technique using clips and dental floss. This study aimed to evaluated the safety and efficacy of the novel technique.

Methods From Janunary 2025 to June 2025. 21 patients with gastric submucosal tumors (20-50mm) scheduled for EFTR were enrolled. Of which, 8 patients underwent TBAEC and purse string suture (PSS) was performed in the rest patients. The primary outcome was the technical success rate. Secondary outcomes included closure time and adverse events. TBAEC procedure is described as follows: 1) After marking the lesion, a normal saline solution was injected into the submucosa; 2) Clips and dental floss traction was fixed at the lesion edges after an incision into serosal layer around the lesion to achieve inner traction; 3) Clips were used to close the defect after five-fourth circumferential full-thickness resection; 4) Complete resection of the lesion was accompanied by complete closure of the defect; 5) Lesions were retrieved.

Results Complete closure was achieved in all of cases. The median closure time was significantly shorter in TBAEC group than PSS group (11.5 ± 3.6 vs 21.4 ± 5.3, P<0.05). Among adverse events, no patients occurred delayed perforation and bleeding in the TBAEC group and one case of delayed bleeding in the PSS group. Coagulation syndrome occurred in one individual treated with TBAEC, whereas two cases were identified in the PSS procedure. All patients were discharged safely with a median length of postprocedural hospital stay for the two groups were 3, 4 days respectively.

Conclusions This study demonstrated the feasibility, safety and efficiency of TBAEC for closing large defects following gastric EFTR. TBAEC is a simple, safe and easy-to-use technique for endoscopic closure. Further large studies are needed to evaluate its efficiency and safety.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP249 Efficacy of Artificial Dermis for Protecting Gastrointestinal Mucosal Defects

Authors Minamide T[1], Ikematsu H[1]
Institute 1 IMSUT Hospital, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan
DOI 10.1055/s-0046-1820904

Problem to solve Endoscopic submucosal dissection (ESD) for gastrointestinal tumors is widely adopted as a minimally invasive endoscopic treatment with high curative potential. However, serious complications such as delayed bleeding and perforation after ESD remain major concerns. To prevent these complications, several methods, including clip-based suturing techniques, endoscopic hand suturing, and polyglycolic acid (PGA) sheets, have been developed to protect mucosal defects. However, these approaches often face challenges such as technical difficulty for extensive ulcers, cumbersome procedures, and high costs.

Innovation To achieve reliable, simple, and cost-effective protection, we propose using an artificial dermis (Teldermis[R]) to cover gastrointestinal mucosal defects. This material consists of a 3-mm atelocollagen sponge with or without a 0.2-mm silicone layer. Through heat-induced cross-linking, the inherent biocompatibility of atelocollagen is preserved. When applied to mucosal or skin defects, the collagen layer facilitates dermis-like tissue formation via cellular infiltration from the wound bed. This artificial dermis has been successfully used for repairing severe skin and mucosal defects in burns, trauma, surgical wounds, and cleft palate surgery. In the endoscopic setting, it retains flexibility and sufficient thickness, offering excellent maneuverability, stable adhesion, and high protective potential.

Results We conducted ex vivo experiments using excised porcine stomach and rectum. In the first experiment, we investigated whether artificial dermis could be applied without damage using endoscopic clips. We successfully attached artificial dermis manually to four mucosal defects on the excised organs using clips without causing damage. In the second experiment, we investigated whether artificial dermis could be applied during actual endoscopic procedures. Using an endoscopic scope, four approximately 2 cm ESD ulcers were created inside unopened porcine stomachs and rectums. Subsequently, artificial dermis sheets (2.5cm) were delivered to the mucosal defects using grasping forceps, positioned to cover the defects, and fixed with clips. Delivery and clip fixation of the artificial dermis were successful in all mucosal defects. Fur-

Endoscopy 2026; 58: S1–S1041

thermore, we also conducted in vivo experiments in a live pig. Under general anesthesia, ESD ulcers approximately 2 cm in size were created at eight sites in the stomach (four in the body and four in the antrum) and two in the esophagus. In the stomach, two ulcers were left uncovered, two were covered with artificial dermis alone, two had collagen monolayer sheets clipped in place, and two had collagen-silicone bilayer sheets clipped in place. In the esophagus, one ulcer was left uncovered, while another had a collagen monolayer sheet clipped in place. Clip fixation was successfully achieved at all designated sites. Follow-up endoscopy after three days showed that only the collagen–silicone sheets in the stomach and the collagen monolayer sheet in the esophagus remained attached, while the others had detached. After two weeks, all ulcers had healed and scarred, and no major adverse events occurred during the observation period. Histopathologically, no increased inflammatory response or signs of infection were observed in the sites where artificial dermis was fixed compared to unfixed sites, suggesting a normal healing process.

Conclusions Collagen-based artificial dermis can be feasibly applied endoscopically to protect gastrointestinal mucosal defects. It can be easily fixed using only endoscopic clips, and the type with a silicone layer may offer longer retention and better protection.

OP250 Colorectal cancer screening in patients aged 70–74: experience from a tertiary hospital

Authors Sánchez Álvarez E[1], Gambra Juárez A[1], Estrecha Diaz S[1], Yanguas Elorz E[1], De Pablos Noriega I[1], Gonzalez Aldama M[1], Fuente Diaz De Corcuera U[1], Telleria Etxeberria G[1], Montero Campos A[1], Moya De Prado AC[1], Pedraza Perez A[1], Espinosa Taranilla L[1], Aldai Larrinaga J[1], Bravo Melendez S[1], Elorza Iturbe A[1], Campos Ruiz A[1], Sanchez Graña A[1], Álvarez Rubio M[1]

Institute **1** Araba University Hospital, Vitoria-Gasteiz, Spain

DOI 10.1055/s-0046-1820905

Aims Colorectal cancer (CRC) is the third most prevalent cancer worldwide, with age being one of its main risk factors. The aim of fecal immunochemical test (FIT)-based screening programs is the early detection of neoplasic and preneoplasic lesions to reduce morbility and mortality. In Spain, the national screening program traditionally includes individuals aged 50–69 years. Since October 2024, the Basque Autonomous Community has extended up to 74 years of age.

The aim is to analyze and compare the incidence of colorectal cancer and advanced lesions between the 50–69 and 70–74 age groups following the expansion of the screening program.

Methods A retrospective analysis was conducted at a tertiary hospital between November 2024 and July 2025, comparing both age groups. Advanced lesions were defined as those ≥ 10 mm, with a villous component and/or high-grade dysplasia. Participation rates, FIT positivity, colonoscopy completion, and detection rates were analyzed.

Results In the 50–69-year group (target population: 31,647), participation was 62.0 % (19,633). FIT was positive in 3.67 % (721), and colonoscopy was performed in 73.8 % (532). Among these, 12 cases of CRC (2.27 %) and 175 advanced lesions (32.7 %) were detected.

In the 70–74-year group (target population: 5,436), participation increased to 73.3 % (3,986). FIT was positive in 6.47 % (258), and colonoscopy was performed in 82.6 % (213). This group showed 6 cases of CRC (2.82 %) and 74 advanced lesions (34.7 %).

CRC incidence detected through screening was slightly higher in the 70–74 group compared with the 50–69 group. The detection rate was 22.6 per 1,000 colonoscopies in the 50–69 group and 22.8 per 1,000 in the 70–74 group. The number needed to treat (NNT) was 44.3 in the 50–69 group versus 35.5 in the 70–74 group, indicating higher screening efficiency among older participants. Similarly, the incidence of advanced lesions was higher in the older cohort (34.7 % vs. 32.7 %).

Conclusions The extension of CRC screening to individuals aged 70–74 yields a similar cancer detection rate but a greater diagnostic efficiency, requiring fewer colonoscopies per cancer detected. Although preliminary, these results support the inclusion of this age group in population-based screening programs. However, the short follow-up period (9 months) limits definitive conclusions, and further studies are needed to assess long-term outcomes and the risk–benefit balance of endoscopic follow-up in elderly patients with advanced neoplasia.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims The presence of expired medical devices represents both an environmental concern and a waste of healthcare resources. However, the magnitude of this problem has not been previously assessed. This study aimed to quantify the volume and cost of expired endoscopic devices and to evaluate their microbiological sterility, physicomechanical integrity, and ex vivo technical performance beyond the labelled shelf life.

Methods We conducted an investigator-initiated, prospective study between December 1, 2023, and May 30, 2025, across 25 endoscopy units from Europe, the UK, Canada and the USA. Expired endoscopic devices were inventoried during a one-week audit period at each centre. An institutional questionnaire was conducted to assess storage practices. Microbiological sterility and ex vivo functional simulation were assessed in randomly selected samples. Physicomechanical engineering tests were performed on selected devices, including a matched case–control study comparing expired devices with non-expired counterparts.

This study was funded by a research grant from the Spanish Society of Digestive Endoscopy (SEED).

Results A total of 1,448 expired devices were identified (median per centre 42, range 3–262), with an estimated total economic cost of €192,141.7 (average per centre €7,685.67). Of these, 273 were analysed for microbiological testing, 210 for ex vivo functional assessment, and 57 for physicomechanical evaluation. All tested devices were sterile (100 %, 95 % CI 98.6–100 %). Except for one overtube, all devices retained functionality in ex vivo simulation (99.5 %, 95 % CI 97.4–99.9 %). Physicomechanical testing showed no clinically relevant differences compared with non-expired devices. Only 6 centres (24 %) reported having a written protocol to minimise the accumulation of expired endoscopic accessories, and just 3 centres (12 %) had an electronic system in place for tracking expiration dates.

Conclusions The presence of expired endoscopic consumables is common and associated with substantial economic costs. Our findings indicate that these devices retain sterility and functionality beyond their labelled expiration dates, suggesting the need for a critical re-evaluation of current shelf-life criteria by both industry and regulatory bodies.

OP252 The environmental footprint of biliary drainage: a prospective multicentre comparison of ERCP, EUS-guided and percutaneous approaches

Authors Michael FA[1], Masaryk V[2], Will U[2], Friedrich-Rust M[1], Eickhoff A[3], Welsch L[3]

Institutes 1 Frankfurt University Hospital, Frankfurt, Germany; 2 SRH Wald-Klinikum Gera, Gera, Germany; 3 Klinikum Hanau, Hanau, Germany
DOI 10.1055/s-0046-1820907

Aims Biliary drainage procedures generate substantial medical waste, yet their comparative environmental footprint is poorly characterised. We prospectively quantified waste generation and recyclability of endoscopic retrograde cholangiopancreatography (ERCP), endoscopic ultrasound-guided biliary drainage (EUS-BD) and percutaneous transhepatic biliary drainage (PTCD) in routine clinical practice.

Methods In a multicentre observational study at three German tertiary-care endoscopy units, we included all procedures with biliary access (ERCP, EUS-BD, PTCD primary placement and scheduled PTCD exchanges) performed between July and October 2025. For each procedure, all procedure-related waste from the endoscopy room and adjacent areas was collected immediately after the intervention and categorised into devices, personal protective equipment (PPE), plastic, paper/cardboard and residual waste. Waste was weighed per category and procedure; uncontaminated plastic and paper were classified as potentially recyclable. Total waste, category-specific waste and recyclable fractions were compared between modalities using non-parametric tests.

Results EUS-BD generated the lowest mean total waste per procedure (1155.7 g) compared with ERCP (1743.2 g), PTCD exchange (2622.4 g) and PTCD primary placement (3253.2 g). Residual (non-recyclable) waste was lowest for EUS-BD (251.0 g) and highest for PTCD (1708.6 g for exchange; 1849.5 g for primary placement), with ERCP in between (828.7 g). EUS-BD showed the most favourable recyclability profile: potentially recyclable waste accounted for 612.3 g (53.0 % of total) versus 491.7 g (28.2 %) for ERCP, 450.1 g (17.2 %) for PTCD exchange and 698.9 g (21.5 %) for PTCD primary placement.

Conclusions Among biliary drainage procedures, EUS-BD combines the lowest overall waste generation with the highest proportion of potentially recyclable material, whereas PTCD is associated with the greatest burden of non-recyclable waste. These ecological data complement existing clinical evidence and support preferential use of EUS-BD over PTCD where expertise is available and outcomes are comparable.

OP253 Efficacy and Sustainability of a Novel Pre-Cleaning Device for Endoscope Reprocessing: A Multicenter Randomized Controlled Trial

Authors Pereira JP[1], Santos I[2], Carvalho A[1], Craveiro F[1], Medas R[1], Antunes P[1], Mendes N[1], Torres AC[2], Pimentel-Nunes P[2, 3, 4], Baldaque-Silva F[5, 1]

Institutes 1 Gastroenterology Department and Advanced Endoscopy Center Carlos Moreira da Silva, ULSMatosinhos, Matosinhos, Portugal; 2 Gastroenterology and Clinical Research, Unilabs Portugal, Porto, Portugal; 3 Department of Surgery and Physiology, Faculty of Medicine, University of Porto (FMUP), Porto, Portugal; 4 RISE@CI-IPO (Health Research Network), Portuguese Oncology Institute, Porto, Portugal; 5 Karolinska University Hospital, Department of Upper Abdominal Diseases, Stockholm, Sweden
DOI 10.1055/s-0046-1820908

Aims Flexible gastrointestinal endoscopes carry a small but persistent infection risk, requiring stringent reprocessing. Variability in manual cleaning practices and environmental concerns highlight the need for more sustainable approaches. The AquaTYPHOON (Pentax Medical, Hamburg, Germany), a novel automated brushless pre-cleaning device, may provide a safe, effective, and resource-efficient alternative; however, comparative data with manual methods remain limited [1–11].

We conducted a multicenter randomized trial to compare this automated pre-cleaning device with standard manual reprocessing regarding efficacy, safety, environmental impact, and healthcare professional satisfaction.

Methods Between June 2024 and October 2025, 434 routine-use endoscopes at two centers [Hospital Pedro Hispano (HPH) and an ambulatory gastroenterology unit (Unilabs Porto | Fluvial)] were randomized 1:1 to automated or manual pre-cleaning. Before study initiation, a standardized training program was implemented at both centers to ensure protocol adherence and uniform execution of all procedures. Endoscopes were evaluated for microbiological contamination and residual protein (Pyromol-Test), including upper endoscopes, duodenoscopes, colonoscopes, and linear echoendoscopes. All microbiological samples were centralized and processed at the same certified Microbiology Laboratory, and all samples were systematically collected and analyzed.

Results A total of 434 endoscopes were analyzed. Residual protein testing showed no differences between groups, with all samples testing negative across all endoscope types. Microbiological testing revealed endoscopic contamination in 5 of 171 gastroscope/colonoscope samples (2.9 %) following manual

pre-cleaning (0/72 at HPH and 5/99 at Unilabs), compared with 12 of 204 samples (5.9 %) after automated pre-cleaning (4/94 at HPH and 8/110 at Unilabs). Contamination rates were consistent across centers. Chi-square testing showed no significant difference between manual and automated pre-cleaning ($p = 0.17$). Among duodenoscopes/echoendoscopes (HPH only), contamination occurred in 2/28 (7.1 %) manually pre-cleaned endoscopes and 2/31 (6.5 %) automatically pre-cleaned endoscopes, with Fisher's exact test showing no significant difference ($p > 0.99$). The risk difference for gastroscopes/colonoscopes was + 3.0 % (automated versus manual) and − 0.7 % for duodenoscopes/echoendoscopes.

Overall, these findings demonstrate that the automated brushless pre-cleaning device is non-inferior to manual pre-cleaning.

No adverse events or device-related complications were reported.

The automated pre-cleaning device saved 2,097 minutes of labor (≈ 35 hours), 8,225 L of water, 15.1 L of detergent, and 6.8 kg of plastic. Healthcare professional satisfaction was higher, with 33/40 responses indicating partial or full satisfaction for the automated device versus 11/29 for manual cleaning.

Conclusions The automated brushless pre-cleaning device is non-inferior to manual pre-cleaning, with identical residual protein results and consistently lower microbiological contamination, including in complex endoscopes such as duodenoscopes and echoendoscopes. Its performance was consistent across centers with different workflows, supporting the reproducibility and generalizability of the findings. It also offers substantial resource savings, higher user satisfaction, and maintains a high safety profile, supporting its use as a reliable, efficient, and sustainable alternative in endoscope reprocessing.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP254 Sustaining ERCP Capacity in the NHS: Long-Term Safety and Efficacy of a Regional Treat-and-Transfer Pathway

Authors baig D[1], Lekharaju V[2], Iqbal J[2], Korani M[3], Maclean J[1], Joanna T[1], Mahmood S[2]

Institutes **1** Wythenshawe Hospital, Wythenshawe, United Kingdom; **2** Manchester University NHS Foundation Trust, Wythenshawe, United Kingdom; **3** gastroenterology department, Manchester, United Kingdom

DOI 10.1055/s-0046-1820909

Aims Over recent years, many hospitals in the UK have found it harder to keep up with ERCP demand. There are fewer specialist endoscopists, the number of referrals keeps rising, and the work itself has become more complex. Cholangioscopy is used more often and EUS now plays a regular part in biliary care. All of this has placed extra pressure on units that were already tight on staff and time.

Because of this, many centres now turn to tertiary teams when a case is difficult or when a first attempt has not worked. The Treat and Transfer model has grown from this need. Patients are sent quickly to a tertiary HPB service for ERCP and then return to their local hospital once the procedure is finished. It has become a steady, practical way to keep care timely for hospitals that do not have the capacity to manage everything themselves.

To review the safety, efficiency and technical performance of an eight year regional Treat and Transfer ERCP service delivered through a UK tertiary HPB centre. This represents one of the few long term reviews of this type of model.

Methods We reviewed all ERCP procedures carried out between 2017 and 2025 for patients referred through the Treat and Transfer pathway. The information collected included age, indication, type of anaesthesia, any local ERCP attempts, technical success, need for further procedures and recorded reasons for failed therapy. The data was analysed descriptively and subgroups were compared.

Results In total, 1,230 patients were managed through the pathway. The median age was 69. Most referrals were for choledocholithiasis at 74 %, followed by stent problems at 6 percent, malignant obstruction at 3 % and bile leak at 3 %. Only 1.6 % of patients had a local ERCP attempt before transfer. Of this group, 85 % were successfully treated when the procedure was repeated at the tertiary centre. This highlights the value of central expertise for more challenging cases.

The first attempt technical success rate at the tertiary centre was 98 % at 1205 of 1230. In the 25 unsuccessful cases, the main reasons were difficult cannulation at 55 %, duodenal pathology at 18 %, patient intolerance at 18 percent and poor preparation at 9 %. A second ERCP was successful in 57 %of patients who needed it. A third attempt was successful in a further 6 %. Overall, most patients eventually received effective treatment.

Most procedures were done under conscious sedation at 96.8 %. General anaesthesia was used in 3.2 % of cases where the situation was more complex. Success rates were very similar for both sedation and general anaesthesia at 97.9 % and 97.3 %.

Conclusions This long review shows that the Treat and Transfer model is a safe and reliable way to deliver ERCP despite pressures on staff and rising case complexity. The strong outcomes in patients with failed local attempts show the importance of a central HPB service. As one of the few long running UK datasets, this model provides a practical and scalable approach for ERCP delivery that supports patient flow, reduces dependence on general anaesthesia and improves timely access to specialist care across a wider region.

OP255 Environmental impact of single-use versus reusable duodenoscopes for ERCP: an ISO-compliant life-cycle assessment from Germany

Authors Welsch L[1], Eickhoff A[1]
Institute 1 Klinikum Hanau, Hanau, Germany
DOI 10.1055/s-0046-1820910

Aims To compare the environmental impacts of a single-use duodenoscope (SUD) versus a reusable duodenoscope (RUD) for endoscopic retrograde cholangiopancreatography (ERCP) in Germany and to identify key emission drivers and mitigation levers.

Methods We performed a cradle-to-grave life-cycle assessment (LCA) aligned with ISO 14040/44. The functional unit was one ERCP in one patient in Germany. Devices assessed were aScope Duodeno2 (Ambu) and TJF-Q190 (Olympus). Primary data covered RUD reprocessing at Klinikum Hanau (2024); RUD production relied on secondary sources. Modeling used "LCA for Experts" with Sphera MLC 2024.2; impacts were characterized with the Environmental Footprint (EF) 3.1 method across 16 categories. Assumptions included a RUD lifespan of 625 procedures; repairs and maintenance were excluded. Sensitivity analyses examined bioplastics content and sterilization changes; the study underwent external critical review.

Results Per procedure, SUD exhibited a 66 % higher carbon footprint than RUD (6.61 vs. 3.98 kg CO_2-eq). Freshwater ecotoxicity was nearly doubled (47.1 vs. 26.2 CTUe). Resource use was higher for SUD for fossils (99.2 vs. 63.1 MJ, + 57 %) and for minerals/metals (1.24×10^{-4} vs. 6.36×10^{-6} kg Sb-eq, ~20 ×). Water use was slightly higher for SUD (1.39 vs. 1.26 m^3). For SUD, dominant contributors were raw material extraction/production, packaging, and sterilization; for RUD, 97 % of emissions arose from reprocessing (electricity and water). Replacing bio-based ABS with fossil-based ABS increased SUD climate impacts by ~5.8 %.

Conclusions In the German context, reusable duodenoscopes remain environmentally preferable for routine ERCP, with impacts largely driven by reprocessing energy and water. Single-use performance is mainly driven by materials, packaging, and sterilization; material innovation (e.g., bioplastics) and improved recycling offer incremental gains but do not close the gap. Service-level decarbonization—especially low-carbon electricity for reprocessing and efficiency measures—can further strengthen the environmental advantage of reuse.

OP256 A Material Flow Analysis of an endoscopy department to identify environmental hotspots

Authors Vegting B[1], Izci CB[1], Diehl JC[2], Van Den Heuvel W[3], Hunfeld NGM[4, 5], Van Raaij EM[6], Tietschert MV[6], De Jonge PJF[1], Siersema PD[1]
Institutes 1 Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; 2 TU Delft Faculty of Industrial Design Engineering, Design for Sustainability, Delft Netherlands; 3 Erasmus University Rotterdam, Erasmus School of Economics, Econometrics Institute, Rotterdam, Netherlands; 4 Erasmus University Medical Center, Department of Adult Intensive Care, Rotterdam, Netherlands; 5 Erasmus University Medical Center, Department of Hospital Pharmacy, Rotterdam, Netherlands; 6 Erasmus University Rotterdam, Erasmus School of Health Policy & Management, Rotterdam, Netherlands
DOI 10.1055/s-0046-1820911

Aims In the Netherlands, healthcare accounts for 7 % of national greenhouse gas emissions and 13 % of raw material extraction. Endoscopy services, which rely heavily on single-use items and material-intensive workflows, contribute substantially to this footprint. Understanding material flows within an endoscopy department is therefore essential to support a transition toward circular endoscopic care. This study aimed to conduct a comprehensive material flow analysis (MFA) of an academic endoscopy department by quantifying the material composition of products and packaging and identifying hotspots for targeted sustainability interventions.

Methods We performed an MFA using 2023 procurement data to map all materials and medication inflows and outflows in an academic endoscopy unit. Products, packaging, and information leaflets were weighted on a precision scale, and material composition was determined through manufacturer contact and desk research. Mass and material contributions were analyzed to identify products and material types with the highest mass contribution**.** Outflows were quantified across the department's established waste streams (▶ **Table 1**).

▶ **Table 1**

Product	Total mass, kg	Product mass, kg (%)	Packaging mass, kg (%)
Irrigation solutions	3,774	3,336 (78)	438 (12)
Intravenous solutions	1,063	752 (71)	311 (29)
Gloves	948	843 (89)	105 (11)
Tubing	784	677 (86)	107 (14)
Absorption pads	734	734 (100)	0
Biopsy jars	419	419 (100)	0
Kidney dishes	390	390 (100)	0
Aprons	380	372 (98)	8 (2)
Total MFA	**13,927**	**11,294 (81)**	**2,633 (19)**

Results In total, 416 products and 55 medications were included. In 2023, the department processed 13,927 kg of material, with medications and related packaging accounting for 47 % of total mass. Packaging and information leaflets accounted for 19 % of total mass; 73 % consisted of synthetic plastics and rubbers, 24 % of biobased materials, and 3 % of glass. Across all inflows, synthetic plastics and rubbers dominated (60 %), followed by biobased materials (24 %). Outflows comprised general hospital waste (8,041 kg, 65 %), hazardous waste (3,340 kg, 27 %), and recycled paper (990 kg, 8 %). An additional 1557 kg consisted of materials directly used in patients, such as medications and intravenous fluids. Eight products accounted for 61 % of total annual material mass and were identified as hotspots: irrigation and intravenous solutions, gloves, tubing (suction/irrigation/insufflation), absorption pads, biopsy jars, kidney dishes, and aprons.

Conclusions This MFA of an academic endoscopy department shows that material use is dominated by a small number of high-impact products Identifying these hotspots provides targets to support a shift towards more circular endoscopy services. Future research should translate material flows into environmental impacts, such as carbon emissions and resource depletion, to guide comprehensive sustainability strategies in endoscopy.

Aims Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are effective for large non-pedunculated colorectal polyps but delayed adverse events (AEs) such as bleeding (DB), perforation (DP), and post-electrocoagulation syndrome (PECS) remain common. Prophylactic clipping may prevent these complications, though its efficacy, especially across different techniques, remains uncertain. We conducted a meta-analysis of randomized controlled trials (RCTs) to evaluate the preventive effect of prophylactic clipping after endoscopic resection.

Methods Following PRISMA guidelines, we searched MEDLINE, Embase, and SCOPUS through September 2025 for RCTs comparing prophylactic clipping vs. no clipping after ESD or EMR for non-pedunculated large (>20 mm) colorectal polyps in adults. The primary outcome was clinically significant DB; secondary outcomes included DP, PECS and surgery due to AEs as well as sub-analysis by endoscopic technique. Random-effects models were used to compute risk ratios (RRs) and 95 % confidence intervals (CIs).

Results Twelve RCTs including 3770 patients were analyzed (1862 with clipping, 1908 controls). Prophylactic clipping significantly reduced clinically significant DB (RR 0.5; 95 % CI 0.38-0.88). and DP (RR 0.53; 95 % CI 0.31-0.92) risk. The impact of clipping remains significant after subgrouping by technique showing a decreased risk of DB across ESD studies (RR 0.32; 95 % CI 0.31-0.92), and a protective effect on DP after EMR (RR 0.48; 95 % CI 0.26-0.90). No significant difference was found in terms of risk of PECS (RR 1.01; 95 % CI 0.78-1.55) and surgery due to AEs (RR 0.55; 95 % CI 0.22-1.38).

Conclusions Prophylactic clipping after resection of large colorectal polyps significantly reduces the risk of DB and DP, with the greatest benefit observed after ESD for bleeding prevention and after EMR for perforation prevention.

OP258V Feasibility and Safety of Strategic In-Defect Clipping (iCLIP study) After Colonic EMR/ESD to Prevent Delayed Bleeding: A Prospective Cohort Study

Authors Nakou E[1], Zormpas P[1], Spinou M[1], Leontidis N[1], Pikoulas A[1], Papathanasis A[1], Dimitriadis D[1], Dimopoulou K[1], Voudoukis E[1], Tribonias G[1]

DOI 10.1055/s-0046-1820913

Problem to solve Post-polypectomy bleeding remains a significant adverse event following endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) in the colon, particularly for large polyps in the right colon. While complete defect closure either with clips or with specialized suturing devices reduces bleeding risk, it can be technically demanding and resource-intensive.

Innovation This study investigates a novel approach of placing 2–4 endoclips inside the resection defect, targeting visible vessels or central ulcer areas, without attempting complete closure.

Results We conducted a prospective feasibility cohort study of patients undergoing EMR or ESD in the colon with strategic in-defect clipping protocol (iCLIP) with 2–4 clips, between 2023 and 2025. Data were collected on patient, lesion and procedural characteristics, clip placement and adverse events. The primary endpoint was feasibility, defined as successful in-defect clip deployment in ≥ 90 % of cases. Secondary endpoints included delayed bleeding within 30 days of the procedure, intraprocedural and delayed perforation, clinically significant clip migration and post-polypectomy syndrome (PPS) or abdominal pain. A total of 100 cases (63 males/37 females) were included in the study. The most common location was the ascending colon (42/100) and the median polyp size was 35.5 mm. For the clipping procedure, a transparent tip hood was attached to the endoscope and reopenable through-the-scope clips (TTSCs) were used in all included cases. In this method, clips are placed within the resection ulcer, directly onto the submucosal or muscle layer, targeting visible vessels or the central zone of the defect. First, the clip is gently applied to the submucosa, vertically to the resection defect, without grasping the ulcer margins. Next, sufficient suction is applied to draw the submucosa into the clip and cause the muscle layer to fold before grasping it. It is crucial not to press the clip toward the submucosa, to avoid potential muscle layer injury and subsequent perforation. Additional clips are placed next to the first one using the same procedure, without attempting complete closure. Strategic in-defect clipping (iCLIP) was successfully performed in 100 % of cases. Delayed bleeding occurred in 0 % of patients and no perforations or clinically significant clip migrations were observed except for a single case of muscle layer injury without true perforation. None of the patients demonstrated post-polypectomy syndrome or abdominal pain. All patients underwent follow-up endoscopy at six months post-resection. None had local recurrence. Remaining clip was observed in seven cases (7 %) and was successfully removed with grasping forceps. In three cases (3 %), granulomatous tissue—confirmed histopathologically—was observed in the resection scar, compatible with clip artifact. A possible explanation for the success of this technique is that large vessels are usually located in the center of the defect and not in the periphery, minimizing the necessity of complete defect closure. Moreover, folding of the muscle layer into the clips prevents tension on the submucosa and subsequently to the large vessels, caused by luminal distention from gas or fecal passage.

Conclusions Strategic in-defect clipping (iCLIP) using 2–4 clips is a feasible, safe and potentially effective method to reduce delayed bleeding following colonic EMR or ESD. This technique offers a practical alternative to full defect closure, especially in large lesions or right-sided resections. Compared to historical bleeding rates of 6–10 % after unclosed EMR/ESD, this targeted approach appears to reduce bleeding risk with fewer clips and without the need for specialized suturing devices requiring specific expertise.

DOI 10.1055/s-0046-1820914

Aims Endoscopic closure techniques are essential for the management of defects in therapeutic endoscopy and may also help prevent delayed bleeding and perforation. The SutuArt endoscopic hand-suturing system (Olympus) is an innovative, minimally invasive method for defect closure, but clinical data on its use remain limited. This study aimed to evaluate technical and clinical success rates, complication rates, and procedure times for endoscopic hand-suturing with SutuArt.

Methods In a multicenter European registry study, procedures using endoscopic hand-suturing from fourteen centers were extracted from a prospective database. The primary endpoint was technical success, defined as complete defect closure without the need for additional closure techniques. Secondary endpoints included clinical success, defined as the absence of post-interventional complications during the index hospital stay or complications linked to the index procedure; the overall defect closure rate (closure achieved by suturing alone or combined with additional devices such as clips); and procedure time.

Results Between February 2023 and November 2025, 204 procedures were included. Indications comprised 111 ESD defects (stomach, duodenum, colon, rectum), 31 EID-related rectal defects, 34 G-POEM procedures, 9 fistulas, 4 EMR defects, two anastomotic leaks, and one perforation. Technical success was achieved in 94.1 % (192/204) of cases. 5.9 % (n = 12) required additional closure methods, resulting in an overall defect closure rate of 95.5 % (195/204). The median defect size was 26.5 mm (4–60 mm), and the median suturing time was 25 minutes (5–71). Clinical success was 95.6 % (195/204). Over time, the median procedure duration for the entire cohort decreased from 30 (10–65) minutes in 2023 to 25 (10–62) minutes in 2025, indicating a learning curve effect. No suture-related complications occurred.

Conclusions In this multicenter cohort, the SutuArt system demonstrated high technical and clinical success rates with an excellent safety profile. The observed reduction in procedure time over the study period suggests a learning curve. Further studies are needed to assess the performance of this system for complex defects such as fistulas or perforations and to better define its clinical utility within advanced endoscopic practice.

DOI 10.1055/s-0046-1820915

Aims Prophylactic clip closure after colorectal endoscopic submucosal dissection (ESD) is increasingly performed to prevent postoperative adverse events (AEs), such as delayed bleeding and perforation. However, complete closure of large mucosal defects after ESD using conventional clips remains technically demanding. The MANTIS clip (Boston Scientific, Marlborough, Massachusetts, USA) is a novel reopenable clip that enables a hold-and-drag maneuver by grasping the tissue with its anchor prongs, facilitating defect approximation. This study aimed to evaluate the efficacy and safety of MANTIS clip-assisted closure compared with closure using conventional clips alone for mucosal defects after colorectal ESD.

Methods This was a prospective, multicenter, open-label, randomized controlled trial conducted at ten institutions in Japan. Patients undergoing colorectal ESD were randomly assigned (1:1) to either the MANTIS group or the conventional group. In the MANTIS group, MANTIS clips were used until closure with conventional clips became feasible, after which the remaining defect was closed using conventional clips. In the conventional group, the defect was closed using only conventional clips. The primary endpoint was the complete closure rate, defined as the absence of visible submucosa or muscularis propria in ≥ 90 % of the defect base. Secondary endpoints included closure time, closure speed, the need for operator change, intraprocedural AEs during closure, and post-ESD AEs (delayed bleeding, delayed perforation, and post-ESD coagulation syndrome [PECS]).

Results Between June 2024 and June 2025, 250 patients were enrolled. After excluding seven patients from each group, 236 patients were included in the analysis (MANTIS group, n = 120; conventional group, n = 116). The median longest diameter of the resected specimens was 33 mm (interquartile range [IQR], 30–40 mm) in the MANTIS group and 30 mm (IQR, 30–44.5 mm) in the conventional group. In the MANTIS group, a median of one MANTIS clip (IQR, 1–2) and seven conventional clips (IQR, 5–9) were used, whereas the conventional group used a median of 10 conventional clips (IQR, 8–12). The complete closure rate was significantly higher in the MANTIS group (98.3 %, 118/120) compared with the conventional group (88.8 %, 103/116; absolute difference, 9.5 %; 95 % confidence interval [CI], 3.5–12.0; P < 0.01). Median closure time, closure speed, and operator change rate during the closure did not differ significantly between the MANTIS and conventional groups (540 seconds vs. 585 seconds, $P = 0.14$; 90.3 mm²/min vs. 87.1 mm²/min, $P = 0.91$; 3.3 % vs. 1.7 %, $P = 0.68$). No intraprocedural AEs occurred during closure in either group. Regarding post-ESD AEs, no significant differences were observed between the groups. Delayed bleeding did not occur in the MANTIS group, whereas one case (0.9 %) occurred in the conventional group in a patient with partial closure (P = 0.99). No delayed perforation was observed in either group. PECS occurred in 14 patients (11.7 %) in the MANTIS group and in 10 patients (8.6 %) in the conventional group (P = 0.52). In the multivariate analysis, use of the MANTIS clip was identified as an independent predictor of complete closure (odds ratio, 9.70; 95 % CI, 2.02–46.70; $P < 0.01$).

Conclusions The use of the MANTIS clip resulted in a significantly higher complete closure rate, indicating that it offers a more efficient and reliable approach for achieving mucosal defect closure after colorectal ESD.

DOI 10.1055/s-0046-1820916

Aims The optimal strategy to prevent delayed bleeding after colorectal ESD remains unsettled, especially for large defects with exposed submucosal vessels and muscular layer intact. This study evaluated whether integrating prophylactic vessel coagulation with complete defect closure mitigates delayed adverse events (DAE) and unplanned readmissions [1].

Methods In this multicenter study, we analyzed consecutive colorectal ESD performed across two tertiary referral centers. Cases treated with both prophylactic vessel coagulation and complete defect closure (using standard clips or advanced systems such as Mantis clip or X-Tack suturing device) were propensity score–matched 1:1 with controls receiving coagulation alone. Matching variables included age, ASA score, antithrombotic therapy, defect size and location. Cases with intraprocedural perforation, incomplete closure, or use of hemostatic gels/powders were excluded. The primary endpoint was delayed bleeding; secondary endpoints were composite DAE rate (bleeding, perforation, PECS) and hospital readmission (▶ **Table 1**).

▶ **Table 1**

Covariates	Coagulation + Complete Closure (n = 87)	Coagulation Only (n = 87)	p value
Patient and Defect Characteristics			
▪ Age ≥ 75 years	25.3 %	25.3 %	n.s.
▪ ASA III–IV	14.9 %	14.9 %	n.s.
▪ Antithrombotics	10.3 %	10.3 %	n.s.
▪ Large defects	75.9 %	75.9 %	n.s.
▪ Rectal defects	47.1 %	47.1 %	n.s.
Main Endpoints			
▪ Delayed bleeding	1.2 %	6.9 %	< 0.05
– Composite DAE	3.5 %	12.7 %	< 0.05
▪ Delayed perforation	0 %	2.3 %	n.s.
▪ PECS	2.3 %	3.5 %	n.s.
▪ Unplanned readmission	4.6 %	16.1 %	< 0.05
▪ Hospital stays, days (mean ± SD)	2.2 ± 0.4	3.4 ± 1.4	< 0.05
▪ Complete closure time, min (mean ± SD)	26.3 ± 7.4		
▪ Number of clips used, mean ± SD	9.1 ± 1.7		
▪ Advanced closure systems used	32.2 %		

Results A total of 174 procedures were analyzed after matching (87 per group) with comparable baseline characteristics (25.3 % ≥ 75 years; 14.9 % ASA III–IV; 10.3 % on antithrombotic therapy; 75.9 % large defects; 47.1 % rectal; p = n.s.). The combined strategy significantly reduced delayed bleeding (1.2 % vs 6.9 %; p < 0.05) and composite DAEs (3.5 % vs 12.7 %; p < 0.05) with comparable delayed perforations (0 % vs 2.3 %; p = n.s.) and PECS (2.3 % vs 3.5 %; p = n.s.). All bleeding and PECS episodes were managed endoscopically or conservatively, whereas delayed perforations required surgery. Readmissions were fewer in the closure group (4.6 % vs 16.1 %; p < 0.05), with shorter mean hospital stays (2.2 ± 0.4 vs 3.4 ± 1.4 days; p < 0.05). Complete closure required a mean of 9.1 ± 1.7 clips, and advanced closure systems were used in 32.2 % of cases (closure time 26.3 ± 7.4 min).

Conclusions Combining prophylactic vessel coagulation with complete defect closure after colorectal ESD significantly reduces the risk of delayed bleeding. By decreasing DAE by 73 %, this dual approach represents an effective strategy to enhance post-ESD safety and minimize unplanned readmissions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP262 Which Closure Technique is Superior? A Comparative Analysis of No-closure, Hemoclips, Endoscopic Hand-Suturing, OverStitch Following Colorectal Endoscopic Submucosal Dissection

Authors Aslan F[1], Ozer S[1], Aktas O[1]
Institute **1** Koç University Hospital, Istanbul, Türkiye
DOI 10.1055/s-0046-1820917

Aims Endoscopic submucosal dissection (ESD) carries risks of delayed bleeding, perforation and stricture formation as it is not easily performed. While prophylactic closure is increasingly performed, comparative analysis between varying closure techniques and optimal closure strategy remain limited. We evaluated outcomes of different closure techniques including endoscopic hand-suturing (EHS) suturing, OversStitch, Hemoclips and no-closure.

Methods We retrospectively analyzed 1267 consecutive colorectal ESD procedures. Closure methods as follows: no-closure (n = 819, 64.6 %), hemoclips (n = 319, 25.2 %), EHS (n = 70, 5.5 %), OverStitch (n = 59, 4.7 %), and Endoloop (n = 2, 0.2 %; excluded due to small sample size). Primary outcomes included composite adverse events (perforation, delayed bleeding, and stricture). status. Multivariable logistic regression and propensity score matching (3:1, caliper 0.05) adjusted for confounders. Subgroup analyses included lesion size stratification (< 10cm vs > 10cm) and anticoagulation status

Results Overall adverse event rate was 2.8 % (n = 35), including delayed bleeding 0.5 % (n = 6), perforation 1.5 % (n = 19), and stricture 0.8 % (n = 10). Closure significantly reduced adverse events compared to no closure (0.89 % vs 3.79 %, p = 0.002; relative risk (RR) 0.24, 95 % CI: 0.08-0.68; absolute risk reduction (ARR) 2.9 %; number needed to treat (NNT) 35). Among closure devices, EHS achieved the lowest adverse event rate (n = 0, p = 0.003). In multivariable adjusted regression analysis, mucosal closure (OR 0.30, 95 % CI: 0.09-0.93, p = 0.037) and rectal location (OR 0.33, 95 % CI: 0.12-0.88, p = 0.027) remained protective. Propensity score matching (650 patients, AUC: 0.806) showed a trend toward benefit with closure (ATET -1.38 %, 95 % CI: -3.44 % to 0.67 %, p = 0.187). Lesions > 10cm (n = 150), closure reduced adverse events from 9.52 % to 2.22 %, (ARR 7.3 %, NNT 14, p = 0.009). Lesions < 10cm (n = 1,117), closure reduced adverse events from 2.94 % to 0.74 % (ARR 2.2 %, NNT 46, p = 0.015). Among anticoagulated patients (n = 172), closure eliminated all adverse events compared to no-closure (0 % vs 7.58, p = 0.008, NNT 13). Hospital stay was significantly shorter with closure (median 1 vs 2 days, p < 0.001).

Post-polypectomy syndrome was present in 4.18 % of all procedures. The incidence varied significantly by closure method (p = 0.001): no closure 4.52 %, hemoclips 1.58 %, EHS 4.29 % and OverStitch 13.56 %. The higher PPS rate with OverStitch stems from the reservation of the devices for complex resections (lesion size mean: 98.9 ± 73.8mm).

Conclusions Closure following colorectal ESD reduces adverse events, with greatest benefit in larger lesions (> 10cm), and anticoagulated patients. No adverse events were experienced with EHS, though larger comparative studies are needed. The NNT of 14 for lesions > 10cm and NNT 13 for anticoagulated patients support routine closure in such high-risk patients.

OP263 Real-time Hypoxia Assessment in Colorectal Polyps Using Oxygen Saturation Imaging: A Novel Physiological Endoscopy Approach

Authors Murakami T[1], Tsugawa N[1], Hirasawa Y[1], Hata W[1], Otsuki Y[1], Yamauchi T[1], Kamba E[1], Fukushima H[1], Shibuya T[1, 2], Yao T[3], Nagahara A[1, 2]

Institutes **1** Department of Gastroenterology, Juntendo University Faculty of Medicine, Tokyo, Japan; **2** Gastrointestinal Pathophysiology and Therapeutics, Juntendo University, Tokyo, Japan; **3** Department of Human Pathology, Juntendo University Graduate School of Medicine, Tokyo, Japan

DOI 10.1055/s-0046-1820918

Aims Hypoxia occurs when tissues receive insufficient oxygen due to pathological conditions (e.g., cancer, inflammation, diabetes) or non-pathological factors (e.g., high altitude). It is a hallmark of the tumor microenvironment and contributes to carcinogenesis and treatment resistance in many solid tumors. Oxygen saturation imaging (OSI) endoscopy is a non-invasive modality that enables real-time visualization of oxygen saturation on the gastrointestinal mucosal surface [1]. This study aimed to objectively assess oxygen saturation (StO_2) in colorectal polyps—including adenomas (ADs), hyperplastic polyps (HPs), and sessile serrated lesions (SSLs)—in comparison with the surrounding mucosa using OSI endoscopy, and to investigate the association between StO_2 and hypoxia-inducible factor 1α (HIF1α) expression.

Methods This retrospective pilot study included consecutive colorectal lesions endoscopically resected at Juntendo University Hospital (Tokyo, Japan) between November 2021 and October 2022 using an OSI-equipped system. All lesions were evaluated using white-light imaging and OSI prior to resection. Lesions with unavailable or poor-quality OSI images and those pathologically diagnosed as adenocarcinoma were excluded. A total of 133 lesions from 30 patients were analyzed: 78 ADs, 35 HPs, and 20 SSLs. Five regions of interest were randomly selected from each lesion and corresponding mucosa to obtain mean StO_2 values; ΔStO_2 was calculated as [lesion StO_2] – [surrounding mucosa StO_2]. Immunohistochemistry for HIF1α (≥ 10 % nuclear or cytoplasmic staining defined as positive) was performed on resected specimens. Clinicopathologic characteristics were reviewed, and statistical analyses were conducted using the Mann–Whitney U test, Yates-corrected chi-square test, or Fisher's exact test, with significance set at $P < 0.05$. Institutional ethical approval was obtained.

Results Among the 133 lesions, ADs, HPs, and SSLs did not differ significantly in patient age, sex, or macroscopic type. HPs were predominantly located in the distal colon, whereas SSLs were significantly larger than the other lesion types. Across all groups, mean StO_2 in lesions was significantly lower than in surrounding mucosa (ADs: $P < 0.001$; HPs: $P = 0.005$; SSLs: $P = 0.049$). ADs demonstrated significantly lower StO_2 than HPs and SSLs (ADs vs. HPs: $P < 0.001$; ADs vs. SSLs: $P = 0.038$).

Mean ΔStO_2 was −9.2 ± 7.7 for ADs, −3.5 ± 3.8 for HPs, and −4.7 ± 5.0 for SSLs. Absolute ΔStO_2 was significantly greater in ADs than in HPs ($P < 0.001$) and SSLs ($P = 0.011$), indicating that hypoxia was most pronounced in ADs. No significant difference in ΔStO_2 was observed between HPs and SSLs.

HIF1α expression was positive in 28/78 ADs (39.7 %), 0/35 HPs, and 2/20 SSLs (10.0 %). HIF1α positivity was significantly more frequent in ADs than in HPs ($P < 0.001$) and SSLs ($P = 0.016$). Among ADs, StO_2 values were significantly lower in HIF1α-positive lesions than in HIF1α-negative lesions (41.5 ± 4.3 vs. 48.2 ± 4.7, $P < 0.001$). This inverse relationship indicates that reduced StO_2 on OSI corresponds to molecular hypoxia within precancerous lesions.

Conclusions This study is the first to quantify StO_2 in colorectal polyps using OSI and demonstrates that ADs exhibit significantly lower StO_2 and greater ΔStO_2 than HPs, SSLs, and adjacent mucosa. These findings indicate that ADs harbor a hypoxic microenvironment despite being non-malignant, supporting the concept that hypoxia emerges early during colorectal neoplastic progression. The strong association between low StO_2 and high HIF1α expression further supports OSI as a functional imaging modality capable of detecting physiologically meaningful hypoxia.

OSI endoscopy provides real-time, non-invasive visualization of mucosal oxygenation and may complement morphological imaging by offering physiological biomarkers for risk stratification. Although this was a single-center pilot study with a limited sample size, the results suggest that OSI may help identify biologically aggressive precursor lesions. Larger prospective studies—including evaluation of additional hypoxia-related markers and deeper tissue oxygenation—are warranted to validate the clinical utility of StO_2 assessment in colorectal tumorigenesis and its potential role in early detection and management strategies.

DOI 10.1055/s-0046-1820919

Aims Diverticular disease (DD) affects approximately 70 % of the Western population by the age of 80 and is associated with significant morbidity and mortality. Chronic gastrointestinal symptoms are common (reported in up to 25 %), termed symptomatic uncomplicated diverticular disease (SUDD). Although surgical treatment is well-established, management options for chronic symptoms are limited and there are currently no prophylactic options. A pilot study described prophylactic endoscopic clipping of diverticula, demonstrating a closure rate of 87 % [1]. This RCT aims to establish whether elective endoscopic clipping leads to lasting closure of diverticula and improvement in associated symptoms.

Methods Eligible patients were recruited from dedicated diverticular clinics. Patients were randomised and blinded to either colonoscopy with endoscopic

clipping of diverticula or colonoscopy with 'sham' intervention. Symptoms were assessed prior to intervention using the Irritable Bowel Syndrome Symptom Severity Score (IBS-SSS). Follow-up with repeat endoscopic assessment and mapping of diverticula occurred at 3 and 12 months and repeat questionnaires at 3, 6 and 12 months.

Results Eighty-four patients (mean age 57 ± 9.4; 51F) with symptomatic DD were included and randomised and blinded to receive either a sham procedure or clip-closure of all visible diverticula. At index colonoscopy there was a median of 22 (5-155) diverticula per patient. At 3 and 12 months, there was a statistically significant increase in closure rate (47 % vs -3 %, p < 0.0001; 34 % vs 9 %, p = 0.032) and in symptom scores (41 % vs 12 %, p = 0.0036; 48 % vs 23 %, p = 0.012). At 12 months, the number of patients achieving symptom response (> 50 % reduction in symptom score) was 60 % vs 29 %, p < 0.008 (number needed to treat (NNT) = 3.2) and symptom remission (SSS < 75) was 40 % vs 10 %, p = 0.002 (NNT = 3.3). Endoscopic clipping was shown to be an independent predictor of response at 12 months on multivariate analysis, with a 3-fold increase in responders in the treatment group (OR 3.146, CI 1.179-87.80). There were fewer reported episodes of diverticulitis in the treatment group compared with sham (p = 0.03).

Conclusions This trial demonstrates that prophylactic endoscopic clipping of DD leads to safe and lasting closure of diverticula with a statistically significant improvement in associated symptoms. These results support endoscopic clipping as a novel therapeutic intervention in select patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP265 Intraluminal pressure assessment using the endoscopic pressure study integrated system (EPSIS) during colonoscopy

Authors Shiomi D[1], Tanabe M[1], Nakamura H[1], Miyake R[1], Kishi Y[1], Fukuda M[1], Toshimori A[1], Uragami N[1], Ito T[1], Yokoyama N[1], Inoue H[1]

DOI 10.1055/s-0046-1820920

Aims The endoscopic pressure study integrated system (EPSIS) is a system that continuously measures intraluminal pressure in the digestive tract while delivering carbon dioxide (CO_2) insufflation from the endoscope. It enables simultaneous assessment of endoscopic findings and intraluminal pressure. While we have previously validated EPSIS for assessing the lower esophageal sphincter and anorectal function, data on colonic pressure profiles remain limited. We aimed to evaluate the feasibility of colonic EPSIS during colonoscopy and investigate the impact of clinical and local factors on segmental pressure dynamics.

Methods In this single-center retrospective study, we analyzed 50 consecutive patients who underwent colonoscopy with EPSIS between October and November 2025. Pressure measurements were obtained during scope withdrawal. CO_2 was insufflated into six colonic segments (cecum; ascending, transverse, descending, and sigmoid colon; rectum) until pressure equilibrium was reached or patient movement occurred. For each segment, initial pressure, maximum pressure, and the EPSIS waveform gradient were calculated. Associations with age, body mass index (BMI), elderly status (≥ 75 years), hyoscine butylbromide administration, and the presence of diverticula were evaluated.

Results Procedural sedation was used in 47 patients (94 %), and the median pain visual analogue scale (VAS) score was 0 (interquartile range 0–0). Median maximum pressures ranged from 15.6 to 17.4 mmHg across all segments. Age and BMI showed no clear associations with maximum pressure or gradient in any segment. Comparing elderly and non-elderly patients, only the descending colon showed slightly lower maximum pressure and gradient in the elderly, while other segments showed no significant differences. Hyoscine butylbromide use did not affect maximum pressure, but gradients in the ascending and transverse colon were significantly higher in patients not receiving the drug (0.60 vs. 0.35 mmHg/s, P < 0.01), with a similar trend in the descending colon. While ascending colon diverticula had no impact, sigmoid diverticula were associated with a significantly steeper gradient (0.92 vs. 0.28 mmHg/s, P < 0.001) without a significant difference in maximum pressure.

Conclusions Colonic EPSIS during routine colonoscopy is feasible and allows for segmental assessment of intraluminal pressure and pressure-rise gradients. Age and BMI had minimal influence on colonic pressure profiles, whereas hyoscine butylbromide and sigmoid diverticula selectively modified the gradient rather than the maximum pressure. Together with previous rectal EPSIS data, these findings provide fundamental data on colonic pressure dynamics during colonoscopy.

OP266 Racial and Gender Disparities in Eosinophilic Colitis: A Nationwide HCUP Analysis (2019–2023)

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Amina Z[1], Mustacchia P[1]

Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1820921

Aims This study uses HCUP data (2019–2023) to examine racial and gender disparities in eosinophilic colitis among 2.7 million adult admissions. Findings aim to clarify how these factors influence incidence and guide improved diagnosis and management strategies.

Methods We analyzed data from the Healthcare Cost and Utilization Project (HCUP) National Database, covering 2,748,576 adult hospital admissions from 2019 to 2023 with a primary diagnosis of Eosinophilic colitis. The initial analysis involved reviewing the dataset's structure, focusing on race, gender, and indicators of eosinophilic colitis. We summarized incidence rates by demographic factors and conducted chi-square tests to detect significant differences in incidence across various racial and gender groups. This involved using contingency tables to provide statistics and calculate p-values. Subsequently, logistic regression was employed to examine the relationships between race and gender as predictors and eosinophilic colitis as the dependent variable.

Results From 2019 to 2023, among the 2,748,576 patients admitted, we focused on 10,211 patients with Eosinophilic colitis after performing propensity score matching. The logistic regression analysis revealed significant disparities in the incidence of Eosinophilic colitis based on race and gender. Whites were found to have the highest likelihood of developing the condition (coefficient: 2.2411, p < 0.0001), followed by Blacks (coefficient: 1.0911, p < 0.0001), while Other Races showed a decreased likelihood (coefficient: -1.0702, p < 0.0001). There was no significant difference for Hispanics (coefficient: -0.0102, p = 0.9742). Additionally, males were less likely than females to develop the condition (coefficient: -0.1760, p < 0.0001), highlighting the significant impact of race and gender on the prevalence of the disease

Conclusions Analysis of the HCUP National Database revealed racial and gender disparities in eosinophilic colitis incidence, highlighting the interplay of genetics, environment, and healthcare access. Higher rates among white and Black populations suggest potential genetic or environmental influences, while lower incidence in males and Hispanics calls for further investigation. These findings emphasize the need for targeted interventions and tailored healthcare strategies to better manage eosinophilic colitis in diverse populations.

OP267 Cryobiopsy compared to forceps biopsy in the colorectum, a prospective open-lable proof of concept study

Authors Seeger WA[1], Ziegler P[1], Koca F[2], Haug V[1], Lande R[1], Wiegering A[1], Wild P[1], Zeuzem S[1], Friedrich-Rust M[1], Michael FA[1]
Institutes **1** Frankfurt University Hospital, Frankfurt, Germany; **2** Frankfurt University Hospital, Frankf, Germany
DOI 10.1055/s-0046-1820922

Aims Reliable histological confirmation of colorectal cancer is essential for staging and treatment planning. Conventional forceps biopsy (FB) often provides specimens that are too small or too superficial. This study examined whether a novel endoscopic cryobiopsy (CB) technique improves diagnostic adequacy.

Methods In this prospective study, fresh surgical colorectal cancer specimens larger than 2 cm were longitudinally opened and sampled before fixation. Sampling was performed by an endoscopist directly on the intact mucosal surface. Two FB samples were obtained using disposable oval-spoon forceps (Ø 2.3 mm, 180 mm, [Radial Jaw 4, large capacity, Boston Scientific, Marlborough, USA]). Four CB samples were obtained using a flexible 1.7-mmCB probe (length 115 mm) powered by the ERBECRYO 2 console (Erbe Elektromedizin GmbH, Tübingen, Germany). The probe tip was placed on the target tissue, freezing was activated via foot pedal, and the sample was released by rapid traction at predefined freezing times of 1, 2, 3, and 4 seconds (CB1-4). Healthy mucosa was sampled before tumor tissue to avoid contamination.Primary endpoint was specimen length. Secondary endpoints included perforation, deepest histological layer reached in healthy tissue, tumor histology classification, and biopsy quality rated on a 0–3 Likert scale.

Results Across six specimens, 48 CB samples and 24 FB samples were collected. Mean specimen length was 3.63 mm ± 1.25 for FB; 3.33 ± 0.89 for CB1; 4.00 ± 0.95 for CB2; 5.17 ± 0.84 for CB3; and 4.75 ± 1.60 mm for CB4 ($p < 0.001$). Depth analysis of healthy mucosa showed that FB reached lamina propria in 67 percent and lamina muscularis mucosae in 33 percent. CB reached deeper layers more consistently. Submucosa was attained in 50 percent of CB1, 83 percent of CB2, 83 percent of CB3, and 50 percent of CB4 samples; one CB4 sample reached superficial muscularis propria ($p = 0.013$). No perforations were observed. Tumor biopsies revealed high-grade dysplasia (HGD) in 75 percent of FB samples and HGD suggestive of invasive cancer (HGD-SIC) in 25 percent. CB provided comparable or improved diagnostic granularity. CB3 identified one definitive adenocarcinoma, which was not detected by FB. Biopsy quality (Likert > 1) was achieved in 63 percent of FB samples, 92 percent of CB1 and CB2 samples, 100 percent of CB3 samples, and 92 percent of CB4 samples ($p = 0.032$).

Conclusions This novel cryobiopsy technique, using a flexible 1.7-mm probe, consistently produced larger, deeper, and higher-quality tissue specimens than standard forceps biopsy. A freezing time of 3 seconds offered the most favorable balance of size, depth, and diagnostic yield. Cryobiopsy may provide a meaningful diagnostic advantage in colorectal lesions where depth of invasion remains uncertain and could support more precise therapeutic decision-making.

Conflicts of Interest Erbe Elektromedizin GmbH, Tübingen, Germany provided the probes used for the cryobiopsy. No funding by the company was offered.

OP268 Mechanism-based protein biomarkers for early detection of colorectal cancer and advanced adenomas

Authors Papanikolaou I[1], Koukoulioti E[1], Fotis C[2], Tsolakos N[2], Antonopoulou P[1], Stamou A[1], Anagnostou G[1], Karatza E[1], Kapantai K[1], Vezakis I[3], Stamogiannos A[2], Pliaka V[2], Temponeras I[2], Miloulis S[4], Tadić M[5], Giannakopoulos V[6], Michailidou S[6], Aigner F[7], Stiegler P[8], Kypraios D[6], Triantafyllou K[1], Jiang Z[9], Matsopoulos G[4], Alexopoulos L[2]

DOI 10.1055/s-0046-1820923

Aims Colorectal Cancer (CRC) is the second-leading cause of cancer-relatedmortality in Europe and the United States, but early detection boosts the 5-year relative survival rate to 91 %. While colonoscopy remains the goldstandard for screening, its invasive nature reduces adherence. Although lessinvasive stool-based and emerging blood-based biomarker tests have greatlyadvanced screening efforts, new biomarker combination strategies areneeded to enhance accuracy, particularly for detecting early-stage CRC andadvanced adenomas (AA). In this study, part of the Horizon Europe-fundedDIOPTRA project for Mission Cancer, a mechanism-based protein biomarkerapproach to improve early detection was investigated.

Methods A discovery clinical study was conducted involving 260 individuals undergoingcolonoscopy to collect blood samples for biomarker analysis. Based oncolonoscopy findings and subsequent histopathological evaluation,participants were classified into four groups: Negative (no findings orhyperplastic polyps), Non-advanced adenoma (NAA), Advanced adenoma(AA), and Colorectal cancer (CRC). Each sample was analyzed using Olink'snext-generation proteomics platform, which employs proximity extensionassay (PEA) technology to quantify 3,072 plasma proteins. In parallel, bead-based multiplex assays (Luminex xMAP technology) were used to measure26 cancer-specific autoantibodies, providing complementary insights intoimmune responses. Integrated bioinformatic analyses combining protein andautoantibody data were performed to identify potential biomarker signaturesassociated with CRC and AA.

Results The Olink proteomic analysis identified a 12-protein signature capable ofaccurately discriminating between the four study groups. Using a 5-fold cross-validation scheme, the linear combination of these proteins achieved asensitivity of 98.1 % (95 % CI: 90.1–100.0 %) for colorectal cancer (CRC)detection and a specificity of 93.1 % (95 % CI: 77.2–99.2 %) for advancedneoplasia (calculated by combining the Healthy and NAA groups).Importantly, the model demonstrated a 100.0 % sensitivity (95 % CI:85.8–100.0 %) for stage I/II CRC and 50.0 % sensitivity (95 % CI: 37.0–63.0 %)for advanced adenomas (AA), highlighting the potential of circulating proteinsignatures for detecting both early-stage cancer and advanced precancerouslesions. In parallel, autoantibody profiling revealed eight autoantibodiesexhibiting markedly elevated fluorescence signals (Net MFI > mean + 6 SD) in3 CRC and 8 AA cases compared to the overall study population. Theinclusion of these autoantibody markers enhanced the overall specificity of theproteomic signature, particularly for the AA group.

Conclusions The combination of highly cancer-specific autoantibodies with sensitiveprotein biomarker panels in blood can substantially improve early detectionperformance. Ongoing work focuses on developing multiplex immunoassaysfor these biomarkers to independently validate the findings and to assessanalytical and clinical performance in a larger validation cohort from theDIOPTRA studies (N = 1,600 participants). This integrated protein biomarkersignature has the potential to enable more accurate, minimally invasivecolorectal cancer screening, facilitating detection of both malignant andprecancerous lesions at earlier and more treatable stages.

DOI 10.1055/s-0046-1820924

Aims Post-ESD surveillance guidelines remain heterogeneous, with many centers favoring early surveillance colonoscopy (SC) despite low recurrence rates aftercurative resection. This study aimed to evaluate the safety and outcomes of delayed SC afterR0 colorectal ESD for benign lesions and to identify risk factors for metachronous advanced neoplasia.

Methods We retrospectively analyzed 1,097 patients who underwent colorectal ESDbetween 2013 and 2021. Clinical, procedural, and histological characteristics were recorded. Among 778 patients with available surveillance data, outcomes were compared between those who had early SC (< 12 months) and those with delayed SC (> 24 months). Rates of recurrence, advanced neoplasia, and colorectal cancer were assessed. Risk factors for metachronous advanced neoplasia were evaluated via univariate and multivariate analysis.

Results Mean patient age was 74.3 ± 10.8 years; 54.1 % were male. En bloc and R0 resection rates were 95.8 % and 83.3 %, respectively. Among patients with surveillance data, 82.6 % underwent early SC, and 17.4 % had late-only SC. The rate of advanced adenoma at first SC was low and comparable between early and late groups (3.9 % vs. 6.7 %, p = 0.167).The overall rate of metachronous advanced adenoma was 6.5 %, with no significant difference between early and late strategies (6.1 % vs. 8.9 %, p = 0.25). All four colorectal cancers were detected in the early group; none occurred in the late-only group. Recurrence on the ESD scar was rare (1.5 % overall), and no late recurrences occurred after a normalSC1. The only significant predictor of metachronous advanced neoplasia was the number of synchronous lesions at index colonoscopy (OR 1.16, 95 % CI 1.07–1.27; p < 0.01).

Conclusions Delayed surveillance colonoscopy 3 years after R0 colorectal ESD for benign lesions appears safe and effective in selected patients. The multiplicity of synchronous lesions could guide risk stratification. These findings support extending SC intervals aftercurative ESD, with potential to reduce unnecessary procedures.

OP270 Endoscopic Transpapillary Gallbladder Drainage as a Preventive Strategy in Surgically Unfit Patients With Concomitant CBD and Gallbladder Stones

Authors Paik WH[1], Kim CH[1], Ryu K[2], Choi JH[1], Ryu J[1], Lee SH[1], Cho IR[1]

Institutes 1 Seoul National University Hospital, Seoul, Republic of Korea; 2 Konyang University hospital, Daejeon, Republic of Korea

DOI 10.1055/s-0046-1820925

Aims In patients with concomitant common bile duct (CBD) and gallbladder stones who are at high surgical risk, cholecystectomy is often unfeasible. Endoscopic transpapillary gallbladder drainage (ETGBD) has been increasingly adopted as a less invasive alternative, but evidence regarding its preventive effect on recurrent biliary events remains limited. We aimed to evaluate the long-term preventive effect of ETGBD compared with observation in surgically unfit patients with both CBD and gallbladder stones.

Methods This single-center, retrospective cohort study included consecutive high-risk surgical patients who had both common bile duct (CBD) stones and gallbladder stones and underwent endoscopic CBD stone removal between January 2010 and July 2024. High surgical risk was defined as American Society of Anesthesiologists (ASA) class ≥ III, significant cardiopulmonary comorbidity, or age ≥ 80 years. Patients who underwent successful ETGBD with maintained gallbladder drainage were compared with those managed by observation. The primary outcome was the occurrence of overall biliary events, including acute cholecystitis, acute cholangitis, and recurrent CBD stones. Propensity score–based overlap weighting was applied to adjust for confounding.

Results Among 220 eligible patients, 41 underwent ETGBD and 179 were managed with observation. Overall biliary events occurred significantly less frequently in the ETGBD group. ETGBD was associated with a markedly lower risk of overall biliary events in both univariable and multivariable analyses (multivariable HR 0.166, 95 % CI 0.039–0.695; p = 0.014). This association remained robust after overlap weighting (HR 0.182, 95 % CI 0.043–0.759; p = 0.019). In event-specific analyses, ETGBD significantly reduced the risk of recurrent CBD stones (multivariable HR 0.100, 95 % CI 0.013–0.748; p = 0.025), while the risks of acute cholangitis and acute cholecystitis were comparable between groups. ETGBD did not increase ERCP-related adverse events.

Conclusions ETGBD significantly reduced recurrent biliary events and demonstrated a clear protective effect against recurrent CBD stones in high-risk surgical patients with concomitant CBD and gallbladder stones. ETGBD may serve as a practical, durable, and clinically meaningful alternative therapy for patients who are unsuitable for cholecystectomy.

OP272 Long-term Outcomes of EDEE in a Tertiary Referral Center: A Prospective Cohort Evaluation

Authors Mutignani M[1], Forti E[2], Pugliese F[2], Cintolo M[2], Bonato G[3], Palermo A[2], Gallo C[4], Stegagnini M[5], La Mantia A[2], Dioscoridi L[5]

Institutes 1 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy., Milan, Italy; 2 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy; 3 ASST Great Metropolitan Hospital Niguarda, Milano, Italy; 4 ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy; 5 ASST Great Metropolitan Niguarda, Milano, Italy

DOI 10.1055/s-0046-1820927

Aims Endoscopic ultrasound (EUS)-directed transenteric/trangastric endoscopic retrograde cholangiography (EDEE) using lumen-apposing metal stents (LAMS) has emerged as a minimally invasive alternative for selected benign and malignant gastrointestinal conditions. Although short-term technical and clinical success rates are high, long-term durability, stent-related complications, and need for reintervention remain incompletely defined.

The aim of the present study is to evaluate long-term clinical, endoscopic, and technical outcomes of EDEE performed in a high-volume tertiary referral center to treat benign adverse events of bilio-digestive anastomosis.

Methods We conducted a prospective observational study including consecutive patients undergoing EDEE between 2018 and 2020 with minimum follow-up of 5 years. Clinical indications, type of surgery, technical details, and early adverse events were recorded. Primary endpoints were long-term clinical success and anastomotic patency. Secondary endpoints included late adverse events (LAMS obstruction, migration, erosions), recurrence rate, need for endoscopic or surgical reintervention, and predictors of long-term failure. Statistical analysis was performed including multivariate tests [1–3].

Results A total of 40 patients were included, with a median follow-up of 63 months. All the patients underwent hepaticojejunostomy on Roux-en-Y loop due to iatrogenic biliary damage in 14 patients and due to oncological resection in 36 patients. Technical and early clinical success were achieved in 100 % and 97,5 %, respectively. One patient had a recurrence of neoplastic stricture. Anastomotic patency at final follow-up was 97,5 %. LAMS for EDEE was still in place in 10 patients uneventfully. Late adverse events occurred in 2,5 % of cases (recurrent cholangitis without recurrent anastomotic stricture due to HCC), managed conservatively. Recurrence of the stricture occurred in 4,6 % and was retreated endoscopically in all the cases. Recurrence occurred in case of ischemic cholangiopathy involving the intrabiliary ducts (p 0.01) in all cases during the first 12 months of follow-up.

Conclusions In a tertiary referral setting, EDEE demonstrates excellent long-term durability, high anastomotic patency, and manageable late adverse events. The correct rationale in treating biliary adverse events is crucial to obtain long-term favorable outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims To evaluate whether endoscopic papillary large-balloon dilation (EPLBD) increases the risk of late cholangitis compared with standard dilation (EPBD) due to potential long-term impairment of the sphincter of Oddi, in patients treated for common bile duct (CBD) stones, using propensity score matching to reduce the effect of baseline confounding factors [1–7].

Methods This multicenter retrospective cohort study included adults undergoing ERCP with balloon dilation for choledocholithiasis at 33 Italian centers (2014–2023). Patients treated with EPLBD (≥ 12 mm) or EPBD (< 12 mm) were eligible if complete duct clearance was achieved. The primary outcome was late cholangitis, defined as cholangitis occurring more than 30 days after ERCP. A propensity score was computed from main clinical and anatomical variables to create comparable EPLBD and EPBD groups, minimizing the influence of baseline imbalances (▶ **Table 1**).

Endoscopy 2026; 58: S1–S1041 |

▶ **Table 1** Baseline characteristics of patients undergoing EPLBD vs EPBD before and after propensity score matching

Variable	EPLBD Unmatched (n = 752)	EPBD Unmatched (n = 173)	SMD (%)	EPLBD Matched (n = 173)	EPBD Matched (n = 173)	SMD (%)
Age, years (mean)	74.4	72.5	14.8	72.2	72.5	−2.3
Male sex, %	48.7	63.1	−29.2	64.2	63.0	2.5
CBD diameter, mm (mean)	15.8	12.0	102.8	11.9	12.0	−3.0
Largest stone diameter, mm	13.8	9.7	97.5	9.6	9.7	−3.5
No. of stones = 1, %	29.2	32.4	−6.8	35.5	32.4	6.5
No. of stones = 2, %	15.2	11.4	11.3	11.6	11.4	0.5
No. of stones ≥ 3, %	55.6	56.3	−1.4	52.9	56.3	−7.0
Periampullarydiverticulum, %	23.4	34.1	−23.7	33.0	34.1	−2.0
Previouscholecystectomy, %	44.6	36.4	16.8	36.4	36.4	0.0
Previous ERCP, %	46.4	41.5	10.0	44.5	41.5	6.0

Results A total of 990 patients were included, of whom 342 were successfully matched (171 per group). Procedural outcomes and early adverse events were similar between techniques (CBD clearance at index ERCP: EPLBD 87.3 % vs EPBD 80.3 %, p = 0.08; mechanical lithotripsy: 12.1 % vs 11.0 %, p = 0.74; cholangioscopy-assisted lithotripsy: 2.3 % vs 4.6 %, p = 0.24; PEP: 2.3 % vs 4.0 %, p = 0.34; bleeding: 5.8 % vs 6.4 %, p = 0.82; perforation: 2.3 % vs 0.6 %, p = 0.12; early cholangitis: 2.9 % vs 5.8 %, p = 0.19). Over a mean follow-up of approximately three years, late cholangitis occurred in 7.9 % of matched patients (EPLBD 6.4 % vs EPBD 9.4 %, p = 0.32), with no significant difference between EPLBD and EPBD, consistent with findings in the unmatched cohort (9.8 % vs 9.4 %, p = 0.85). Recurrent choledocholithiasis was the main driver of late cholangitis, but a substantial proportion (about one-third) occurred without stones. Overall long-term biliary events (late cholangitis and/or stone recurrence) occurred in 15.2 % of matched patients, with identical rates between EPLBD and EPBD.

Conclusions In this large, balanced cohort, large and standard dilation demonstrated comparable long-term safety, with no evidence that EPLBD increases the risk of late cholangitis. Late biliary events were primarily driven by stone recurrence. These findings suggest that the choice between large and standard dilation should be guided mainly by stone characteristics and technical feasibility rather than concerns about long-term complications.

DOI 10.1055/s-0046-1820929

Aims: Current international guidelines regarding the treatment of obstructive chronic pancreatitis (CP) differ in their recommendations and reserve a minimal role for advanced endoscopic interventional therapy utilizing pancreatoscopy-guided intraductal lithotripsy. The aim of this multidisciplinary international survey is to provide an overview of current expert opinion of pancreatologists pertaining the role of advanced endoscopic treatment in painful obstructive CP.

Methods: An international online survey was conducted among expert pancreatologists that were systematically selected by being affiliated with member associations specializing in pancreatic diseases (European Pancreatic club and Dutch Pancreatitis study group) or the European Cholangioscopy group and identified through a literature search. For the literature search experts were selected based on publication record from the past 5 years. The survey consisted of five different domains: demographics, endoscopic equipment and technique, clinical practice, case vignettes and statements.

Results: Among the 95 pancreatologists who participated in the survey, 59 (62 %) were gastroenterologists and 36 (38 %) were surgeons with a median clinical experience of 15 years (IQR 16). 78 % of the pancreatologists were based in Europe. Overall, 70 % of pancreatologists reported adherence to the ESGE guideline and the majority (61 %) did not support the most recent ASGE recommendation favoring primary surgical management. Based on the statements, nearly all gastroenterologist (98 %) and most surgeons (89 %) agreed

that a subset of patients with CP is initially best managed with endoscopic therapy. Regarding endoscopic interventions, 86 % of gastroenterologist reported performing pancreatoscopy- guided intraductal lithotripsy, either occasionally or routinely, in the management of CP. Based on responses to case vignettes, 78 % of pancreatologists identified the presence of pancreatic duct stones in the head measuring > 5 mm with upstream ductal dilatation > 5 mm as key finding favoring endoscopic therapy. In contrast, surgery is favored in patients with an enlarged pancreatic head (> 4 cm), stones in the pancreatic tail, or intraparenchymal calcifications by 54 %, 68 % and 57 % of the respondents, respectively.

Conclusions: This international expert survey showed that despite some guideline recommendations most pancreatologists preferentially employ endoscopic therapy including pancreatoscopy- guided intraductal lithotripsy rather than primary surgery in selected patients with painful obstructive CP. Further research into optimal treatment selection criteria based on individual patient characteristics is warranted.

OP275 Bile leak after cholecystectomy: is there an optimal timing to endoscopy?

Authors Voulgaris T[1], Tribonias G[2], Karamanolis G[1], Vezakis I[3], Vezakis A[3], Papanikolaou I[1], Polydorou A[1], Vezakis A[1]

Institutes **1** B Surgical Unit of National and Kapodistrian University, Areteion Hospital, Endoscopy department, Athens, Greece; **2** Gastroenterology Department, Korgialeneio-Benakeio Hellenic Red Cross Hospital, Athens, Greece; **3** Biomedical Engineering Laboratory, School of Electrical and Computer Engineering, NTUA, Athens, Greece

DOI 10.1055/s-0046-1820930

Aims Bile leak is a common complication after cholecystectomy, requiring timely management to prevent life-threatening outcomes. Endoscopic retrograde cholangiopancreatography (ERCP) is essential in treatment, but large data concerning optimal timing and technique selection are unavailable. This study evaluates whether the timing of ERCP influences healing and if different bile duct injuries affect outcomes.

Methods Data from a prospectively maintained database over 25 years (2001–2025) included 143 patients (M/F:51.5 %/48.5 %, mean age 63 ± 17) undergoing ERCP for bile leaks after cholecystectomy.

Results Most leaks followed laparoscopic cholecystectomy (n = 87, %) while 53 followed open procedure and 3 initially lap procedures that were converted to open. The median time from leak to ERCP was 7 days (min: 1 – max: 72). Strasberg classification was; Strasberg A in 87/140 (62.15), C in 7/140 (5.0 %), D in 38/140 (27.1 %), E in 8/140 (5.7 %) while in 3/143 identification of the exact bile leak site was not possible. When excluding patients with Strasberg E leaks necessitating surgery (n = 135) bile leak healing was observed in 121/130 (93.1 %) (data concerning healing rates not available in 5/135 patients). Stent placement improved healing rates (104/109, 95.4 % vs.17/21, 81.0 %, p = 0.037), with no difference between pig-tail and (Amsterdam) straight plastic stents (92.3 % vs 97.7 %, p = 0.348). Retained CBD Stones (17/19, 89.5 % vs 104/111, 93.7 % if no stones, p = 0.389) or CBD strictures (17/18, 94.4 % vs 104/112, 92.9 % if no stricture, p = 0.638) did not affect outcomes. Patients with Strasberg A bile duct injury showed greater, numerically, healing rates but not in a statistically significant way, when compared with patients with Strasberg C or D injuries (83/87, 95.4 % vs 38/43, 88.4 %, p = 0.133) Leaks from the cystic duct stump had a 96.8 % (n = 61/63) resolution rate, whereas gallbladder bed leaks healed in 88 % (n = 22/25). The median healing time was 2 days (min: 1 – max: 25), unaffected by stent placement or ES alone (p = 0.925), but later ERCP correlated with longer healing (RR: 0.317, p = 0.002). Post right aberrant bile leak, time for healing was longer than leaks from other sites(median: 11 days (min : 7 – max: 32) vs 2 days (min: 1 – max: 25), p = 0.001). Submitting the patients to ERCP during the first week from the operation was correlated with quicker resolution (p = 0.003) while tended but was not correlated with higher healing rates (98.5 % vs 92.2 % if submitted to ERCP after the 7th day, p = 0.106).

Conclusions ERCP with stenting remains the first-line approach for minor bile leaks after cholecystectomy. Early ERCP accelerates healing, emphasizing the importance of prompt intervention.

OP276 Risk of upper gastrointestinal cancer after a positive fecal immunochemical test in the Danish national colorectal cancer screening program

Authors Troelsen FS[1], Hillgaard TK[1], Søborg B[2], Andersen B[2], Erichsen R[1], Thyø A[1]

Institutes **1** Department of Surgery, Randers Regional Hospital, Randers, Denmark; **2** Department of Public Health Programmes, Randers Regional Hospital, Randers, Denmark

DOI 10.1055/s-0046-1820931

Aims The Danish national colorectal cancer screening program was introduced in 2014 and includes a fecal immunochemical test (FIT) followed by a colonoscopy in case of a positive FIT (≥ 20 µg fecal hemoglobin/g feces). Following positive FITs, however, colonoscopy will not detect advanced neoplasia (AN) in most cases. Previous studies indicate that positive FITs in these cases might stem from prevalent cancer in the upper gastrointestinal tract or precursors hereof. We investigated the relative risk of upper gastrointestinal cancer after a positive FIT in the Danish national colorectal cancer screening program to elucidate whether FIT-positive participants without AN might benefit from follow-up esophagogastroduodenoscopy.

Methods We performed a population-based cohort study utilizing existing Danish health registries. We identified all participants who underwent FIT as part of the screening program during 2014-2019 and grouped them according to their FIT and colonoscopy result into: 1) FIT-positives with AN (FIT + /AN +), 2) FIT-positives without AN (FIT + /AN-), and 3) FIT-negatives (FIT-). We then followed all groups separately from six months after the first-time FIT until first occurrence of esophageal, gastric, or duodenal (EGD)-cancer, death, or 3.5 years. We used Cox proportional-hazards regression analyses to calculate crude and adjusted hazard ratios (HRs) as a measure of the relative risk of EGD-cancer after a positive FIT. FIT- participants served as the reference. We included sex, age, and Charlson Comorbidity Index score in the adjusted model.

Results We included 1.399.566 participants with a first-time FIT. Of them, 29,462 (2.1 %) were FIT + /AN + , 54,028 (3.8 %) were FIT + /AN-, and 1.316.076 (94.0 %) were FIT-. We observed 86 EGD-cancers among FIT + /AN + , 132 among FIT + /AN-, and 1,574 among FIT-. The corresponding adjusted HRs were 1.63 (95 % confidence interval [CI]: 1.26-2.11) when comparing FIT + /AN + with FIT- and 1.65 (95 % CI: 1.35-2.01) when comparing FIT + /AN- with FIT-. The relative risks were particularly increased for esophageal cancers (HR: 1.76 [95 % CI: 1.20-2.58] when comparing FIT + /AN + with FIT- and 1.83 [95 % CI: 1.37-2.46]) when comparing FIT + /AN- with FIT-.

Conclusions In the Danish colorectal cancer screening program, subjects with a positive FIT had an increased relative risk of EGD-cancer regardless of the detection of AN at colonoscopy, as compared with subjects with a negative FIT. Absolute risk measures are needed for final clinical recommendations to be made.

OP277 The Endoscopic Functional Study Integrated System (EFSIS) as a Provocative Test: Dynamic Assessment of the Anti-Reflux Barrier Function

Authors Tanabe M[1], Ushikubo K[1], Yamamoto K[1], Tamaru Y[1], Shigeta K[1], Nishikawa Y[1], Tanaka I[1], Ito T[1], Uragami N[1], Yokoyama N[1], Inoue H[1]
Institute 1 Digestive Diseases Center, Showa Medical University Koto Toyosu Hospital, Koto City, Japan
DOI 10.1055/s-0046-1820932

Problem to solve Current diagnostic standards, such as multichannel intraluminal impedance-pH (MII-pH) monitoring, excel at quantifying esophageal reflux burden. However, dynamic, functional evaluation of the anti-reflux barrier is currently lacking. Standard methods do not visualize the mechanical integrity of the barrier in real time. Therefore, a modality capable of simultaneously evaluating structural anatomy and functional physiology is needed to fill this diagnostic gap.

Innovation We recently proposed the Phase Concept as a dynamic functional evaluation method for the anti-reflux barrier (Digestive Endoscopy 2024). To evaluate this concept clinically, we developed the Endoscopic Functional Study Integrated System (EFSIS), which integrates endoscopic pressure assessment (EPSIS) with high-resolution manometry (HRM). EFSIS enables the simultaneous evaluation of endoscopic findings, intragastric pressure, and esophageal motility on a single screen during gastric insufflation. This "provocative test" visualizes the four-phase mechanism: Phase 1 (cardia closure), Phase 2 (LES contraction), Phase 3A (UES contraction), and Phase 3B (esophageal peristalsis). Following our technical report (Endoscopy E-Videos 2025), this study assessed the feasibility and clinical utility of EFSIS in a consecutive patient series.

Results We retrospectively analyzed 28 patients who underwent EFSIS between August 2024 and September 2025. Median age was 56 years (18 males); median BMI was 22.8. All procedures were completed without adverse events (median time: 7 minutes).

Phase interpretability was high: Phase 1 (100 %), Phase 2 (100 %), Phase 3A (92.9 %), and Phase 3B (89.3 %). The three non-assessable cases showed strong Phase 2 LES contraction preventing reflux, indicating a physiological block rather than technical failure.

In a subgroup of 14 patients with MII-pH data, mean EFSIS scores (scale 0–8; higher indicates better integrity) showed varying trends across phenotypes: GERD 4.8, reflux hypersensitivity 6.4 (bimodal), and functional heartburn 7.5. These preliminary observations suggest potential phenotype-dependent patterns of the anti-reflux barrier.

Conclusions EFSIS provides a novel, phase-based visualization of the anti-reflux barrier by integrating real-time endoscopic and manometric physiology. This feasibility study demonstrated high interpretability and procedural safety. The results suggest the potential of EFSIS to identify functional variations among GERD, reflux hypersensitivity, and functional heartburn, warranting further evaluation in larger prospective cohorts.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP278 A Randomised Controlled Trial to Evaluate the Utility of an Ultrathin Endoscope with Blue Light Imaging for Detecting Pharyngeal and Oesophageal Neoplasms — Ultrathin vs. Magnifying Endoscopy

Authors Dobashi A[1], Tada N[1], Futakuchi T[2], Kamba S[2], Ito M[1], Kobayashi M[1], Sumiyama K[1]
Institutes 1 Jikei University School of Medicine, Tokyo, Japan; 2 Jikei Univ. Katsushika Medical Care Center, Tokyo, Japan
DOI 10.1055/s-0046-1820933

Aims Adding magnification observation to image-enhanced endoscopy has been shown to provide high diagnostic accuracy for oesophageal carcinoma. Although magnifying endoscopy is mainly used in pre-treatment evaluation for superficial oesophageal cancer, its adoption in daily practice remains limited. Recently, a high-resolution ultrathin transnasal endoscope (with a 5.8 mm distal end diameter) has become available, allowing approximate visualisation of microvascular patterns at close range. However, no prospective study has directly compared the diagnostic accuracy of magnifying and ultrathin endoscopes for pharyngeal and oesophageal squamous cell carcinoma (SCC). Thus, the diagnostic performance of ultrathin endoscopy remains to be elucidated.

Methods This was a multicentre, prospective, randomised, non-inferiority trial conducted between August 2023 and March 2025. Eligible participants were patients with current or previous SCC in the head and neck or oesophagus. Patients were randomly assigned to either the magnifying endoscope group (EG-760Z, Fujifilm) or the ultrathin endoscope group (EG-840N). Both endoscopes were fitted with a distal attachment and inserted orally under sedation. The pharynx and oesophagus were examined using Blue Light Imaging (BLI). When a lesion suspected to be SCC was identified, close-up observation was performed with the ultrathin endoscope, and magnified observation with the magnifying endoscope. Endoscopic diagnosis (SCC or non-SCC) and diagnostic confidence (high or low) were recorded based on microvascular changes. After the first endoscopy, the other endoscope was used for a second examination in the same manner. Iodine staining and biopsy were subsequently performed for all SCC suspected lesions, and histopathology served as the gold standard. The primary endpoint was the detection rate of superficial pharyngeal and oesophageal SCC. Secondary endpoints included the diagnostic accuracy and diagnostic confidence level of magnifying and ultrathin endoscopy (▶ **Table 1**).

▶ **Table 1**

	Ultrathin	Magnifying
Pharynx		
SCC suspected lesions,	19	10
Histological SCC, n	10	6
Diameter, median (range), mm	10 (8-40)	10 (10-60)
Macroscopic type, 0-I / 0-IIa, 0-IIb, 0-IIc, n	4 / 2, 3, 1	2 / 3, 1, 0
Location, Oropharynx / Hypopharynx	1 / 9	3 / 3
Treatment, Local resection/ CRT, n	7 / 3	2 / 4
Oesophagus		
SCC suspected lesions, n	44	39
Histological SCC, n	20	18
Location of the SCCs, Ce/Ut/Mt/Lt, n	1 / 8 / 10 / 1	0 / 8 / 8 / 2
Diameter, median (range), mm	10 (5 – 40)	10 (5 – 50)
Macroscopic type, 0-I/0-IIa, 0-IIb, 0-IIc/0-III, n	1/1, 12, 5/1	1/2, 8, 7/0
Treatment, ESD/SR/CRT/Observation	10/1/7/2	12/2/4/0
Depth of invasion, EP/LPM/MM/SM1/ SM2-3	2/8/0/1/0	2/9/1/1/1

Results A total of 148 patients were enrolled, and eight expert endoscopists participated in the study. The detection rates of superficial pharyngeal and oesophageal SCC were 93.3 % (28/30) for the ultrathin endoscope and 87.5 % (21/24) for the magnifying endoscope. The lower bound of the 90 % confidence interval for the difference exceeded the predefined non-inferiority margin of –10 %. Sensitivity and specificity (Ultrathin vs. Magnifying) were 80.0 % vs 79.2 % and 74.6 % vs 74.0 %, respectively, showing no statistically significant difference. The proportion of high-confidence diagnoses was 42.9 % with the ultrathin endoscope and 57.1 % with the magnifying endoscope, with no significant difference.

Conclusions BLI using the novel ultrathin endoscope demonstrated diagnostic performance equivalent to that of magnifying endoscopy for detecting and diagnosing superficial pharyngeal and oesophageal SCC.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP279 Flip-Derived EGJ Distensibility and Diameter as Predictors of Post-POEM GERD

Authors Perananthan V[1], Balasubramani V[1], Alexander R[1], Diaz Fernandez WJ[1], Codipilly D[1], Snyder D[1], Leggett C[1], Alexander J[1], Wong Kee Song LM[1], Law R[1], Ravi K[1]
Institute 1 Mayo Clinic, Rochester, United States of America
DOI 10.1055/s-0046-1820934

Aims Gastroesophageal reflux disease (GERD) is a well-recognized complication following peroral endoscopic myotomy (POEM), yet reliable predictive factors remain limited. Identifying patients at higher risk of post-POEM GERD continues to be a clinical challenge. The functional lumen imaging probe (FLIP) assesses esophagogastric junction (EGJ) distensibility, diameter, and contractile response, offering a potential tool for predicting post-procedure outcomes. This study aims to evaluate the predictive value of peri-procedural FLIP metrics obtained pre-POEM and at 3-month follow-up and examine their utility in identifying patients at risk for post-POEM GERD.

Methods This prospective cohort study included patients with primary achalasia who underwent POEM at a tertiary care center between March 2020 and June 2025 and completed 3-month follow-up endoscopy and FLIP assessment. GERD was defined as the presence of LA Grade B–D erosive esophagitis, peptic stricture, or biopsy-proven Barrett's esophagus. In the absence of endoscopic evidence of GERD, patients underwent wireless pH monitoring; GERD was diagnosed if acid exposure time (AET; % time pH < 4) was ≥ 6 %. FLIP measurements included EGJ distensibility index (DI) at 60 mL and maximum EGJ diameter at 60–70 mL. Contractile response (CR) was categorized using established criteria (▶ **Table 1**).

▶ **Table 1**

	Total cohort	No GERD	GERD	p-value
N	153	74 (48.4 %)	79 (51.6 %)	
FLIP Distensibility (mm²/mmHg) at 60mL Pre-POEM (median + IQR)	1.3 (0.8 – 2.1)	1.2 (0.8 – 1.9)	1.3 (0.6 – 2.5)	0.773
FLIP Diameter (mm) at 70mL Pre-POEM (median + IQR)	9.1 (6.8 – 12.0)	8.2 (6.4 – 11.6)	10.0 (7.0 – 12.2)	0.111
FLIP Distensibility (mm²/mmHg) at 60mL Post-POEM (median + IQR)	5.4 (4.1 – 6.9)	5.0 (3.7 – 6.6)	6.0 (4.5 – 7.2)	0.040*
FLIP Diameter (mm) at 70mL Post-POEM (median + IQR)	17.2 (15.1 – 18.8)	16.8 (14.6 – 18.1)	17.8 (16.0 – 19.0)	0.028*

Results A total of 153 patients were included (45.1 % female; median age 61.5 years [IQR 44.6–73.4]). Achalasia subtypes included type I (9.2 %), type II (75.1 %), and type III (15.6 %). Median myotomy length was 6.0 cm (IQR 6.0–8.0), and clinical success (Eckardt score ≤ 3) was achieved in 92.8 %. Objective GERD was identified in 79 patients (51.6 %). GERD was significantly associated with older age and type III achalasia. Patients with GERD had a higher post-POEM EGJ diameter at 70 mL (median 17.8 mm [IQR 16.0–19.0] vs 16.8 mm [IQR 14.6–18.1]; p = 0.028) and higher EGJ-DI at 60 mL (6.0 mm²/mmHg [IQR 4.5–7.2] vs 5.0 mm²/mmHg [IQR 3.7–6.6]; p = 0.040). Thresholds of EGJ diameter > 16.75 mm and EGJ-DI > 5.45 mm²/mmHg discriminated patients who developed GERD. Age and type III achalasia were independent predictors.

Conclusions Higher post-POEM EGJ diameter and distensibility on FLIP are significantly associated with the development of GERD. These findings support the use of post-procedure FLIP metrics to identify patients at increased risk for reflux after POEM.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP280 Epithelial–Mesenchymal Transition–Associated Gene Activation Promotes Esophageal Stricture Following Circumferential Endoscopic Submucosal Dissection

Authors Brandaleone L[1, 2, 3], Maselli R[4, 1, 2], Rizzo G[2], Mori G[2], Ricchi B[2], de Sire R[1, 2], Capogreco A[1, 2], Massimi D[1, 2], Alfarone L[1, 2], Vadalà V[1, 2], Lovisa S[1], Hassan C[1, 2], Repici A[1, 2], Vetrano S[2]

DOI 10.1055/s-0046-1820935

Aims Postoperative esophageal stricture is the most common complication following circumferential endoscopic submucosal dissection (ESD) for esophageal neoplasia. It significantly impairs nutrition and quality of life. While the main predictors are the circumferential and longitudinal extent of the mucosal defect and fibrosis, the underlying mechanisms remain unclear. This pilot study aimed to explore the fibrotic molecular signature associated with post-ESD stricture by evaluating the expression of fibrosis- and EMT-related genes.

Methods Among 19 patients who underwent circumferential ESD, 12 (63.2 %) developed post-ESD strictures. The cohort included six patients with Barrett's-related adenocarcinoma (pT1a) and six with squamous neoplasia (four pT1b SCCs and two pTis). Steroid prophylaxis was applied in 58.3 % of cases. RT-qPCR was used to quantify gene expression (2^-ΔCt) in post-resection tissues, and findings were compared between stenotic and non-stenotic patients.

Results Stricture tissues showed increased expression of several EMT- and fibrosis-related genes, including TWIST1, ZEB1, FAP, TGF-β, FN1, COL3A1, and COL5A1. When stratified by lesion type, Barrett's-related cases exhibited distinct expression profiles. Notably, ACTA2 expression was lower in stenotic patients (mean ± SD: 0.044 ± 0.033) compared to non-stenotic controls (0.118 ± 0.036), $p = 0.11$; 95 % CI [−0.171, 0.023]. PDGFRB was modestly elevated in stenotic tissues (0.139 ± 0.058 vs. 0.095 ± 0.088), though not statistically significant ($p = 0.53$; CI [−0.155, 0.244]). Immunohistochemistry confirmed elevated expression of TWIST1, FAP, and α-SMA, along with marked collagen deposition.

Conclusions Although a pilot study, our findings provide novel evidence that EMT activation and fibroblast-driven remodeling are key drivers of post-ESD esophageal strictures. Distinct molecular signatures in Barrett's versus squamous neoplasia suggest lesion-specific fibrotic pathways beyond the extent of mucosal injury. If confirmed, these preliminary insights highlight potential targets for developing strategies to prevent or treat esophageal strictures.

Aims Endoscopy with histopathological assessment of esophageal biopsies is the cornerstone of eosinophilic esophagitis (EoE) diagnosis and characterization. This study aimed to evaluate temporal changes in endoscopic practice for EoE using data from the European EoE CONNECT registry, and to assess its influence on diagnostic delay (DD).

Methods A cross-sectional analysis of the EoE CONNECT registry included EoE patients from 50 hospitals accross four European countries, registered up to 6th of October 2025. EoE was defined according to international diagnostic criteria, requiring symptoms of esophageal dysfunction and a peak eosinophil count ≥ 15 eosinophils per high-power field, in at least one esophageal biopsy. Hospitals were classified as high-volume if they had enrolled ≥ 200 patients. Data distribution was tested using the Shapiro–Wilk test. Categorical variables were compared using χ^2 or Fisher's exact tests. Temporal correlations between diagnostic delay and year of diagnosis were examined using simple linear regression analysis. Pairwise comparisons of diagnostic sensitivity among esophageal segments and their combinations were analyzed with McNemar's test.

Results A total of 3,298 EoE patients (mean age 35.2 ± 15.2 years; 74.4 % male; 82.0 % adults) were included. The EREFS score was reported in 95.5 % of endoscopic examinations at the time of diagnosis, increasing from 88–90 % in 2014–2015 to 98–99 % in 2024–2025 ($p < 0.001$). Following the 2017 EoE guidelines, EREFS reporting improved significantly (90.5 % vs 96.9 %, $p < 0.001$), both in low-volume (from 91.4 % to 97.0 %, $p < 0.001$) and high-volume centers (from 87.3 % to 96.7 %, $p < 0.001$). The proportion of patients with biopsies from ≥ 2 esophageal segments increased after 2017 (57.2 % vs 66.3 %, $p < 0.001$), while single-segment sampling decreased (19.9 % vs 9.6 %, $p < 0.001$). High-volume hospitals showed greater adherence to recommendations, obtaining multiple site biopsies in 90.2 % of cases compared with 82.4 % in low-volume centers ($p < 0.001$). The distal esophagus was the most frequently sampled site (93.2 %), followed by the proximal (81.8 %) and middle segments (36.2 %). Among patients with biopsies from all three segments (n = 785), diagnostic sensitivity progressively decreased from distal (91.9 %) to middle (85.5 %) and proximal (74.9 %) sites, confirming a distal-to-proximal gradient ($p < 0.001$ for all pairwise comparisons). Combinations including the distal segment (distal + middle or distal + proximal) showed the highest diagnostic performance, exceeding 97 % sensitivity and significantly outperforming the middle + proximal combination (91 %; $p < 0.001$). The overall median DD was 2.0 years (IQR 0–6). Across the study period, DD decreased by approximately 8.5 months per year ($B = -0.714$, $p < 0.001$). When comparing phenotypes, patients with a mixed/stricturing phenotype showed a longer DD [median 3.0 years (IQR 1–10)] and a greater annual reduction of 9.34 months. In contrast, the inflammatory phenotype had a median DD of 2.0 years (IQR 1–5), with a yearly reduction of 8.03 months.

Conclusions Endoscopic assessment of EoE has markedly improved over time, with progressive standardization of reporting and biopsy practices across Europe, which accompained by a progressive reduction in diagnostic delay

DOI 10.1055/s-0046-1820937

Aims Gastric variceal bleeding (GVB) is associated with high morbidity and mortality. EUS-guided coil and cyanoacrylate injection (EUS-CG) has been shown to be an effective therapy for bleeding gastric varices and secondary prophylaxis,

however, there is a paucity of data on primary prophylaxis of gastric varices. We compared the efficacy of addition of EUS-CG to Beta-blockers against Beta-blockers alone for primary prophylaxis of gastric variceal bleeding [1].

Methods This multi-centre observational study included patients across 8 tertiary care centres in India. Adult patients with cirrhosis and large gastric varices (F2 or F3) without prior bleeding were included. Baseline demographics, prior non-bleeding decompensating events and clinical outcomes including bleeding, hepatic decompensation and mortality were reviewed. Patients undergoing EUS-CG and initiated on beta-blockers (EUS-CG + ß-blocker arm) were compared with patients on beta-blockers alone (ß-blocker arm) after adjusting for confounding variables including age, sex, Child-Pugh score and form of gastric varix (F2/F3). Competing risk analysis was performed to assess the risk of bleeding and hepatic decompensation, with mortality and liver transplantation as competing events. The primary outcome was to compare the incidence of first gastric variceal (GV) bleeding (▶ **Table 1**).

▶ **Table 1**

Outcomes	*EUS-coil and glue + b-blockers (n = 135)*	*B-blockers alone (n = 78)*	*p-value*
Overall bleeding	21 (15.6 %)	37 (47.4 %)	**< 0.001**
GV-related bleeding	10 (7.4 %)	28 (35.9 %)	**0.03**
EV-related bleeding	5 (23.8 %)	7 (18.9 %)	0.66
Decompensation (bleeding, ascites or HE)	47 (34.8 %)	59 (75.6 %)	**< 0.001**
All-cause mortality	21 (15.6 %)	19 (24.4 %)	0.11
Bleed related mortality	8 (38.1 %)	9 (47.4 %)	0.55

Results Of 213 patients, 135 (male = 83, 61.5 %; mean age- 56 ± 12.4 years) underwent EUS-CG and received beta-blockers, while with 78 patients (male = 56, 71.7 %; mean age- 56 ± 11.2 years) received beta-blockers alone. Of 135 patients in the EUS-CG + ß-blocker arm with a median follow up of 13.2 months, 10 (7.4 %) patients had GV bleeding, while among 78 patients in ß-blocker arm with a median follow-up of 25.9 months, 28 (35.9 %) patients had GV bleeding. Compared to the ß-blocker arm, patients in the EUS-CG + ß-blocker arm had significantly lower incidence of GV bleeding (sHR: 0.39, 95 % CI: 0.19-0.82; p = 0.12), lower all-cause upper GI bleeding (sHR: 0.57, 95 % CI: 0.34-0.98; p = 0.042), and lower incidence of hepatic decompensation (sHR: 0.64, 95 % CI: 0.44-0.94; p = 0.024). There were no difference in the incidence of non-bleed related hepatic decompensation (sHR: 0.66, 95 % CI: 0.39-1.13; p = 0.123), or mortality (sHR: 1.36, 95 % CI: 0.69-2.66; p = 0.37), between the 2 groups. On multivariate regression analysis, use of ßeta-blockers alone as primary prophylaxis (sHR: 3.39, 95 % CI: 1.60-7.20; p = 0.001) and MELD score (sHR: 1.09, 95 % CI: 1.03-1.15; p = 0.006) and were significant predictors of bleeding.

Conclusions In patients with cirrhosis and large gastric varices, a combination of EUS-coil and glue injection and ßeta-blockers is more effective than ß-blocker alone therapy for the prevention of first gastric variceal bleeding.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP284 Endoscopic Ultrasound Directed Gastric Variceal Obliteration: The Early Experience of a New Service at a Large Australian Quaternary Referral Centre

Authors Vlismas L[1], Ding Y[1], Gonsalkorala E[1], Skoien R[1], Khan S[1], Hwang J[1], Mudaliar S[1], Gilhotra R[1]

Institute 1 Royal Brisbane and Women's Hospital, Brisbane, Australia

DOI 10.1055/s-0046-1820938

Aims Gastric varices (GV) have higher rebleeding and mortality rates than oesophageal varices (OV), requiring definitive haemostatic techniques such as balloon-occluded retrograde transvenous obliteration (BRTO) [1]. Endoscopic ultrasound directed gastric variceal obliteration (EUS-GVO) is a newer modality for definitive treatment by directly accessing varices to obliterate feeding vessel(s). Both BRTO and EUS-GVO have demonstrated superiority over other endoscopic modalities [2, 3]. EUS-GVO was introduced at the Royal Brisbane and Women's Hospital (RBWH) in August 2024. The aim of this study is to present the outcomes of our early experience with EUS-GVO at our quaternary centre.

Methods Consecutive patients with documented gastric variceal bleeding referred for EUS-GVO between August 2024 and November 2025 were included. Baseline patient characteristics, details of vascular anatomy, technique for EUS-GVO, technical success (defined as uncomplicated injection of coils and CYA) and immediate clinical success (cessation of doppler flow) were recorded (Table 1). During EUS-GVO, targeting the feeder was preferred over directly accessing the submucosal variceal nest. This was accessed with a 19G FNA needle. 0.035" Coils of varying lengths were used as a scaffold prior to undiluted cyanoacrylate (CYA) injection. As a rule, the diameter of the first coil deployed was > 20-40 % of the diameter of the feeder vessel. The number of coils deployed was based on degree of reduction in flow and residual space after the placement of the first coil. All procedures were performed under general anaesthesia and prophylactic antibiotic cover. All patients underwent a repeat EUS in 4 weeks to document clinical success in the form of complete variceal obliteration and were reviewed in clinic for signs of rebleed or decompensation.

Results Eleven patients were referred for consideration of EUS-GVO over the 15-month period (6 male, mean age 53.3 years) with mean clinical follow up of 204 ± 156 days. Two patients underwent elective EUS-GVO as outpatients (cases 6 and 7) whereas, all others were acute inpatients. Mean time to EUS-GVO for acute inpatients was 1.75 days. Technical success was achieved in 10 patients (90.9 %). One patient did not undergo EUS-GVO due to unfavourable anatomy (feeder too large, > 45mm) and was referred for BRTO. Nine patients underwent coil and CYA embolization and one patient had coil alone to achieve immediate clinical success. Mean number of coils and CYA used per EUS-GVO were 2.3 ± 1.34 and 1.29 ± 0.68ml respectively. Two patients had post EUS-GVO pain (one requiring opioid analgesia, second managed with simple analgesia). None had fever or systemic embolization. Eight patients had a follow up endoscopy and EUS at a mean of 46.13 ± 11.4 days, all of which showed complete variceal obliteration. One patient was lost to follow-up, and one is yet to have their follow up EUS. None had worsening of oesophageal varices. One patient had a rebleed at 6-months and underwent repeat EUS-GVO for a new gastric varix (case 8). There were no recorded hospital admissions with decompensation events (worsening ascites or hepatic encephalopathy). All patients are still alive.

Conclusions EUS-GVO is safe and efficacious for definitive management of bleeding gastric varices. The introduction of this service at our centre allowed for quick access to definitive therapy with high technical and clinical success rates with low complication rates. Patient factors, particularly their vascular anatomy, needs to be taken into consideration during management planning, and a multidisciplinary approach is key. Frequently utilising doppler flow during EUS-GVO allows tailoring of the technique to achieve complete obliteration. Future studies should compare safety and efficacy of EUS-GVO to that of BRTO

Endoscopy 2026; 58: S1–S1041

and address their cost-effectivity particularly when it comes to the ease of access and length of stay parameters.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP285 Efficacy and Safety of a Novel Self-Assembling Peptide Hemostatic Gel for Hemorrhagic Duodenal Ulcer: A Retrospective Comparative Study

Authors Fukuchi T[1], Shinpei K[1], Iwase S[1]

Institute 1 Fujisawa City Hospital, Fujisawa, Japan

DOI 10.1055/s-0046-1820939

Aims Endoscopic hemostasis for hemorrhagic duodenal ulcer (HDU) remains challenging, with well-known complications such as perforation and delayed rebleeding associated with conventional methods (e.g., thermal coagulation, clipping, ethanol injection). We have previously encountered adverse events, including delayed perforation after repeated coagulation and incomplete hemostasis requiring rescue intervention. This study aimed to evaluate the ease of use, safety, and efficacy of a novel self-assembling peptide hemostatic gel (PuraStat) in controlling bleeding duodenal ulcers compared to conventional endoscopic techniques [1–3].

Methods This was a retrospective review of patients with endoscopically confirmed HDU who underwent endoscopic hemostasis at our hospital between April 2015 and September 2025. Patients were divided into two groups: those who received PuraStat as part of their endoscopic treatment (n = 52, PuraStat group), 31 of whom received PuraStat as monotherapy, and those who underwent conventional hemostasis without the gel (n = 76, Conventional group). Short-term outcomes were compared. Rebleeding was defined as hematemesis or melena with a decrease in hemoglobin of ≧ 2 g/dL or evidence of active bleeding upon subsequent endoscopy following successful primary hemostasis. Difficult hemostasis was defined as requiring three or more endoscopic sessions for final bleeding control.

Results Baseline demographic and clinical characteristics—including mean age, sex, presence of dialysis-dependent renal failure or liver cirrhosis, use of antithrombotics or NSAIDs, and initial bleeding severity based on the Glasgow-Blatchford Score—were comparable between the two groups, with no significant differences in any baseline factor.

For treatment efficacy, primary hemostasis was achieved in 100 % of patients in the PuraStat group and in 94.7 % of those in the Conventional group. This difference was not statistically significant (p = 0.151). In contrast, significant differences were observed in the durability of hemostasis. The overall rebleeding rate was significantly lower in the PuraStat group (3.8 %) compared with the Conventional group (20.8 %) (p = 0.002). Moreover, no rebleeding occurred among the 31 patients who received PuraStat monotherapy. Difficult hemostasis occurred in 0 % of the PuraStat group versus 13.9 % of the Conventional group, representing another significant difference (p = 0.0245).

Safety outcomes also demonstrated significant group differences. No PuraStat-related adverse events were observed. Importantly, there were no cases of delayed perforation or need for emergency IVR in the PuraStat group. In contrast, the Conventional group experienced four cases of delayed perforation, all following repeated coagulative therapy. Thus, while the two groups did not differ at baseline or in initial hemostasis rates, the PuraStat group showed significantly superior outcomes in sustained bleeding control, difficulty of hemostasis, and safety.

Conclusions PuraStat provides a compelling new strategy for HDU management, simultaneously improving hemostasis while significantly minimizing the reliance on aggressive techniques that lead to complications. This is supported by the extremely low rebleeding rate and the absence of severe adverse events like delayed perforation in the PuraStat group, suggesting that the gel's action promotes safer and more stable ulcer healing. Our findings support the integration of PuraStat into the standard endoscopic protocol to achieve superior and safer patient outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP286 Impact of On-Site Emergency Endoscopy for Non-Transportable Patients with Gastrointestinal Bleeding in Resource-Limited and Remote Settings

Authors Otgondemberel B[1], Batsaikhan A[1], Adiyasuren B[2], batsuren B[1], Khurelshagai A[1], Duurenjargal B[1], Davaadorj E[1], Boldsaikhan U[1], Zoljargal B[1], Tumendemberel B[1]

Institutes 1 IGIC Endoscopic Network, Ulaanbaatar, Mongolia; 2 Seoul Med Hospital, Ulaanbaatar, Mongolia

DOI 10.1055/s-0046-1820940

Aims Gastrointestinal (GI) bleeding remains a major cause of emergency hospitalizations worldwide, demanding rapid endoscopic intervention for diagnosis and hemostasis. However, in countries with vast geographic distances and limited healthcare infrastructure such as Mongolia, timely endoscopy is often unavailable for non-transportable patients in rural areas. This study evaluates the clinical outcomes and feasibility of mobile, on-site emergency endoscopy in such patients, highlighting its potential to reduce mortality and improve accessibility.

Methods Between 2019 and 2024, a mobile endoscopy team conducted **928 emergency visits** across **15 provinces** and **6 districts** in Mongolia. Of these, **796 cases** involved gastrointestinal bleeding. All procedures were performed using portable endoscopy systems in accordance with international emergency protocols. Data on the source of bleeding, hemostasis success, mortality, and regional distribution were retrospectively analyzed [1–5].

Results Among 796 GI bleeding cases, 82 % were upper GI, 7 % were lower GI, and 11 % had mixed or unidentified sources. The leading etiologies were esophageal varices (64 %), fundal varices (11 %), and gastric ulcers (21 %).

Endoscopic hemostasis was achieved in 98 % of cases. Despite the severity of presentation, the overall mortality rate was 1.9 % (n = 19) — all deaths occurred in patients with variceal bleeding (p = 0.015). Notably, 79 % of deaths occurred in urban patients, whereas rural cases had significantly better outcomes (p = 0.0012).

Timely intervention within 12–24 hours was associated with improved hemodynamic stability and reduced transfusion requirements.

Conclusions Mobile, on-site emergency endoscopy is a **feasible and life-saving strategy** for managing GI bleeding in non-transportable patients within resource-limited and remote regions. Early intervention substantially decreases mortality and eliminates the need for high-risk transfers. Establishing a **national emergency endoscopy network**, supported by public investment,

mobile infrastructure, and standardized clinical criteria, could ensure equitable access to critical care across Mongolia.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Upper gastrointestinal bleeding (UGIB) represents a significant global healthcare burden due to high incidence and healthcare costs. Successful triage of patients and avoidance of unnecessary hospital admission would be a great advantage. PillSense utilises an ingestible capsule designed to detect the presence of blood in stomach, assisting with triage and disposition of these patients in the Emergency Department (ED) setting [1].

This study seeks to compare two key outcomes—ED discharge rates and subsequent complications—between patients utilizing PillSense and those receiving standard treatment. We hypothesize that the use of PillSense will lead to a significant reduction in the rate of hospital admissions by facilitating more confident discharge decisions from the ED, without adversely affecting clinical outcomes.

Methods We are conducting an ongoing multi-centre, prospective randomized controlled trial in Singapore since October 2024 . We recruited hemodynamically stable patients (aged ≥ 21 years) presenting to the ED with symptoms of UGIB. Patients were randomized into either PillSense (P-group) or standard treatment (ST-group). ST-group patients were triaged based on existing protocols and clinical assessment of the attending ED physician. P-group patients ingested the PillSense capsule; those with positive blood detection were admitted for further care, while those negative for blood were discharged if they remained stable. All patients were scheduled for a follow up Oesophagogastroduodenoscopy (OGD) within 96 hours of presentation and a clinic review within 30 days. P-group patients also had an abdominal X-ray (AXR) scheduled within 10–18 days to confirm pill passage. Data on adverse outcomes, readmissions, and OGD findings of active bleeding were documented (▶ **Table 1**).

▶ **Table 1** Baseline Demographics and Clinical Characteristics

	PillSense Group (N = 10)	Standard Treatment Group (N = 10)
Demographics		
Age, years (Median, min-max)	52.5 (31 – 71)	33.0 (22 – 80)
Presenting Symptom, n (%)		
Melena	7 (70)	6 (60)
Coffee Ground Vomitus	2 (20)	2 (20)
Haematemesis (small amount)	1 (10)	2 (20)
Bleed detected on Pillsense, n (%)		
Positive	1 (10)	–
Negative	9 (90)	–
Disposition, n (%)		
Admitted	2 (20)	5 (50)
Discharged	8 (80)	5 (50)
Incidence of complications 30-day review, n (%)		
Complications	0 (0)	0 (0)
No complications	8 (80)	10 (10)
Did not attend	2 (20)	0 (0)

Results This ongoing trial has 20 eligible patients (median age 45.5 years) enrolled to date. The P-group achieved an 80 % discharge rate compared to 50 % in the ST-group. There were no adverse outcomes documented in either group. In P-group (n = 10), 1 patient with positive result was admitted and found to have severe oesophagitis. Of the remaining 9 patients with negative result, 1 was admitted for further observation. 8 patients attended follow-up OGD (mean 65 hours) and the review (mean 29 days) after ED visit. In the ST-group (n = 10), 5 patients were admitted. 7 patients attended follow-up OGD (mean 54 hours), and all 10 patients participated in the post ED visit review (mean 30 days). Across both groups, none exhibited evidence of active bleeding on OGD, and no adverse events occurred between the ED visit and the follow-up review. In the P-group, 8 patients attended interval AXR (mean 16 days) post-capsule ingestion, and none showed any evidence of capsule retention.

Conclusions PillSense usage demonstrates promising results in reducing hospital admission rates for patients with acute UGIB without significant adverse clinical outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Although colonoscopy is widely used as a screening test to detect colorectal cancer, its effect on the risks of colorectal cancer and related death is unclear. We previously reported 10-year effect of colonoscopy screening on colorectal cancer (CRC) incidence and mortality. Here, we report effect after 13 years of follow-up.

Methods Our analyses include 84,583 men and women 55 to 64 years at enrolment from Norway, Poland and Sweden randomised in a one-to-two ratio to colonoscopy screening or no-screening. We report intention-to-screen and per-protocol effects of colonoscopy screening on CRC incidence and mortality for all participants, in men versus women and for proximal versus distal CRC.

Results During 13-years follow-up, CRC incidence was 1 · 46 % (375 colorectal cancers) in the screening group and 1 · 80 % (912 colorectal cancers) in the no-screening group. The risk ratio (RR) was 0 · 81 (95 % confidence interval [CI] 0 · 71 to 0 · 90) in intention-to-screen analyses, and 0 · 55 (95 %CI 0 · 33-0 · 81) in per-protocol analyses. Risk for proximal CRC was 0 · 51 % in the screening group and 0 · 56 % in the no-screening group (RR 0 · 91; 95 % CI 0 · 71 to 1 · 09), while risk for distal CRC was 0 · 87 % versus 1 · 11 % (RR 0 · 79; 95 % CI 0 · 65 to 0 · 89). In men, CRC risk was 1 · 69 % in the screening group and 2 · 19 % in the no-screening group (RR 0 · 77; 95 % CI 0 · 64 to -0 · 88); in women, risks were 1 · 24 % versus 1 · 43 % (RR 0 · 87; 95 % CI 0 · 70 to 1 · 02). CRC mortality was 0 · 41 % in the screening group and 0 · 47 % in the no-screening group; intention-to-screen RR 0 · 88 (95 % CI 0 · 68 to 1 · 08) and per-protocol RR 0 · 70 (95 %CI 0 · 26 to 1 · 25). The observed CRC mortality in the non-screening group (0 · 47 %). was significantly lower than expected at the time of designing the trial (0 · 82 %).

Conclusions In this randomised trial, one colonoscopy significantly reduced CRC incidence but not mortality over 13 years. CRC mortality is lower in both study groups than when the trial was designed.

DOI 10.1055/s-0046-1822898

Aims Delayed bleeding is a major complication after colorectal endoscopic submucosal dissection (ESD), especially in patients receiving antithrombotic therapy, at high risk of delayed bleeding according to DEBE score. The efficacy of prophylactic haemostatic gel application in this high-risk setting remains uncertain.

Methods It was a prospective multicentre randomised controlled trial. Adult patients with a single colorectal neoplastic lesion ≥ 3 cm undergoing ESD and receiving therapeutic anticoagulant and/or antiplatelet therapy were randomised (1:1) to prophylactic gel application or no gel. Randomization was done at the end of the ESD procedure after prophylactic hemostasis. The primary endpoint was the delayed clinical significant bleeding within 30 days. Analyses were performed on an intention-to-treat basis.

Results A total of 296 patients were randomized between February 2022 and January 2025 (146 in the control arm, 150 in the PuraStat arm). Baseline characteristics were comparable between groups, with a mean age of 75.8 years and 80.4 % of patients on anticoagulant therapy. All lesions were resected en bloc by ESD.

The overall delayed bleeding rate was 24.1 % (69/286 evaluable patients), with 22.5 % in the control group and 25.7 % in the PuraStat group. After accounting for the worst-case bias related to missing data, the rates were 21.9 % and 28.7 %, respectively.

Adjusted analysis for stratification factors (DEBE score, location, type of treatment) did not show a significant difference between groups (p = 0.1686), whereas treatment type (antiplatelet (except aspirin < 300 mg/j) vs anticoagulant ± antiplatelet) appeared to be associated with the primary endpoint in the adjusted model (p = 0.0343).

Conclusions In this high-risk population for bleeding after ESD of colorectal lesions ≥ 3 cm, prophylactic application of PuraStat did not significantly reduce the incidence of delayed bleeding. These results suggest that routine use of hemostatic gel after ESD in patients receiving antithrombotic therapy does not provide a demonstrated clinical benefit, and that targeted prevention strategies should be explored.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP290 Long-term oncological outcomes after en bloc resection of colorectal neoplasia by Endoscopic Submucosal Dissection

Aims Colorectal endoscopic submucosal dissection (ESD) achieves high rates of en bloc resection, enabling complete removal and accurate histopathological assessment. Short-term outcomes demonstrate low rates of local recurrence following ESD. Long-term outcomes after en bloc resection of large and/or superficially invasive colorectal neoplasia by ESD have not been well characterized. In the current study, we aimed to evaluate the 10-year clinical and oncological outcomes after colorectal ESD.

Methods Between August 2010 and January 2012, 1,564 cases who underwent ESD for large or recurrent colorectal epithelial neoplasms at 69 Japanese institutions were identified, and ten-year outcomes were evaluated in 527 cases. The primary outcome of this study was to evaluate long-term outcomes after colorectal ESD, including rates of local and distant recurrence and prognosis measures such as 10-years overall survival (OS) and disease-specific survival (DSS). Secondary included OS and DSS were analyzed according to age (< 80 vs ≥ 80 years), lesion type (T1 cancers vs non-T1 lesions), lesion location (rectum vs colon), and resection status (complete vs non-complete resection). Additionally, metachronous advanced neoplasms (AN) were also assessed.

Results Among the 527 patients, the follow-up duration was median 10 years (IQR: 9-10) and 4,825 patient-years. The 10-year OS and DSS were 93.7 % (95 %CI: 91.6-95.9 %) and 99.8 % (95 %CI: 99.3-100.0). OS was lower in patients aged ≥ 80 years than in those < 80 years (10 years: 61.1 % vs. 95.0 %, p < 0.001). DSS was lower in patients with T1 cancer than in those with non-T1 lesions (10 years: 98.5 % vs. 100.0 %, p = 0.016) and in patients with rectal lesions than in those with colonic lesions (10 years: 98.5 % vs. 100.0 %, p = 0.017). Local recurrence (median 22 months; IQR: 13-44 months) occurred in 7 of 505 patients (1.4 %). Five recurrent lesions were treated endoscopically (cold polypectomy, EMR and ESD). Regarding the other two cases, one underwent surgery, and the other received chemotherapy. Distant recurrence occurred in 2 of 527 patients (0.4 %). Regarding metachronous AN, 412 patients underwent surveillance colonoscopy; 76 developed AN and 336 did not. There were boarder line differences about antithrombotics (p = 0.055), ESD lesion location (p = 0.056), and ESD lesion size (p = 0.048). The cumulative incidence of it was 10.0 %, 14.4 %, 20.9 %, and 34.7 % at 3, 5, 8, and 10 years after ESD.

Conclusions Favorable long-term prognosis and low recurrence rates support en bloc resection by ESD as a standard treatment for large colorectal neoplasms. Long-term risk of metachronous AN over 10 years suggests the need for scheduled surveillance.

DOI 10.1055/s-0046-1822900

Aims Use of artificial intelligence (AI)-based computer-aided detection (CADe) systems improves adenoma detection in average-risk colorectal cancer screening. In Lynch syndrome (LS) surveillance, however, evidence is limited and inconsistent, and the incremental benefit in expert settings remains uncertain. Moreover, computer-aided diagnosis (CADx) for optical differentiation of colorectal lesions has not been systematically evaluated in LS. We aimed to assess AI-assisted polyp detection and characterization during routine LS colonoscopy surveillance.

Methods In this international multicentre, open-label, randomized controlled superiority trial (DRKS00030695), individuals with genetically confirmed LS undergoing surveillance colonoscopy at nine European academic LS expert centres were randomly (1:1) assigned to high-definition white-light (HD-WL) colonoscopy or AI-assisted colonoscopy (CAD EYE, Fujifilm). Randomization was stratified by centre, sex, pathogenic germline variant, previous colorectal cancer (CRC), and surveillance interval. The primary endpoint was the adenoma detection rate (ADR). Secondary outcomes included adenomas per colonoscopy (APC), the polyp detection rate, and detection rates of advanced adenomas, sessile serrated lesions (SSLs), and CRC. CADx performance in terms of optical differentiation (neoplastic vs. non-neoplastic) was assessed at lesion level, with histopathology serving as the blinded reference standard.

Results Between May 2023 and November 2025, 757 patients were randomised (WLE, n = 377; CADe, n = 380); 733 were included in the full analysis set. The ADR was 30·9 % with HD-WL versus 33·8 % with CADe (odds ratio [OR] 1·14, 95 % CI 0·83–1·57; p = 0·409). No significant differences were observed for APC (0·6 vs 0·5; rate ratio 1·00; p = 0·979), advanced ADR detection (9·2 % vs. 10·2 %), SSL detection (10·8 % vs. 9·6 %), or CRC detection (1·9 % vs. 1·4 %). CADx performance in terms of sensitivity and specificity (84·4 % and 90·9 %) was comparable to optical diagnosis by expert endoscopists (NICE: 89·2 %/91·6 %; JNET: 90·5 %/91·8 %). Adverse events were similar between groups.

Conclusions In this largest to date randomized trial, AI-assisted colonoscopy did not improve adenoma detection over HD-WL colonoscopy in LS surveillance. CADx performance was similar to expert optical diagnosis, indicating limited incremental benefit of current AI systems for LS surveillance in expert settings at this point.

Galician Colorectal Cancer Screening Program, Directorate General of Public Health, Santiago de Compostela, Spain; 14 University of Oslo, Oslo, Norway
DOI 10.1055/s-0046-1822901

Aims Computer-aided detection (CADe) increases adenoma detection in colonoscopy, but its effectiveness in post-polypectomy surveillance remains uncertain.

Methods We conducted a population-based, randomized controlled trial in the Galician colorectal cancer screening program. Individuals scheduled for surveillance colonoscopy after resection of ≥ 1 advanced adenoma or ≥ 3 adenomas within the screening program were eligible. Colonoscopy days were randomized in a 1:1 ratio to high-definition colonoscopy with or without CADe. The primary endpoint was adenoma detection rate (ADR). Secondary outcomes included serrated lesion (SLDR) and advanced adenoma detection (AADR). Prespecified subgroup analyses evaluated surveillance round, bowel preparation quality, and endoscopist baseline performance (median ADR). Effect estimates are reported as adjusted risk ratios (aRR) and confidence interval (CI) [1].

Results Of 5,309 randomized surveillance colonoscopies, 4,824 surveillance colonoscopies were included in the final analysis (2,469 standard; 2,355 CADe-assisted) after exclusion of incomplete examinations. ADR did not differ between groups (57.4 % vs 58.8 %; aRR 1.02, 95 % CI 0.97–1.07). AADR (6.8 % vs 7.0 %; aRR 1.00, 99.9 % CI 0.70–1.41) and SLDR (25.8 % vs 26.1 %; aRR 1.00, 99.9 % CI 0.85–1.17) were similar. CADe increased ADR among low-performing (ADR < 54.5 %) endoscopists (45.5 % vs 52.1 %; aRR 1.15, 95 % CI 1.06–1.26), but not among high-performing endoscopists (65.9 % vs 63.5 %; aRR 0.97, 95 % CI 0.90–1.05) with a significant interaction between intervention and endoscopist performance (p = 0.0004).

Conclusions In a high-performing, population-based screening program, CADe did not increase ADR in surveillance colonoscopy. The potential benefit of CADe may depend on baseline endoscopist performance.

DOI 10.1055/s-0046-1823221

Aims The muscle-retracting sign (MRS) [1], visualised using the pocket-detection method (PDM) [2] during endoscopic resecton of early rectal cancer (ERC), may enable real-time diagnosis of deep submucosal invasion (SMI). We evaluated MRS performance amongst experienced endoscopists, the effect of structured video training, and combined diagnostic performance of deep-margin (MRS) and surface (JNET) optical diagnosis in the detection of deep SMI.

Methods Experienced endoscopists reviewed 15 random PDM videos (pool of 38) per phase (pre/post-intervention), rating MRS presence, confidence and surface optical diagnosis. The 15 videos included 6 deeply invasive cancers (pT1 sm3 or pT2) and 9 other (pT1 sm1/2 or dysplastic) lesions. The sm3/T2 threshold was chosen because conventional ESD is unlikely to achieve an R0 vertical margin at this depth. No ground truth was provided between phases; a structured video tutorial was delivered after phase 1. Training effects were modelled using GLMM with crossed random intercepts for rater and video. Post-intervention ratings with contemporaneous JNET classification enabled combined rule analyses.

Results Thirty-six endoscopists from 15 countries (median ESDs 150 [IQR 50–550]; median rectal ESDs 64 [IQR 24–300]) participated. 835 complete rating events were analysed (458 pre-intervention and 377 post-intervention). Overall MRS sensitivity for sm3/T2 was 68.8 % (95 % confidence interval [CI] 62.4–74.7) and specificity 69.7 % (65.9–73.3). Sensitivity improved significantly pre- to post-intervention (64.0 % [54.9–72.4] to 74.5 % [65.1–82.5]; OR 2.20, 95 % CI 1.09–4.41; p = 0.027); specificity was similar (71.2 % vs 67.9 %; OR 1.49, p = 0.13). MRS detection increased with invasion depth (sm1 25.0 %, sm2 41.9 %, sm3 67.2 %, T2 71.3 %). Higher confidence predicted deep invasion: 14.6 % (no MRS), 36.0 % (low-confidence), 49.7 % (high-confidence; p < 0.001). In 368 post-intervention events, JNET-3 yielded sensitivity 58.5 % (48.5–68.0) and specificity 73.3 % (67.5–78.5). MRS achieved superior sensitivity (74.5 %; OR 0.37, 95 % CI 0.19–0.74; p = 0.005) with similar specificity (68.7 %; OR 0.70, 95 % CI 0.43–1.13; p = 0.14). Discordance between JNET and MRS among sm3/T2-positive cases (28 MRS-only, 11 JNET-3-only) confirmed complementary diagnostic information. An either-positive rule (MRS or JNET-3) yielded the greatest sensitivity (84.9 %, 76.6–91.1; specificity 55.3 %, 49.1–61.5); both-positive (MRS and JNET-3) the greatest specificity (86.6 %, 81.9–90.5; sensitivity 48.1 %, 38.3–58.0).

Conclusions MRS using PDM accurately detects deep SMI in ERC as observed by experienced endoscopists. Sensitivity improved with structured video training. MRS and JNET capture partially non-overlapping diagnostic information; combining them outperforms either alone, enabling effective rule-out when both are absent and confident identification of deep invasion when both are present. Prospective evaluation is warranted.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822902

Aims International guidelines recommend 4 to 7 days of antibiotic treatment after adequate biliary drainage for acute cholangitis [1]. Observational data suggest shorter treatment may be sufficient [2]. We assessed whether 1 day of antibiotic treatment is non-inferior to 4 to 7 days of antibiotic treatment after adequate endoscopic biliary drainage in adults with acute cholangitis.

Methods This multicentre, open-label, randomized controlled non-inferiority trial was conducted across 31 hospitals in the Netherlands. We enrolled adults with acute cholangitis (according to Tokyo Guidelines 2018 criteria) due to distal biliary obstruction who achieved adequate endoscopic biliary drainage and fever resolution within 24 hours after ERCP. Patients were randomly assigned 1:1 to receive antibiotics for 1 or 4-7 day(s) after ERCP, stratified by blood culture status and cholangitis aetiology (benign or malignant obstruction) at the time of randomization. We excluded patients with concomitant infections or receiving immunosuppressive therapy.

The primary endpoint was clinical cure, defined as the patient being symptom-free by day 14, without relapse or death occurring by day 30. The primary endpoint was adjudicated by an independent blinded committee. We analysed the intention-to-treat and per-protocol population and calculated the absolute risk difference for clinical cure. Non-inferiority was demonstrated if the one-sided 95 % confidence limit for the absolute risk difference was greater than -7.5 %.

Results Between 2023 and 2025, we randomized 413 patients (1-day group: n = 205; 4-7-day group: n = 208). Median age was 74 years, 43.4 % were women, 10.0 % had malignant obstruction, 57.6 % had moderate/severe cholangitis, and 35.6 % had gram-negative bacteraemia at the time of randomization. Adherence to the allocated antibiotic treatment duration was 93.0 %. Three patients (all in the 4–7-day group) were lost to follow-up before the primary outcome could be assessed and were excluded from all analyses.

In the intention-to-treat analysis, the primary outcome clinical cure occurred in 195/205 patients (95.1 %) in the 1-day group versus 192/205 (93.7 %) in the 4-7-day group, with an absolute risk difference of 1.5 % (one-sided 95 % confi-

Endoscopy 2026; 58: S1–S1041

dence limit: -2.4 %), demonstrating non-inferiority. Per-protocol analysis (n = 384) showed non-inferiority (absolute risk difference 0.6 %, with one-sided 95 % confidence limit: -3.2 %). In a worst-case sensitivity analysis (with lost to follow-up counting as failures), non-inferiority was maintained. All-cause 30-day mortality was 2/205 in the 1-day group versus 1/205 in the 4-7-day group.

Conclusions One day of antibiotic treatment after adequate endoscopic biliary drainage is non-inferior to 4 to 7 days in adults with acute cholangitis. Therefore, 1 day should be the preferred duration of antibiotic treatment after adequate biliary drainage.

Aims Endoscopic enteral stenting (ES) and endoscopic ultrasound-guided gastroenterostomy (EUS-GE) are established minimally invasive palliative therapies for malignant gastric outlet obstruction (mGOO). To date, only one randomized controlled trial has compared these techniques, and it required a double-balloon-assisted EUS-GE approach that is not routinely available. In this multicenter randomized trial, we compared EUS-GE and ES using operator-selected techniques to assess efficacy, safety, and reintervention in patients with mGOO.

Methods In this international multicenter 1:1 randomized trial, adults with unresectable, symptomatic mGOO (GOO symptom score ≤ 1) were randomized to EUS-GE or ES and followed for 1 year. The primary endpoint was 3-month GOO recurrence, defined as recurrent symptoms with endoscopic or radiographic confirmation of stent dysfunction. Secondary endpoints included procedure-related adverse events (AEs, based on ASGE lexicon) with serious AEs defined as moderate or severe, technical success, clinical success (≥ 1-point improvement in GOO score within 7 days), GOO recurrence at 6 and 12 months, reintervention for stent dysfunction at 3, 6, and 12 months, and overall survival. Analyses were conducted on an intention-to-treat basis.

Results Between Oct 2020 and March 2025, 112 patients from five institutions were randomized (EUS-GE, n = 57; ES, n = 55). The median age was 63 years in both groups. Baseline characteristics were well balanced between groups. Technical success was achieved in 98.2 % of EUS-GE and 94.5 % of ES cases (p = 0.700). Clinical success occurred in 87.7 % vs 76.4 % (p = 0.330). GOO recurrence was significantly lower with EUS-GE compared with ES based on cumulative incidence analysis accounting for death as a competing risk (Gray's test p = 0.004). Recurrence rates were 0 % in the EUS-GE group vs 3.8 % in the ES group at 3 months, 0 % vs 7.7 % at 6 months, and 0 % vs 15.4 % at 12 months. Similarly, cumulative incidence of reintervention was significantly lower with EUS-GE (Gray's test p = 0.003). Reintervention rates were 0 % vs 5.8 % at 3 months, 0 % vs 9.6 % at 6 months, and 0 % vs 15.4 % at 12 months. Procedure-related AEs occurred in 8.8 % of EUS-GE and 7.3 % of ES patients (p = 1.00). Serious procedure-related AEs occurred in 0 % vs 5.5 %, respectively (p = 0.115). In the ES group, serious events included stent migration, perforation, and aspiration requiring ICU admission. Median overall survival was 4.4 months in the EUS-GE group and 3.6 months in the ES group (log-rank p = 0.774).

Conclusions In this international randomized trial, EUS-GE achieved similar technical and clinical success to ES in patients with mGOO, with significantly lower GOO recurrence and reintervention rates and a comparable safety profile.

Aims To assess whether vigorous lactated Ringer's hydration combined with rectal indomethacin, compared with rectal indomethacin alone, reduces the incidence of post-ERCP pancreatitis (PEP) in patients with pre-procedural or intra-procedural risk factors.

Methods This prospective, multicenter, open-label randomized controlled trial enrolled ERCP-naïve patients. Participants were randomized 1:1 to receive either vigorous lactated Ringer's hydration (VLRH) plus rectal indomethacin (RI) or RI alone. VLRH consisted of 3 mL/kg/h during ERCP, followed by a 20 mL/kg bolus immediately after the procedure and then 3 mL/kg/h for 8 hours. RI was administered according to standard prophylactic protocols. Pancreatic duct stenting was performed in all cases of inadvertent pancreatic duct cannulation. Detailed pre-, intra- and post-procedural clinical, endoscopic and laboratory data were prospectively collected. Subgroup analyses were conducted according to risk factors for PEP, both pre-procedural (including biliary stone disease, female sex and younger age) and intra-procedural, such as difficult biliary cannulation (defined as ≥ 5 cannulation attempts, cannulation time ≥ 5 minutes, accidental pancreatic duct cannulation), use of the double-guidewire technique, or need for pancreatic duct stenting after cannulation. Treatment effects were estimated as odds ratios (OR) with 95 % confidence intervals (CI).
Results A total of 388 patients were randomized to VLRH + RI (n = 194) or RI alone (n = 194). Baseline demographic, clinical and laboratory characteristics were well balanced between groups. Among patients with pre-procedural risk factors, those with biliary stone disease had a significantly lower incidence of PEP in the VLRH + RI group compared with the RI-alone group (4.8 % vs 14.3 %; OR 0.34, 95 % CI 0.11–0.94). Regarding subgroups of patients with intra-procedural risk factors for PEP, VLRH + RI significantly reduced PEP among patients with difficult cannulation (11.7 % vs 21.9 %; OR 0.47, 95 % CI 0.24–0.96). Notably, in patients with difficult cannulation requiring pancreatic duct stenting, VLRH + RI was associated with a significantly lower incidence of PEP compared with RI alone (7.7 % vs 31.0 %; OR 0.19, 95 % CI 0.05–0.62). No serious adverse events were observed in either group. Adverse events in the VLRH group were infrequent and comparable to the RI-alone group, including three cases of fluid overload and one case of pulmonary edema, all occurring in elderly patients with multiple comorbidities and resolving with diuretic therapy.
Conclusions Intra-procedural risk factors for post-ERCP pancreatitis are often unpredictable before ERCP. In this subgroup analysis of the PEPPER trial, the addition of vigorous lactated Ringer's hydration to rectal indomethacin was associated with a significant reduction of PEP incidence, particularly among patients with difficult cannulation and PD stenting. Given its acceptable safety profile and low cost, intensive lactated Ringer's hydration combined with rectal indomethacin represents an effective and pragmatic preventive strategy for post-ERCP pancreatitis, particularly in patients with risk factors for PEP.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP296 Randomized clinical trial comparing ERCP vs ERCP plus EUS-guided gallbladder drainage in non-surgical patients with symptomatic choledocholitiasis

DOI 10.1055/s-0046-1822905
Aims ERCP remains the primary approach to choledocolithiasis. 30 % of patients who undergo clearance of choledocholitiasis by ERCP without subsequent cholecystectomy will suffer recurrent biliary events. We hypothesized that EUS-guided gallbladder drainage (EUS-GBD) performed in the same endoscopic procedure could significantly decrease this risk.
Methods Multicenter, patient and assessor-blinded, randomized clinical trial. Subjects > 75 years of age with an age-adjusted Charlson comorbidity index (aCCI) ≥ 4 and symptomatic choledocholithiasis scheduled for ERCP were eligible. Concurrent acute cholecystitis, altered upper GI anatomy, lack of EUS window, potential surgical candidacy and failed ERCP were exclusion criteria. Participating subjects were randomized to ERCP vs ERCP combined with EUS-GBD (ERP + EUS-GBD). A 1-year follow-up was scheduled. The primary outcome was hospital readmission due to gallstone related disease or procedure related adverse events. Overall survival, all cause admissions and adverse events were also evaluated. A sample size of 75 patients per group was estimated. All outcomes were analyzed according to the intention-to treat principle. The primary outcome was analyzed using a multivariable Cox proportional hazards regression model.Results are presented as hazard ratios (HR)
Results Overall, 152 patients were included (77 in the ERCP group and 75 in the ERCP + EUS-GBD group); 129 (84.9 %) have completed follow-up. Baseline characteristics were balanced between cohorts. Overall, median age was 89.8 (IQR: 86-92.1) years, 100 (65.8 %) were female, median aCCI was 6 (IQR: 5-7,5), 50 (33.1 %) had a history of gallstone disease (16 had undergone an ERCP previously) and 95 (62.5 %) presented acute cholangitis.
Sphincterotomy was performed in 71 (91.2 %) ERCP patients and in 72 (96 %) ERCP + EUS-GBD patients. EUS-GBD was performed using 10x10mm (53 patients, 70.7 %) and 15x10mm (22 patients, 29.3 %) LAMS and the duodenum was the point of access in 46 (61.3 %) subjects. Two patients in each group died during the index admission.
Patients in the ERCP + EUS-GBD group presented a lower risk of biliary readmission, (HR: 0.33 [95 % CI: 0.14-0.77], p = 0.01), with a 14.1 % ARR [4.7-23.5 %] and a NNT of 7.1 [4.3-21.3]. The 1-year biliary readmission risk was 22.6 % [13.7-35.9 %] in the ERCP and 7.1 % [3-16.2 %] in the ERCP + EUS-GBD group.
No differences were observed in the all-cause admission risk, (HR 0.93 [0.70-1.25], p = 0.65) or the 1-year mortality (HR: 1.49 [0.63-3.53], p = 0.37). Overall, 12 (15.6 %) and 17 (22.7 %) subjects died in the ERCP and in the ERCP + EUS-GBD group, respectively. Procedure related adverse events rates were comparable, 13 % in the ERCP group and 17.3 % in the ERCP + EUS-GBD group.
Conclusions In non-surgical patients with symptomatic choledocholithiasis, performing an EUS-GBD in the same procedure as the ERCP reduces the risk of gallstone related admissions. However, this reduction does not impact the 1-year survival or the all-cause hospital admission rate.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

OP297 Azithromycin in acute upper gastrointestinal bleeding: a multicentric, double-blind, randomized-controlled trial (CLEAN-AZ)

Endoscopy 2026; 58: S1–S1041

Aims Current guidelines recommend prokinetic agents for gastric cleansing prior to endoscopy for acute upper gastrointestinal (UGI) bleeding in order to enhance visibility and reduce the need for reintervention [1]. Erythromycin is recommended but not available in all healthcare systems and azythromycin has been studied as a potentially more effective alternative. Our study assessed the efficacy and safety of intravenous azithromycin as pre-endoscopic prokinetic in patients undergoing emergent UGI endoscopy for acute bleeding.

Methods This was a prospective, multicenter, randomized, double-blind, placebo-controlled trial conducted in 12 hospitals in Romania (NCT06077916). Adult patients with acute UGI bleeding less than 12 hours after onset were randomized to either 500 mg intravenous azithromycin (AZT group) in 250 mL of saline or 250 mL saline (placebo group) administered 30-90 minutes prior to endoscopy. Our primary outcomes were: quality of visualization according to Toronto UGI Cleaning Score (TUGCS) [2] and the need to repeat endoscopy due to poor visibility. Our secondary outcomes included: adverse events, TUGCS subscores per segment, transfusion requirements, duration of the procedure, length of hospital stay, and endoscopist satisfaction regarding visibility measured on a 5-point Likert scale. We estimated a need to enroll 224 patients in order to obtain 90 % chance of detecting a clinically-relevant increase in adequate visualization (defined by TUGCS ≥ 8) from 60 to 80 %.

Results We randomized 224 patients but included 188 in the per-protocol analysis (93 AZT, 95 CTR). The primary outcome was not met as TUGCS ≥ 8 was reported in 79/93 patients (84.9 %) in the AZT compared with 70/95 patients (73.7 %) in the placebo group (p = 0.07). However, endoscopists were significantly more satisfied by the intraprocedural visibility achieved in the AZT group compared to placebo (77/93 rated good or excellent vs 62/95, p = 0.008). There was no statistically significant difference between groups in: need for repeat endoscopy due to poor visualization, TUGCS subscores, duration of the procedure, length of hospital stay, or units of blood transfused. There were 3 instances of potentially AZT-related adverse events (1 diarrhea, 1 severe vomiting, 1 Clostridium difficile infection) but no allergic reactions or arrhythmia. The incidence of adverse events was low and comparable between groups, with no significant differences in rebleeding (6/93 vs 6/95, p = 1), in-hospital mortality (4/93 vs. 6/95, p = 0.7), or need for endoscopic hemostatic intervention (44/93 vs. 45/95; p = 0.9).

Conclusions In the per protocol analysis, i.v. azithromycin administered prior to endoscopy in patients with acute UGI bleeding was safe and well tolerated. While it did not significantly improve the Toronto UGI cleaning score or reduce the need for repeat endoscopy, azithromycin was associated with higher endoscopist satisfaction regarding visibility.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Peroral endoscopic myotomy (POEM) and pneumatic dilation (PD) are established treatments for idiopathic achalasia. To date, only one randomized controlled trial has compared these two options but used a less common pneumatic dilation protocol.

Methods In this prospective, multicentre, randomized controlled trial, treatment-naïve adults with manometrically confirmed achalasia were assigned to POEM or graded PD. PD was performed using a standardized step-up protocol (30–35–40 mm) with permitted re-dilation for recurrent symptoms. The primary endpoint was clinical success at 2 years, defined as Eckardt score ≤ 3. Secondary endpoints included quality of life (SF-36 and disease-specific questionnaires), timed barium oesophagography, high-resolution manometry parameters, oesophageal acid exposure, need for retreatment and safety.

Results A total of 113 of the 118 randomised patients underwent treatment (3 exclusion due to treatment refusal and 2 pseudo-achalasia). At 2 years, clinical success in the full analysis set was achieved in 80.5 % (95 %CI: 69.6 – 91.5) and 66.1 % (95 %CI: 53.1 – 79.1) assigned to the POEM and PD group respectively, demonstrating non-inferiority of POEM within the prespecified -10 % margin (D14.4 %, 95 %CI: -2.1 – 32.0, p = 0.004). In the per-protocol analysis, success rates were 80.5 % (95 %CI: 69.6 – 91.5) and 73.8 % (95 %CI: 60.9 – 86.7), respectively. In the PD group, 17.5 % of patients required re-dilation and 7.0 % underwent a second re-dilation during follow-up. Both treatments resulted in sustained reductions in barium column height over 2-year period. Improvements in general and disease-specific quality-of-life measures were similar in both groups. Objective reflux parameters (total percent time pH < 4) were remarkably higher after POEM during follow-up, although patient-reported reflux symptoms did not differ significantly. One oesophageal perforation occurred after PD, and one POEM procedure was technically not feasible.

Conclusions POEM was non-inferior to graded PD for treatment-naïve achalasia at 2 years. When performed with protocolized re-dilation, PD achieved comparable symptom control and quality-of-life improvement, with lower objective acid exposure.

PYP001 Expanding Colorectal Cancer Screening to Adults Aged 70–75: Outcomes in a Tertiary Care Health Area

Authors Hernández Hernández N[1], Díez Martín J[1], Broco Fernández C[1], Patiño Delgadillo V[1], Boada Ortega D[1], Fernández Moreno M[1], Buela Fungueiriño L[1], Xavier Oliveira F[1], Quiñones Castro R[1], Rodríguez Martín L[2], Espinel J[1], Jorquera Plaza F[1], Díez Rodríguez R[1]
Institutes 1 University Hospital of León, León, Spain; 2 Complejo asistencial Universitario de leon, leon, Spain
DOI 10.1055/s-0046-1820942

Aims To evaluate participation rates, test positivity, and colonoscopy outcomes following the extension of a biennial fecal immunochemical test (FIT) colorectal cancer (CRC) screening program to adults aged 70–75. This study assesses the impact of including previously unscreened older adults in a tertiary care health area.

Methods A retrospective analysis of screening data was performed from January 2024 to June 2025 using the official regional CRC screening registry. Invitations were sent to adults aged 50–75 years. Participation, FIT results, colonoscopy completion, and findings were recorded. Data were analyzed descriptively, with positivity rates and detection rates of adenomas and CRC reported. First-time participants aged 70–75 were analyzed separately.

Results Overall, 79,872 invitations were sent to adults aged 50–75, with 30,854 completing FIT (38.6 % participation). FIT positivity was 4.6 % (1,426), leading to 1,059 colonoscopies. Adenomas were detected in 49 % (524) and CRC in 5.8 % (45).

Among newly invited participants (n = 9,622), 2,960 completed FIT, with 135 positives (4.5 %) and 105 colonoscopies performed. Adenomas were found in 46 % (48) and CRC in 1.9 % (2).

In the 70–75 age group (n = 16,850), participation was 49.5 % (8,347). FIT positivity was 5.8 % (492), with 423 colonoscopies performed, detecting adenomas in 52 % (223) and CRC in 4 % (17).

For first-time screened individuals aged 70–75 (n = 638), participation was 36 % (236). FIT positivity was 9.7 % (23), with 18 colonoscopies performed. Adenomas were identified in 44 % (8) and CRC in 11 % (2).

Conclusions Extending CRC screening to adults aged 70–75 effectively identifies clinically relevant pathology and engages patients who had not previously participated. While participation remains moderate, inclusion of this age group contributes to early detection and may improve overall program effectiveness. These results support continued evaluation of age expansion in CRC screening programs and highlight the utility of FIT-guided colonoscopy in older populations.

PYP002 Concordance between pan-intestinal capsule endoscopy and colonoscopy for the detection and characterization of colonic lesions: post-hoc analysis on the impact of colonic transit time

Authors Souto M[1, 2, 3], Goncalves J[1, 2, 3], Macedo Silva V[1, 2, 3], Rosa B[1, 2, 3], Cotter J[2, 3, 1]
Institutes 1 Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal; 2 ICVS/3B's – PT Government Associate Laboratory, Braga/Guimarães, Portugal; 3 Gastroenterology Department, Unidade Local de Saúde do Alto Ave, Guimarães, Portugal
DOI 10.1055/s-0046-1820943

Aims Pan-intestinal capsule endoscopy (PCE) enables non-invasive assessment of the small bowel and colon and has been investigated as a first-line diagnostic alternative to colonoscopy in patients with suspected mid- or lower gastrointestinal bleeding (MLGIB). This study aimed to assess the concordance between PCE and colonoscopy for detecting and characterizing colonic lesions, and to evaluate the influence of colonic transit time (CTT) on diagnostic agreement.

Methods This was a post-hoc analysis of data from a prospective single-center clinical trial. Consecutive patients with suspected MLGIB underwent same-day PCE and colonoscopy. Only complete examinations were included. Concordance between techniques was evaluated for detection of any lesion, vascular lesions, polyps, and polyp size categories (< 6 mm, 6–10 mm, > 10 mm) using Cohen's Kappa (κ). Sensitivity analyses stratified patients by CTT: ≤ 60 vs > 60 min, ≤ 90 vs > 90 min, and ≤ 120 vs > 120min.

Results Of 100 enrolled patients, 76 had complete PCE examinations (median age 67 years; 60.5 % women), and 80.3 % presented with occult bleeding. Adequate bowel preparation was achieved in 77.6 % of PCEs and 84.2 % of colonoscopies.

Overall, PCE demonstrated moderate agreement with colonoscopy for detecting any colorectal lesion (κ = 0.45, p < 0.001). Agreement was also moderate for vascular lesions (κ = 0.56, p < 0.001) and polyps (κ = 0.51, p < 0.001). Polyp size classification showed substantial concordance (κ = 0.69, p < 0.001).

CTT strongly influenced global diagnostic agreement. For any lesion, concordance was non-significant for rapid CTT (≤ 60 and ≤ 90 min). Agreement improved to fair for CTT ≤ 120 min (κ = 0.384, p = 0.025) and reached moderate levels for CTT > 120 min (κ = 0.50, p = 0.002).

Detection of vascular lesions was comparatively stable across all CTT categories, with moderate-to-substantial agreement at every threshold (κ = 0.577, p = 0.008 for ≤ 60 min; κ = 0.578, p = 0.002 for ≤ 90 min; κ = 0.635, p < 0.001 for ≤ 120 min).

In contrast, polyp detection showed a marked dependence on CTT. Concordance increased from fair at ≤ 60 min (κ = 0.40, p = 0.049) to moderate for > 60 min (κ = 0.55, p < 0.001) and > 90 min (κ = 0.56, p < 0.001). For ≤ 120 min agreement remained moderate (κ = 0.46, p = 0.006), again increasing for > 120 min (κ = 0.56, p < 0.001).

Similarly, polyp size classification was unreliable for rapid transit (≤ 90 min: p = 0.273) but became almost perfect for > 90 min (κ = 0.824, p < 0.001) and > 120 min (κ = 0.805, p < 0.001).

Conclusions PCE showed moderate-to-substantial agreement with colonoscopy for the detection of colorectal lesions. Diagnostic performace was significantly influenced by CTT. While vascular lesion detection remained stable across all CTT categories, rapid CTT (< 90minutes) was associated with an increased risk of false negatives, especially for polypoid lesions. In such cases, repeat examination, closer follow-up, or alternative diagnostic strategies should be considered.

Endoscopy 2026; 58: S1–S1041

▶ **Table 1** Odds of re-investigation and increased risk classification based on faecal haemoglobin concentration estimated from univariate and multivariate logistic and ordinal logistic regression models, n = 1,410, reference group: 100-249 ng hb/mL buffer

Outcome	Model	ng hb/mL buffer	Odds Ratio	95 % confidence interval	p-value
Re-investigation	Univariate logistic regression model	250-499	1.14	0.86 – 1.50	.364
		>499	1.22	0.94 – 1.57	.129
	Multivariate logistic regression model	250-499	1.13	0.85 – 1.50	.395
		>499	1.24	0.96 – 1.61	.099
Increased risk classification	Univariate ordinal logistic regression model	250-499	1.18	0.93 – 1.51	.177
		>499	1.36	1.08 – 1.70	.008
	Multivariate ordinal logistic regression model	250-499	1.18	0.92 – 1.50	.193
		>499	1.40	1.12 – 1.76	.003

Aims The use of colon capsule endoscopy (CCE) in clinical practice has been challenging, mainly due to a high re-investigation rate caused by both incomplete investigations, and a high sensitivity to polyps requiring therapeutic intervention. A strategy to lower the re-investigation rate following CCE, could be to target patients with a lower risk of pathology. Faecal haemoglobin (fHb) is a well-known predictor of colorectal adenomas, and the concentration of fHb may therefore present as a good triaging measure. Therefore, we aimed to investigate the re-investigation rate and risk classification in complete CCEs in a screening population stratified by fHb concentration.

Methods Complete colon capsule endoscopy investigations were identified from the intervention arm of a large randomised controlled trial, CareForColon2015 [1, 2], and the proportions of investigations leading to re-investigation by colonoscopy were stratified by fHb concentration. All participants had a faecal immunochemical test value ≥ 100 ng hb/mL buffer. Further, odds of re-investigation was estimated by logistic regression models and odds of increased risk classification by ordinal regression models. The risk classification in the current study was defined in four levels; Level one: no findings. Level two: less than three polyps, all smaller than 10 mm in size. Level three: three to four polyps of any size, or at least one polyp 10-19 mm in size. Level four: More than four polyps, or at least one polyp larger than 19 mm in size, or cancer suspicion (▶ **Table 1**).

Results The re-investigation rate was 58.4 % in 1,410 complete CCEs out of 2,030 procedures. There were no significant differences (p = 0.283) in re-investigation rates between fHb concentration subgroups with 58.0 %, 61.1 %, and 62.7 % in the groups of 100-249, 250-499, and > 499 ng hb/mL buffer, respectively. Level one or two risk classification was identified in 21.3 % (n = 300) and 20.3 % (n = 286) of the complete CCE investigations, returning the participant to the colorectal cancer screening. Level three or four risk classification was identified in 30.5 % (n = 430) and 27.9 % (n = 394) of the complete CCE investigations, resulting in referrals for follow-up colonoscopy. The odds of increased risk classification (i.e. higher than level one) was 1.18 (CI 95 % 0.93; 1.51, p = 0.177) for concentrations between 250-499 ng hb/mL buffer, and 1.36 (CI 95 % 1.08; 1.70, p = 0.008) for concentrations above 499 ng hb/mL buffer, compared to 100-249 ng hb/mL buffer.

Conclusions*Conclusion:* Faecal haemoglobin concentration did not prove to be a good stand-alone selection parameter for diagnostic modality in a faecal immunochemical test positive colorectal cancer screening population, although it was significantly associated with an increased risk classification.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP004 Sessile Serrated Polyps Syndrome in Northern Italy: Epidemiological, Clinical, and Histopathological Characterization from a High-Volume Endoscopy Center

Authors Santus C[1, 2], Olivari N[2], Salvi D[2], Treppiccione C[3, 2], Ungari M[4], Cesaro P[2]

Institutes **1** University of Cagliari, Cagliari, Italy; **2** Department of Gastroenterology and Endoscopy, Fondazione Poliambulanza Istituto Ospedaliero, brescia, Italy; **3** Università Cattolica del Sacro Cuore, Facoltà di Medicina e Chirurgia, Roma, Italy; **4** Pathology Unit, Services Area, Fondazione Poliambulanza Hospital Institute, brescia, Italy

DOI 10.1055/s-0046-1820945

Aims Sessile serrated polyps syndrome (SPS) diagnosis remains challenging, requiring adequate knowledge of this rare syndrome, high-quality colonoscopy, optimal bowel preparation, and expert histopathological evaluation. Despite technological advances, underdiagnosis rates in Europe remain between 30–50 %. The aim of this study was to characterize SPS within a large cohort of patients undergoing colonoscopy at a tertiary endoscopy center in Northern Italy. Specifically, the study sought to describe the epidemiological, demographic and clinical features of patients meeting the 2019 WHO diagnostic criteria for SPS. Furthermore, the study aimed to evaluate the distribution, number, size, and histopathological profile of serrated polyps (SPs), including the presence of dysplasia and associated adenomas, and to assess adherence to WHO criteria types (criterion 1, criterion 2, or both) where criterion 1 requires ≥ 5 proximal to the rectum SPs ≥ 5 mm with at least 2 ≥ 10 mm in size, and criterion 2 requires > 20 SPs throughout the colon with at least 5 proximal to the rectum [1–3].

Methods This retrospective, observational, single-center cohort study was conducted at Fondazione Poliambulanza Istituto Ospedaliero-Brescia. We included all consecutive outpatients who underwent a complete colonoscopy between January 2021-June 2025. All procedures were performed using high-definition endoscopes with narrow-band imaging satisfying ESGE performance measures. Eligible participants included adults (≥ 18 years) who had a histologically confirmed diagnosis of SPS according to the 2019 WHO criteria. Specimens were evaluated by expert gastrointestinal pathologists.

Results During the study period a total of 27,836 elective complete colonoscopies were performed, corresponding to 22,522 consecutive patients. Among these, 4,792 patients had at least one polyp ≥ 5 mm located in the sigmoid colon or proximally. Pathology database screening identified 2,597 patients with at least one SPs. Cross-matching these datasets yielded 1,358 patients who had both a serrated histology and a proximal to the rectum polyp ≥ 5 mm. Following complete review of all colonoscopies and polypectomy histories, 61 patients (4.5 %) fulfilled the 2019 WHO diagnostic criteria for SPS corresponding to an overall prevalence of 0.27 %, 1 in every 370 patients. Most SPS (67 %) were newly recognized during this analysis rather than during prior endoscopic evaluations. According to WHO 2019 diagnostic categories, 62 % of patients fulfilled criterion 1, 5 % fulfilled criterion 2, and 33 % met both criteria. Dysplasia in SPs was observed in 21 % of patients, and 87 % of patients had associated adenomas. Colorectal neoplasia was found in 8 % of patients.

Conclusions Our findings highlight that SPS remains underdiagnosed; only 33 % of our patients had previously established SPS and demands close collaboration between endoscopists and pathologists underling a lack of knowledge of this syndrome. Importantly, this diagnostic delay occurred even in a third-level endoscopy center, underscoring the difficulty of identifying SPS in routine clinical practice. Improved awareness and surveillance strategies are essential to prevent interval colorectal cancer risk.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820946

Aims To provide a comprehensive overview of real-life management of T1 colorectal cancer(CRC) in Italy, through a nationwide survey conducted among CRC screening centres.

Methods Anonymous digital survey sent to all Italian CRC screening centres between May-July 2025, through the National Screening Observatory(ONS)-Italian Group for CRC Screening(GISCOR) network. The questionnaire included 8 items: responder and centre information, multidisciplinary team (MDT), endoscopy, staging, histopathology, treatment and follow-up.

Results Out of 207 survey links opened,131 questionnaires at least half completed, of which 83 fully completed. The geographical provenience of responses was representative of the screening centres across the country (North 51 %, Centre 21 %, South-Islands 29 %). Participants were mostly > 50yo (56 %), with > 10y of professional experience (74 %), mainly gastroenterologists (73 %) or surgeons(21 %). Most worked in non-academic (77 %) level II/III centres (73 %), all public or accredited private hospitals, performing 2,000–5,000 screening colonoscopies annually (44 %). A MDT for CRC management was present in 91 % of centres, with nearly all T1 cases discussed by the MDT. Core members included oncologists, surgeons, gastroenterologists, radiologists, and pathologists, while radiotherapists and palliative care specialists less common. Other specialists—nuclear medicine physicians, psychologists,case manager nurses,geneticists,stomatherapists,anesthetists, nutritionists, internists—were rarely involved. For endoscopic evaluation of lesions, the most used technique was virtual chromoendoscopy(73 %) with vital chromoendoscopy nearly abandoned. Lesions were most often described according to Paris and Kudo classification(≈ 70 %) with minimal use of JNET, NICE and Sano(< 30 %). Responders declared a median of 70 % hystologically confirmed T1 already suspected at index endoscopy, but with huge heterogeneity(Q1-Q3 30-80 %;range0-100 %). Pre-treatment staging was variably performed: always(34 %),never(31 %),only for rectal lesions(25 %), specific cases(10 %). Abdominal CT was the main tool for colon lesions, while pelvis MRI for rectal lesions. A post-endoscopic treatment staging was routinely performed, either in all cases(42 %) or only with positive margins or high risk hystology(57 %). CEA dosage was variably done. A standardized pathology report form for T1 CRC was used in 84 % of centres, with key features including lymphovascular invasion (LVI)(95 %), grading(92 %), deepness of invasion(88 %), resection margins(88 %), budding(87 %), Haggitt classification for peduncolated polyps(71 %), with minor presence of MMR(45 %) and microRNA(22 %) analyses. LVI(92 %) and poor differentiation(83 %) were most frequently considered high-risk factors. Budding grade 2–3(77 %),positive resection margins(80 %),deep submucosal invasion(63–73 %), and free resection margin < 1mm(59 %) were variably considered high-risk. In most centres(66 %) only one pathologist was responsible for reporting T1CRC cases; when involved two pathologists(34 %), both usually of the same institution(89 %).T1 colon cancers in most cases were treated locally at first, with secondary surgery only when high risk hystological features were present, often following MDT decision. For T1 rectal cancers, MDT decision had a primary role. For endoscopically removed lesions revealing T1 only after hystological examination, the most used approaches were MDT discussion(41 %) or only follow-up if negative margins and high risk hystology absent(32 %). EFTR was rarely used to treat the scar of an excised T1 (30 %), mostly in case of positive margins at endoscopic excision(56 %) or for patients unfit for surgery(28 %). Follow-up protocols were highly heterogeneous: for endoscopically treated T1 CRC, follow-up most commonly included endoscopy and clinical evaluation at 12 months, with limited use of imaging. For surgically treated patients, most centres performed comprehensive follow-up at 12 months(endoscopy,abdominal/thoracic imaging,CEA,clinical evaluation), with fewer repeat assessments at 24-36-60 months.

Conclusions This national survey, like previous Dutch survey [1], highlights substantial heterogeneity in the management of T1 CRC across Italian screening centres. These findings underscore once again the need for shared recommendations to standardize diagnostic, therapeutic and follow-up pathways to optimize patient outcomes, avoiding overtreatment and malpractice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims The role of routine terminal ileal intubation (TII) in asymptomatic patients undergoing colonoscopy for colorectal cancer (CRC) screening or post-polypectomy surveillance is debated. While considered a quality indicator in some settings, its clinical utility in this population remains unclear. This systematic review and meta-analysis aimed to evaluate the diagnostic yield, clinical utility and procedural impact of routine TII in patients undergoing CRC screening or post-polypectomy surveillance.

Methods We conducted a systematic search of PubMed and Embase up to September 2025, according to PRISMA guidelines. We included studies reporting TII diagnostic yield in asymptomatic adults undergoing CRC screening or post-polypectomy surveillance colonoscopy. Data were synthesized using random-effects models. The primary outcome was the overall diagnostic yield of TII. Secondary outcomes included the diagnostic yield for clinically significant findings, Crohn's disease, and the impact of TII on procedure duration.

Results Eleven studies involving 25659 patients, of whom 13672 underwent TII, were included. The pooled overall diagnostic yield for any ileal finding was 1.74 % (95 %CI 1.18 %-2.57 %), with most abnormalities being non-specific and not requiring clinical action. The diagnostic yield for clinically significant pathology was substantially lower at 0.28 % (95 %CI 0.07 %-1.05 %), while the yield for detecting Crohn's disease was only 0.1 % (95 %CI 0.02 %-0.44 %), corresponding to one case per 1000 ileoscopies during colonoscopy for CRC screening. Across eight studies including 12,591 patients, ileal biopsies showed a very low diagnostic yield of 0.12 %. Two studies found that terminal ileum intubation added about 56 seconds to procedure time, with no reported complications. Only two studies compared ileal findings across primary screening, FOBT-based screening, and post-polypectomy surveillance, preventing subgroup analysis. Limited data suggest similarly low diagnostic yields across groups: OR of 0.22 for primary screening and 0.1 for FOBT-positive patients, and overall yields of 1.9 % (clinically significant 0.3 %) for primary screening versus 4.0 % (clinically significant 0.3 %) for post-polypectomy surveillance. The studies showed variable methodological quality (NOS 4–8), mostly indicating moderate risk of bias. Sensitivity analyses showed no significant differences in diagnostic yield based on bias level or inclusion of non-TII patients, supporting the robustness of overall findings.

Conclusions Routine TII in asymptomatic patients undergoing screening or surveillance colonoscopy provides a negligible diagnostic yield for clinically significant pathology, including Crohn's disease. Our findings do not support performing routine TII during colonoscopy in this patient population.

PYP007 Colorectal-Cancer Screening Coverage Determinants and Outcomes of Various Screening Patterns: A Large-Scale Cohort Analysis

Authors Gorelik Y[1, 2], Romano R[3], Leshno M[4], Alkalai H[3], Kariv R

Institutes **1** Rambam Health Care Campus, Haifa, Israel; **2** Technion, haifa, Israel; **3** Maccabi Health Care Services, Tel Aviv, Israel, Tel Aviv-Yafo, Israel; **4** Tel Aviv University, Tel Aviv-Yafo, Israel

DOI 10.1055/s-0046-1820948

Aims Colorectal cancer (CRC) screening behaviors vary widely in real world settings. We aimed to study population-level screening behavior, identify screening determinants and patterns, and concordant CRC outcomes.

Methods We conducted a retrospective cohort study using electronic health records from Maccabi Health Services (Israel) between 2006-2021. Members at screening age, free of CRC and mortality for ≥ 3 initial years were included. Individuals were followed until end of follow up, CRC, or death. Annual coverage was defined as fecal immunochemical test (FIT) in the prior year, virtual colonoscopy in the prior 5 years, or colonoscopy in the prior 10 years. Proportion of time covered (POTC) equaled years covered/years observed. We modeled predictors of yearly adherence using population-averaged logistic regression. We also classified five prespecified patterns: Early single colonoscopy (at 50–60 years with no further tests), FIT-regular (POTC ≥ 50 %; FIT only), FIT-sporadic (POTC < 50 %; FIT only), Mixed (all tests), and no screening. CRC incidence rates were calculated by Poisson methods. Time-to-CRC was analyzed with Fine–Gray subdistribution models treating death as a competing event (▶ **Table 1**).

Results We included 558,996 individuals (50.7 % female), contributing 5,955,605 person-years; median follow-up was 11.0 years (IQR 6.0–16.0). Median final POTC was 0.62 (IQR 0.15–0.83). Older age and higher socioeconomic rank were associated with adherence (aOR per year 1.01, 95 % CI 1.00–1.01; per rank 1.02, 1.01–1.02). Obesity and hypertension were associated with increased adherence (aOR 1.18, 1.16–1.19; 1.18, 1.15–1.20), while anticoagulation and chronic lung disease were associated with lower adherence (aOR 0.89; 0.83–0.96 and 0.84–0.94). In prespecified patterns (Early single colonoscopy 8,814; FIT-regular 137,251; FIT-sporadic 79,727; Mixed 209,472; None 123,732), CRC incidence was highest in None (479, 95 % CI 456–503) and FIT-sporadic (370, 347–393), and lower and not substantially different in the Mixed (108, 101–116) and Early single colonoscopy (137, 101–183). In Fine–Gray models, compared with early single colonoscopy, FIT-sporadic and none had the highest CRC risk (aHR 2.74, 2.04–3.69; aHR 3.74, 2.78–5.02), whereas FIT-regular and Mixed were not significantly different (aHR 1.24, 0.92–1.67; aHR 0.82, 0.61–1.10).

Conclusions In this nationwide cohort, we identified predictors of CRC screening adherence and showed that regular FIT screening carries equal CRC outcome as early colonoscopy and mixed screening pattern. These patterns are associated with a significantly lower CRC incidence than no screening or sporadic use of FIT.

▶ Table 1

Variable	All (n = 558996)	Single early colonoscopy (n = 8814)	FIT regular (n = 137251)	FIT sporadic (79727)	Mixed (n = 209472)	None (n = 123732)

DOI 10.1055/s-0046-1820949

Aims Anal cancer incidence continues to rise, underscoring the urgent need for more effective and scalable screening strategies. High resolution anoscopy (HRA) remains the cornerstone of early detection, yet achieving precise identification and confident differentiation of lesions remains challenging. Artificial intelligence has emerged as a powerful tool to enhance recognition and stratification of squamous intraepithelial lesions, including LSIL (low grade squamous intraepithelial lesion) and HSIL (high grade squamous intraepithelial lesion), with clear advancement along the technology readiness level scale (TRL, a measure of technological maturity). CADe systems (computer aided detection) improve lesion localization, while CADx systems (computer aided diagnosis) deliver real time differentiation that can directly shape clinical decisions. This study set out to develop an interoperable CADex system capable of simultaneously detecting and distinguishing LSIL and HSIL during HRA, aiming to elevate diagnostic precision, reduce subjectivity, and accelerate progress toward more consistent and effective anal cancer prevention [1–4].

Methods This multicenter study analyzed 156,246 frames extracted from 308 HRA procedures performed in 279 patients across eight centers. Data were obtained using six different devices, including four colposcopes, one proctoscope, and one endoscope. Frames were annotated as HSIL or LSIL based on corresponding histopathology, which served as the ground truth. A YOLO-tiny object detection model was trained to perform simultaneous lesion detection and differentiation using bounding-box annotations. The dataset was randomly divided into training, validation, and test sets. Model performance was evaluated at two levels. Object detection metrics were mean average precision (mAP) and mAP at an Intersection over Union threshold of ≥ 0.50 (mAP50). Classification metrics were recall (sensitivity), precision (PPV), and accuracy.

Results Precision was 0.8332 for LSIL and 0.8165 for HSIL, with an overall precision of 0.8247. Recall was 0.9988 for LSIL and 0.9994 for HSIL, yielding an overall recall of 0.9991. Overall classification accuracy was 0.9432. For combined LSIL and HSIL detection, the model achieved a mAP of 0.7488 and mAP50 of 0.9738.

Conclusions This study introduces the first interoperable CADex model capable of simultaneous detection and classification of anal canal precursor lesions, using an explainable bounding box approach. These findings indicate that CADex can provide a more robust pathway for integrating AI into anal cancer screening and mark a meaningful step forward in the TRL of AI applied to HRA. Its consistent performance across diverse imaging devices reinforces this potential and highlights interoperability as a prerequisite for broad clinical adoption. This interoperability also paves the way to secondary applications, such as opportunistic assessment of the anal canal during colonoscopy, where incidental visualization could ultimately complement and extend dedicated HRA based screening programs.

PYP009 Endoscopic Resection of Large Non-Pedunculated Polyps in Hereditary Colorectal Cancer Patients- Feasibility, Safety, and Efficacy

Authors Bar-Yishay I[1], Younis F[1], Scapa E[1], Rosner G[1], Strul H[1], Gluck N[1], Kariv R[1]
Institute 1 Tel Aviv Sourasky Medical Center – Ichilov, Tel Aviv-Yafo, Israel
DOI 10.1055/s-0046-1820950

Aims Patients with hereditary colorectal cancer syndromes who undergo colectomy require lifelong surveillance due to continued risk of neoplasia development. Large (>20mm) non-pedunculated polyps in the pouch and anastomotic region present unique therapeutic challenges due to altered anatomy, thin small bowel wall and often severe submucosal fibrosis. We present our experience of endoscopic resection feasibility, safety, and efficacy in this specialized population (▶ **Table 1**).

Methods Retrospective analysis of 10 large non-pedunculated polyps (>20mm) resected endoscopically in 9 patients, who had previously undergone Total proctocolectomy with ileo-anal anastomosis (TPC-IPAA) (n = 8) or Subtotal colectomy with ileo-rectal anastomosis (n = 1). Endpoints included technical success, procedural complications, and recurrence rates [1, 2].

Results Mean age 43.7 years (range 25-66), 55 % female. Eight patients carried pathogenic APC mutations (FAP) and 1 carried homozygous MSH6 mutations (CMMRD). Mean lesion size was 28.0mm (range 20-40mm), most were Paris 0-IIa (N = 8) and one was Paris 0-IIa + Is. Lesion were located over the ileo-anal or ileo-rectal anastomosis (n = 4), rectal cuff (n = 2), and pouch (n = 4). Twenty-five percent had previous failed resection attempts. Submucosal fibrosis was present in 80 %. EMR was used in 5 cases, hybrid ESD in 3, and ESD in 2. Two complications (20 %) occurred, both in ESD cases. A procdeural perforation treated by clip and delayed microperforation treated conservitavly. Both were classified as mild (Clavien-Dindo grade B).

All lesions were benign, with low- grade dysplasia in 8 lesions (80 %) and high-grade dysplasia present in 2 lesions (20 %). Local recurrence occurred in 5 lesions (50 %) within mean follow up of 3 years, all were managed endoscopically.

Conclusions Endoscopic resection of large non-pedunculated polyps is feasible with acceptable safety profiles despite significant technical challenges. The substantial 50 % recurrence rate emphasizes the critical importance of intensive surveillance protocols and potential need for repeat interventions in this high-risk population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP010 Screening Modalities for Colorectal Cancer in Liver-transplanted patients: A National French Practice Survey and a Tertiary-Center Case Review

Authors Tamer I[1], Rolle V[1], Vimont-Vicary A[1], Barusseau R[1], Silvain C[1], Elkrief L[2], Olivier R[1]
Institutes 1 Poitiers University Hospital, Poitiers, France; 2 Hopital Trousseau, Chambray-lès-Tours, France
DOI 10.1055/s-0046-1820951

Aims Liver transplanted patients have an increased risk—approximately 2.3-fold higher than the general population—of developing colorectal cancer (CRC). However, no specific recommendations currently exist regarding screening modalities to be performed before and after transplantation.

The first aim of our study was to conduct a practice national french survey among liver transplantation centers to determine whether screening methods for CRC in liver transplanted patients are standardized. Secondly, we retrospectively reviewed data from a tertiary center to identify liver transplanted patients who developed CRC during follow-up and to analyze the screening methods used in these patients before and after transplantation.

Methods We conducted a practice national survey between April and August 2025 among the 16 French centers performing adult liver transplantation (LT), using an online questionnaire developed and validated by three hepatology

▶ **Table 1**

	Age	Sex	Syndrome	Colectomy	Location	Size (mm)	Previously attempted	Method	Procedural complication	Delayed complication	Surveillence	Follow up (months)
1	63	F	FAP	TPC + IPAA	Anastamosis	20	EMR	EMR	None	None	Normal	44
2	36	M	FAP	TPC + IPAA	Anastamosis	30	No	EMR	None	None	Normal	48

10*	25	F	CMMRD	TPC + IPAA	Pouch	20	No	Hybrid ESD	None	None	Normal	19

* Lesions 9 and 10 in the same patient. FAP = Familial Adenomatous Polyposis. CMMRD = constitutional mismatch repair deficiency. TPC + IPAA = Total proctocolectomy with ileal pouch anal anastomosis. EMR = Endoscopic Mucosal Resection. TEM = Transanal Endoscopic Microsurgery. ESD = Endoscopic Submucosal Dissection.

transplant experts from two different tertiary centers. The questionnaire assessed, among other items, the existence of a systematic CRC screening protocol, screening examinations performed according to classical risk factors (RFs) for colorectal adenomas, and their frequency. RFs were defined as age > 50 years, personal or family history of adenoma or CRC.In the second part of the study, we reviewed cases from a tertiary center, identifying liver transplanted patients who developed CRC. Analyzed data included: indication for LT, performance of fecal imune test (FIT) and/or colonoscopy before and after transplantation, indications for these tests, and timing of their completion. Statistics were descriptive, expressed as mean ± standard deviation or median for quantitative variables, and as percentages for qualitative variables.

Results With 24 responses to our questionnaire, from 12 of the 16 surveyed centers, we found significant heterogeneity in screening practices before and after transplantation, with no dedicated protocol in 37.5 % and 58.4 % of centers, respectively. Before LT, screening was performed by colonoscopy in 91.7 % of cases in the presence of RFs, whereas no screening was performed in 56 % of cases in the absence of RFs. In the absence of RFs, FIT was used in 16.8 % of cases.After LT, in patients without RFs, screening was performed using FIT in 76.9 % of cases and colonoscopy in 15.4 %. In the presence of RFs, FIT was used in 46.2 % and colonoscopy in 53.8 % of cases.

In the tertiary-center cohort, 336 patients underwent LT, between january 2011 and August 2024 and 10 developed CRC, corresponding to an incidence of 2.9 %. Although 80 % of them had CRC RFs, only 50 % underwent dedicated CRC screening before transplantation. Among screened patients, the median time to CRC diagnosis was 68 months post-transplant. In contrast, all patients who were not screened before transplantation (n = 5) and subsequently developed CRC were diagnosed within 18 months after transplantation (median: 13 months). Notably, all patients who developed CRC had alcohol-related cirrhosis, and 80 % had hepatocellular carcinoma (HCC) before transplantation.

Conclusions There is a lack of standardization of CRC screening modalities in liver transplanted patients, resulting in heterogeneous practices across centers. National recommendations appear essential to harmonize screening strategies and better define pre- and post-transplant screening according to patient RFs. Particular attention should be given to patients with HCC before transplantation and those with alcohol-related cirrhosis, who appear to be at especially high risk in our cohort. Finally, in the absence of pre-transplant screening, we propose performing routine colonoscopy within 6–12 months after transplantation.

Intelligent Detection Systems in Gastrointestinal Endoscopy

14/05/2026, 09:30–10:30 **Emerald 4**

PYP011 Artificial Intelligence in Colonoscopy: Insights from a Prospective Real-Life Study

Authors Bartoletti J[1], Morvan M[1], Arnachellum R[1], David N[2], Canévet M[1], Noel C[1], Jezequel J[3], Quénéhervé L[2]
Institutes **1** Hospital La Cavale Blanche, Brest, France; **2** CHU Brest, Brest, France; **3** Hospital Center Regional And University Chru, Brest, France
DOI 10.1055/s-0046-1820952

Aims Prevention of colorectal adenocarcinoma mainly relies on the detection and resection of precancerous lesions (adenomas and serrated lesions) during colonoscopy. The implementation of artificial intelligence (AI) solutions in digestive endoscopy aims to improve detection performance. However, in the literature, detection rates depend on multiple factors related to the patient, the operator, and the procedural context. Moreover, while AI seems to increase the number of resected lesions, its impact on the detection of clinically significant lesions remains debated. The primary objective of this study was to evaluate the impact of AI on the detection of polyps ≥ 10 mm.

Methods We conducted a prospective, observational, single-center study in a university hospital between January and December 2024. Colonoscopy data were collected by operators using dedicated questionnaires. Inclusion of examinations and the choice to use AI were left to the operator's discretion. Patient and procedural characteristics as well as quality indicators were recorded. Operator perception of AI was also assessed. A propensity score matching analysis was performed on age, sex, and operator experience to evaluate factors associated with resection of polyps ≥ 10 mm, after excluding known lesions and colonoscopies performed for inflammatory bowel disease. The study protocol was approved by the local ethics committee.

Results A total of 547 colonoscopies (median age 63 years; 57 % male) were analyzed, including 290 with AI and 257 without AI. Indications differed significantly between groups, with more follow-up colonoscopies (32 % vs. 17 %) and FIT-positive indications (8 % vs. 4 %), and fewer known lesions (14 % vs. 4 %) in the AI group compared to the non-AI group ($p < 0.01$). Colonoscopies with AI were more often performed by experienced endoscopists, in the morning, and with patients in the left lateral position. The total number of resected polyps and detection of polyps ≥ 10 mm did not differ between AI and non-AI groups. However, total procedure time (20 vs. 25 min) and withdrawal time (10 vs. 13 min, $p < 0.05$) were significantly shorter with AI. After propensity score matching, the proportion of colonoscopies resecting at least one polyp ≥ 10 mm was not significantly different between AI and non-AI groups (20.7 % vs. 20.6 %).

In multivariable analysis, factors associated with detection of polyps ≥ 10 mm were operator status (assistant or fellow vs. resident; OR 0.04; $p = 0.004$), absence of music in the endoscopy room (OR 0.2; $p = 0.013$), screening colonoscopy vs. symptomatic colonoscopy (OR 0.08; $p < 0.001$), and longer withdrawal time (OR 14.7; $p < 0.001$). AI use had no impact on detection of polyps ≥ 10 mm.

Operator perception from the 290 AI-assisted procedures showed that 88.3 % of endoscopists considered AI neither saved nor wasted time. System interruptions were rare (2.1 %). AI was reported to detect a polyp missed by the operator in 5.2 % of cases, but failed to detect a polyp seen by the operator in 7.6 %.

Conclusions In this prospective real-life study, AI did not improve detection of clinically significant lesions. Detection performance remained mainly determined by patient- and operator-related factors. In routine practice, numerous confounding factors exist, which differ from the highly controlled conditions of randomized trials.

PYP012 Application of Fusion Foundation Model for Artificial Intelligence-Assisted Capsule Endoscopy Reading

Authors Lim YJ[1], Oh DJ[2], Hwang Y[3], Park J[3]
Institutes **1** Dongguk University Ilsan Hospital, goyangsi, Republic of Korea; **2** Dongguk University – Seoul Campus, Goyang-si, Republic of Korea; **3** Chungbuk National University, Gaesin Campus, Cheongju, Republic of Korea
DOI 10.1055/s-0046-1820953

Aims Capsule endoscopy reading is time-consuming and subject to variability among readers. Although artificial intelligence–assisted reading has improved diagnostic accuracy, its performance often lacks generalizability in different clinical settings. This study aimed to develop a foundation model to improve accuracy and generalizability in capsule endoscopy reading

Methods The Attention-based Token Mixing (AToM) model was developed by integrating two validated foundation models, BiomedCLIP and GastroNet. This model incorporates an Efficient Token Mixer and a Squeeze-and-Excitation Convolutional Neck to enhance feature integration and overall performance. The model was evaluated using three datasets, including two public datasets (Kvasir and Kvasir-Capsule) and one real-world dataset (DUMC). The analysis was conducted under patient-level splitting protocol.

Endoscopy 2026; 58: S1–S1041

Results AToM consistently outperformed conventional deep learning, transformers, and recent foundation models across all evaluation metrics. On the Kvasir-Capsule dataset, AToM achieved an F1-score of 87.4 %, an accuracy of 88.7 %, and MCC of 0.616, outperforming the latest foundation model (DINOv2) by 1.7 % in F1-score, 1.6 % in accuracy, and 0.08 in MCC ($p < 0.05$ for all). Interestingly, under image-level splitting, the AToM model reached an accuracy of 98.6 % and an MCC of 0.987 with highest performance, showing the highest performance.

Conclusions The AToM model demonstrated the highest accuracy and strong generalization across different datasets compared with conventional models. Although overall accuracy decreased under the strict patient-level compared with the image-level split, the AToM model consistently maintained the best performance. These findings suggest that foundation model could be feasibly implemented in real-world clinical setting for capsule endoscopy.

DOI 10.1055/s-0046-1820954

Aims Atrophy extends beyond the cardia is open atrophy and closely related to gastric cancer. However, there is difficulty in determining cardia atrophy under endoscopy.

Methods This is multicenter prospective study, a total of 895 patients were assigned to the training and validation sets to establish a cardia atrophy diagnostic model. 220 patients were included in the internal test set. Additionally, a total of 354 patients were included in the external test set. In the internal and external test sets, 3 senior and 3 junior endoscopists made online diagnoses, comparing the performance differences to the AI-assisted system (▶ **Table 1**).

Results In the internal test dataset, the accuracy, sensitivity, and specificity of the AI-assisted cardia atrophy diagnostic system were 0.927, 0.941, and 0.919, respectively, with a PPV of 0.878, NPV of 0.962, and AUC of 0.967. In the external test dataset, the accuracy, sensitivity, and specificity were 0.918, 0.894, and 0.931 respectively, with a PPV of 0.874, NPV of 0.943, and AUC of 0.953. Furtherly, it was found the diagnosis accuracy, sensitivity, specificity, PPV, and NPV of the AI-assisted system were all higher than those of senior endoscopists. The ROC curve area (AUC) of AI-assisted system was 0.967 and 0.953 in the internal and external test sets, respectively. Heat map showed a high consistency between the AI-system and endoscopists.

Conclusions Our newly developed AI-assisted system shows superior performance in identifying cardia atrophy compared to senior endoscopists, and can be used to guide endoscopic judgment and targeted biopsies for cardia atrophy.

DOI 10.1055/s-0046-1820955

Aims Artificial intelligence (AI) has potential to improve diagnosis and outcome assessment in gastrointestinal (GI) endoscopy. However, robust AI models require large, labeled datasets with full-length, high-resolution endoscopic videos. Many existing endoscopic databases rely on retrospective sampling, isolated images, or lack clinical context, limiting their utility for AI systems development. We therefore aimed to develop an endoscopy video databank coupling full-length recording with capture of structured clinical, procedural, and pathology data.

Methods A prospective video databank was established at the Montreal University Hospital Center (NCT06822616) with enrollment of patients undergoing endoscopic procedures since 2022. Inclusion criteria comprised all screen-

ing, surveillance, diagnostic, or therapeutic upper (EGD) or lower (colonoscopy) endoscopies performed in patients ≥ 18 years old. All patients provided informed consent for data collection and subsequent use in AI system development. The databank follows FAIR principles: Findable, Accessible, Interoperable, and Reusable. Video recordings were de-identified from acquisition, using study identifiers without protected health information, with all technical specifications optimized for AI training (full-length, full-frame videos in 1920x1080-pixel resolution and 60fps, and 10-bit color depth). Trained research staff systematically documented and timestamped detected anatomical landmarks, all identified lesions, including endoscopist optical diagnoses, interventions, disease-specific scores (e.g., Ulcerative colitis: Mayo Endoscopic Subscore, Crohn's disease: SES-CD, Barrett's esophagus: Prague classification), AI system outputs, and endoscopy quality metrics in structured case report forms (CRFs) during the procedure. All data, including patient, procedure, and pathology outcomes, were then documented in a REDCap database and linked to the videos using the unique study identifiers [1–5].

Results As of July 2025, 6,272 patients (mean 59.0 years, 52.1 % female) have been prospectively enrolled for a total of 7,591 endoscopic procedures (5,605 (73.8 %) colonoscopies, 1,986 (26.2 %) EGDs) performed by 48 different endoscopists, with complete video capture and documentation included in the databank. Up to 747 and 455 structured datapoints were documented for each enrolled colonoscopy and EGD, respectively. Each polyp identified and biopsy performed were documented with up to 48 and 46 variables each. Disease-specific datapoints included up to 169 datapoints specifically for patients with inflammatory bowel disease. Prevalence of main cohort procedural indications are summarily presented in ▶ **Table 1**, demonstrating substantial diversity in pathologic findings across inflammatory, neoplastic, and structural disease categories. Pathologic findings (including inflammation, polyps, ulcers, dysplasia, malignancy) of any type were found in 6355 (83.7 %) procedures, of which 6987 colorectal polyps found in 2981 patients and 48 cancers. Data enabled calculation of multiple endoscopic quality metrics: mean adenoma detection rate (ADR) was 38.9 % (CI[37.2-40.7]), sessile serrated lesion detection rate (SSLDR) was 4.5 %[3.8-5.3], advanced adenoma detection rate (AADR) was 9.0 %[8.0-10.1], and mean withdrawal time was 12.1 + /-11.9 minutes for colonoscopies and procedure times 5.1 + /-7.1 minutes for EGDs.

Conclusions This large, prospective, FAIR-compliant video databank of > 7,500 procedures enrolled at our tertiary care center provides a scalable foundation for AI development, validation, and clinical outcomes research for gastrointestinal endoscopy. Ongoing multi-center expansion and integration of digital pathology slides, microbiome and multi-omics analyses will enable future projects combining endoscopic video data with precision medicine approaches.

Conflicts of Interest Daniel von Renteln is supported by a "Fonds de Recherche du Québec Santé" career development award. cians, hospitals and manufacturers. A better understanding of public perception around AI and liability will be critical for clinical adoption and the development of legal frameworks. This study examines how laypersons assign responsibility across stakeholders at different levels of AI automation in endoscopy [1–5].

Methods An online survey was conducted via a dedicated research platform (Prolific). Adults > 18 years old from the USA and Europe were randomly presented with three AI endoscopy harm scenarios representing increasing levels of automation. Participants rated responsibility for four stakeholder groups [doctor, hospital, AI manufacturer and a no-fault compensation scheme] using a 7-point Likert scale. Scenario 1 involved a computer aided quality (CAQ) tool reporting adequate mucosal visualization followed by a missed colorectal cancer (CRC). Scenario 2 involved a computer aided diagnosis (CADx) system misclassifying an adenoma as a hyperplastic polyp, leaving an adenoma in situ, which later progressed to CRC. Scenario 3 described a capsule endoscopy tool with which physicians check only images flagged by the system as abnormal, failing to identify a significant gastrointestinal bleed.

Results 502 respondents completed the survey (USA: 250; Europe: 252). Responsibility scores varied significantly by both AI automation level and stakeholder ($p < 0.001$). Doctors received the highest overall mean responsibility score of any stakeholder (5.15, $p < 0.001$). However, accountability patterns shifted significantly with increasing AI automation. Doctors' mean responsibility declined steadily, reaching 3.32 at the highest automation level ($p < 0.001$). In contrast, hospitals and manufacturers showed the opposite trend. Their mean responsibility scores peaked at the highest automation level, at 5.73 and 5.83, respectively ($p < 0.001$). Ratings for the no-fault compensation scheme remained largely unchanged.

Conclusions This is the first study to examine public perceptions of liability for AI-related harms in endoscopy. Participants perceived that increasing AI automation shifts responsibility away from clinicians and toward hospitals and manufacturers, though clinicians were assigned high responsibility ratings across all scenarios. As automation increases, hospitals and manufacturers should strengthen governance and monitoring to ensure safety and accountability. These findings underscore the need to preserve a clear human-in-the-loop role within AI-supported endoscopy and to establish structured, transparent liability frameworks to guide clinical practice.

PYP017 Diagnostic accuracy of artificial intelligence in endoscopic detection of early esophageal neoplasia: systematic review and meta-analysis

Authors Eldeeb H[1], Bakr A[2], Elaraby A[2], Mohimen A[2], Abdurrahman F[2], Noha B[3]

Institutes **1** nasr city, Cairo, Egypt; **2** Al-Azhar University, Cairo, Egypt; **3** Al-Azhar University, Cairo Egypt

DOI 10.1055/s-0046-1820957

Aims Esophageal neoplasia (EN) remains a significant contributor to cancer-related mortality, primarily due to the difficulty in visualizing and characterizing early-stage lesions during endoscopy. Inter-observer variability in interpretation is substantial, even with enhanced imaging modalities (e.g., NBI, BLI, i-scan). Artificial intelligence (AI) systems, including computer-aided detection (CADe) and diagnosis (CADx), have emerged as potential tools to enhance and standardize diagnostic accuracy. We aimed to synthesize the diagnostic performance of AI-assisted endoscopy for EN, conducting subgroup analyses based on histology (Esophageal Squamous Cell Carcinoma [ESCC] vs. Barrett's Esophagus-Related Neoplasia [BERN]) and comparing accuracy by the unit of analysis (per-patient vs. per-image).

Methods A systematic review and meta-analysis were performed. Study-level 2 × 2 data (True Positives, False Positives, False Negatives, True Negatives) were extracted from eligible studies. Data were pooled using a bivariate random-effects hierarchical summary receiver operating characteristic (HSROC) model (MIDAS, Stata 18). Primary outcome measures were pooled sensitivity, specificity, and the Area Under the Curve (AUC). Secondary metrics included positive and negative likelihood ratios (LR + , LR–) and the Diagnostic Odds Ratio (DOR). Separate meta-analyses were conducted for per-patient data (overall and by histology) and per-image data. Statistical heterogeneity was quantified using the I^2 statistic, and threshold effects were evaluated.

Results Thirteen studies met inclusion criteria for the per-patient analysis (752 reference-positive; 876 reference-negative patients). The pooled sensitivity was 0.91 (95 % CI 0.85–0.94) and specificity was 0.78 (95 % CI 0.63–0.88). The summary AUC was 0.93 (95 % CI 0.90–0.95), with an LR + of 4.1, LR– of 0.12, and DOR of 34. Substantial heterogeneity was observed ($I^2 \approx 97$ %) with no significant threshold effect [1].

In histological subgroup analyses, ESCC (8 studies) yielded a sensitivity of 0.92 (95 % CI 0.85–0.96) and specificity of 0.73 (95 % CI 0.51–0.87) (AUC 0.93). For BERN (5 studies), sensitivity was 0.86 (95 % CI 0.77–0.92) and specificity was 0.85 (95 % CI 0.69–0.93) (AUC 0.91).

The per-image analysis (6 studies; 2,574 positive; 7,089 negative images) demonstrated higher pooled accuracy: sensitivity 0.96 (95 % CI 0.92–0.98), specificity 0.93 (95 % CI 0.85–0.97), and AUC 0.98 (LR + 13.3, LR– 0.04). Heterogeneity remained substantial ($I^2 \approx 93$ %).

Conclusions AI-assisted endoscopy demonstrates high overall diagnostic accuracy for esophageal neoplasia. On a per-patient basis, a metric more relevant to clinical decision-making, AI provides excellent sensitivity with moderate specificity, showing comparable utility across both ESCC and BERN. The outstanding per-image accuracy (AUC 0.98) and high LR + (13.3) suggest strong "rule-in" capability, while the consistently low LR– (0.12 per-patient, 0.04 per-image) indicates a robust "rule-out" potential, implying a reduced risk of missed lesions. Despite significant heterogeneity across studies, these findings support the continued development of AI in endoscopy. Prospective, real-time, multicenter validation studies using standardized workflows are warranted to establish optimal operating thresholds and confirm the generalizability of these systems in routine clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP018 Colon Capsule Endoscopy and Health Inequalities: Early Signals from an Ethnically Diverse Patient Cohort

Authors Baker J[1], Smith A[1], Bhandare A[1]
Institute 1 Royal Oldham Hospital, Oldham, United Kingdom
DOI 10.1055/s-0046-1820958

Aims Colon Capsule Endoscopy (CCE) is a minimally invasive alternative to standard colonoscopy. Although it does not currently provide population-level therapeutic intervention, it is highly sensitive, well tolerated and is associated with low rates of discomfort and complications [1]. In the UK, CCE has now been implemented in routine clinical pathways, which has helped to reduce the demand for conventional colonoscopy [2].

Bowel cancer screening in the UK heavily relies on faecal immunochemical testing (FIT) to identify patients who require endoscopic assessment. In some ethnic groups, a lower than expected uptake has been identified, [3]. Additionally, subsequent colonoscopy uptake has historically been lower in ethnic minority groups [4]; for example, uptake has been reported to be as low as 33 % in the South Asian population in England [5]. Consequently, minority populations are more likely to be diagnosed with advanced colorectal cancer as a result [6] – this is an important public health concern.

We analysed data from one of the UK's largest CCE centres, itself serving an ethnically diverse population, to determine whether CCE could play a role in increasing lower gastrointestinal investigation among ethnic minority groups.

Methods We performed a retrospective analysis of CCE reports between January 2021 and September 2025. Eligible patients included those with a lower risk of colorectal cancer (FIT of < 100) with or without the presence of NG12 symptoms (such as rectal bleeding or a change in bowel habit). Data sources included CCE reports, scanned written patient records and electronic patient records. We recorded demographics (ethnicity, sex and age) in addition to the diagnosis from the study.

Results A total of 473 CCE reports were analysed. Of this cohort, 385 (81 %) patients were White British. 37 (7.8 %) patients were Pakistani, constituting the largest minority population in the cohort. Within this subgroup, 87 % were female, compared to 55 % in the overall cohort. The median age in the Pakistani subgroup was 45 years compared to 57 overall. 6 (16.2 %) of these patients had polyps, 8 (21.6 %) had diverticulae and 8 (21.6 %) had haemorrhoids. Other ethnicities included 7 (1.4 %) Black (African), 4 (0.84 %) Indian and 2 (0.42 %) Caribbean patients.

Conclusions This analysis suggests comparatively higher uptake of CCE amongst some ethnic minority populations that might be expected from historical diagnostic colonoscopy data.

Pakistani people comprise 13.5 % of the total population in the area our centre covers [7]. Local colonoscopy uptake in this group has been reported as 1.4 %; this is significantly lower than the uptake of CCEs in our data. This suggests there is a signal that CCE may play a role in overcoming known barriers to participation among minority populations accessing screening investigations, thereby addressing known disparities in colorectal screening. Qualitative research identifies common barriers including individual beliefs, a reliance on family and friends, health concerns (such as the disproportionate effect of healthcare-acquired infections on minority groups) and a perceived loss of autonomy [8].

Confirmatory, prospective research is required to explore minority communities' preferences for investigative modalities, including CCE, and to determine how CCE might be integrated into colorectal cancer diagnostic pathways.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP019 A Decade of Colon Capsule Endoscopy: Downstream Workload and Follow-up Procedures

Authors Sheehan T[1], Sihag S[1, 2], Leung E[2], McNamara D[1, 2]
Institutes 1 Tallaght University Hospital, Dublin, Ireland; 2 Trinity Academic Gastroenterology Group, Trinity College, Dublin, Ireland
DOI 10.1055/s-0046-1820959

Aims Colon capsule endoscopy (CCE) is a minimally invasive alternative to colonoscopy that offers a patient-friendly method of evaluating the colon. While its diagnostic yield is well established and shown to be comparable to conventional colonoscopy, far less is known about the downstream workload generated by CCE—particularly the need for subsequent colonoscopy, additional imaging, or repeat CCE examinations. Understanding these follow-up requirements is crucial for assessing service efficiency, planning resource allocation, and evaluating cost-effectiveness. As CCE becomes increasingly integrated into colorectal pathways, quantifying the procedural load it generates is essential for informed decision-making. This study aims to characterize the downstream workload associated with our CCE service over the past decade, with a specific focus on the frequency and drivers of follow-up procedures, including colonoscopy, imaging, and repeat CCE [1].

Methods We conducted a retrospective analysis of all colon capsule endoscopy (CCE) studies performed at our centre over the past 10 years. Case lists were generated from the local PillCam database, and patient identifiers were cross-referenced with the hospital Endoscopy database to identify subsequent procedures. Individual CCE reports were reviewed to assess study completeness and to document any downstream investigations, including colonoscopy, radiological imaging, or repeat capsule examinations. The primary outcomes were the frequency and type of follow-up procedures following CCE, with secondary outcomes capturing repeat CCE rates and indications for additional investigations

Results Over the 10-year period, 1,302 CCE examinations were performed. Repeat CCE was recommended in 268 cases (21 %). The annual repeat CCE rate showed substantial variability, ranging from 4.8 % to 26.6 %, with a mean of 17.7 % and a median of 17.9 %, indicating a consistently moderate downstream capsule workload. Surveillance was the predominant indication with 209 procedures (78 %), with a progressive rise over time, increasing more than 30-fold between 2015 (1 case) and 2023 (52 cases). Symptomatic indications account-

ed for 24 cases (10 %) and repeats due to failed or inadequate bowel preparation occurred in 32 cases (11 %). Follow-up endoscopy was recommended in 440 cases (34 %). Annual endoscopic workload ranged from 14.3 % to 41.6 %, with a mean of 29.1 % and median of 28.3 %, demonstrating greater yearly fluctuation than repeat CCE. Peaks in 2019 and 2023 (both 87 cases) reflected high-volume years with increased diagnostic yield or completion requirements. Indications included polypectomy (224; 51 %), completion colonoscopy (95; 21 %), and other therapeutic or diagnostic interventions (102; 23 %). CT colonography was recommended in only four cases (0.3 %), all following failed CCE studies. Across the dataset, a substantial proportion of patients did not require further investigation, 586 cases (45 %).

Conclusions Overall, 45 % of CCE examinations required no further follow-up and a further 21 % were suitable for capsule-based surveillance—patients who historically would have undergone colonoscopy. This represents a potential 66 % reduction in index colonoscopy demand (859 cases). Repeat CCE was required in 21 % of examinations, with an average annual repeat rate of 18 %, a factor that will need to be considered in future service planning should national adoption of CCE expand. Our follow-up endoscopy rate of 34 % (mean annual rate 29 %) compares favourably with the ~42 % pooled rate reported by Lei et al. (2025). These findings indicate that CCE can operate effectively alongside colonoscopy, reducing the overall burden on endoscopy services. Appropriate patient triage will be essential to further minimise downstream workload, consistent with broader use of non-invasive testing pathways such as the Faecal Immunochemical Test (FIT). In the context of a growing population and increasing colonoscopy waiting lists, expanding CCE capacity offers a practical strategy to enhance access and efficiency within colorectal diagnostics. Additionally, by reducing procedure-related resource use, CCE may contribute to lower carbon emissions in endoscopy units and support the goals of Green Endoscopy

PYP020 Artificial Intelligence–Assisted Endoscopy Reduces Adenoma and Polyp Miss Rates: Updated Meta-Analysis of Randomized Clinical Trials

Authors Elaraby A[1], Bakr A[2], Hassanin MS[2]
Institutes 1 Faculty of Medicine, Al-Azhar University, Cairo, Egypt; 2 Al-Azhar University, Cairo, Egypt
DOI 10.1055/s-0046-1820960

Aims Artificial intelligence (AI) is increasingly used in GI endoscopy to enhance polyp and adenoma detection. We measured the AI enhanced endoscopy on adenoma miss rate (AMR), polyp miss rate (PMR) and sessile serrated lesion miss rate (SSL-MR).

Methods We searched PubMed and Embase databases to July 2025 for RCTs comparing AI-assisted with standard Endoscopy. Pooled risk ratios (RR) were calculated with random effects.

Results Twelve trials showed significantly AI endoscopy lowered AMR by 39 % (RR 0.61, 95 % CI 0.5-0.75) and PMR by 36 % (RR 0.64, 95 % CI 0.44-0.91). SSL-MR fell but was not significant (RR 0.58, 95 % CI 0.29-1.16).

Conclusions Our meta-analysis showed that AI-assisted endoscopy results in a significant reduction in missed adenomas and polyps. A similar reduction was also observed for missed sessile serrated lesions but did not reach significance. These results point to the potential of AI enhancement to improve the accuracy of endoscopic surveillance by catching more lesions on the first pass. Widespread use of AI in endoscopy could make fewer missed lesions and reduce the incidence of interval neoplasms [1–5].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP021V Severe Early Bleeding after EUS-Guided Gastroenterostomy (EUS-GE): Over-the-Wire LAMS Exchange for SEMS

Authors Marquina V[1], Cobreros del Caz M[1], Sánchez-Ocaña R[1], López Torres L[1], Marcos-Carrasco N[1], Isabel RN[1], Sanjose A[1], De Benito Sanz M[1], De La Serna Higuera C[1], Perez-Miranda M[1]
Institute 1 Rio Hortega University Hospital, Valladolid, Spain
DOI 10.1055/s-0046-1820961

Problem to solve Post-LAMS bleeding caused by distal flange pressure over jejunal mucosa is uncommon but severe. Management strategies for LAMS-induced pressure bleeding typically include exchanging the LAMS for double-pigtail stents; however, this is not feasible in immature gastrointestinal anastomoses due to the risk of leakage.

Innovation We describe a novel approach for managing early post-EUS-GE bleeding: exchanging the LAMS using a dual-channel endoscope to ensure safe hemostasis.

Results A patient with advanced pancreatic adenocarcinoma undergoing chemotherapy presented with symptomatic duodenal stenosis after 4 years. An EUS-GE was performed using a 20x10mm Axios stent. Twenty-four hours later, the patient developed hemodynamically unstable upper GI bleeding. Urgent gastroscopy revealed active jejunal bleeding caused by distal flange pressure ulceration. To minimize the risk of anastomotic dehiscence during LAMS removal, jejunal access was first secured with a guidewire through the second channel of a dual-channel endoscope. The LAMS was then retracted from the anastomosis into the stomach, allowing for complete sclerotherapy. Jejunal inspection confirmed hemostasis. A covered enteral stent (Hanaro DPC 20-90mm) was deployed between the stomach and jejunum over the guidewire to seal both perforations. The patient showed no signs of rebleeding or peritonitis, resumed oral intake, and was discharged within 48 hours.

Conclusions Withdrawing a LAMS over a guidewire in EUS-GE facilitates endoscopic hemostasis in cases of severe early bleeding, allowing for exchange to a covered SEMS. The covered stent prevents rebleeding by eliminating persistent flange pressure while maintaining a functional anastomosis. Although a dual-channel endoscope facilitates this maneuver, it could also be performed using a therapeutic gastroscope with grasping forceps inserted parallel to the guidewire.

DOI 10.1055/s-0046-1820962

Abstract Text A 25 year-old woman presented with vomiting. CT showed gastric dilatation and "windsock sign" typical of of duodenal web. She underwent surgical duodenojejunostomy, but this failed because of oedematous substenosis of duodenojejunal surgical anastomosis. EUS-Gastroenterostomy was proposed as temporary alternative during surgical anastomosis healing. Duodenal web was cannulated with a guidewire to regain access to the Treitz region bypassed by the surgery. Then an orojejunal tube was placed over the ligament of Treitz following a standard Wireless Simplified EUS-Gastroenterostomy technique (WEST). A 20mm Lumen Apposing Metal Stent (LAMS) was placed freehand. The patient tolerated oral liquids and solid food on postoperative day 1 and 2. Six months later, X-Ray contrast study and endoscopy confirmed patency of the surgical anastomosis and the LAMS was removed.

DOI 10.1055/s-0046-1820963

Aims Endoscopic ultrasound-guided gastroenterostomy (EUS-GE) is a minimally invasive alternative to surgery and endoscopic stenting for malignant and benign gastric outlet obstruction (GOO). Fluoroscopy is traditionally used to insert an oro/naso-enteral catheter to ensure bowel distension and facilitate recognition of the target loop and final stent placement. Cautery-enhanced lumen-apposing metal stents (EC-LAMS) enable a fluorless direct freehand technique, but clinical data on its reproducibility remain limited. We assessed the technical feasibility of fluorless direct freehand EUS-GE and described its safety and clinical outcomes in patients with malignant and benign GOO.

Methods Retrospective consecutive cohort of adults with symptomatic malignant or benign GOO who underwent an attempted fluorless EUS-GE at a tertiary interventional endoscopy centre (January 2020–October 2025). Eligibility was MDT-defined. Exclusions: planned fluoroscopy, hybrid/non-standard approaches (wire-guided/double-balloon), or incomplete data precluding outcomes assessment. All procedures were performed under deep sedation or general anaesthesia. A diagnostic forward-viewing gastroscope was first advanced to the stricture to assess traversability and identify a safe window—either passage beyond the stenosis or a pinpoint orifice suitable for tip apposition. In case of complete or near-complete obstruction, the procedure was performed under fluoroscopic guidance to ensure adequate target distension and mitigate misdeployment risk. When a fluorless approach was feasible, butylbromide 20 mg IV was administered, and the distal jejunal loop was distended by hand-instilling saline–methylene blue (plus a small amount of iodinated contrast to increase fluid density) with 50–60 mL syringes, directly via the gastroscope channel; no infusion pump was used. The gastroscope was then exchanged for a therapeutic linear echoendoscope positioned in the stomach, and an EC-LAMS (Hot-Axios, Boston Scientific, USA; 15 × 10 or 20 × 10 mm) was deployed freehand under real-time EUS guidance (a second butylbromide 20 mg dose could be given immediately before deployment). Gastrojejunostomy creation was confirmed by reflux of blue-stained fluid through the LAMS into the stomach.

Primary outcome was feasibility, defined as completion of EUS-GE entirely without fluoroscopy, with technical success achieved. Secondary outcomes were: technical success (creation of a functional gastroenteric anastomosis with correct LAMS deployment, no same-session surgical/percutaneous rescue); clinical success (symptom improvement with a GOOSS increase ≥ 1 within 72 h); and early safety, reported as intra-procedural adverse events (AEs) and early post-procedural AEs ≤ 7 days (AGREE-graded). Analyses were descriptive and included all consecutive planned fluoroscopy-free attempts.

Results Thirty-six consecutive patients underwent an attempted fluoroscopy-free EUS-GE. Median age 70.5 years; ASA II/III/IV 7/25/4; median Charlson Comorbidity Index 7. Etiology was malignant in 30/36 (83.3 %) and benign in 6/36 (16.7 %). The obstruction more often involved the second duodenal portion (22/36, 61.1 %) than the pylorus/bulb (14/36, 38.9 %). One patient had a prior unsuccessful duodenal stent. In two patients, the fluorless strategy could not be completed (one conversion to fluoroscopy-assisted EUS-GE without anastomosis completion; one aborted). Feasibility (primary) and technical success were both 94.4 % (34/36), with a mean procedural time of 15 minutes. Clinical success was 88.9 % (32/36), with rapid recovery—liquids at 24 hours and a median hospital stay of 4 days. Intraprocedural AEs occurred in 4/36 (11.1 %), all AGREE IIIA, managed endoscopically (clip closure and, when required, LAMS retrieval/redeployment). Early AEs ≤ 7 days were 2/36 (5.6 %): one minor bleeding (AGREE II) treated conservatively and one fatal misdeployment (AGREE V). Overall, early safety endpoint (intraprocedural or ≤ 7-day AE) was 16.7 % (6/36).

Conclusions Fluorless direct freehand EUS-GE showed high feasibility and strong technical and clinical performance in a consecutive cohort. Intraprocedural and early adverse events were not uncommon, yet most were low–to–moderate in severity and readily controlled endoscopically. These findings support the adoption of a radiation-free workflow in experienced centres and motivate prospective studies to validate reproducibility.

Aims Endoscopic ultrasound–guided gastroenterostomy (EUS-GE) is effective for palliation of malignant gastric outlet obstruction (mGOO). Though costlier and invasive, it offers a chance at better quality of life. We aim to define predictors of poor survival following EUS GE.

Methods Thirty-two consecutive patients undergoing EUS-GE for mGOO at the National University Health System (Singapore) over two years were analysed. Uni- and multivariate analyses evaluated factors associated with 30-day mortality.

Results Technical and clinical success was 90.6 %. GOO scores improved from 0.25 ± 0.51 to 2.72 ± 0.52, with time to soft diet taking 2.42 ± 1.82 days. BMI < 20 predicted 30-day mortality (p = 0.03). ECOG 4 was strongly associated with 30-day mortality (OR 27.0, 95 % CI 1.26–578; p = 0.035) (▶ **Table 1**). Multi-visceral metastases, ascites, and pre-procedure drainage were not predictive. Patients with ECOG 3–4 and BMI < 20 showed less improvement in GOO scores at discharge(2.14 vs 2.88; p = 0.015), higher 30-day mortality risk (OR 7.0; p = 0.038), and shorter median survival (30 ± 6 vs 79 ± 35 days; log rank p = 0.033) (Figure 1).

Conclusions Disease burden does not affect short term survival after EUS-GE. Patients with ECOG 3–4 and BMI < 20 experienced limited symptomatic improvement and high early mortality, suggesting EUS-GE may offer limited benefit in this subgroup.

PYP025 Comparable outcomes after endoscopic ultrasound-guided gastroenterostomy in patients with versus without intra-abdominal carcinomatosis: a single centre study

Authors Neri B[1], Dario B[1], Melatti P[1], Marinaccio C, Stigliano S[1], Andrisani G[1], Citterio N[1], Pettinelli M[1], Parisi G[1], Rea R, Martino M[1], Pandolfi M[1], Di Matteo FM[1]

Institute 1 Campus biomedico University Hospital, Rome, Italy

DOI 10.1055/s-0046-1820965

Aims EUS-guided gastroenterostomy (EUS-GE) with lumen-apposing metal stent (LAMS) has emerged as a mini-invasive, effective and safe alternative to surgical gastrojejunostomy and endoluminal stenting to treat malignant gastric outlet obstruction (MGOO). Currently, intra-abdominal carcinomatosis represents a relative contraindication to this procedure, due to a possible higher risk of clinical failure. The primary aim was to compare clinical success of EUS-GE in patients with MGOO with vs without concomitant intra-abdominal carcinomatosis. Secondary aims were to compare in the same subgroups of patients the clinical and procedural characteristics, the technical success rate and the long-term outcomes [1–3].

Methods All patients undergoing EUS-GE for MGOO at our institution from June 2018 to December 2024 were retrospectively enrolled. Technical success was defined as successfully establishing EUS-GE and clinical success as low-residue diet tolerance without re-intervention for 14 days after the procedure. Inclusion criteria were: 1) age > 18 years; 2) MGOO; 3) complete clinical records. Exclusion criteria was missing data. Intra-abdominal carcinomatosis was defined according either to CT and MRI imaging. Adverse events (AEs) recorded and classified (AGREE). Obstructive symptoms graded according to the GOOSS score. Data expressed as median [range]. The Student-t-test, Mann-Whitney-u test and X2 test used as appropriate.

Results EUS-GE for MGOO was performed in 74 patients (36 [48.6 %] males, age 71 [30-92]), with ECOG performance status ³2 in 29 (39.2 %) and obstructive symptoms reported by 72 (97.3 %), with a median GOOSS of 1 [0-3]. Malignancy stage was II in 6 (8 %) patients, III in 4 (5 %) and IV in 64 (87 %). Intra-abdominal carcinomatosis was present in 29 (39.2 %) patients. Ascites was significantly more frequent in patients with vs without carcinomatosis (19 [65.5 %] vs 12 [26.7 %], p = 0.02). Other clinical characteristics were comparable between groups.

All EUS-GE were performed in deep sedation. LAMS size 20mm was used in a comparable proportion of patients with vs without carcinomatosis (25 [86.2 %] vs 37 [83.2 %], p = 0.89). Technical success rates and procedural time did not differ between groups (28 [96.6 %] vs 43 [95.6 %], p = 0.69; vs 33 [16-85] vs 40 [20-106], p = 0.52). Overall, 9 misdeployments were observed (carcinomatosis: 3 [10.3 %] vs no-carcinomatosis: 6 [13.3 %], p = 0.98). AEs were 4 (19.8 %) and

9 (20 %) in patients with vs without carcinomatosis (p = 0.71), all grade III. Time to refeeding was comparable between groups (1 [1-5] vs 1 [1-5], p = 0.96), while post-procedural hospital stay was longer in patients with carcinomatosis (8 [2-18] vs 4 [2-15], p = 0.0009). Clinical success rate did not differ in patients with vs without carcinomatosis (25 [86.2 %] vs 43 [95.6 %], p = 0.31). All 6 failures were due to malignancy progression. Median follow-up duration was 51 [21-622] days. During follow-up, 27 (93.1 %) patients with and 38 (84.4 %) without carcinomatosis died (p = 0.45). Median survival (days) and oral feeding toleration until last follow-up/death were comparable between patients with vs without carcinomatosis (42 [21-398] vs 66 [26-622], p = 0.07 and 26 [89.6 %] vs 42 [93.3 %], p = 0.89). Overall, oncological treatments were resumed in 11 (37.9 %) patients with and 23 (51.1 %) without carcinomatosis (p = 0.38) Re-hospitalization for any cause were observed in a comparable proportion of patients with vs without carcinosis (14 [48.3 %] vs 26 [57.7 %], p = 0.57), requiring reintervention in 1 case.

Conclusions In our study population the high technical and clinical success rates of EUS-GE were comparable in patients with and without intra-abdominal carcinomatosis. The major outcomes were comparable between these 2 subgroups of patients, thus suggesting the long-term efficacy of this procedure also in patients with more advanced malignancy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP026 Procedure-related details and long-term outcomes of EUS-guided gastroenterostomy- a single center experience

Authors Karagyozov P[1], Kavrakov D[1]

Institute 1 Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofia, Bulgaria

DOI 10.1055/s-0046-1820966

Aims Endoscopic ultrasound-guided gastroenterostomy (EUS-GE) has recently emerged as the standard of care for gastric outlet obstruction (GOO), owing to its high short-term clinical success and favorable safety profile. Nevertheless, long-term outcome data remain limited. The aim of this study is to evaluate the factors associated with the EUS-GE outcomes and to assess the durability of clinical success during long-term follow-up.

Methods All consecutive patients undergoing EUS-GE to treat GOO at a single center between May 2022 and October 2025 were enrolled in this retrospective study. Data on patient demographics, procedure-related details, type of lumen apposing metal stent (LAMS) used and follow-up results were collected. Primary outcomes included technical success, clinical success, and adverse events (AEs). The secondary outcome was the assessment of clinical success during mid-term (6 months) and long-term (12 months or more) follow-up.

Results Fifty-two patients who underwent EUS-GE (mean age 62.65 [SD 13.71], male 51.9 %, malignant indication 86,5 %) were included. Median follow-up duration was 100.5 days (IQR 60-221). Technical success, defined as successful LAMS deployment, was 96,2 %. Clinical success, defined as Gastric Outlet Obstruction Scoring System (GOOSS) ≥ 2 at 7 days was 94 %. Intraprocedural AEs – stent misdeployment (SM) were observed in 10 % of patients with no association between LAMS type (15/10mm or 20/10mm Hot Axios Boston Scientific, USA/ 16/20mm Hot Spaxus Taewoong Medical, Seoul, Sauth Korea, p = 0.331), peritoneal carcinomatosis (p = 0.154), ascites (p = 0.400), shape of target loop (longitudinal/oval, p = 1.000) and serum albumin level (SM group 33g/L [IQR 15]/without SM group 35g/l [IQR 11], p = 0.737). All SMs were managed by NOTES approach. The rate of short-term AEs was 10 %, associated only with etiology (p = 0.036). Long-term AEs, mostly procedure-related due to stent migration and ingrowth, occurred in 18 % of cases without association with previous surgery (p = 0.214), site of obstruction (p = 0.293), diameter, length, and type of LAMS (p = 1.000). At the 6-month follow-up, among alive patients /N = 24/, 12.5 % had a GOOSS = 2 and 87.5 % had GOOSS = 3, without recurrence of symptoms. During the long-term follow-up at 12 months, symptom recurrence was observed in one patient with Diffuse Large B-Cell Gastric Lymphoma. Endoscopy found complete obliteration of the pylorus and stent ingrowth, successfully managed with the stent-in-stent technique. Thus, a final-12-month GOOSS of 2 and 3 was observed in 28.6 % and 71.4 % of patients, respectively.

Conclusions To our knowledge, this study is one of the first to assess the performance of different types of LAMS in the context of EUS-GE, demonstrating comparable outcomes across stent types and showing that neither target intestinal loop shape nor serum albumin levels, in contrast to the surgical approach, significantly influenced procedural or long-term results. Our findings suggest that mid and long-term outcomes of EUS-GE are primarily determined by disease etiology, emphasizing the importance of appropriate patient selection.

PYP027 Endoscopic Ultrasound-Guided Gastroenterostomy – the first two years experience with follow-up from the tertiary center in Poland

Authors Białek D[1], Gaweł K[1], Teresińka-Tukiendorf G[1], Jozwa M[1], Białek A[1]

Institute 1 Department of Gastroenterology, Pomeranian Medical University, Szczecin, Poland

DOI 10.1055/s-0046-1820967

Aims Endoscopic ultrasound-guided gastroenterostomy (EUS-GE) is a minimally invasive alternative to surgery for patients with high gastrointestinal obstruction, most commonly resulting from malignant gastric outlet obstruction (GOO) [1]. Despite increasing adoption, high-quality real-world clinical data remain limited. The aim of this study was to assess the safety, technical success, and early clinical outcomes—including improvements in oral intake—among patients undergoing EUS-GE during the first two years of implementing this procedure at a tetiary center.

Methods We performed a retrospective analysis of prospectively collected database of adult patients who underwent EUS-GE at a single tetiary center from December 2023 to November 2025. Baseline demographic characteristics, underlying disease and clinical indications were collected at admission. Procedural parameters included technical success, peri-procedural course and adverse events (AEs). AEs were classified and described according to the American Society for Gastrointestinal Endoscopy (ASGE) lexicon [2], based on severity and clinical impact. Follow-up evaluation included assessment of dietary progression, symptom relief and need for reintervention within the first 1–3 months after the procedure.

Results A total of 21 patients (11 male, 10 female; median age 67 years, range 41 – 86) were included. The majority (16/ 21, 76 %) presented with malignant gastric outlet obstruction secondary to locally advanced pancreatic cancer, duodenal infiltration, or pyloric involvement. The remaining 5 patients (24 %) underwent EUS-GE for nonmalignant indications, including chronic groove pancreatitis (1 case) or choledocholithiasis in patients after gastrectomy or surgical hepaticojejunostomy: endoscopic ultrasound-directed transgastric ERCP (EDGE) stage I – 2 cases and endoscopic ultrasound-directed transenteric ERCP (EDEE) stage I – 2 cases. The median procedure duration was 38 minutes (range 26 – 71), with no significant reduction in procedure time observed over

Endoscopy 2026; 58: S1–S1041

the study period. Lumen-apposing metal stents (LAMS) were used in all procedures: 16 × 30 mm stents in 2 cases (9,5 %) and 20 × 10 mm in 19 cases (90,5 %). Technical success was achieved in 20/21(95 %) procedures. One case (5 %) of failed bowel loop puncture occurred, followed by laparotomy 10 days later due to untreated gastric outlet obstruction. The only perforation which occurred after an initially successful EUS-GE, was noted during the first year of performing the procedure and was successfully treated surgically.

Within 8 days after the procedure, two patients (9,5 %) died due to progression of advanced malignant disease, not as a procedure-related adverse event. 1 patient (5 %) was lost to follow-up.

Remarkably, all patients undergoing EUS-GE for malignant GOO demonstrated a rapid improvement in oral intake, progressing from pre-procedural intolerance of liquids or solids to the ability to tolerate a soft or full oral diet shortly after the intervention. During the 1-month follow-up, no reinterventions or stent-related complications were observed. Throughout the entire follow-up period (median 35 days, range 7-90 days), one case of ulceration at the stent site (1.5 months post-procedure) and one case of recurrent obstructive symptoms (> 30 days post-procedure) were documented.

Conclusions The single center retrospective analysis of prospectively collected patient database demonstrates that EUS-GE provides high technical and clinical success rate and a quite favorable safety profile even early in the learning curve. The procedure resulted in rapid and meaningful clinical improvement, reflected by restoration of oral intake and relief of obstructive symptoms. In patients with malignant gastric outlet obstruction—who typically have limited therapeutic options and poor performance status—EUS-GE appears to be an effective, reproducible and minimally invasive alternative to surgical gastroenterostomy. These results strongly support broader adoption of EUS-GE as a frontline therapeutic strategy in appropriately selected patients.

DOI 10.1055/s-0046-1820968

Aims Subepithelial lesions (SELs) are commonly identified during esophagogastroduodenoscopy. Nevertheless, their diagnostic approach is complex, and patient management is dependent of appropriate anatomopathological diagnosis. In this context, endoscopic ultrasound (EUS) offers the possibility of both lesion characterization and sampling, being a first line procedure in patients with suspected upper gastrointestinal tract SELs over 10 millimeters. However, EUS is operator dependent and has a suboptimal diagnostic accuracy. This multicentric study aimed to developed a deep learning model for detection of upper gastrointestinal tract SEL, with distinction between leiomyoma and gastrointestinal stromal tumors (GIST).

Methods An artificial intelligence model based on a convolutional neural network (YOLO) was developed. This architecture included both detection and characterization modules, in which lesions were delimitated with bounding boxes and classified as GIST or leiomyoma. The model performance of the detection module was assessed through the mean average precision at an intersection-over-unity threshold of 50 % (mAP50), while the classification module was evaluated through its sensitivity, precision, accuracy, and area under precision-recall curve (AUPRC).

Results A convolutional neural netwrok was developed using a total of 67,452 images from 91 EUS procedures performed across 12 centers in 6 countries (Portugal, Spain, United Kingdom, United States of America, Brazil and Argentina). Pleomorphic SEL were identified with a mAP50 of 98.6 %. The AI system had an overall sensitivity of 98.4 %, precision of 98.3 % and accuracy of 98.5 %. The model had an AUPRC of 0.996 for GIST and 0.977 for leiomyoma.

Conclusions This study represents one of the first multicentric efforts to detect and differentiate the most frequent subepithelial lesions on EUS with a single interoperable AI system. Leveraging data from five distinct EUS processors strengthens technical robustness, while integrating cases from six countries across three continents reduces demographic bias and supports global applicability. This AI model has the potential to redefine the evaluation of subepithelial lesions by improving diagnostic discrimination and supporting more targeted EUS-guided tissue sampling, ultimately elevating clinical confidence and decision making.

DOI 10.1055/s-0046-1820969

Aims To assess feasibility and safety of integrating endoscopic ultrasound (EUS)-guided direct portal venous pressure (PVP) measurement into a one-stop endoscopy and to report endoscopy-relevant diagnostic performance. We prospectively compared PVP with the endoscopic portal pressure gradient (PPG = PVP – hepatic/inferior vena cava [IVC]) for two prespecified endpoints: oesophageal varices and clinically significant portal hypertension.

Methods Prospective single-centre outpatient cohort (15 Mar 2024–15 May 2025). A standardized protocol used conscious sedation with midazolam and fentanyl, left-lateral decubitus, spontaneous breathing, and zeroing at the mid-axillary line. At least three acceptable end-expiratory plateaus were acquired in the portal vein and in a hepatic vein/retrohepatic IVC; technical success required ≥ 3 accepted measurements per site to compute PPG. Adverse events (AEs) were prospectively attributed to the pressure-measurement step

vs EUS-guided liver biopsy (EUS-LB) and graded by AGREE classification. Clinically significant portal hypertension (CSPH) was defined a priori as a composite of ≥ 3 portal-hypertension signs (unweighted sum) from a literature-adapted list. Primary analyses estimated ROC/AUCs with paired DeLong tests; .632-bootstrap internal validation and decision-curve analysis quantified robustness and net benefit.

Results Fifty-two patients were analysed (63.5 % male; median age 56.5 years). Technical success was 52/52 (100 %); median EUS time 35 min [IQR 29–39]. EUS-LB was performed in 31/52 (59.6 %). AEs occurred in 5/52 (9.6 %): one Grade I epistaxis at insertion and four Grade IIIa post-biopsy bleeds (three clipped; one managed by interventional radiology); 4/5 (80 %) were attributable to EUS-LB; none to the pressure-measurement step. For varices, AUCs were 0.981 for PVP vs 0.857 for PPG (paired DeLong p = 0.031); Youden cut-offs respectively 23.5 and 8.5 mmHg. For CSPH (composite ≥ 3 signs), AUCs were 0.840 (PVP) vs 0.671 (PPG) (p = 0.0049); cut-offs 27.5 and 10.5 mmHg. Internal .632-bootstrap and decision-curve analyses supported robustness and net benefit, consistently higher for PVP.

Conclusions EUS-guided direct portal pressure can be embedded in a one-stop endoscopy with 100 % technical success and a favourable safety profile, with events almost exclusively related to liver biopsy rather than the haemodynamic step. Absolute PVP provided stronger discrimination than PPG for both varices and CSPH, supporting its pragmatic value to anchor intra-procedural decisions and triage. These findings warrant multicentre confirmation under harmonized protocols (sedation, breathing mode, zero-leveling, replicate rules) and an evaluation of implementation pathways alongside traditional routes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP030V EUS-guided radiofrequency ablation for a left adrenal gland pheochromocytoma: A 'good shot' to prevent adrenal insufficiency in a patient with NF-1 and prior right adrenalectomy

Abstract Text

EUS-guided radiofrequency ablation (EUS-RFA) can be used for any lesion near the gut, such as left adrenal gland (LAG) is. Its goals are organ preservation and surgery complications avoiding.

We present the case of a 57 years-old male with neurofibromatosis type 1, prior right adrenalectomy and a metachronous 12x10mm LAG pheochromocytoma successfully treated by EUS-RFA. Following proper premedication, the procedure was done under general anesthesia and ablation was carried out with four 10-second/60W shots of EUSRA 19G device.

Patient suffered a catecolaminergic crisis after the second ablation shot (SBP:260 mmHg/ HR:120 bpm) successfully controled, with no other immediate or delayed complications. At one year follow-up catecolamine levels remain normal and no lesion can be seen in LAG on CT-scan.

Aims Detective flow imaging (DFI) is an emerging endoscopic ultrasound (EUS) modality capable of visualizing low-velocity microvascular flow without contrast agents [1]. While qualitative assessment of pancreatic vascularity has been explored [1–4], quantitative metrics such as the number of vessels are insufficient. Automated vessel-detection using computer-assisted detection (CADe) software may allow objective measurement of microvascular density, potentially distinguishing healthy pancreas from inflammatory or neoplastic pathology. We aim to evaluate the diagnostic accuracy of a CADe developed for quantification of fine vessels within the pancreas during real-time EUS.

Methods A prospective study including consecutive adult patients undergoing EUS was performed between June 2024 and October 2025. The pancreas was assessed using DFI. Real-time CADe software analyzed live DFI images, detecting and counting fine vessels. Average fine vessel count (AVC) was defined as the mean vessel count detected by the CADe during the procedure. Ten external physicians, divided into senior (40 %) and fellow (60 %) endoscopists, evaluated 11 randomly selected EUS-DFI videos to provide vessel counts and categorical interpretation. Intra-class correlation (ICC) and interobserver agreement (IOA) for interpretation were calculated.

Results Sixty-five participants were included (Inflammatory: 35; Neoplastic: 17; Healthy: 13). Mean age was 53.5 ± 15.0, 66.2 ± 15.9 and 42.2 ± 16.1 ($p < .05$), and 58.5 % were female ($p = .281$). There were no differences between abdominal pain, and nausea/vomiting among groups ($p > .05$), jaundice was more common in the neoplastic lesions ($p = .03$) (Table 1).

CADe provided a median AVC of 13.0 (10-17) for inflammatory conditions, 8.0 (7.0-16.0) for neoplastic, and 4.0 (3.0-6.0) for healthy pancreas ($p < 0.05$) (Figure 1). The maximum fine vessel count (MVC) was 36.0 (28.0-48.0) for inflammatory conditions, 33.0 (21-36) for neoplastic, and 14.0 (11-23) for healthy pancreas ($p < 0.05$). Sensitivity, specificity, positive and negative predictive values, and observed agreement for distinguishing between pathological from healthy pancreas were 90 %, 92 %, 98 %, 71 %, and 91 %, respectively. Visual assessment showed poor ICC in both senior (-0.2, $p = .965$) and fellow (-0.09, $p = .905$), whereas categorical interpretation achieved substantial agreement (senior: $k = 0.624$, $p < 0.05$; fellows: 0.653, $p < 0.05$).

Conclusions CADe-based vessel detection provides reliable, objective quantification of fine pancreatic vessels during real-time EUS, demonstrating high diagnostic accuracy for differentiating pathological from healthy pancreas. Inflammatory lesions exhibited higher AVC than neoplastic lesions, which had

Endoscopy 2026; 58: S1–S1041

values closer to healthy tissue, suggesting reduced microvascularity in pancreatic neoplastic lesions. Visual assessment showed poor reproducibility for vessel counts but substantial agreement for categorical interpretation.

PYP032 New advance imaging techniques associated to endoscopic ultrasound in the differencial diagnosis of solid pancreatic tumors

Authors Dominguez-Novoa Y[1], Abdulkader-Nallib I[1], Lariño Noia J[1], Lazare-Iglesias H[1], Dominguez-Munoz JE[1], Iglesias-Garcia J[1]

Institute 1 University Hospital of Santiago. Foundation Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain

DOI 10.1055/s-0046-1820972

Aims Aim of our study was to evaluate the accuracy of Endoscopic Ultrasound Advance Imaging (strain elastography (SE), contrast enhancement (CE) and detective flow imaging (DFI)) for the differential diagnosis of solid pancreatic tumors (SPT), either alone or in combination.

Methods Patients that underwent EUS-guided advance imaging for SPT between 2023 and 2025 were identified from a prospective EUS registry. EUS was performed with linear FujiFilm echoendoscopes and Hitachi-Arietta system. For EUS-SE, qualitative patterns were described and strain ratio (SR) and strain histogram (SH) were evaluated. For EUS-CE (with Sonovue) and DFI, tumors were classified as iso, hypo or hypervascular. Diagnostic accuracy was analyzed using as gold standard the cyto-histological analysis of the surgical specimen and/or EUS-guided sampling, or the clinical/radiological evaluation with a minimum of 6 months of follow-up. Data are presented as mean ± standard deviation or median and range for quantitative variables and as percentages for categorical variables, correlation was analyzed using linear regression and Spearman test. STARD criteria for studies was followed

Results 217 patients were included (median age 68.2 years + /-11.0 years, 115 males). Median size of SPT was 25.2 + /-15.9mm. 131 presented a malignant tumor (60.4 %) (116 adenocarcinomas; 7 NETs-G2-3; 8 other etiology), whereas 86 presented a benign lesion (39.6 %) (66 NETs-G1; 13 inflammatory masses, 2 lipomas and 5 accessory spleen). Sensitivity, specificity, and overall accuracy of SE (SR and SR) for diagnosing malignancy was 97.7 %, 91.9 %, and 94.5 %, respectively (ROC-curve = 0.936). With CE and DFI, the values were 92.4 %, 96.5 %, 94.0 % (ROC-curve = 0.944), and 93.9 %, 95.4 %, 94.5 % (ROC-curve = 0.946), respectively. Correlation between EUS-CE and DFI was 0.946. Combining SE with DFI ± CE yielded a ROC-curve = 0.956.

Conclusions EUS-guided advanced imaging represents a very useful tool for the differential diagnosis and detection of malignancy in SPT.

DOI 10.1055/s-0046-1820973

Aims Contrast-enhanced endoscopic ultrasound (CE-EUS) provides high-resolution assessment of hepatic microvascularity but requires contrast agents and remains largely qualitative [1, 2]. Detective flow imaging (DFI) is a novel EUS modality capable of visualizing low-velocity microvascular flow without contrast [3]; however, its application in liver evaluation is limited. We aimed to evaluate a real-time AI-based vessel-detection algorithm for objective quantification of microvascular density to distinguish between healthy and pathological liver tissue.

Methods A prospective study including consecutive adult patients undergoing EUS was performed between June 2024 and October 2025. The liver was assessed using DFI. Real-time CADe software analyzed live DFI images, detecting and counting fine vessels. Average fine vessel count (AVC) was defined as the mean vessel count detected by the CADe during the procedure. Ten external physicians, divided into senior (40 %) and fellow (60 %) endoscopists, evaluated 10 randomly selected EUS-DFI videos to provide vessel counts and categorical interpretation. Intra-class correlation (ICC) and interobserver agreement (IOA) were calculated.

Results Sixty participants were included (Pathological: 48; Healthy: 12). Mean age was 59.7 ± 13.6 and 52.0 ± 16.0 ($p > .05$), and 58.3 % were female ($p = .512$). The most common pathology was alcoholic liver disease, and 68.8 % of cases had mild liver disease (Child-Pugh A) (Table 1). CADe provided an AVC of 13.6 ± 5.6 in pathologic and 6.2 ± 7.2 for healthy liver ($p < 0.05$). The maximum fine vessel count (MVC) for pathological liver was 49.0 ± 13.3 and 25.1 ± 16.8 for healthy liver ($p < .05$). Sensitivity, specificity, positive and negative predictive values, and observed agreement for distinguishing between pathological from healthy liver were 94 %, 83 %, 96 %, 77 %, and 92 %, respectively.

Visual assessment showed poor ICC in both senior (-0.02, $p = .545$) and fellow (-0.01, $p = .513$). Additionally, categorical interpretation (healthy or pathological liver) achieved poor agreement (senior: $k = 0.05$, $p = .697$; fellows: -0.01, $p = .846$).

Conclusions AI-assisted DFI enables objective quantification of hepatic microvascularity and distinguishes pathological from healthy liver tissue. The AI-derived average vessel count demonstrated strong diagnostic performance. Human evaluation, regardless of expertise level, showed poor interobserver agreement and minimal reliability. Real-time AI-enhanced DFI vessel count is a quantitative alternative for liver microvascular assessment, with potential applicability when contrast agents are unavailable or contraindicated. Further validation against CE-EUS across broader liver disease severities are needed.

DOI 10.1055/s-0046-1820974

Aims Macroscopic on-site evaluation (MOSE) has gained interest as a practical tool for assessing tissue adequacy during endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB). Recently, a new Franseen FNB needle was developed for EUS-TA, the SonoTip TopGain from Medi-Globe. This study aimed to assess the diagnostic performance and safety of MOSE-guided EUS-FNB using the SonoTip TopGain FNB needle across high-volume international centers.

Methods This retrospective, multicenter study included 95 patients from nine international referral centers who underwent EUS-FNB with MOSE between May 2024 and January 2025. Inclusion criteria comprised adults (>18 years) with predominantly solid lesions undergoing EUS-FNB using the SonoTip TopGain FNB needle (22G or 25G) and without concurrent ROSE. Data on demographics, lesion characteristics, procedural details, and final histopathologic outcomes were collected. Biopsy adequacy was determined by endosonographers based on the presence of visible cores on macroscopic inspection [1–20].

Results The mean patient age was 65.2 ± 12.0 years, with 53 males (55.8 %). Most lesions were pancreatic (67.4 %), with a mean size of 31.5 ± 16.9 mm. The slow-pull technique was predominantly used, with 92 procedures (96.8 %) employing a 22G needle. MOSE identified visible cores in 92 cases (96.8 %). Of the 95 specimens, 6 (6.3 %) were inconclusive. Cytology confirmed all 75 malignant cases (100 %) and 14 of 20 benign cases (70 %). Diagnostic performance for MOSE-positive samples demonstrated a sensitivity of 100 %, specificity of 50 %, positive predictive value of 96.7 %, negative predictive value of 100 %, and overall accuracy of 96.7 %. Adverse events were minimal (3.2 %).

Conclusions MOSE using the SonoTip TopGain FNB needle demonstrates high diagnostic accuracy and excellent sensitivity for detecting malignancy, with a favorable safety profile. These findings support its utility as a reliable tool for real-time adequacy assessment in clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820975

Aims Advances in endoscopic ultrasound–guided tissue acquisition (EUS-TA) have increasingly shifted diagnostic strategies toward histology-based assessment, expanding the need for needles capable of providing consistent core tissue while maintaining optimal flexibility and procedural control. To assess, in pancreatic solid lesions, the technical performance, histological yield, and diagnostic accuracy of a novel 22-gauge (22G) FNB needle featuring a Franseen tip made of cobalt-chromium alloy, designed to optimize puncture control and flexibility through a spring-coiled, dual-coated sheath.

Methods Consecutive patients undergoing EUS-FNB for solid pancreatic lesions at a single referral center were prospectively included. Each lesion was sampled with three standardized passes using the study needle. All specimens were fixed in formalin and assessed for microcore quantity and quality. The primary endpoint was microcore procurement (number and size > 550 µm). Secondary endpoints included diagnostic accuracy and adverse events.

Results From May to October 2025, 51 patients (51 % male; mean age 62 years, range 38–86) were enrolled. Technical success was achieved in all cases. High-quality histological cores were obtained in 75 % of procedures. Overall diagnostic accuracy was 90.2 %. No major adverse events occurred. Endoscopists reported excellent needle sharpness, low puncture resistance, and improved maneuverability, particularly within anatomically challenging regions of the pancreas.

Conclusions This novel cobalt-chromium 22G Franseen-tip FNB needle demonstrated excellent technical performance, reliable core tissue procurement, and high diagnostic accuracy in EUS-guided sampling of solid pancreatic lesions. The combination of controlled tip penetration and enhanced shaft flexibility appears to facilitate safe, effective access to difficult pancreatic locations and may represent an advancement in EUS-TA technology.

PYP036 Endoscopic ultrasound fine-needle biopsy of solid pancreatic lesions: histologic yield of suction versus no-suction technique in a high-volume tertiary center

Authors Pavel C[1, 2], Plotogea O[1, 2], Sandru V[2, 1], Dascalu RI[3], Constantinescu G[2, 1], Ilie M[1, 2]

Institutes 1 Clinical Emergency Hospital of Bucharest, 014461, Bucharest, Romania; 2 Carol Davila University of Medicine and Pharmacy, 020021, Bucharest, Romania; 3 Clinical Emergency Hospital of Bucharest, 014461, Bucharest, Romania, bucharest, Romania

DOI 10.1055/s-0046-1820976

Aims Endoscopic ultrasound–guided fine-needle biopsy (EUS-FNB) is the recommended method for tissue acquisition in suspected pancreatic cancer. Third-generation biopsy needles provide improved histologic yield; however, the optimal sampling technique—particularly the use of suction—remains unclear. This prospective study compared suction versus no-suction sampling during EUS-FNB of solid pancreatic lesions using a Franseen-tip needle [1, 2].

Methods In a tertiary center, 88 consecutive patients with pancreatic solid lesions highly suggestive of malignancy on cross-sectional imaging were en-

rolled. All underwent EUS-FNB using a 22-gauge Franseen needle. Patients were randomized to an aspiration technique (stylet removal and 20-ml negative suction) or a non-aspiration technique (NAT, no application of negative pressure). Macroscopic on-site evaluation guided the number of needle passes. A single blinded gastrointestinal pathologist assessed tissue integrity, blood contamination, and final histopathologic diagnosis. The primary endpoint was diagnostic accuracy for pancreatic cancer.

Results 46 procedures were performed using NAT and 42 using the aspiration technique. Demographic characteristics were comparable between groups. Non-aspiration sampling yielded significantly less blood contamination (39.1 % vs 64.2 %, $p < 0.05$). Diagnostic confirmation of adenocarcinoma was higher in the non-aspiration group (95.6 % vs 88 %). Negative results occurred only in the aspiration group (12 %). Indeterminate samples were noted in the NAT group (4.4 %). The number of needle passes did not differ significantly (1.39 vs 1.25, $p = 0.228$).

Conclusions EUS-FNB without suction resulted in higher diagnostic accuracy and lower blood contamination compared with suction-assisted sampling. Avoiding suction may optimize tissue quality when using a Franseen-tip needle for solid pancreatic lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Endoscopic ultrasound (EUS) has become a cornerstone in the diagnostic work-up of pancreatobiliary and mediastinal diseases. EUS-guided fine needle aspiration (FNA) and fine needle biopsy (FNB) provide high diagnostic yield with a generally low risk profile. However, procedure-related complications still occur and may have multiple contributing factors, especially when EUS is performed together with ERCP. The present study aimed to evaluate the incidence, type, and clinical outcome of complications following EUS-guided tissue acquisition in a tertiary referral center over a seven-year period.

Methods All EUS procedures performed between December 2018 and September 2025 were retrospectively reviewed. Demographic and procedural data were collected, including type of needle, number of passes, puncture route, and clinical course. Complications were classified according to their type, timing, and severity. Cases with combined EUS–ERCP were analyzed separately. Descriptive statistics were used to summarize the findings.

Results During the study period, 2,759 EUS procedures were performed, of which 1,237 involved tissue sampling (EUS-FNA or EUS-FNB). Complications occurred in 89 patients (7.2 %). The mean age of affected patients was 66.6 years (median 68, IQR 57–75), and 49 % were male and 45 (50.6 %) were female. Most procedures were performed with FNB (91 %) using a 22G needle (92 %), with a median of three needle passes. The median hospital stay was five days (IQR 4–6).

Of all complications, 47.2 % occurred after combined EUS–ERCP and 52.8 % after EUS alone. The most frequent event was pancreatitis (n = 65; 73 %), including five severe cases (5.6 %) and two deaths. Other complications included cholecystitis (n = 6), bleeding-related events (n = 6), sepsis (n = 3), peritonitis (n = 2), intracystic hemorrhage (n = 3; one fatal), and several isolated events such as retroperitoneal hematoma and hemoperitoneum (two fatal). Overall, four patients (4.5 %) died due to procedure-related complications. Conservative management was effective in 95.5 % of cases, while two patients required interventional and two-surgical treatment. The procedure-related mortality rate was 0.32 % among EUS-FNA/FNB cases and 0.15 % of all EUS procedures.

Conclusions EUS-guided tissue acquisition remains a safe diagnostic procedure with a low complication rate and very low mortality. Nearly half of all complications were observed in combined EUS–ERCP sessions, highlighting the complex interplay of risk factors in such cases. Most complications were mild pancreatitis managed conservatively, while bleeding and infectious events were rare and effectively treated. These real-world data confirm that EUS-FNA and EUS-FNB are safe and reliable when performed in experienced hands within a high-volume center.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP038 Histologic Changes in the Pancreas Following EUS-FNA: Insights from Resected Specimens

DOI 10.1055/s-0046-1820978

Aims Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is widely used for the diagnosis of pancreaticobiliary diseases. Although its clinical safety profile is generally favorable, procedure-related adverse events such as bleeding, pancreatitis, and infection have been reported. Most existing evidence is based on clinical observations, whereas studies evaluating tissue-level effects are scarce. This study aimed to assess the histopathological impact of EUS-FNA on the pancreas using resected surgical specimens and to clarify the procedure's safety from a pathological perspective.

Methods We retrospectively reviewed patients who underwent EUS-FNA followed by pancreatic resection between 2021 and 2024 (EUS-FNA group, n = 29). A control group consisted of patients who underwent pancreatic resection during the same period without preceding EUS-FNA or ERCP (n = 35). Clinical characteristics and procedural details were collected, and histopathological findings in resected specimens were compared between the two groups. Fat necrosis, neutrophil infiltration, fibrosis, protein plugs, fat replacement, and squamous metaplasia were graded on a four-point scale (0: none, 1: mild, 2: moderate, 3: severe). Group differences were analyzed using t-tests. For neoplastic lesions, needle tract seeding was specifically evaluated.

Results Baseline characteristics for the EUS-FNA and control groups were as follows: median age 70 and 72 years; male sex 31.0 % and 51.4 %. Underlying diseases included conventional pancreatic ductal adenocarcinoma (21 vs. 8), IPMN (1 vs. 5), other pancreatic tumors (6 vs. 11), extrapancreatic malignancies (1 vs. 10), and benign disease (0 vs. 1). Surgical procedures included pancreatoduodenectomy (19 vs. 16) and distal pancreatectomy (10 vs. 19). All EUS-FNA procedures were performed using a 22-gauge needle, with a mean of two passes. The only clinical abnormality was asymptomatic hyperamylasemia in five patients; no procedure-related pancreatitis, bleeding, or infection occurred. Mean histological scores in the EUS-FNA and control groups, respectively, were: fat necrosis 0.167 vs. 0.059 ($p = 0.289$), neutrophil infiltration 0.033 vs. 0.059 ($p = 0.637$), fibrosis 0.967 vs. 0.706 ($p = 0.177$), protein plugs 0.300 vs. 0.235 ($p = 0.618$), fat replacement 0.900 vs. 0.909 ($p = 0.968$), and squamous metaplasia 0.100 vs. 0.031 ($p = 0.278$). None of the differences were statistically significant. No needle tract seeding was identified in any specimen.

Conclusions Pancreatic resection specimens obtained after EUS-FNA showed no significant histopathological alterations compared with specimens from patients without prior puncture, suggesting that EUS-FNA does not induce measurable tissue injury. Notably, even patients who developed transient hyperamylasemia demonstrated no corresponding histopathological changes, indicating that asymptomatic enzyme elevation may not reflect true pancreatic damage. The absence of clinically apparent adverse events in this cohort represents a limitation; larger studies including cases with documented complications are warranted to further clarify the tissue-level safety profile of EUS-FNA.

DOI 10.1055/s-0046-1820979

Aims Recently, a third-generation FNB needle (SecureFlex, Olympus, Japan), featuring a dual-beveled front-cutting raptor tip, was introduced. We aimed to evaluate the diagnostic performance and safety of this needle in an international, multicenter, prospective study.

Methods Consecutive patients undergoing EUS-guided sampling using the SecureFlex EUS-FNB needle were enrolled across eight centers. The primary endpoint was diagnostic accuracy; secondary endpoints included adequacy, number of needle passes, and adverse events. Final diagnosis was based on surgical pathology or FNB findings with clinical/radiologic follow-up. Operators rated needle performance on a 5-point Likert scale evaluating insertion, flexibility, tip control, echogenicity, puncturability, and overall use.

Results Eighty-five patients (58.8 % male, median age 68 [IQR 60-76]) were included. Targets included pancreatic masses (51.8 %), lymph nodes (18.8 %), subepithelial lesions (9.4 %), liver lesions (8.2 %), and other sites (11.8 %); median lesion size was 25 [IQR 15-32] mm. Needle calibers used were 22G (58.8 %), 19G (23.5 %), and 25G (17.6 %); sampling techniques included dry suction (37.6 % %) slow-pull (29.4 %), and wet suction (21.2 %) and a combination of dry and wet suction (11.8 %), respectively. MOSE was used in all cases and ROSE in 1 case; one pass was required in 38.8 %, two in 49.4 %, and ≥ 3 in 11.8 % of cases. Sample adequacy was 98.8 %; sensitivity and specificity for malignancy were 97.1 % and 100 %, with overall diagnostic accuracy of 97.6 %. Four patients (4.7 %) had mild adverse events (3 self-limiting bleeding, AGREE I; 1 mild acute pancreatitis, AGREE II, in a patient undergoing same-session ERCP with stent). Operator ratings were consistently high, with "excellent" or "very good" scores across needle insertion (74.1 % and 25.9 %), flexibility (85.9 % and 14.1 %), tip control (71.8 % and 25.9 %), echogenicity (72.9 % and 22.4 %), puncturability (67.1 % and 32.9 %), and overall performance (74.1 % and 25.9 %).

Conclusions The new dual-beveled raptor-tip EUS-FNB needle demonstrated excellent accuracy and core procurement, with optimal safety. Physicians' assessments were excellent in most cases in all domains across different centers and operators.

Conflicts of Interest Andrea Lisotti received consultancy from Olympus company.

PYP040 Balanced propofol sedation versus general anaesthesia for endoscopic ultrasonography-guided tissue acquisition for solid pancreatic lesions

DOI 10.1055/s-0046-1820980

Aims To compare the adequacy of balanced propofol sedation (BPS) and general anaesthesia (GA) for endoscopic ultrasonography-guided tissue acquisition (EUS-TA) of solid pancreatic lesions.

Methods This is a single-center, controlled cohort study with retrospective analysis of a prospectively collected database including all patients who underwent EUS-TA for diagnosis of a solid pancreatic mass at the gastrointestinal endoscopy unit in a tertiary referral cancer center. According to our institutional protocol, all ERCP is performed under GA. Many patients with pancreatic masses present with jaundice, thus requiring endoscopic biliary drainage, and it is common for ERCP and EUS to be indicated concomitantly. Patients who underwent ERCP and EUS on the same day under general anaesthesia as well as some cases in which EUS was performed alone but under intubation were analysed in the GA group.All procedures were performed by advanced fellows under the direct supervision of expert endoscopists. The material obtained was subsequently analysed by a pathologist specialising in the gastrointestinal tract. However, the pathologist was not present in the endoscopy room during the procedure, i.e., there was no rapid on-site evaluation (ROSE). The sample was considered adequate if sufficient material was obtained for histological interpretation, and inadequate if sufficient cells were absent or if aspirates contained only blood or gastrointestinal epithelial cells. The final diagnosis was based on histology or clinical/radiological follow-up [1–4].

Results From April 2013 to February 2025, a total of 491 EUS-guided pancreatic punctures were conducted on 433 patients, of whom 50.3 % were female. Overall, 85.7 % (95 % CI 82.3–88.6 %) of the samples were considered adequate. Three hundred sixty-three (73.9 %) received BPS, ninety-three (18.9 %) received GA, twenty-six (5.3 %) were sedated by an anaesthetist (AS), and sedation data was not available for nine procedures (1.8 %). The demographic and lesion characteristics did not differ between groups. Adequacy was 84.3 % (95 % CI 80.6–88.0 %) in the BPS group, 89.2 % (95 % CI 83.0–95.2 %) in the GA group, and 89.7 % (95 % CI 78.8–100 %) in AS procedures (p = 0.202). Comparing only BPS and GA also did not achieve statistical significance (p = 0.223). Comparison of endoscopist (BPS) versus anaesthetist (GA + AS) similarly showed no statistically significant difference (p = 0.175).

Conclusions To the best of our knowledge, this real-world cohort study comprising 491 EUS-TA procedures for solid pancreatic lesions represents the largest single-centre series directly comparing BPS with GA and AS regimens. This study conveys a clear message: endoscopist-administered BPS is as effective as GA and AS for EUS-TA.

Although a minor numerical difference was observed, GA does not confer any meaningful advantage in terms of adequacy. While patient immobility is undeniably superior under GA, this does not result in increased efficacy for obtaining adequate samples when experienced endoscopists perform sedation

with propofol. Thus, mandating GA for all pancreatic EUS-TA procedures is unwarranted, even in the context of training fellows in EUS-TA.

BPS directed by trained endoscopists must remain the standard of care. GA should be reserved selectively for high-risk patients and concomitant ERCP. In summary, in a contemporary real-world setting, endoscopist-administered BPS delivered an adequacy equivalent to GA for EUS-TA of solid pancreatic lesions. Further studies evaluating adverse event rates, recovery time, and cost-effectiveness are needed to strengthen these findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Aims & Background: Endoscopic submucosal dissection (ESD) is state-of-the-art en-bloc resection for early gastro-intestinal cancers and precursors developed and validated in Japan. Western expertise with this complex technique remains limited. Tutored training might be optimal for patients and ESD learning [1]. **Aims**: We established ESD tutoring courses led by experienced Japanese experts to provide (i) optimal long-term curative outcomes and low complication rates for patients, and (ii) hands-on training on difficult lesions for European endoscopists under direct expert supervision.

Methods Prospective data from 2011–2015 (follow-up to 12/2024) were analyzed. A total of 118 neoplasms (50 % HGIEN & cancer) in 101 patients (median age 68 [37–91] years; 38 % with significant comorbidities) were treated with expert or tutored ESD. The neoplasms (n) were located in esophagus & cardia (22), stomach (14), duodenum (9), and colorectum (72). Japanese experts performed 28 ESDs, while 22 trained beginners conducted 90 supervised procedures on *difficult* lesions during 5 live and 20 tutoring events (1–4 days each, total 54 d).

Results Analysis of the complete data showed en bloc and curative resection rates of 95 % and 88 %, with no recurrence after R0 resections during a median follow-up of 9.8 [1.5–14.9] years. Long-term survival remained recurrence-free after endoscopic resection of 3 recurrent adenomas (at R1/Rx) and curative surgery /2nd ESD for 5 non-curative ESD. Adverse events occurred in 9.3 % without emergency surgery or 30-day mortality. Comparing expert only vs. tutored ESD procedures, beginners correctly applied curative ESD indications in 94 % of ESD. Experts resected larger lesions (22 cm²) at 9.3 cm²/h in 121 minutes. Tutored beginners achieved a 75 % [25–100] self-completion rate on 33 % smaller lesions in 112 min.

Conclusions ESD tutoring courses led by Japanese top experts ensure curative patient outcomes and standardized training on complex lesions during routine endoscopy program. This model may advance current ESD performance across European referral centers.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Endoscopic submucosal dissection (ESD) has emerged as an organ-preserving strategy for superficial colorectal neoplasia, offering high rates of en bloc and curative resections. However, the ileocecal valve (ICV) remains one of the most technically challenging sites because of its complex anatomy, thin wall, and potential ileal extension. Evidence from Western countries is limited, with few studies and small sample sizes. This national multicenter study aimed to evaluate the efficacy, safety, and long-term outcomes of ESD for ICV neoplasia in expert Italian centers.

Methods A retrospective multicenter study involving 14 high-volume Italian units of the Endoscopic Resection Italian Network (ERIN) was performed. Patients with superficial neoplastic lesions involving the ICV treated with ESD or hybrid ESD (h-ESD) between January 2018 and July 2025 were retrospectively enrolled in this study. The primary outcomes were en bloc, R0, and curative resection rates. Secondary outcomes included intra-procedural and delayed adverse events (AEs), the need for surgery, local recurrence rate, recurrence-free survival (RFS), and surgery-free survival (SFS).

Results A total of 142 patients were included (median age, 67 years). Lesions had a median size of 34 mm, and nearly half (49 %) extended into the terminal ileum. Most lesions were LST-G (56 %), and ESD was performed in 88 % of cases, with h-ESD in 12 % of cases. En bloc resection was achieved in 93 % of patients, and R0 resection was achieved in 89 % of patients. Curative resection according to the ESGE guidelines was achieved in 87 % of patients. Intraprocedural AEs occurred in 22 % of patients, all of whom were successfully managed endoscopically. Delayed AEs occurred in 5 % of patients, with only two cases requiring surgery. Most lesions were benign, with adenocarcinoma in 12 %(n = 17) of cases. At 10 months follow-up, local recurrence occurred in 7 % of patients, and only 5 % of patients required surgery. In the Firth logistic regression, h-ESD was significantly associated with an increased risk of non-R0 resection (OR 7.59; p = 0.001) and non-curative resection (OR 12.40, p < 0.001). Moreover, T-ESD was a protective factor for R0 resection (OR 0.22; p = 0.038). Lesion morphology, size, circumferential involvement, and ileal extension were not associated with adverse outcomes. The estimated probability of RFS at 6 months was 97.3 %, 88.9 % at 12 months, then stabilized at 14 months.

Conclusions In expert hands, ESD for ICV neoplasia demonstrates high efficacy and safety, yielding excellent curative resections. Despite the anatomical complexity inherent to the ileocecal region, these findings endorse ESD as a viable organ-preserving alternative to surgery for these superficial neoplastic lesions,mostly benign,of the ICV. This affirms the long-term durability and safety of endoscopic management of ICV lesions.

DOI 10.1055/s-0046-1820983

Aims Endoscopic submucosal dissection (ESD) enables en-bloc resection of large or fibrotic colorectal lesions that are not amenable to snare-based techniques. Its uptake for proximal colonic lesions in Western practice remains limited, largely due to technical complexity and anatomical challenges. The Saline Immersion/irrigation TEchnique (SITE) has emerged as a strategy to help overcome these limitations. This study evaluated the procedural efficacy and safety of SITE-facilitated ESD for proximal colonic lesions in a tertiary center [1–4].

Methods All proximal colonic ESDs performed between April 2018 and October 2025 were retrospectively analyzed from a prospectively maintained institutional database. All cases were discussed in a multidisciplinary team meeting beforehand. SITE was applied in every procedure, in combination with the pocket-creation method (PCM) or its variants. Baseline characteristics, procedural parameters, histopathological outcomes and adverse events were recorded.

Results Of 106 lesions referred for ESD, eight (7.5 %) procedures were abandoned due to intra-procedural detection of deep submucosal invasion, and 12 lesions were resected using snare-based techniques. Eighty-six lesions were removed by ESD and included in the analysis. Eighty-two procedures (95.3 %) were performed under operator-delivered conscious sedation. Mean patient age was 68 ± 9.1 years, and 51 patients (59.3 %) were male. Lesion location was caecum (n = 29), ascending colon (n = 41) and transverse colon (n = 16). Nine lesions (10.5 %) were recurrent.

Median lesion size was 40 mm (IQR 35–58.8) × 35 mm (IQR 25–50). En-bloc resection was achieved in all cases. Resection status was R0 in 76 (88.3 %), R1 in 8 (9.3 %) and Rx in 2 (2.3 %). Median resection time was 120 min (IQR 90–160), with a median dissection speed of 10.8 mm²/min (IQR 6.2–16.1). Histopathology revealed low-grade dysplasia in 68 lesions (79 %), high-grade dysplasia in 10 (11.6 %), SM1 cancer in 1 (1.2 %), deeply invasive cancer in 3 (3.5 %) and sessile serrated lesions with dysplasia in 4 (4.7 %).

Among the eight R1 resections, four were vertical and four lateral. Three patients with vertical R1 margins and invasive cancer underwent surgery, with residual cancer identified in one case. The remaining vertical R1 (LGD) lesion was successfully managed endoscopically. Six patients had lateral R1/Rx resections, all LGD; only one case—located at the ileocecal valve—developed recurrence, which was treated endoscopically.

Four adverse events occurred (4.7 %): two microperforations and one delayed bleed requiring embolization. None required surgical intervention. Thirty-two patients (37.2 %) were admitted, with a median length of stay of 1 day (IQR 1–2). Defect closure was achieved in 60 cases (69.7 %).

Conclusions SITE-facilitated ESD for proximal colonic lesions was performed predominantly under conscious sedation and achieved consistently high en-bloc and R0 resection rates with low adverse-event rates. These results support consideration for routine adoption for right-sided colonic ESD. Further multicenter prospective studies are needed to validate these outcomes as the preferred approach for proximal colonic ESD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP044V Right colon tumor endoscopic submucosal dissection (ESD) with thulium laser (case report video)

Authors Babadzhanian A[1], Andreychikova O[1], Markarian D[1]
Institute 1 MSU University clinic, Moscow, Russia
DOI 10.1055/s-0046-1820984

Abstract Text

The patient had no complains, blood stool test was positive. Colonoscopy revealed a laterally spreading tumor granular-type, NICE type 2, KudoIIIL, measuring 3,5x3,0 sm. Biopsy showed an adenoma HGD. Underwater conditions were required for the laser ESD. Tumor lifting was satisfactory. 1940-nm thulium laser with 940-µm fiber was used. Dissection began caudally, continued to both sides, and ended cranially. The laser enable contactless cutting and effective coagulation; hot forceps were occasionally used for hemostasis. The lesion was removed en block. Postoperative histology confirmed tubular adenoma HGD. Advantages: contactless coagulation and cutting, strong coagulation effect, energy is delivered locally, minimizing the lateral thermal damage, cost effective. Conclusion: thulium laser appears safe for colonic ESD thought further evaluation is needed.

DOI 10.1055/s-0046-1820985

Aims Colorectal serrated lesions (CSLs) are increasingly recognized as important precursors of colorectal cancer, accounting for up to a quarter of cases. Recent advances include the 2019 WHO classification, which categorizes CSLs into sessile serrated lesions (SSL), SSL with dysplasia (SSLD), traditional serrated adenomas (TSA), and unclassified serrated adenomas. Although piecemeal resection is widely used, larger CSLs may harbor unexpected dysplasia and carry a higher risk of metachronous neoplasia, underscoring the importance of achieving accurate histological evaluation. Endoscopic submucosal dissection (ESD) enables en bloc resection and precise pathological assessment, but its technical difficulty and risk profile are influenced by factors such as lesion size, location, and submucosal fibrosis. This study aimed to clarify the association between CSLs and submucosal fibrosis, and to determine how fibrosis affects therapeutic outcomes in colorectal ESD.

Methods This retrospective cohort study reviewed consecutive colorectal ESD procedures performed at Kyoto Prefectural University of Medicine from January 2020 to November 2024. To align with the 2019 WHO classification, only lesions measuring ≥ 20 mm was included. Indications followed Japanese ESD guidelines, with serrated lesions treated when SSLs were ≥ 30 mm or when lesions ≥ 20 mm were suspected to be SSLD or TSA based on magnified endoscopic evaluation. Lesions were classified histologically as CSLs—including SSL, TSA, SSLD, and unclassified serrated adenomas—or as adenomas/T1 cancers. Data on patient and lesion characteristics, fibrosis status, and therapeutic outcomes were collected. Submucosal fibrosis was graded endoscopically. ESD outcomes included procedure time, en bloc and R0 resection, and adverse events such as perforation or delayed bleeding. The primary outcome was the frequency of any or severe fibrosis in CSLs compared with adenomas/T1 cancers. Logistic regression analyses identified predictors of fibrosis, severe fibrosis, and prolonged procedure time (> 90 min), with lesion size categorized as < 40 or ≥ 40 mm.

Results Among 445 colorectal ESD cases, 72 were CSLs (16.2 %) and 373 were adenoma + T1 cancers. Submucosal fibrosis was present in 46.3 % of all lesions, and severe fibrosis in 16.4 %. CSLs showed significantly lower rates of fibrosis than adenoma + T1 cancers (34.7 % vs 48.5 %, p = 0.04) and lower severe fibrosis (6.9 % vs 18.2 %, p = 0.03). CSLs were more common in females (61.1 % vs 41.0 %, p < 0.01), predominantly right-sided (73.6 %), and more frequently non-polypoid (95.8 % vs 77.7 %, p < 0.01). Mean procedure time was shorter for CSLs (53.0 ± 25.6 min vs 67.1 ± 44.2 min, p < 0.01). In multivariate analysis, serrated histology independently reduced the risk of fibrosis (OR 0.58, 95 % CI 0.33–0.99; p = 0.04), while lesion size ≥ 40 mm increased it (OR 2.03, 95 % CI 1.30–3.20; p < 0.01); rectal location lowered risk (OR 0.40, 95 % CI 0.22–0.70; p < 0.01). Severe fibrosis was associated with lesion size ≥ 40 mm (OR 2.45, 95 % CI 1.40–4.27; p < 0.01) and polypoid morphology (OR 3.42, 95 % CI 1.92–6.06; p < 0.01). Prolonged procedure time ≥ 90 min was linked to lesion size ≥ 40 mm (OR 25.00), fibrosis (OR 3.73), and severe fibrosis (OR 5.14). Among five CSLs with severe fibrosis, R0 resection was achieved in 60 %.

Conclusions This study investigated serrated histology as a predictor of reduced submucosal fibrosis in colorectal ESD. These results may aid therapeutic decision-making. ESD should be considered for lesions ≥ 40 mm or those with polypoid morphology, as characteristics were associated with a higher risk of severe submucosal fibrosis.

Aims Endoscopic Submucosal Dissection (ESD) enables en bloc resection of large colorectal lesions [1], yet evidence on its efficacy and safety in elderly patients remains limited in Western countries, with most data originating from Asia [2–4]. The definition of "elderly" varies, although individuals aged 65 years or older are commonly included [5]. This study aimed to evaluate the efficacy and safety of colorectal ESD in patients aged ≥ 65 years, stratified by age group, compared with younger controls (< 65 years).

Methods This retrospective multicenter study included consecutive patients who underwent colorectal ESD across 19 European referral centers (2010–2025). Patients were grouped as < 65 or ≥ 65 years, with elderly patients further divided into 65–74, 75–84, and ≥ 85 years. Demographic, endoscopic, and histologic data were collected. Primary outcomes included successful, en bloc, R0 resection, adverse events (bleeding, perforation, delayed events) rates, and need for surgery.

Results A total of 3.493 ESDs were analyzed (≥ 65: 2.273; < 65: 1.220). Overall success (89.2 % vs 89.5 %; p = 0.81), R0 resection rates (76.6 % vs 78.2 %; p = 0.42), and en bloc rates (89.1 % vs 90.9 %; p = 0.1059) were comparable between elderly and younger patients. Lesion size, fibrosis, morphology, JNET classification, lesion site, and resection time did not differ significantly. Adverse events (perforation, bleeding, delayed bleeding, delayed perforation, and other delayed events such as strictures) occurred in 9.3 % of elderly patients and 8.8 % of younger patients (p = 0.51). Most were managed conservatively, with the need for surgery due to complications being 0.3 % and 0.6 % respectively (p = 0.18). Within elderly subgroups, patients aged 75–84 had higher rates of perforation (OR 1.6; p = 0.014) and delayed bleeding (OR 1.8; p = 0.037) than those aged 65–74, while ≥ 85 showed no significant difference, likely due to limited sample size. Complication odds increased by 3.1 % per year of age (OR 1.031; p = 0.009). The need for surgery due to complications or malignancy did not differ by age (p = 0.123). The distribution of submucosal invasive cancer was also similar (p = 0.357).

Conclusions Colorectal ESD in elderly patients is effective and curative, maintaining high en-bloc, successful, and R0 resection rates. While age independently increases the risk of procedural complications, most events were endoscopically manageable, resulting in low surgical conversion rates. These findings, derived from one of the largest Western elderly ESD cohorts, confirm and expand prior Asian data, supporting the use of ESD as a curative, minimally invasive option in selected elderly patients, with appropriate risk stratification. Future studies incorporating comorbidity and frailty are warranted to refine patient selection beyond biological age.

Aims Endoscopic intermuscular dissection (EID) and per anal endoscopic myectomy (PAEM) are advanced techniques derived from endoscopic submucosal dissection (ESD) in which the dissection plane extends into the muscularis propria. These techniques enable en bloc resection of rectal lesions with severe fibrosis or deep submucosal invasion, as reported in recent series. In our center, EID is planned for lesions with optical suspicion of deep invasion, whereas PAEM is performed as a salvage technique when unexpected fibrosis or deep invasion is encountered during ESD. The aim of the study was to evaluate the efficacy (technical success, R0 resection, and curative resection) and safety of EID and PAEM in rectal lesions. As a secondary aim, to compare R0 and curative resection rates with those of rectal ESD in pT1 lesions [1, 2].

Methods Multicenter cohort study based on a prospective consecutive registry. Patients ≥ 18 years with rectal lesions treated with ESD, EID, or PAEM were included. Non-adenoma/adenocarcinoma histologies were excluded. Curative resection was defined as pT1, G1–G2 differentiation, absence of lymphovascular invasion, low tumor budding, and a deep free margin ≥ 0.1 mm.

Results A total of 176 procedures were included (EID: 9; PAEM: 13; ESD: 154). Mean age was 67 years (SD 11.7); 51.7 % were men.

Technical success with en bloc resection was achieved in 100 % of EID and PAEM cases, and in 99.4 % and 96.8 % respectively in the ESD group. R0 resection was obtained in 9 (100 %) cases in EID, 122 (79 %) in ESD, and 8 (61.5 %) in PAEM. Considering only pT1 lesions, R0 rates were 100 % for EID, 80 % for PAEM, and 47.1 % for ESD. Curative resection among pT1 lesions was achieved in 2 (50 %) with EID, 2 (15.4 %) with PAEM, and 5 (29.4 %) with ESD.

Median procedure time was 85 minutes (IQR 70–114) for EID and 145 minutes (IQR 108–285) for PAEM. Dissection speeds were: EID 21.3 mm^2/min (SD 9.2), PAEM 21.6 mm^2/min (SD 13.1), and rectal ESD 28.8 mm^2/min (SD 16). Median hospital stay was 1 day (IQR 1–2) in both groups.

Adverse events included mild post-procedural pain in 1 EID (11.1 %) and 1 PAEM (7.7 %) case, and abdominal pain prolonging admission by 1 day in 1 EID patient (11.1 %). A stenosis occurred in 1 PAEM case (7.7 %), successfully managed with three dilation sessions. One PECS-like reaction occurred in the EID group (11.1 %).

Conclusions EID and PAEM are effective and safe techniques for complex rectal lesions, achieving high R0 rates in pT1 tumors with curative potential. These methods represent valuable options within organ-preserving strategies for selected rectal neoplasms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Endoscopic submucosal dissection (ESD) allows en bloc resection of early colorectal neoplasia, providing precise histopathological evaluation and lower recurrence. However, colorectal ESD remains technically demanding due to prolonged procedure times and higher complication rates, especially in cases with severe fibrosis. Severe submucosal fibrosis may arise from prior interventions or inherent lesion characteristics, and it often obscures the dissection plane. Gel-immersion ESD (GI-ESD), using Viscoclear (Otsuka Pharmaceuticals, Tokushima, Japan), a highly viscous and transparent gel approved in Japan, has emerged as a potential solution. This gel maintains luminal clarity through its retention effect, stabilizes scope operability, and provides a durable submucosal lift via buoyancy even in fibrotic lesions. These effects are superior to saline. This study aimed to evaluate the clinical outcomes of GI-ESD for colorectal lesions with severe submucosal fibrosis compared with conventional ESD (C-ESD).

Methods This single-center retrospective cohort study included all consecutive colorectal ESDs at a high-volume Japanese center from January 2022 to June 2025. Only cases with intraoperatively confirmed severe fibrosis were analyzed. Procedures were performed by expert endoscopists or supervised trainees. All lesions underwent preprocedural evaluation using high-definition magnification. ESD was performed using Fujifilm or Olympus colonoscopes with waterjet function and this water jet function was used for gel injection. Submucosal lifting used sodium hyaluronate or alginate mixed with indigo carmine. Dissection utilized scissors-type, needle-type, or mixed-knife strategies, with traction applied at the operator's discretion. C-ESD was performed before April 2024; thereafter, GI-ESD was introduced, involving suction of intraluminal gas and gel instillation to maintain visualization. Primary outcome was procedural safety (delayed bleeding, perforation, post-ESD coagulation syndrome [PECS]). Secondary outcomes included en bloc and R0 resection rates, procedure duration, and operator conversion.

Results A total of 85 colorectal ESDs with severe fibrosis were analyzed (GI-ESD: n = 22; C-ESD: n = 63). Baseline demographics were comparable (mean age: 68.7 vs 66.5 years, female rate: 27.3 % vs 33.3 %), right-colon location (54.5 % vs 49.2 %; p = 0.199), median lesion size [IQR] (25 ± 10 mm vs 30 ± 25 mm), polypoid morphology (23.8 % vs. 47.6 %; p = 0.480), and expert operator (81.8 % and 73.0 %; p = 0.953). Regarding primary endpoints, no adverse events occurred in GI-ESD, whereas 14 events (22.2 %) occurred with C-ESD: perforations (n = 5; 7.9 %), delayed bleeding (n = 2; 3.2 %), and PECS (n = 7; 11.1 %). En bloc resection was achieved in all completed cases; R0 rates were higher with GI-ESD (85.7 % vs 72.8 %; p = 0.191). Median procedure time was shorter in GI-ESD (56 vs 87 min; p = 0.015), and mean time favored GI-ESD (74.2 vs 101.2 min; p = 0.075). Procedure discontinuation was similar (4.5 % vs 6.3 %). In multivariable regression, GI-ESD was not independently associated with procedure duration of severe fibrotic cases (p = 0.500); lesion size remained the only independent predictor (p < 0.001).

Conclusions In this high-risk cohort, GI-ESD was associated with favorable safety and procedural efficiency compared with conventional ESD. No adverse events occurred in GI-ESD. The findings suggest that a viscous gel environment can mitigate challenges associated with severe fibrosis without compromising resection quality, potentially offering clinical and economic benefits by reducing complications and associated resource use.

DOI 10.1055/s-0046-1820989

Aims Endoscopic resection is central to the management of colorectal neoplasia. EMR is widely available and technically simple, whereas ESD allows en-bloc and R0 resection but is more demanding. High-quality, long-term, real-world comparative data from European centers remain scarce.This study aimed to compare technical performance, histopathology, and long-term oncological outcomes of EMR versus ESD over a 10-year period (2015-2025). The primary endpoint was R0 resection. Secondary endpoints included en-bloc resection, recurrence, carcinoma detection, procedural time, fibrosis, complication rates, and follow-up completeness. Additional objectives included identifying independent predictors of carcinoma and local recurrence using multivariate modeling.

Methods This retrospective cohort included 292 consecutive colorectal lesions resected at a single high-volume expert center (EMR n = 166, 56.8 %; ESD n = 126, 43.2 %) over 10 years. Demographic variables, lesion morphology (Paris, LST), anatomical location, size, fibrosis severity, use of traction and hood, procedural time, and adverse events were extracted. Histopathological endpoints included dysplasia grade and carcinoma. Follow-up duration, recurrence,

and loss to follow-up were recorded. All procedures were performed by a single expert endoscopist to eliminate operator-dependent variability.

Results Lesions treated with EMR were distributed throughout the colon, most commonly right-sided (38.5 %), whereas ESD was strongly concentrated in the rectum (66.7 %, $p < 0.0001$).Paris morphology differed significantly ($p < 0.001$): EMR was used for protruding Is/IIa lesions, while ESD was preferentially applied to flat or mixed IIa/IIa + IIc lesions.LST morphology was evenly balanced between granular and non-granular subtypes in both groups, indicating no preferential selection based on LST subtype. Rectal lesions were significantly larger (50.6 vs 32.0 mm, $p < 10^{-11}$) and required markedly longer procedure time (57.8 vs 26.5 min, $p < 10^{-12}$). Recurrence was higher in rectal lesions (20.7 % vs 7.9 %, $p = 0.0029$), whereas en-bloc and R0 rates were similar between rectal and colonic locations ($p = 0.82$ and $p = 0.93$).

Fibrosis severity differed markedly ($p < 0.0001$): EMR lesions were mostly non-fibrotic (81.3 %), whereas ESD targeted lesions with higher fibrosis burden (46.0 % moderate/severe vs 18.7 %).Hood use was strongly associated with ESD (73.0 % vs EMR 3.6 %, $p < 0.0001$). Traction was uncommon (1–2 %, p = NS).

ESD achieved significantly higher en-bloc (84.1 % vs 37.3 %, $p < 0.0001$) and R0 resection rates (65.9 % vs 49.4 %, $p = 0.006$). Median procedure time was longer (45 vs 20 min, $p < 0.0001$).Time-per-mm was almost doubled in ESD (1.17 vs 0.60 min/mm, $p < 0.0001$).In multivariate analysis restricted to ESD, lesion size was the sole independent predictor of procedural time ($\beta = 1.16$ min/mm, $p < 0.0001$; $\rho = 0.71$), while fibrosis showed a non-significant trend ($\beta = +16.9$ min, $p = 0.12$).

ESD identified more high-grade dysplasia (38.9 % vs 31.9 %, $p = 0.004$) and more than twice as many carcinomas (34.1 % vs 12.0 %, $p < 0.0001$).Independent predictors of carcinoma were rectal location (OR ≈ 2.1) and use of ESD (OR ≈ 2.9). Lesion size, fibrosis, and LST subtype were not independent predictors.

Adverse events were infrequent and comparable ($p = 0.21$): EMR had 11 intraprocedural bleeds (6.6 %, all controlled endoscopically), while ESD had 4 intraprocedural events (3.2 %) and one delayed bleed (0.8 %). No patient required surgery.

Among patients with follow-up, EMR had longer surveillance (median 24 vs 8 months, $p < 0.001$), while loss-to-follow-up was similar (38.6 % vs 40.5 %, $p = 0.73$).

Recurrence was significantly higher after EMR (20.5 % vs 5.6 %, $p < 0.001$).Independent predictors of recurrence were lesion size ($p = 0.005$), rectal location (OR ≈ 3.1), and en-bloc resection, the strongest protective factor (OR ≈ 0.07, $p < 0.0001$). Fibrosis, LST morphology, R0, and technique were not independent predictors.

Conclusions In real-world practice over 10 years, ESD consistently outperformed EMR across all major oncological outcomes—en-bloc, R0, carcinoma detection, and recurrence—despite being used for significantly more complex lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP050V ONE-PEDAL-DRIVING ESD: The "Zero-Exchange" Technique Using Hydro-Modulated PowerCoag on the ESG-300 Generator

Authors De María Pallarés P[1], Tavecchia M[1], Martin Arranz E[1], Burgos García A[1]

Institute 1 La Paz University Hospital, Madrid, Spain

DOI 10.1055/s-0046-1820990

Problem to solve Endoscopic Submucosal Dissection (ESD) is the gold standard for large colorectal neoplasms but is hampered by technical complexity and prolonged procedural times. A primary inefficiency is the repetitive instrument exchange required to manage intraprocedural bleeding. Standard protocols dictate switching from a dissection knife to hemostatic forceps (e.g., Coagrasper) upon encountering vessels, a cycle that disrupts the surgical plane, increases cognitive load, and significantly raises procedural costs. Furthermore, precise settings for the *ESG-300 (Olympus)* generator in certain situations in advanced endoscopy are lacking in comparison to other brands like the *VIO3* generator (*ERBE)*.

Innovation We introduce the "**ONE-PEDAL-DRIVING ESD**" concept. Analogous to electric vehicles (EVs) where a single pedal controls both acceleration and regenerative braking—enhancing efficiency and reducing wear—this technique utilizes a single electrosurgical setting (**PowerCoag E2 30W**) and a single instrument (***DualKnife J***, *Olympus*) for the entire submucosal phase. The innovation lies in **hydro-modulation**: leveraging the physics of electrosurgery where saline immersion drops impedance by 99 % (Capogreco et al., *Sci Rep* 2025). By altering the environment from CO2 (higher cutting effect) to static saline (moderate cutting effect) or active saline infusion (high coagulation effect due to electrodispersion), the operator achieves diverse tissue effects without modifying the generator settings or changing instruments [1, 2].

Results The video demonstrates the resection of a 50mm bulky sessile lesion (JNET 2A) in the mid-rectum, characterized by thick penetrating arterial vessels. Using the ESG-300 on PowerCoag E2 30W, the procedure was completed in 55 minutes with **zero instrument exchanges**.

1. **High-Speed Dissection:** Under CO2, high voltage allows agile cutting of submucosal tissue with no or small vessels.
2. **Moderate-Speed Dissection:** Submerging the submucosal plane in saline utilizes the voltage drop to seal small-to-medium vessels with a low spark.
3. **Hemostasis:** Active saline infusion during activation created an electrodispersion effect, mimicking soft coagulation for large bleeders or vessel sealing. The technique eliminates the need for hemostatic forceps, reducing cost and maintaining surgical flow.

Conclusions "One-Pedal-Driving ESD" transforms the ESG-300 and DualKnife J into a high-performance all-in-one solution for ESD. By understanding and manipulating the electrophysical behavior of the PowerCoag waveform in different media, endoscopists can eliminate the hemostatic forceps, reducing procedural time, cost, CO2 emissions and complexity while mimicking the efficiency of modern EV operation.

DOI 10.1055/s-0046-1820991

Aims In patients with perihilar cholangiocarcinoma (pCCA) who are considered for surgical resection, biliary drainage of the future liver remnant (FLR) is essential. The conventional approach is placement of a transpapillary plastic stent during endoscopic retrograde cholangiopancreatography (ERCP). However, ERCP is associated with considerable risks, including cholangitis (37 %), stent dysfunction (19 %) and post-ERCP pancreatitis (19 %) within 90 days [1]. Some of these complications may result from bridging the papilla, which leads to duodenobiliary reflux and colonization of the biliary tract with upper gastrointestinal flora, increasing the risk of cholangitis. To mitigate these risks while preserving ease of removal, a suprapapillary stent equipped with a retrieval string could offer a viable alternative. The primary aim was to evaluate the safety and feasibility of preoperative endobiliary drainage using a suprapapillary plastic stent with a retrieval string.

Methods This prospective single-center pilot study included patients with pCCA eligible for hemihepatectomy. Patients were excluded when the stricture was located ≤ 2 cm from the papilla. Procedures were performed using a modified plastic biliary stent (7, 8.5 or 10 Fr) with a retrieval string attached distally. The primary outcome was safety, defined as the number of severe drainage related complications until exploratory laparotomy. Severe complications are defined as any complication leading to additional invasive interventions, admission to hospital, or death. Secondary endpoints included technical and clinical success rates, defined as successful placement of the stent and a ≥ 20 % reduction in bilirubin levels at day 7, respectively. Patients underwent a scheduled stent exchange if surgery had not taken place after 6-12 weeks, depending on the diameter of the stent.

Results Between March 2023 and August 2025, 40 patients with presumed resectable pCCA were enrolled (14 female [35 %], median age 72 years [IQR 65-76]. Bismuth classification was distributed as follows: type I (1, 3 %), type II (4, 10 %), type IIIa (19, 48 %), type IIIb (3, 8 %), and type IV (13, 33 %). Suprapapillary stent placement was technically successful in the first procedure in all cases (40/40, 100 %), in 35 patients one stent was placed (35/40, 88 %) and in five patients two stents (5/40, 13 %) were placed. A precut sphincterotomy was performed during the procedure in four patients (4/40, 10 %), and five patients (5/40, 13 %) had undergone a sphincterotomy prior to referral. Eleven patients (11/40, 28 %) had one or more severe drainage related adverse event following the index procedure within 90 days. Cholangitis occurred in four of these patients (4/40, 10 %), of which one case was associated with stent dysfunction (1/40, 3 %); in the remaining three cases (3/40, 8 %) there were no signs of stent dysfunction. Stent dysfunction without cholangitis occurred in five patients (5/40, 13 %), caused by partial migration (n = 3; one inward, two outward) or occlusion with debris (n = 2). Four patients (4/40, 10 %) developed post-ERCP pancreatitis. Clinical success was achieved after the initial procedure in 34/39 (87 %) patients, with a minimum follow-up of two weeks. In one patient, clinical success could not be evaluated due to death within two weeks, resulting from rapid clinical deterioration. Overall, 29 patients underwent surgical exploration or scheduled stent exchange without the need for an unplanned re-intervention (29/40, 72 %). Nineteen patients (19/40, 48 %) ultimately underwent surgical resection. One patient remains under evaluation for liver transplantation. Surgery was not performed in 20/40 (50 %) included patients. In 14 patients this was due to locally advanced or metastatic disease, in two patients due to inadequate FLR volume, in one due to patient withdrawal, and three patients died prior to surgery.

Conclusions This prospective pilot study demonstrates that endoscopic biliary drainage using a suprapapillary plastic stent with a retrieval string is both technically feasible and appears safe in patients with potentially resectable pCCA. Most patients did not require any unplanned re-intervention, and the incidence of cholangitis was substantially lower compared with previous studies [1]. Larger comparative trials are warranted to further evaluate its efficacy, and define its role within the preoperative management strategy for pCCA.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Conventional fully covered self-expandable metal stents (FCSEMS) for malignant distal biliary obstruction (MDBO) are typically cylindrical in shape. Recently, a newly designed tapered-and-flared FCSEMS (K-papilla stent; SB Kawasumi Co., Ltd., Tokyo, Japan) has become available. This stent features a tapered waist toward the distal end and a large distal flare. Its design is expected to reduce stent migration and sludge formation. This multicenter retrospective study evaluated the clinical outcomes of this novel stent.

Methods Forty patients (median age: 76 years; 19 males and 21 females) who underwent placement of a 10-mm K-papilla stent for unresectable MDBO between May 2023 and July 2024 at five institutions in Japan were retrospectively analyzed.

Results The underlying diseases were pancreatic cancer in 32 patients, cholangiocarcinoma in 5, and others in 3. Reasons for unresectability were distant metastasis (n = 20), locally advanced disease (n = 9), and poor general condition

Endoscopy 2026; 58: S1–S1041

or patient refusal (n = 11). Twenty-seven patients received chemotherapy. The procedure was performed as primary drainage in 13 cases and as reintervention in 27. Pancreatic duct obstruction was present in 26 cases. Regarding the gallbladder, 3 patients had undergone cholecystectomy, 11 had cystic duct invasion, and 26 did not. The technical success rate was 100 % (40/40). Stent lengths of 8, 7, and 6 cm were used in 16, 3, and 21 cases, respectively. The clinical success rate was 98 % (39/40); one patient failed due to bleeding, which improved after replacement with a 12-mm FCSEMS. Early adverse events included mild pancreatitis (n = 4), cholecystitis (n = 1), and bleeding (n = 1), all of which were resolved conservatively or endoscopically.

Among the 39 patients with clinical success, recurrent biliary obstruction (RBO) occurred in 10 cases during a median observation period of 271 days. The median time to RBO (TRBO) was 539 days (95 % CI: 389–NR). The non-RBO rates at 3, 6, and 12 months were 94 % (33/35), 71 % (20/28), and 61 % (11/18), respectively. The causes of RBO were sludge impaction (n = 6), overgrowth (n = 2), and stent migration (n = 2). In addition, three asymptomatic migrations were observed. Late adverse events other than RBO included non-obstructive cholangitis (n = 5) and liver abscess (n = 1), all managed conservatively without ERCP or drainage. The median overall survival was 252 days.

Conclusions Placement of a tapered-and-flared FCSEMS for unresectable MDBO demonstrated favorable outcomes with a low rate of migration and acceptable safety profile. This novel stent may represent a useful option, warranting further prospective evaluation.

PYP053 What type of second biliary stent should be used after SEMS obstruction in malignant distal strictures? A multicenter retrospective study with competing risk analysis

Authors Ollivier M[1], Verdonck L[2], Boursier J[2], Kaassis M[3], Moreau C[4], Olivier A[2], Luet D[2], Roquin G[2], Vitellius C[2], Jezequel J[1], Quénéhervé L[1], Cesbron-Metivier E[2]

Institutes 1 CHU Brest, Brest, France; 2 Angers University Hospital Center, Angers, France; 3 Hospital Center De Cholet, Cholet, France; 4 Laboratoire HIFIH, UPRES EA3859, SFR 4208, Université d'Angers, Angers, France

DOI 10.1055/s-0046-1820993

Aims Malignant distal biliary obstruction is a frequent complication of advanced pancreatic and biliary tract cancers. Endoscopic placement of self-expandable metal stent (SEMS) is the standard treatment, but dysfunction occurs in 19–40 % of cases. The optimal management after SEMS occlusion remains unclear. The aim of this study was to assess and compare three types of second biliary stents (plastic (PS), covered SEMS (CSEMS) and uncovered SEMS (USEMS)) for treatment of primary SEMS occlusion in malignant distal biliary obstruction.

Methods We conducted a multicenter retrospective study in three hospital centers. All patients suffering from malignant distal biliary obstruction and treated for SEMS occlusion between January 2012 and December 2023 were enrolled. Patients with hilar obstruction or benign disease were excluded. All second stents were placed endoscopically using a "stent-in-stent" transpapillary technique. Stent obstruction, stent lifespan and overall survival were compared in patients with PS, CSEMS and USEMS. A competing risk analysis was performed to estimate the cumulative incidence of stent obstruction, taking into account death and surgery as competing events.

Results A total of 142 patients (median age 71.2; 64 % male) were included; PS, CSEMS and USEMS were placed in 42, 40 and 60 patients, respectively. Pancreatic cancer was the most common diagnosis (70.4 %). Median time to stent obstruction did not differ significantly between groups, but occlusion rates were lower in the CSEMS group (25 %) than in the PS (59.5 %) or USEMS groups (45 %) (p = 0.007). This result was confirmed in the competing risk analysis. In multivariable analysis, stent type was the only independent predictor of obstruction, with PS (SHR = 3.76, p = 0.004; ref: CSEMS) and USEMS (SHR = 2.32, p = 0.042) associated with stent obstruction. Median overall survival was 157 days and did not differ between groups, but was significantly lower in patients with metastatic disease, best supportive care, and higher bilirubin levels. Adverse event rates were low and similar across groups.

Conclusions As new chemotherapy protocols increase survival of patients with pancreatic cancer and cholangiocarcinoma, the issue of managing biliary stent obstruction is crucial. This study is the largest series evaluating the type of second biliary stent following obstruction of a first SEMS and provides important insights. Compared to USEMS or PS, using CSEMS reduces the risk of second stent occlusion in patients with malignant distal biliary obstruction treated by trans papillary drainage. Second stent type was the only significant predictor of obstruction but did not improve patient overall survival which was mainly determined by the underlying malignant disease.

PYP054 Biodegradable Biliary Stents in Benign Biliary Disease: A Systematic Review of Effectiveness and Safety

Authors Gardezi SAA[1], Saleh A[1], Alomar M[1], Alghawi R[1], Alabbasi F[1], Alawami M[1], Muafa F[1]

Institute 1 Johns Hopkins Aramco Healthcare Dhahran, Dhahran, Saudi Arabia

DOI 10.1055/s-0046-1820994

Aims Benign biliary strictures and bile leaks remain challenging clinical conditions, frequently managed with plastic or metal stents, which require endoscopic retrieval [1]. Biodegradable biliary stents (BDBS) offer an innovative, non-removable alternative, potentially reducing the need for repeat procedures [2]. This systematic review aimed to evaluate the effectiveness and safety of BDBS in managing benign biliary strictures and post-cholecystectomy bile leaks, identifying pooled success and complication rates, and assessing the quality of existing evidence.

Methods A systematic literature review was performed using PubMed, Scopus, and Web of Science databases, covering studies from January 2000 to March 2025. Search terms included "biodegradable stents," "benign biliary stricture," and "bile leak." Inclusion criteria comprised original human studies reporting outcomes of BDBS in benign biliary conditions. Excluded were animal studies, case reports, editorials, and studies on malignant strictures. Four eligible studies met inclusion criteria, encompassing both prospective and retrospective designs. Key outcomes extracted were clinical success (defined as resolution of stricture or leak without need for reintervention) and complication rates (e.g., stent migration, occlusion, incomplete degradation). This systematic review has been prospectively registered in PROSPERO (Registration number: CRD420251084759 (▶ **Table 1**).

▶ Table 1

Study	Design	Population	N (Patients)	Success Rate	Complication Rate
Giménez et al. (2016)3	Prospective	Benign biliary strictures	13	84.6 %	15 % (migration)
De Gregorio et al. (2020)4	Prospective Registry	Benign biliary strictures	40	88 %	12 % (occlusion)
Ahmad et al. (2022)5	Retrospective multicenter	Post-cholecystectomy bile leaks	52	90 %	10 % (migration)
Mauri et al. (2013)6	Preliminary Experience	Benign biliary strictures	10	82 %	18 % (incomplete degradation)

Results A total of 115 patients were included across four studies. The pooled clinical success rate for biodegradable biliary stents was 85.07 % (95 % CI: 77.68 %–92.45 %), with no significant heterogeneity ($I^2 = 0$ %), suggesting consistency across studies. The pooled complication rate was 14.81 % (95 % CI: 7.54 %–22.09 %), reflecting a moderate but acceptable safety profile. The most common adverse events reported included stent migration (10–15 %) and incomplete degradation (up to 18 %). Importantly, no major procedure-related mortality was reported across any of the included studies. Subgroup analysis revealed a slightly higher clinical success rate in post-cholecystectomy bile leak cases (90 %) compared to those with benign biliary strictures (ranging between 82 % and 88 %), although the sample sizes were limited.

Conclusions This review supports the clinical utility of biodegradable biliary stents as a safe and effective option for benign biliary strictures and bile leaks. With a high pooled success rate and acceptable complication profile, BDBS may reduce the burden of repeated endoscopic procedures. However, further high-quality prospective trials are needed to optimize stent design, reduce migration risk, and establish long-term outcomes across diverse patient populations. These findings may inform future guideline development and enhance biliary care pathways.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820995

Aims Benign biliary strictures (BBS) are commonly managed by progressive calibration using plastic or metallic stents. While fully covered metallic stents (FC-SEMS) enable immediate calibration to a larger diameter compared to plastic stents, they remain prone to migration and their use is limited in intrahepatic and peri-hilar strictures. We report on using uncovered expandable bioresorbable stents in a series of selected BBS patients.

Methods This retrospective bicentric case series included selected patients treated between 2023 and 2025 in two tertiary hospitals (Beaujon Hospital, Clichy, France and HEGP, Paris, France). All patients presented benign strictures not amenable to conventional stenting, due to inability to retrieve the stent because of altered anatomy or because of intrahepatic location (precluding FC-SEMS) with benign indication (precluding Uncovered SEMS).

The bioresorbable stents used (Unity-B, Q3 Medical, Germany) are fastened onto a balloon and expanded to the desired diameter (up to 10 mm). Complete resorption occurs over 3 months. All patients were followed for several months after the procedure. Technical success, clinical success, and adverse events were recorded.

Results 7 procedures were performed in 7 patients, with a total of 10 bioresorbable stents implanted.

- **Four patients** had altered anatomy with a stricture of a bilio-digestive anastomosis. All initially underwent external drainage with placement of an internal–external drain. Deployment of a Unity-B stent percutaneously enabled removal of the drain and internalization of biliary drainage while maintaining dilation of the anastomosis for an additional 3 months. Three of these patients received two Unity-B stents: two because of a right–left liver disconnection requiring a dual-access approach, and one because of a long stricture.
- **Two patients** were treated with extra-anatomical endoscopic drainage (one choledochojejunostomy and one hepaticogastrostomy) for an anastomotic bilio-digestive stricture after pancreaticoduodenectomy, associated with lithiasis. Placement of a bioresorbable stent allowed replacement of the lumen-apposing metal stent used to create the neo-anastomosis in one case and completed an anterograde lithotripsy in the second case. Both ensured calibration of the tract, and facilitated removal of the upstream bile duct stone.

- **One patient** was treated for dilation of an intrahepatic stricture following radiofrequency ablation, achieving a larger calibration than would have been possible with a plastic stent and while FC-SEMS of Uncovered SEMS were precluded. A follow-up ERCP showed no residual stricture and no remaining stent debris.

Technical success was achieved in all cases (100 %). 86 % had clinical success with one patient experiencing recurrence due to tumoral relapse. No per-procedural or long-term adverse events were reported.

Conclusions The use of bioresorbable UNITY-B stents appears feasible, efficient and safe for selected benign biliary strictures, including intrahepatic locations. Its use allowed calibration of strictures that would have been inaccessible with standard stents. Further studies are needed to confirm these preliminary findings

PYP056 Clinical Outcomes of Metal Stents in Refractory Benign Biliary Strictures: A Multicenter Retrospective Study Comparing Initial Versus Rescue Therapy

Authors Han SY[1], Lee J[2], Kim WJ[3], Lee CM[3], Lee SY[4], Jang SI[5]
Institutes **1** Pusan National University Hospital, Busan, Republic of Korea; **2** Department of Internal Medicine, Pusan National University Hospital, Busan, Republic of Korea; **3** Pusan national university hospital, yangsan, Republic of Korea; **4** Gangnam severance, seoul, Republic of Korea; **5** Gangnam Severance Hospital, Seoul, Republic of Korea
DOI 10.1055/s-0046-1820996

Aims Refractory benign biliary strictures (BBS) often require prolonged endoscopic treatment with multiple plastic stents (MPS), leading to repeated ERCP sessions and a high procedural burden. Fully covered self-expandable metal stents (FCSEMS) have been introduced as an alternative, but the optimal strategy—initial versus rescue FCSEMS—remains unclear. This study aimed to compare clinical outcomes of different stent strategies and to identify risk factors for stricture recurrence in patients with refractory BBS.

Methods In this multicenter retrospective cohort study, 150 patients with refractory BBS treated between 2016 and 2023 at four tertiary referral centers were analyzed. Patients were classified into three groups: plastic–plastic, plastic–metal (conversion to FCSEMS after plastic stents), and metal–metal (initial FCSEMS). Refractory BBS was defined as persistent stricture despite ≥ 12 months of plastic stenting or ≥ 6 months of FCSEMS. The primary outcome was stricture resolution; secondary outcomes included treatment duration, number of ERCP sessions, adverse events, and recurrence-free period. Predictors of recurrence were evaluated using multivariable logistic regression and ROC analysis.

Results Of the 150 patients, 32, 48, and 70 were assigned to the plastic–plastic, plastic–metal, and metal–metal groups, respectively. Initial FCSEMS significantly reduced treatment duration (297.8 vs. 581.4 and 600.7 days; $p < 0.01$) and the number of ERCP procedures (4.0 vs. 7.4 and 6.1; $p < 0.001$). Stricture resolution at 12 and 24 months was higher in the metal–metal group (80.0 % and 92.9 %) than in plastic-first strategies (37.5 % and 73.8 %; $p < 0.001$ and $p = 0.002$). Recurrence rates after stent removal were similar among groups (27.5–31.3 %, $p = 0.786$). Early cholangitis, late cholangitis, and post-ERCP pancreatitis were significantly more frequent in the plastic–plastic group. Living donor liver transplantation (LDLT) (OR 4.13, $p = 0.003$) and stricture length ≥ 12 mm (OR 4.87, $p < 0.001$) were independent predictors of recurrence.

Conclusions In refractory BBS, an initial FCSEMS strategy shortens treatment duration, reduces ERCP burden, and improves stricture resolution without increasing recurrence, while plastic stents are associated with higher infectious complication rates. LDLT and longer strictures identify patients at high risk of recurrence. Early consideration of FCSEMS may represent an efficient therapeutic approach and should be further validated in prospective trials.

DOI 10.1055/s-0046-1820997

Aims Liver transplantation is the gold-standard treatment for irreversible liver failure. Biliary complications, particularly anastomotic choledocho-choledochal strictures, remain frequent and have a significant impact on patient survival. Endoscopie treatment with multiple plastic stents (MPS) is effective but is limiting due to the need for repeated procedures. Fully covered self-expandable metal stents (FCSEMS), especially transpapillary ones, reduce the number of procedures but have limitations, notably the risks of migration and post-ERCP pancreatitis. A new type of stent, the intraductal self-expandable metal stent (IDSEMS), has been designed to improve both safety and efficacy. The aim of this study was to directly compare transpapillary and intraductal covered metal stents in the management of post-liver transplantation anastomotic biliary strictures.

Methods We performed a retrospective bicentric study in two university hospitals between 2010 and 2024, including liver transplant recipients with anastomotic strictures treated with either a transpapillary or an intraductal covered metal stent. Th eprimary endpoint was overal stricture resolution. Secondary outcomes included one-year success rate, recurrence, number of procedures needed, length of hospital stay and adverse events. Statical analysis was based on comparative tests and Kaplan-Meir curves, with a significance threshold set a $p < 0.05$.

Results A total of 61 patients were included, 30 treated with FCSEMS and 31 with IDSEMS. The overal stricture resolution rate was achieved in 76.6 % of FCSEMS cases versus 89.7 % of IDSEMS cases, with no significant difference ($p = 0.299$). For secondary outcomes, one-year success was 86.2 % with IDSEMS vs 70.0 % with FCSEMS ($p = 0.209$). Calibration duration was similar (median 232.5 days for IDSEMS vs 203.0 days for FCSEMS, $p = 0.992$), as were the number of procedures (2 for IDSEMS vs 3 for FCSEMS, $p = 0.817$) and hospital stay (11 vs 12 days, $p = 0567$). Reccurence occurred less frequently and later with IDSEMS (19.2 % with a median delay of 301 days vs 27.3 % and 164 days with FCSEMS), though without reaching statistical signifiance. Overall complication rates were comparable, however IDSEMS were associated with significantly fewer migrations (6.5 % vs 26.7 %, $p = 0.041$) and post-ERCP pancreatitis (6.5 % vs 33.3 %, $p = 011$).

Conclusions This is the first retrospective study comparing the two models of covered metal stents. Both demonstrated similar efficacy in treating post-transplant anastomotic biliary strictures. However, IDSEMS showed a clear favorable trend in overall resolution and recurrence rates. They also appeared better tolerated, with fewer migrations and episodes of pancreatitis, representing a promising alternative. Prospective, randomized, multicenter studies are warranted to confirm these findings.

DOI 10.1055/s-0046-1820998

Aims Endoscopic ultrasound–guided choledochoduodenostomy (EUS-CDS) with lumen-apposing metal stents (LAMS) is an established technique for biliary drainage in malignant distal obstruction [1, 2]. Nevertheless, recurrent biliary obstruction (RBO) due to stent occlusion or migration remains a concern and the placement of a coaxial double-pigtail stent (DPS) has been proposed to improve long-term stent patency [3]. This multicenter Italian study compared RBO rates between EUS-CDS performed with LAMS alone and LAMS combined with a coaxial DPS.

Methods We conducted a retrospective analysis of consecutive patients who underwent EUS-CDS across eleven Italian tertiary centers between October 2023 and October 2025. Patients were stratified into two groups: LAMS-alone and LAMS-plus-DPS. The primary endpoint was the incidence of RBO after achieving clinical success. Secondary outcomes included technical and clinical success, adverse events (AEs), and reintervention rates.

Results A total of 192 patients were included (142 treated with LAMS alone and 50 with LAMS-plus-DPS). RBO occurred in 23/142 (16.2 %) patients in the LAMS-alone group compared with 4/50 (8.0 %) in the LAMS-plus-DPS group (risk ratio 2.02, 95 % CI 0.74–5.57; p = 0.23). Technical and clinical success rates exceeded 95 % in both groups, and no significant differences were observed in adverse events or in the need for reintervention.

Conclusions In this Italian multicenter experience, EUS-CDS using LAMS with a coaxial DPS was associated with a lower rate of RBO compared with LAMS alone. Although the difference was not statistically significant, the data support further investigation in larger, prospective trials to better define the role of DPS in optimizing long-term stent patency.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1820999

Aims EUS-guided biliary drainage (EUS-BD) has become an established therapeutic alternative toERCP. While the efficacy of hepaticogastrostomy (HGS) and choledochoduodenostomy (CDS) is well-documented, the long-term management of their specific adverse events remains a challenge. Dysfunction of transmural stents is a clinically relevant problem, yet data concerning specific dysfunction mechanisms, optimal management strategies, and relative outcomes after reintervention HGS/CDS dysfunction are limited.

The primary objectives of this study are to describe the mechanisms of dysfunction following transmural EUS-BD (HGS or CDS) and their management. Secondary objectives include describing the time to dysfunction for primary stents and after the first biliary reintervention, comparing long-term performance of HGS vs CDS, and identifying independent predictors of recurrent dysfunction.

Methods We conducted a retrospective, multicenter study involving three Spanish tertiary referral centers over a 7-year period (2017-2024). The study population consisted of consecutive patients presenting with dysfunction of a previously placed EUS-guided biliary drainage.

We collected comprehensive data including patient demographics, etiology of obstruction, indication for the initial EUS-BD, and technical characteristics of the primary stents used.

Statistical analysis included descriptive statistics for demographic and clinical variables. Kaplan-Meier curves were generated to estimate the time to dysfunction (both primary and post-reintervention). A stratified Cox regression analysis was performed to identify independent predictors of recurrent dysfunction [1–3].

Results A total of 91 dysfunction events (70 HGS and 21 CDS) were analyzed in 61 patients. The cohort was 59.02 % male with a mean age of 68.61 years (SD ± 10.26). The etiology of biliary obstruction was predominantly malignant (78.43 %), with tumors located mainly in the distal bile duct (50.98 %) and hilar region (27.45 %). The primary indication for the initial EUS-BD was failed ERCP cannulation (35.29 %), followed by dysfunction of a prior indwelling transpapillary stent (25.49 %). The most frequently used stetns were 10x80-mm covered SEMS for HGS and 8 mm LAMS for CDS.

The median time to first dysfunction (primary stent failure) was 168.5 days (IQR 58-337.5). All patients underwent an endoscopic revision. The leading cause of dysfunction was obstruction by sludge and food debris (46.15 %), followed by tissue ingrowth (16.48 %), with no significant difference between access routes (p = 0.48). However, technique-specific failure profiles were identified: gastric stent migration was a specific complication of HGS (15.71 %), whereas duodenal obstruction and sump syndrome were specific to CDS (9.52 %).

Management strategies differed significantly between groups. In HGS dysfunction, stent exchange was the most common intervention (40.57 %), whereas in CDS, clearance followed by coaxial pigtail insertion was the preferred strategy (55 %).

Endoscopy 2026; 58: S1–S1041

Following the first biliary reintervention (BRI), the median time to recurrent dysfunction increased to 456 days (IQR 184-1363). Comparison between HGS and CDS showed no significant differences in the time to recurrent failure (p = 0.79). In the stratified analysis, for HGS, the presence of a distal malignant stenosis was the only independent risk factor associated with recurrent failure (HR 28.98; p = 0.029). Notably, no specific reintervention technique (cleaning, exchange, or coaxial stenting) demonstrated a statistically significant improvement in prolonging the time to dysfunction in either group.

Conclusions This is the first study to jointly analyze dysfunction in HGS and CDS. Although their failure profiles and initial management differ, their long-term patency after reintervention is comparable. Risk factors for recurrent failure are technique-specific. The finding that no single management strategy was superior suggests that a personalized approach, tailored to the specific cause of dysfunction, is required.

Aims Endoscopic ultrasound-guided choledochoduodenostomy(EUS-CDS) has emerged as an alternative to endoscopic retrograde cholangiopancreatography (ERCP) for biliary drainage in patients with malignant distal biliary obstruction (MDBO). With cautery-enhanced lumen-apposing metal stents (CE-LAMS), EUS-CDS has become more feasible, yet concerns remain regarding stent patency and safety. Comparative data between CE-LAMS–based and conventional self-expandable metal stents (SEMS)-based EUS-CDS are lacking.

Methods A systematic review and network meta-analysis was conducted including randomized controlled trials (RCTs) comparing EUS-CDS using CE-LAMS or SEMS with ERCP in MDBO.Procedural outcomes were technical success defined as the rate of accurate placement of either LAMS, or SEMS within the CBD, with bile flowing through the stent, and mean procedure time, defined as the time (in minute) to reach the technical success. Clinical outcomes were clinical success defined as the pooled rate of patients with a ≥ 50 % reduction in serum bilirubin to < 3 mg/dL within two weeks (and clinical improvement in case of concomitant cholangitis), and overall adverse events. Pooled rate of cholangitis, was also assessed, it was defined and classified per the American Society for Gastrointestinal Endoscopy lexicon. Pairwise and network meta-analyses were performed using random-effects models. Ranking probabilities were assessed using the surface under the cumulative ranking curve (SUCRA).

Results Six randomized controlled trials, comprising 707 patients, were included in the analysis.

EUS-CDS with EC-LAMS significantly outperformed both EUS-CDS with SEMS (RR: 1.22; 95 % CI: 1.10 to 1.36) and ERCP (RR: 1.18; 95 % CI: 1.10 to 1.27) in achieving technical success. No significant difference was observed between EUS-CDS with SEMS and ERCP in either the direct (RR: 0.97; 95 % CI: 0.89 to 1.05) or the indirect comparison (RR: 0.97; 95 % CI: 0.89 to 1.05). SUCRA analysis identified EUS-CDS with EC-LAMS as the best-performing approach (SUCRA = 1.00), while EUS-CDS with SEMS ranked lowest (SUCRA = 0.12). In terms of procedure time, EUS-CDS with EC-LAMS demonstrated a significantly shorter duration compared to both EUS-CDS with SEMS (SMD: –0.78; 95 % CI: –1.30 to –0.27) and ERCP (SMD: –0.84; 95 % CI: –1.16 to –0.52). No significant difference in procedure time was found between EUS-CDS with SEMS and ERCP in either the direct (SMD: –0.05; 95 % CI: –0.35 to 0.46) or the indirect comparison (SMD: –0.05; 95 % CI: –0.35 to 0.46). SUCRA rankings again favored EUS-CDS with EC-LAMS as the most effective strategy (SUCRA = 1.00), while EUS-CDS with SEMS and ERCP ranked equally as the least favorable options (SUCRA = 0.25).On network meta-analysis, no difference was observed among the different techniques of performing EUS-CDS in terms of clinical success as

compared to ERCP or compared to each other.SUCRA analysis identified EUS-CDS with EC-LAMS as the best-performing approach (SUCRA = 0.68), while EUS-CDS with SEMS ranked lowest (SUCRA = 0.27).When focusing on safety, in the network meta-analysis, no significant differences in adverse event rates were observed among the various techniques of EUS-CDS compared to ERCP, nor among the EUS-CDS techniques themselves According to SUCRA analysis, EUS-CDS with SEMS was identified as the safest approach (SUCRA = 0.85), while ERCP ranked lowest (SUCRA = 0.29)When specifically assessing the incidence of cholangitis, no significant differences were found among the different biliary drainage strategies [1–6].

Conclusions EUS-CDS with CE-LAMS offers superior procedural efficiency compared to ERCP and SEMS-based approaches with similar clinical success and safety, though concerns about cholangitis warrant further evaluation.

PYP061 Can EUS Predict Malignancy in IPMN with MPD Dilatation? Insights from a Retrospective Cohort

Authors Conti Bellocchi MC[1], Cerioli C[1], De Pretis N[1], Pea A[1], Sina S[1], Luchini C[1], Frulloni L[1], Salvia R[1], Crinò SF[1]

Institute 1 University of Verona, Verona, Italy

DOI 10.1055/s-0046-1821001

Aims Main pancreatic duct (MPD) dilatation in patients with intraductal papillary mucinous neoplasms (IPMN) is a known risk factor for malignancy, yet its predictive value remains debated, especially in non-resected patients. We aimed to evaluate whether endoscopic ultrasound (EUS) features of the MPD can predict malignancy in patients with cyst-associated MPD dilatation.

Methods We retrospectively analyzed 231 patients who underwent EUS for pancreatic cysts with MPD dilatation (≥ 5 mm). Malignancy was defined as high-grade dysplasia (HGD) or invasive carcinoma (IC) in resected patients, or progression to cancer/metastases during ≥ 12 months of follow-up. EUS features (diameter, wall thickening, content, course, nodules) were reviewed by two blinded endosonographers. Statistical analysis included logistic regression, ROC curves, and Kaplan–Meier survival estimates (▶ **Table 1**).

Results Among 231 patients, 88 underwent surgical resection and 141 were managed with surveillance. Malignancy was diagnosed in 70 patients (67 surgical, 3 during follow-up). Malignant patients were younger than non-malignant ones (65.2 ± 10 vs 68.7 ± 9.6 years, p = 0.023). On univariate analysis, several EUS features were significantly associated with malignancy: thickened MPD walls (30 % vs 16 %, p = 0.034), inhomogeneous ductal content (54 % vs 31 %, p = 0.002), tortuous ductal course (56 % vs 37 %, p = 0.014), and presence of nodules (23 % vs 7 %, p = 0.003). MPD diameter was higher in malignant cases (8.2 ± 3.3 mm vs 7.5 ± 4.4 mm), but not statistically significant (p = 0.242). In multivariate analysis, inhomogeneous content (OR = 2.10, p = 0.054) and nodules (OR = 2.53, p = 0.086) showed trends toward independent association with malignancy. The logistic regression model incorporating EUS features yielded an area under the ROC curve (AUC) of 0.783 (95 % CI: 0.556–1.00; p = 0.014), indicating good discriminative ability. In the surveillance subgroup, 3 patients progressed to advanced PDAC during follow-up. Kaplan–Meier analysis showed a gradual decline in progression-free survival, with approximately 30 % of patients experiencing progression at 36 months.

Conclusions EUS features such as inhomogeneous MPD content and nodules were associated with malignancy in IPMN patients with ductal dilatation. These findings suggest that detailed ductal morphology may enhance risk stratification beyond duct diameter alone, supporting its integration into clinical decision-making.

PYP062 Branch-duct IPMNs measuring less than 10 mm exhibit a significantly lower risk of "worrisome features": implications for endosonographic surveillance

Authors Hansen F[1], Ewald P[1], Sorncharoen L[1], Quast D[1], Stögbauer M[1], Torres Reyes C[1], Schlottmann R[1], Zeidler C[1], Ayoub M[1], Kaup B[1], Koch A[1], Weckheuer L[1], Cahyadi O[1], Ebigbo A[1]

Institute 1 St. Josef-Hospital, Ruhr-University Bochum, Bochum, Germany

DOI 10.1055/s-0046-1821002

Aims Pancreatic carcinoma is among the malignant tumours with the highest mortality and remains associated with an extremely poor prognosis. Early identification and surveillance of premalignant lesions, such as intraductal papillary mucinous neoplasms (IPMNs), are therefore of central importance for preventing malignant transformation. According to the current Kyoto Guidelines, for small branch-duct IPMNs (BD-IPMNs) measuring less than 20 mm and lacking high-risk factors ("worrisome features"), endoscopic ultrasonography (EUS) surveillance every 18 months is recommended. However, it remains unclear whether BD-IPMNs smaller than 10 mm carry a comparable risk of progression and therefore require monitoring at the same interval. The aim of this study is to evaluate whether BD-IPMNs smaller than 10 mm exhibit a similar risk for the development of "worrisome features" as BD-IPMNs measuring between 10 and 20 mm.

Methods In this retrospective analysis, all patients who had undergone at least two endoscopic ultrasound (EUS) examinations at St. Josef-Hospital Bochum between January 1, 2006, and September 30, 2025, were identified based on the coded ICD diagnoses K86.2 ("pancreatic cyst") or D37.70 ("neoplasm of uncertain or unknown behaviour: pancreas"). Data were collected from the clinical information system, and a total of 843 patients were identified.

Results As part of an ongoing project, 131 of the 843 identified patients have been fully evaluated to date. Among them, 47 patients (35.9 %) presented with a BD-IPMN measuring < 10 mm at the time of initial diagnosis. The mean follow-up period was 7.6 ± 3.3 years, with an average of 12.9 EUS examinations per patient. For comparison, 39 patients (29.8 %) with BD-IPMNs measuring 10–20 mm were identified (mean follow-up period 7.0 ± 3.4 years; average of 13.4 EUS examinations). Lesions measuring 10–20 mm showed a 7.6-fold higher risk of developing "worrisome features" compared to lesions < 10 mm (6.4 % vs. 48.7 %, $p = 0.0005$). The most common worrisome features in patients with lesions < 10 mm were elevated CA19-9 levels (n = 3), followed by cyst growth ≥ 2.5 mm per year (n = 2). In contrast, the most common worrisome features in patients with BD-IPMNs measuring 10–20 mm were cyst growth ≥ 2.5 mm per year (n = 14), followed by a main pancreatic duct diameter of 5–10 mm (n = 6) and elevated CA19-9 levels (n = 5).

Conclusions The preliminary data indicate a significantly lower risk for the development of "worrisome features" in BD-IPMNs smaller than 10 mm compared to larger lesions (10–20 mm). In the extended analysis of the larger cohort, it will be assessed whether it is safe for this subgroup of patients to extend the surveillance interval or to omit further EUS follow-up.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP063 Through-the-needle biopsy revisited: How Patient Selection and Standardization Reduce Adverse Events in Pancreatic Cyst Evaluation

Authors Conti Bellocchi MC[1], Teso MV[1], Spagnolo S[1], Manfrin E[1], Sina S[1], Pea A[1], De Pretis N[1], Salvia R[1], Frulloni L[1], Crinò SF[1]
Institute 1 University of Verona, Verona, Italy
DOI 10.1055/s-0046-1821003

Aims Pancreatic cystic lesions (PCLs) are increasingly detected due to the widespread use of cross-sectional imaging. Endoscopic ultrasound (EUS) is the preferred modality for evaluating their nature and malignancy risk, yet fluid analysis and cytology offer limited sensitivity. Through-the-needle biopsy (TTNB) has emerged as a more accurate diagnostic tool, though associated with higher adverse event (AE) rates. In 2021, our center implemented a selective TTNB protocol excluding frail or elderly patients and suspected IPMNs, and standardizing the procedure to two passes, complete cyst aspiration, and selective antibiotic prophylaxis. This study aimed to compare AE rates before and after protocol implementation, evaluate safety factors including antibiotic use, and assess TTNB adequacy and diagnostic accuracy (▶ **Table 1**).

Methods We retrospectively analyzed consecutive patients referred for TTNB at AOUI Verona between March 2016 and March 2025, dividing them into two groups: before (Group A) and after (Group B) protocol adoption. Patients not punctured due to technical issues, lack of indication, or presumed pseudo-cystic nature were excluded.

Results Of 970 patients evaluated by EUS, 190 underwent TTNB (100 in Group A, 90 in Group B). Lesions were mainly located in the pancreatic body or tail, with significantly larger size in Group B. Overall AE rate was 6.3 %, significantly higher in Group A (11 %) than in Group B (1 %). Antibiotic prophylaxis was not associated with AE occurrence. TTNB adequacy was 88.9 %, and diagnostic accuracy 75.3 %. Among 68 surgical cases, TTNB was accurate in 79.4 %.

Conclusions A selective and standardized TTNB approach significantly reduces AEs while maintaining high adequacy and diagnostic accuracy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP064 Longitudinal Analysis of DNA From Pancreatic Cysts Across Serial EUS With FNA

Authors Reddy S[1], Robinson M[1], Van Ekdom C[1], Guarner-Argente C[1], Boustani C[1], Chalhoub W[1], Jha R[1], Haddad N[1]
Institute 1 MedStar Georgetown University Hospital, Reservoir Rd NW, Washington, D.C., USA, Washington D.C., United States of America
DOI 10.1055/s-0046-1821004

Aims The ubiquity of imaging has increased pancreatic cysts detection. The Kyoto pancreatic cyst guidelines include concerning characteristics such size > 3 cm, mural nodule, and dilated main pancreatic duct. Mucinous pancreatic cysts are potentially malignant neoplasms. GNAS and K-ras mutations have demonstrated good specificity for pancreatic lesions but sensitivity remains limited. Repetitive FNAs (fine needle aspiration) could increase this specificity by analyzing cysts' DNA fluid longitudinally. We retrospectively analyzed patients who underwent pancreatic resections to assess their precursor cysts for their CEA and DNA.

Methods We performed a retrospective review of patients with pancreatic cysts who underwent multiple EUS with FNA from 2012-2024 at a single tertiary care center. Aspirated cyst fluid was analyzed using the molecular pathology test PancraGen. DNA transformation was defined as presence of GNAS and KRAS from previous negative DNA analysis. Odds ratio was used for statistical analysis. Patients that ultimately underwent pancreatic resections were also specifically analyzed.

▶ **Table 1**

Variables	Univariate analysis		Multivariate analysis	
	AEs Yes/no	p value	P value	OR (95 % CI)
Group				
A	11/89			
B	1/89	0.004	0.023	11.5 (1.40-94.07)

Unknown	2/17			

Endoscopy 2026; 58: S1–S1041

Results 185 patients with pancreatic cysts underwent multiple EUS with FNA with a median of 4 (range 2 to 8). We observed GNAS and K-ras mutations at initial FNA in 22 patients (11.9 %) with DNA transformation following serial EUS with FNA in 35 patients (18.9 %). Among 82 patients with CEA > 192 ng/ml, 11 patients (13.4 %) had GNAS and K-ras mutations at initial FNA with DNA transformation in 24 patients (29.3 %). In contrast, among 103 patients with CEA < 192 ng/ml, only 11 patients (10.7 %) had GNAS and K-ras mutations at initial FNA with DNA transformation in 24 patients (23.3 %; OR: 3.46, p < 0.05). 33 patients (40.2 %) underwent pancreatic resections. Surgical pathology revealed IPMN (intraductal papillary mucinous neoplasm) or MCN (mucinous cystic neoplasm) in 26 samples (78.8 %) while 7 revealed serous pathology. 12 IPMN patients (46.2 %) had KRAS mutations, but specificity of IPMN with positive KRAS mutations was 100 %. None of the IPMN patients had GNAS mutations.

Conclusions GNAS and K-ras mutations can transform across repetitive EUS with FNA particularly when CEA is greater than 192 ng/ml. These findings can validate serial cyst surveillance by EUS with FNA in selected patients. The specificity of K-ras was 100 % in IPMN surgical pathologies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP065 A promising diagnostic role of immunohistochemical expression of insulin-like growth factor II mRNA binding protein 3 (IMP3) in pancreatic lesions using endoscopic ultrasound -Guided –Fine Needle Aspiration (EUS-FNA) Cytology

Author Moaz M[1]
Institute 1 zagazig university, Zagazig, Egypt
DOI 10.1055/s-0046-1821005

Aims This prospective work is to assess the diagnostic role of EUS-FNA combined with the immunohistochemical expression of IMP3 on different benign and malignant pancreatic lesions.

Methods The included pancreatic lesions (*n* = 140) were obtained by EUS-FNA technique and stained for IMP3 immunohistochemically. Paraffin blocks from patients who underwent excision (*n* = 92) or core biopsies (*n* = 48) were performed for confirming diagnosis [1, 2].

Results The combined method for diagnosis showed that IMP3 was positive in 78.7 %, 91.7 %, 100 % PAC, mucinous neoplasm with high grade dysplasia, and IPMN with high grade dysplasia, respectively, while almost all benign lesions showed negative IMP3. Also, this method showed sensitivity (78.26 %), specificity (95.83 %), and accuracy (84.3 %).

Conclusions EUS-FNA cytology with IMP3 could be a reliable diagnostic tool especially for assessment of malignant pancreatic lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP066 Can we predict biopsy accuracy in iPMNs? Preoperative prediction of cytology-histology concordance combining EUS-FNA and a machine learning approach

Authors Tacelli M[1], Zaccari P[1], Petrone MC[1], Rossi G[1], Capurso G[1], Belfiori G[1], Schiavo Lena M[1], Pedica F[1], Crippa S[1], Reni M[1], Falconi M[1], Arcidiacono PG[1]
Institute 1 San Raffaele Hospital, Milano, Italy
DOI 10.1055/s-0046-1821006

Aims Intraductal papillary mucinous neoplasms (IPMNs) are increasingly diagnosed due to rising life expectancy and widespread use of abdominal imaging. Despite the publication of several guidelines to drive the management of IPMNs, a significant proportion of patients still undergo surgical resection for lesions ultimately classified as low-grade dysplasia (LGD), while others managed conservatively may progress to invasive carcinoma (IC). Pancreatic surgery could have high perioperative morbidity and mortality, highlighting the need for improved preoperative stratification. Among the available tools, endoscopic ultrasound with fine-needle aspiration (EUS-FNA) represents a key diagnostic method for assessing the risk of malignancy in IPMN. This study aimed to evaluate the diagnostic accuracy of EUS-FNA in predicting histological dysplasia grade in surgically resected IPMNs.

Methods We retrospectively included patients who underwent both EUS-FNA and surgery at San Raffaele Hospital. Surgical diagnoses were classified into LGD, high-grade dysplasia (HGD), or IC, while cytological diagnoses also included "Negative for malignant cells" (NMC). We defined STRICT criteria (SC) as exact cytological-histological concordance (considering NMC as non-concordant), while LARGE (LC) considered NMC equal to LGD. Concordance was assessed using Fleiss' kappa (κ) and linear weighted κ. Uni- and multivariate logistic regressions were conducted to identify predictors of concordance. Diagnostic performance of EUS cytology in distinguishing LGD and HGD/IC was evaluated through sensitivity, specificity, PPV, NPV, and accuracy. A Random Forest classifier was developed to predict concordance before FNA utilizing three variables: patient age, main pancreatic duct (MPD) dilation, and IPMN subtype. The model was trained on the entire dataset with 100 decision trees and a fixed random state to ensure reproducibility (▶ **Table 1**).

▶ **Table 1**

Sensitivity	*0.750*
Specificity	*0.892*
PPV	*0.931*
NPV	*0.647*
Accuracy	*0.798*

Results Ninety-four patients were included (36 % branch duct-, 41 % main duct-, 23 % mixed type-IPMN). The concordance using SC and LC criteria was moderate (Fleiss' κ respectively 0.41 and 0.36). The weighted κ was 0.55. When stratified, concordance was κ = 0.52 for LGD 0.437 for IC, and 0.109 for HGD. Univariate analysis identified diffuse MPD dilation (p = 0.0016 SC, p = 0.0002 LC), cyst wall enhancement (p = 0.0955 SC), grade of dysplasia (p = 0.0809 SC, < 0.00001 LC), and IPMN subtype (p = 0.0433 LC) as significant. Multivariate analysis confirmed cyst wall enhancement (OR = 0.128, p = 0.0334) and grade of dysplasia (OR = 0.239, p = 0.0094) as independent predictors using SC, while the latter one alone (OR = 0.354, p = 0.0027) when LC were considered. Diagnostic performance of EUS cytology in distinguishing LGD vs HGD/IC showed sensitivity 75 %, specificity 89.2 %, PPV 93.1 %, NPV 64.7 %, accuracy 79.8 %. The Random Forest model demonstrated high predictive performance, achieving an accuracy of 94.7 % and an area under the receiver operating characteristic curve (AUC) of 0.99. It correctly classified 89 out of 94 cases, with 4 false negatives and 1 false positive. Precision and recall were 97.9 % and 92.3 % for the concordant class.

Conclusions EUS-FNA shows moderate concordance with final pathology, especially for LGD and IC, while HGD remains challenging. Pre-FNA imaging features are predictive of concordance. A machine learning model demonstrated high accuracy using preprocedural variables only, supporting its clinical value in biopsy guidance. Strengths include the high-volume pancreatic center setting. Limitations include selection bias from a surgical cohort, which is inherent to histology-based studies.

DOI 10.1055/s-0046-1821007

Aims Pancreatic cystic lesions are increasingly detected as incidental findings, with intraductal papillary mucinous neoplasms representing the most prevalent and clinically significant subtype. Their management hinges on the ability to differentiate low grade dysplasia from high grade dysplasia or carcinoma, a distinction that carries direct implications for surveillance strategies and surgical selection. However, accurate preoperative stratification remains challenging, and current diagnostic tools offer only limited precision. In this context, this study aimed to develop and validate a deep learning model capable of distinguishing high-grade dysplasia or carcinoma from low grade dysplasia using endoscopic ultrasound images, with the objective of enhancing diagnostic accuracy and informing evidence based clinical decision making.

Methods An artificial intelligence (AI) based on a convolutional neural network was developed, including both detection and classification components. Lesions identified by the AI algorithm were identified using a bounding box, and further classified into LGD or HGD/C (Figure 1A). The ground truth classification was based on cytological analysis of the pancreatic cyst fluid, EUS-guided through-the-needle biopsy, or surgical specimens. Model performance was assessed based on mean average precision with an intersection-over-unit threshold of 50 % (mAP50), sensitivity, precision, accuracy, and area under the precision-recall curve (AUPRC).

Results A total of 22,515 EUS images were extracted from 40 exams performed at 5 centers in Portugal, Spain, Brazil and the United States. The model detected IPMNs with a mAP50 of 0.885. Regarding the characterization module, the AI system distinguished IPMNs with HGD/C from those with LGD with an overall sensitivity of 88.2 %, a precision of 89.4 %, and an accuracy of 89.1 %. The AUPRC was 0.874 (Figure 1B).

Conclusions This study constitutes one of the earliest investigations into an AI system capable of concurrently detecting IPMN and classifying the degree of dysplasia. Precise differentiation between HGD/C and LGD remains essential for guiding clinical decisions, ensuring timely identification of high-risk lesions while avoiding unnecessary surgical intervention in patients with lower malignant potential. These findings underscore the need for continued development and validation of such tools to strengthen risk stratification in routine practice.

DOI 10.1055/s-0046-1821008

Aims Managing branch-duct intraductal papillary mucinous neoplasms (BD-IPMNs) remains challenging, as guideline criteria (worrisome features/high-risk stigmata) and nomograms often leave uncertainty. Next-generation sequencing (NGS) on Endoscopic Ultrasound guided fine needle aspiration (EUS-FNA) of cyst fluid may provide actionable molecular information to refine decisions.

Methods We conducted a national, vignette-based decision-impact study involving 132 clinicians (gastroenterologists and surgeons). Four complex BD-IPMN vignettes (each with 2–4 worrisome features) were evaluated twice: pre-NGS and post-NGS after disclosure of either a high-risk mutation (positive) or its absence (negative). The primary endpoint was the within-physician change in management in the NGS-concordant direction (NGS + surveillance to surgery; NGS − surgery to surveillance) assessed McNemar's test and mixed-effects logistic regression. Secondary endpoints included change in decision confidence, inter-physician agreement (Fleiss'kappa), practitioner factors.

Results NGS on EUS-FNA cyst fluid significantly changed management in all vignettes (all $p < 0.001$): with NGS − , surgical plans shifted to surveillance (43 % in distal pancreatectomy; 61 % in pancreatoduodenectomy scenarios); with NGS + , surveillance shifted to surgery (90 % and 72 %, respectively; both $p < 0.001$). In mixed-model, post-NGS reduced surgery in NGS − cases (OR 0.30, 95 %CI[0.16–0.57]) and the post-NGS effect was strongly amplified in NGS + cases (interaction OR 76.51, 95 %CI[26.47–221.13]). Population-averaged probabilities of choosing surgery shifted from 20 % to 7 % (NGS −) and 42 % to 94 % (NGS +). Decision confidence increased (proportional-odds OR 4.66, 95 %CI[3.62–6.02], $p < 0.0001$). Inter-physician agreement rose from $\kappa = 0.044$ (95 %CI[0.033–0.055]) pre-NGS to $\kappa = 0.590$ (95 %CI[0.580–0.601]) post-NGS ($p < 2 \times 10^{-16}$). After NGS, practitioner characteristics no longer explained decision patterns.

Conclusions In complex BD-IPMN scenarios, NGS refines management, promotes surgical decisions when high-risk mutations are present, reinforces surveillance when absent, and homogenizes clinician choices.

PYP069 Real life management of intraductal papillary mucinous neoplasms of the pancreas : final data from the prospective italian pancreatic cysts (Pancy) registry

Authors de Nucci G[1], Belfiori G[2], Crippa S[3], Di Salvo F[4], Manes G[5], Cannizzaro R[6], Bellini M[7], Buscarini E[8], Falconi M[3]

Institutes **1** Garbagnate Milanese Hospital, Milan, Italy; **2** San Raffaele Hospital, Milano, Italy; **3** Pancreatic Surgery Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; **4** San Raffaele Hospital, Milan, Italy; **5** Gastroenterology Unit, Rho-Garbagnate Hospital, ASST Rhodense, Milan, Italy; **6** Oncology Referral Center, Aviano, Italy; **7** Digestive Endoscopy Unit, University Hospital of Pisa, Pisa, Italy; **8** ASST Ospedale Maggiore di Crema, Crema, Italy

DOI 10.1055/s-0046-1821009

Aims The majority of studies on Intraductal Papillary Mucinous Neoplasms (IPMNs) are retrospective with inherited selection bias. We report long-term, real-life data from prospective PANcreatic CYsts (PANCY) registry to analyze outcomes of patients with IPMNs, focusing on low-risk branch duct (BD) IPMN.

Methods patients with pancreatic cystic neoplasms were enrolled in a prospective observational multicentric registry between 2015 and 2017 ; surveillance was proposed to enrolled patients until December 31st, 2021. Primary endpoint was identification of factors associated with development of relevant changes in BD-IPMNs undergoing surveillance including development of worrisome features/high risk stigmata/pancreatic cancer, pancreatectomy, death due to IPMN/pancreatic cancer.

Results A total of 647 patients had an IPMN at diagnosis, of which 547 (60 %) were BD-IPMNs, 87 mixed type IPMN (9 %) and 13 (1 %) main duct IPMN. 57 (8.8 %) patients underwent immediate surgery and 590 (91.2 %) active surveillance. During surveillance 34 patients (5.7 %) underwent surgery with evidence of malignant IPMNs in 2/3 while 30 % had only low-grade dysplasia. Overall pancreatic malignancy rate was 2.7 % for low-risk BD-IPMNs and 12.5 % for mixed-IPMN undergoing initial surveillance. At multivariate analysis, being active smoker (OR 2.2) and a cyst size > 15mm (OR 7.1) at diagnosis were independent risk factors for relevant changes. The combination of cyst size ≤ 15mm & age > 65 was a significant protective factor only at univariate analysis (OR 0.1)

Conclusions in BD-IPMN the risk of progression is very low in lesions < 15 mm found in non-smokers, > 65 years patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP070 Association of QNI criteria With Endoscopic and Clinical Outcomes in Pancreatic Pseudocyst Drainage

Authors Chandrashekar A[1], Khatri P[1], Kanani Y[1], Bhagwat S[1], Gadhikar H[1], Pujari R[1], Bapaye A[1]

Institute 1 Deenanath Mangeshkar Hospital and Research Center, Pune, India

DOI 10.1055/s-0046-1821010

Aims The QNI (Quadrant–Necrosis–Infection) classification system has emerged as a structured framework for characterizing walled-off necrosis (WON). However, its performance in predicting clinical severity, procedural complexity, and Endoscopic Retrograde Cholangiopancreatography (ERCP)-related pancreatic duct pathology during endoscopic management of pancreatic pseudocysts and WON in real-world settings remains underexplored. This study evaluates outcomes among low and high-risk QNI groups undergoing endoscopic drainage.

Methods In this retrospective analysis of 300 patients who underwent endoscopic drainage for pancreatic pseudocysts/WON, subjects were stratified into low-risk (n = 232) and high-risk (n = 68) categories based on QNI criteria. Clinical characteristics, procedural interventions, ERCP requirement and findings, and outcomes were compared using standard statistical methods, with significance set at $P < 0.05$.

Results Baseline age and sex distribution were comparable between groups. High-risk QNI patients demonstrated significantly greater disease severity, with higher rates of sepsis (41.2 % vs 18.5 %, $P < 0.001$) and complications (55.9 % vs 28.0 %, $P < 0.001$). High-risk group was characterised by increased need for necrosectomy (98.5 % vs 37.5 %, $P < 0.001$), more necrosectomy sessions (median 3 vs 1, $P < 0.001$), and higher rates of nasocystic drainage (67.6 % vs 22.8 %, $P < 0.001$). Irrigation—especially with saline or betadine–hydrogen peroxide—was also significantly more frequent in the high-risk cohort. Metal stent use predominated in both groups but was more common in high-risk patients (98.5 % vs 90.5 %, $P = 0.04$). Among high-risk subjects, additional radiologic or surgical interventions were required in 10 patients(14.7 %)- 7 patients(10.4 %) required percutaneous drainage, 3 patients(4.4 %) required percutaneous endoscopic drainage. In high risk subjects, The median length of hospital stay did not differ based on requirement of irrigation ($P > 0.05$) and it was highest among those irrigated with betadine and hydrogen peroxide (21.0 days) and least among those who did not require any irrigation (13.0 days). ERCP requirement was similar between low- and high-risk groups (61.6 % vs 51.5 %, $P > 0.05$), as were pancreatic duct stenting rates (58.7 % vs 60.0 %, $P > 0.05$). Across both groups, pancreatic duct leak was the most common ERCP finding (47.6 % low risk; 57.1 % high risk), followed by duct disconnection (30.1 % vs 28.6 %). Strictures were infrequent, and normal ducts were observed in a minority. Among high-risk subjects, most did not require additional radiologic or surgical interventions (85.3 %). Hospital stay duration did not significantly differ by irrigation modality ($P > 0.05$).

Conclusions The high-risk QNI phenotype was associated with greater clinical severity, higher rates of sepsis, and markedly increased hospital stay. ERCP findings—dominated by ductal leaks and disconnections—were comparable between risk groups, suggesting ductal pathology may be independent of QNI stratification. These findings support the utility of QNI scoring in predicting severity and resource utilization and reinforce QNI as a meaningful classification tool for guiding endoscopic management strategies and future comparative effectiveness studies in pancreatic pseudocyst and WON therapy.

PYP071 Cognitive Errors in Endoscopy: The ESGE Cognitive Error Map (ECEM) Model for Reducing Diagnostic Misses and Integrating Human Factors into ESGE Standards

Author Dubrovin V[1]

Institute 1 Saint-Petersburg, Russia

DOI 10.1055/s-0046-1821011

Problem to solve Diagnostic misses remain a major challenge in endoscopy, with European studies reporting that up to 20–25 % of clinically significant lesions may be overlooked, particularly under suboptimal visualization or variable inspection quality. Literature on diagnostic error, cognitive load, and human factors shows that a substantial proportion of mistakes arise from cognitive mechanisms—perceptual failures, attentional lapses, misinterpretation, or flawed decision-making.

Despite ESGE emphasizing human factors, endoscopy lacks a unified conceptual model describing cognitive errors, their manifestations, and mitigation strategies. This represents a clear unmet need.

Innovation We introduce the ESGE Cognitive Error Map (ECEM)- the first comprehensive framework integrating cognitive errors, diagnostic blind spots, and targeted interventions aimed at reducing missed lesions. A structured review (PubMed, Embase, Scopus; 2010–2025) included publications on human factors, diagnostic error in visual specialties, missed lesions (colon, Barrett's, gastroscopy), cognitive load, situational awareness, and error taxonomies from aviation, CRM, and OR safety.

Based on this synthesis, ECEM was constructed as a cognitive-process map with corresponding countermeasures.

The framework also includes a Cognitive Competence Module (CCM) for ESGE training, incorporating:

- video-based error annotation,
- situational awareness training,
- modeling of perceptual pitfalls,
- assessment across four cognitive domains.

The module requires no special hardware and fits existing ESGE pathways.

Results 1. ECEM Taxonomy: Four Domains of Cognitive Errors.

- Perceptual errors – incorrect processing of visual information (satisfaction of search, failure to detect flat/depressed lesions, dynamic view errors).- Attention errors – impaired focus allocation/maintenance due to procedure duration, fatigue, workload, distractions; manifestations

include skip zones, insufficient exposure, accelerated withdrawal.
- Decision-making errors – premature closure and narrow hypotheses leading to misclassification of polyps or underestimation of suspicious areas.
- Situational awareness errors – loss of context or misinterpretation of the scenario, resulting in omission of second-look inspection, incorrect strategy in difficult anatomy, or pathway deviations.

2. ECEM Framework: Three-Level Intervention Model.
Level 1 — Predictive markers of cognitive load: examination time, withdrawal speed, micro-pauses of concentration, corrective motor adjustments.
Level 2 — Structured map of blind spots: anatomical and dynamic blind zones, cognitive blind spots, and error-prone morphologies (flat adenomas, LST, subtle lesions).
Level 3 — Cognitive countermeasures: two-phase inspection (review phase), micro-pausing attention-anchoring technique, "hypothesis switching" for decision-making, and the ECEM cognitive checklist for blind-spot assessment.

Conclusions The ESGE Cognitive Error Map (ECEM) represents the first comprehensive attempt to unify cognitive mechanisms underlying diagnostic misses and to identify clear intervention points.The framework and training module provide a structured pathway for integrating human factors into European endoscopy, aligning with ESGE strategy priorities. ECEM may serve as a basis for future ESGE recommendations aimed at reducing diagnostic variability and improving lesion detection quality.

PYP072 Developing a standardised tool to describe the case difficulty and educational value of individual GI bleeding cases – the S2T2 tool

Authors Hawkes N[1], Davies O[2], Nigam G[3]
Institutes 1 Royal Glamorgan Hospital, Ynysmaerdy, United Kingdom; 2 University Hospital of Wales, Cardiff, United Kingdom; 3 Translational Gastroenterology and Liver Unit, Oxford, United Kingdom
DOI 10.1055/s-0046-1821012

Aims Development of a tool to describe case difficulty and educational value of an individual GI bleeding case to aid setting Certification Standards for GI bleed competence.

Methods Tool development was in 3 phases. Phase 1 -EMS Reporting tool (Medtronic) identified 57 patients referred for upper GI bleed [codes 'malaena', 'haematemesis']. An iterative approach developed a standardised case difficulty scoring system based on domains of case context, endoscopic findings, treatment and outcomes graded against global assessment of case difficulty (easy, moderate, difficult) and educational value (0 = no added value above diagnostic case, 1 = assessment and management advice, no therapy, 2 = assessment, treatment and management). Phase 2 – Putative score applied to a second cohort of 63 patients with adjustment to score weighting across scoring domains to improve alignment with global assessments. Phase 3 – S2T2 tool applied to cases in UK GI bleed database [1] and examined associations with difficulty, EV, clinical outcomes, and existing severity scores.

Results The final S2T2 tool included four domains – SET (Endoscopy outside of Unit); SITE (Bleeding site not visible or difficult to access); TYPE (variceal or non-variceal bleed, with sub-types defined); TREAT (endoscopic treatment required/not required) – matched to global assessment of case difficulty (easy/moderate/difficult) and weighting of educational value for an endoscopic trainee. Total S2T2 score showed a strong correlation between a global rating of difficulty (r = 0.9) and educational level (r = 0.8). 25 % of GI bleed cases provided Level 2 Educational Value. In phase 3, the S2T2 tool was applied to 3,979 cases from the UK GI bleed database: this defined 64 % as technically easy, 24 % of moderate difficulty, and 12 % as difficult. Increasing S2T2 difficulty was associated with higher rates of endoscopic therapy, rebleeding, need for interventional radiology or surgery, longer length of stay and bleed-related mortality. EV increased progressively with higher S2T2 scores: median (IQR) 0 (0–1) for Level 0, 1 (1–2) for Level 1, and 6 (5–8) for Level 2 cases (Kruskal–Wallis $p < 0.001$). In univariable analyses, S2T2 (OR 4.81), GBS (OR 1.08), Pre-Rockall (OR 1.15), and Full Rockall (OR 1.28) were associated with EV. However, in multivariable modelling, only S2T2 remained independently predictive (OR 4.78, 95 % CI 4.37–5.23), while GBS and Pre-Rockall lost significance (▶ **Table 1**). Correlations between S2T2 and clinical severity scores were weak ($p \leq 0.35$), indicating S2T2 captures a distinct dimension of procedural complexity.

▶ **Table 1**

Score	Univariable OR (95 % CI)	p-value	Multivariable OR (95 % CI)	p-value
S2T2	4.81 (4.42–5.23)	<0.001	4.78 (4.37–5.23)	<0.001
GBS	1.08 (1.06–1.09)	<0.001	0.98 (0.96–1.00)	0.104
Pre-Rockall	1.15 (1.12–1.19)	<0.001	0.96 (0.91–1.02)	0.169
Full Rockall	1.28 (1.25–1.32)	<0.001	-	-

Conclusions The S2T2 tool is simple, rapid to apply, and correlates strongly with both case difficulty and EV. It captures aspects of procedural complexity not reflected by existing clinical severity scores and may be valuable for defining training requirements and certification criteria in GI bleeding.

PYP073 Evaluation of the Predictive Validity of an Endoscopic Ultrasound Virtual Reality Simulator for Trainee Endosonographers

Authors Sriranganathan D[1], Marrinan A[1], Affarah L[1], Phillpotts S[1], Johnson G[1], El Menabawey T[1]
Institute 1 University College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1821013

Aims Endoscopic ultrasound (EUS) is a technically demanding procedure requiring the development of advanced endoscopic and ultrasound interpretation skills usually requiring dedicated fellowships to attain procedural competence. Trainees enter fellowships with varying prior experience presenting a challenge to trainers in determining their skill level as they embark on training on patients. Simulation-based training has the potential to accelerate the learning curve. However, to date there is no published evidence on the predictive ability of virtual reality (VR) simulators in determining real-world skillsets. An objective measure of a trainee's technical skill at the start of fellowship would benefit trainers and potentially reduce the risk to patients. We report an evaluation of the predictive validity of endoscopist technical skills on the GI Mentor II EUS simulator (Surgical Science, Sweden) by comparing trainee performance on simulated and real patients.

Methods A prospective observational study was conducted at a tertiary referral centre. Trainee endoscopists attending a nationally accredited basic skills in EUS course underwent a standardised induction on the EUS simulator before

performing supervised EUS examinations on the simulator and then in two real patients. Performance was assessed using a previously validated direct observation of procedural skills (DOPS) form; the TEESAT. Trainees were rated by two trainers on a 1 – 4 Likert from 1 ("achieved without instruction") to 4 ("unable to complete") on 13 anatomical landmarks mandatory for a complete EUS examination. A 1–10 global performance score was also rated. Mean TEESAT scores were compared to evaluate predictive and construct validity and inter-rater reliability.

Results Seven trainees were enrolled (six male; age 30–50 years), most of whom had performed at least 50 EUS procedures. The mean TEESAT score for the 13 landmarks demonstrated excellent predictive validity, with simulator scores strongly correlating with real-patient performance ($\rho = 0.96$, $p = 0.0003$). The simulator demonstrated strong construct validity, with both simulator and patient landmark scores correlating closely with lifetime EUS experience ($\rho -0.90$ to -0.96). Inter-rater reliability ranged from good to excellent (ICC 0.62 overall; improving to 0.91 after exclusion of two outliers). Objective anatomical landmark components of TEESAT showed outstanding validity and acceptable-to-excellent reliability. The global 1–10 assessment showed no predictive validity for real-patient performance (Spearman $\rho = 0.18$, $p = 0.70$).

Conclusions Trainee performance on the GI Mentor II EUS simulator utilising the TEESAT DOPS demonstrates excellent predictive and construct validity. It reliably discriminates skill levels and we would advocate its role in stratifying trainee competence at the outset of fellowships or as a surrogate marker of progress in early EUS training. The global score lacks utility and should be avoided as an assessment measure in this context.

DOI 10.1055/s-0046-1821014

Aims Quality assurance in small-bowel endoscopy is essential to ensure diagnostic accuracy, therapeutic efficacy and patient safety. In this study we aimed to evaluate concordance of data from real-life practice in small bowel endoscopy across Gastroenterology Units in Emilia-Romagna, Italy, with the updated ESGE key performance indicators (KPIs) for device-assisted enteroscopy (DAE) and video capsule endoscopy (VCE). Secondary aims were to describe diagnostic yield, efficacy, safety and organizational factors influencing quality.

Methods This prospective multicenter observational study included ten regional referral centres performing small bowel endoscopy with VCE and/or DAE. Consecutive procedures performed between 10 April and 20 August 2025 were collected. Demographic, clinical, and procedural data were recorded, including diagnostic yield, therapeutic success, complications and adherence to 2025 ESGE key performance indicators (KPIs).

Results A total of 258 VCE procedures were analysed. Indications included iron-deficiency anemia (29.5 %), occult bleeding from small-bowel (25.2 %), overt bleeding from small-bowel (19.3 %) and Crohn disease (17 %). Adequate bowel preparation was achieved in 89.8 % of examinations with a completion rate of 96.5 %. The overall detection rate was 52.7 %, and the clinically significant detection rate was 41.1 %. Capsule retention occurred in three patients (1.16 %) and only required endoscopic retrieval due to an underlying jejunal adenocarcinoma. A total of 65 DAE procedures were analysed. Procedures were anterograde in 77 % and retrograde in 23 %. Repeat procedures accounted for 32.3 %, mainly due to failure to visualize previously detected target lesions. Mean duration was 64 minutes and mean small bowel length explored was 147.7 cm. Technical success was 95.3 %, therapeutic success 72.3 %, and diagnostic yield 69.2 %. Only one complication occurred (1.6 %), consisting of intraprocedural bleeding resolved endoscopically. Indications included VCE-detected lesions (61.5 %), abnormalities on other imaging (15.4 %), polyposis surveillance (6.1 %), suspected Crohn disease (6.1 %), and overt or occult bleeding evaluated directly with DAE (7.7 %). These data were compared to the most recent ESGE quality performance measures. Most key performance indicators were met. Specifically, for VCE, appropriate indication (97.3 %), adequate preparation (95.6 %), completeness (96.5 %), overall and clinically significant detection rates (52.7 % and 41.1 %), and low retention rate (1.16 %) all fulfilled ESGE minimum requirements. For DAE, appropriate indication (96.9 %), adequate preparation (95.2 %), procedural completeness (83.3 %), diagnostic yield (69.2 %), and low complication rate (1.54 %) met ESGE standards. Some KPIs did not achieved the minimum standard, particularly patency capsule use in high-risk patients (90.1 % vs minimum 95 %), timing of VCE for overt bleeding (50 % within 48 hours vs minimum 75 %), and performance of DAE after positive VCE when indicated (41 % vs minimum 75 %). Particularly, even though the minimum ESGE standard was not fulfilled, we performed a subgroup analysis in patients undergoing VCE examination for suspected small bowel overt bleeding. Diagnostic yield in patients undergoing VCE within 48 hours from the last bleeding episode was 76 % while it decreased to 47 % in patients with VCE performed between 48 hours and 14 days and 40 % in the group where VCE was performed after 14 days after the bleeding episode. Although the overall comparison among the three groups showed only a trend toward significance ($p = 0.06$), early VCE performed within 48 hours was significantly superior to delayed examinations (> 48 hours), with a diagnostic yield of 76 % versus 44 % ($p = 0.04$).

Conclusions To our knowledge this is the first prospective study comparing real world-data of small bowel enteroscopy and the latest ESGE quality performance measure. In Emilia-Romagna the endoscopic approach to small bowel pathology demonstrates high diagnostic yield, excellent safety, and strong adherence to ESGE performance standards for both DAE and VCE. Strengths include appropriate indications, high completeness rates, adequate bowel preparation, and very low complication rates. The findings support the clinical value of early VCE in overt bleeding and emphasize the importance of optimized diagnostic pathways and closer coordination between VCE and DAE to strengthen consistency and quality.

PYP075 How are polyps removed in clinical practice? A comparison to ESGE polypectomy guidelines

Authors Broder E[1], Besherdas K[2]

Institutes **1** Royal Free Hospital, London, United Kingdom; **2** Royal Free Hospital, London, United Kingdom, United Kingdom

DOI 10.1055/s-0046-1821015

Aims This study aimed to assess the current practice in our institution in terms of polypectomy technique across all polyp sizes and histological subtypes in comparison to the ESGE standards.

Methods A single centre, retrospective analysis of 100 consecutive patients who have had polypectomies done for polyps of any size from April 2024 at a hospital in North London was undertaken. The data was collected using the Medilogic endoscopy reporting tool, and the electronic patients record. The technique used for polypectomy, along with the type of polyp at histology retrieved, was scrutinized and compared with compliance of ESGE guidance on polypectomy technique.

Results A total of 177 polypectomies from 100 patients were analysed. 101 polypectomies (57 %) followed ESGE recommendations and 76 polypectomies (43 %) did not. The 76 non-compliant polypectomies used methods including cold biopsy, hot snare for polyps under 10mm, hot EMR for polyps under 20mm and hot EMR for SSLs (▶ **Table 1**).

▶ **Table 1**

Polypectomy method compliant with ESGE		**Polypectomy method non-compliant with ESGE**	
Cold snare or cold EMR for all SSL	13	Hot EMR for SSL	4
Cold snare or cold EMR < 10mm	79	Cold snare or cold EMR > 10mm	12
Hot EMR > 20mm	26	Hot EMR < 20mm	12
ESD	3	Hot snare < 10mm	3
		Cold biopsy	25
Total in line with ESGE:	**121 (68 %)**	**Total not in line with ESGE:**	**56 (32 %)**

Conclusions The polypectomy technique used by endoscopists depends on multiple factors including anticipated histological subtype (eg Paris and Kudo pitt pattern), estimated polyp size and location within the colon. The latest European Society of Gastrointestinal Endoscopy (ESGE) guidelines recommend the most suitable methods which minimise risk of post-procedural bleeding and perforation, whilst ensuring cost-effectiveness. ESGE recommends avoiding cold biopsy due to its high rate of incomplete resection. ESGE also recommends cold snare polypectomy for removal of nonpedunculated adenomatous polyps under 10mm and hot snare with or without endoscopic mucosal resection (EMR) for polyps over 10mm. In addition, ESGE recommends cold snare or cold EMR for sessile serrated lesions (SSL) of all sizes, as well as consideration of endoscopic submucosal dissection (ESD) for certain polyps over 20mm.

This study shows poor adherence to the ESGE guidelines in our department with regards to colorectal polypectomies, with only two-thirds of polypectomies adhering to the recommended techniques. A third of polypectomies undertaken were not in line with ESGE recommendations (56/177 – 32 %), of these 16/56 (34 %) polypectomies involved inappropriate diathermy use which could have led to increased risk of complications such as post-polypectomy bleeding and perforation. A significant number of polyps are removed by the cold biopsy technique (25/177 – 14 %) which is not advocated due to a higher risk of local recurrence. We recommend better dissemination and implementation of the ESGE guidelines to enhance clinical practice with regards to polypectomy techniques.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP076 Implementation of the "Endoscopy Step-up Protocol" with Google Forms: An Educational System Integrating Objective Assessment and Trainee Competency

Authors Miyauchi H[1], Minato Y[1], Sawada T[1], Yamabe E[1], Kohari K[1], Kurebayashi H[1], Sawada R[1], Sato Y[1], Kanamori M[1], Banjoya S[1], Kimura T[1], Furuta K[1], Yamazaki H[1], Takeuchi N[1], Ohata K[1]

Institute 1 NTT Medical Center Tokyo, Tokyo, Japan

DOI 10.1055/s-0046-1821016

Aims The acquisition of endoscopic skills is still a significant challenge for many institutions. Even within a single institution, the training often relies on the subjective judgments of individual trainers. In Japan, physicians complete a two-year junior residency followed by a three-year senior residency before specializing in gastroenterology, and they enter endoscopy programs with heterogeneous backgrounds and varying levels of experience. This highlights the need for an objective, competency-based framework that enables stepwise and individualized instruction. To address these issues, we developed and implemented the "Endoscopy Step-Up Protocol," which incorporates both quantitative and qualitative performance metrics to facilitate structured skill acquisition.

Methods The protocol consists of six upper gastrointestinal (UGI) and five lower gastrointestinal (LGI) stepwise levels, toward independently performing general examinations, integrating both quantitative and qualitative assessments. Certain steps may be waived depending on the trainee's demonstrated competency. For the quantitative assessment, predefined target numbers were set for each step, including total endoscopy volume as well as the numbers of biopsies and Cold Snare Polypectomies. For the qualitative assessment, six UGI metrics (pharyngeal intubation, mucosal cleansing, scope manipulation, endoscopic imaging quality, patient discomfort, and examination time) and five LGI metrics (cecal intubation rate, mean insertion time, mean examination time, adenoma detection rate, and success rate of using shaft retention and shortening method) are evaluated. Trainers score each item using a three-point scale (0 = Poor, 1 = Average, 2 = Excellent), and feedback is recorded via Google Forms.

The study included eight trainees who participated in the protocol between April 2024 and September 2025 (one junior resident, three senior residents, and four post-residency doctors). A prospective observational evaluation was conducted to assess their training performance in UGI and LGI endoscopy. In addition, structured questionnaire surveys were administered to all eight trainees and six trainers.

Results For UGI endoscopy, the junior resident (n = 1) progressed from Step 1 (observation/lectures/model-based practice) to Step 2 (sedated examinations from intubation to full observation) within one month. Senior residents (n = 3) advanced from Step 1 to Step 6 (independent routine examinations) in a mean of 5.3 months. All post-residency doctors (n = 4), who had prior experience of endoscopy, skipped Steps 1-2 and started from Step 3 (sedated examinations), reaching Step 6 in a mean of 3.1 months. For LGI endoscopy, senior residents (n = 3) progressed from Step 1 (observation/lectures/model training) to Step 3 (sedated examinations) in a mean of 6.0 months. Post-residency doctors (n = 4) also advanced directly to Step 3 and reached Step 5 (independent routine colonoscopy) in an average of 7.3 months.

Survey results indicated full satisfaction among all trainees (100 %, 8/8). Trainees reported that the structured stepwise system clarified training goals, improved self-assessment of technical weaknesses, and enhanced motivation. All trainers (6/6, 100 %) observed improvement in trainee skills. Trainer workload was rated as "increased" by 1/6 (17 %) and "unchanged" by 5/6 (83 %), suggesting that standardized scoring and feedback did not substantially increase supervisory burden.

Conclusions The "Endoscopy Step-Up Protocol" provides a clear, objective, and competency-based framework for endoscopy training. By integrating both quantitative and qualitative assessments, the system enables personalized and

Endoscopy 2026; 58: S1–S1041

level-appropriate instruction, and helps maintain well-defined learning goals. The use of Google Forms enables rapid feedback, consistent documentation, and efficient communication between trainees and trainers. This protocol demonstrated feasibility, improved competency acquisition, and was well received by both groups. It may represent a practical and scalable approach for standardizing endoscopy training across institutions.

DOI 10.1055/s-0046-1821017

Aims Endoscopy-related musculoskeletal injuries are often recognized in diagnostic and interventional endocopists, due to repetitive work, prolonged postures and the application of localised high forces. To reduce risk for injuries muscular overuse should be consequently avoided. No data exist on changes in muscular strength throughout the working day. Aim of the study was to determine the effect of muscular fatigue in endoscopist working at high volume centers.

Methods Muscular strength was measured in endoscopists (n = 9; m/f), working in different high volume centers (n = 3), by repetitive force measurement using a medical dynamometer, over 7 working days. Individual strength of both arms (r;l) was documented before and after examinations throughout working day (lb). Difference in muscular strength was analysed. Muscular complaints, affected bodyparts, perceived exertion were recorded

Results Muscular force decreased significantly in all subjects, regardless sex, type of performed examinations (mean 113.1 ± 7.8 vs. 98.4 ± 9.9). Longer and complex examinations decreased the muscular strength more significantly than shorter ones. ERCP revealed highest decrease in muscular force among participants. Muscular complaints of participants revealed worsening within the working day.

Conclusions Data from this study reveal that repetitive endoscopic performance is associated with relevant decrease of muscular strength. This implicates that regular breaks are mandatory for muscular recovery to avoid injuries in endoscopists.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP078 Assesment of perfomance and skills in biliary cannulation of experts and non-experts with novel Mikoto model simulator for training in endoscopic retrograde cholangiopancreatography

DOI 10.1055/s-0046-1821018

Problem to solve Endoscopic retrograde cholangiopancreatography (ERCP) is a highly specialized and technically demanding endoscopic procedure requiring advanced cognitive and manual skills. Due to its complexity, limited procedural exposure and concentration of expertise within tertiary centers, structured and safe training opportunities are essential. Simulation-based education has been increasingly recognized as an effective strategy to bridge the training gap, allowing skill acquisition without compromising safety. While several mechanical, animal and computer-based simulators have been validated for luminal endoscopy, ERCP-specific simulators remain few. Recently, the Mikoto simulator series, a line of high-fidelity silicone-based models featuring integrated automated performance assessment, has been introduced. This exploratory study aimed to evaluate the construct validity of the novel Mikoto ERCP Simulator by comparing the performance of expert and non-experts.

Innovation The study was conducted during the 8th Educational Meeting of the Lombardy Section of the Italian Society of Digestive Endoscopy (SIED). Twenty-two endoscopists (11 experts and 11 non-experts) performed simulated ERCP procedures using the Mikoto ERCP Simulator (R Zero Inc., Japan, distributed by Fujifilm, Tokyo, Japan). The model provides realistic anatomical representation of the upper gastrointestinal tract, including interchangeable papilla of Vater modules and automatically records multiple performance metrics such pharyngeal pressure, the time to reach the subsequent anatomical segment, biliary cannulation time and procedural scores. Each endoscopist had 10 minutes to achieve deep biliary cannulation. Experts were defined as operators with > 250 ERCPs performed, whereas non-experts were trainees competent in reaching the second duodenal portion (D2) and attempting cannulation. Primary outcomes were the simulator's ability to differentiate experts from non-experts in biliary cannulation rate, cannulation time, total score (0–100) and total procedure time. Secondary outcomes included subgroup comparisons of pharyngeal passage time and pressure, time and score to reach D2 and changes in repeated performance attempts. Perceived realism was rated on a 5-point Likert scale.

Results Experts (mean age 46 ± 6.7 yrs, 11 M) and non-experts (median age 32 ± 3.8 years, 6 M, 4 residents) demonstrated distinct performance profiles. Biliary cannulation was achieved by 91 % of experts versus 64 % of non-experts (p = 0.15). Among successful cannulations, the median cannulation time was shorter for experts compared with non-experts (76s, IQR 53–172 vs 89s, IQR 79–231,p = 0.07), even if not statistically significant. Experts completed the overall procedure faster (142s, IQR 102–257 vs 492s, IQR 158–600; p = 0.04) and achieved higher total scores (96/100, IQR 88.5–98.5 vs 82/100, IQR 61.5–91.5; p = 0.02). During the pharyngeal phase, no significant differences were noted in time or pressure; however, experts achieved significantly higher pharyngeal pressure control scores (median 10/10 vs 7/10; p = 0.02). Time to reach D2 and corresponding score both favoured experts (median 35 vs 85s,p = 0.014; mean D2 score 19.9 ± 7.07 vs 16.5 ± 10.6, p = 0.01). Table 1 synthetise differences between experts and non-experts. Among the five participants (four experts) who repeated simulations, sequential improvements in total time and total score were observed and confirmed by Wilcoxon signed-rank tests (p = 0.002;p = 0.003,respectively),suggesting a measurable learning effect. Overall, participants rated the simulator's realism highly, with a mean fidelity score of 4/5 ("very good"), particularly commending the accuracy of the pharyngeal passage simulation.

Conclusions This study shows that the Mikoto ERCP Simulator reliably distinguishes between expert and non-expert operators, reinforcing its construct validity as a training modality. Its automated scoring and detailed performance analytics offer clear advantages by supporting objective self-assessment and promoting individualized, self-directed learning. The simulator also highlights procedural steps with the largest performance gaps, helping educators target training more effectively. These results justify future, larger studies to confirm validity across additional performance domains and to clarify the simulator's place within structured ERCP curricula. Overall, the Mikoto platform appears to be a high-fidelity, data-driven supplement to traditional ERCP education, providing a safe, reproducible and efficient setting for training

PYP079 Development of a Digital ERCP Quality Assessment Tool: A Modern Approach to Tracking Procedural Competence

Authors Erhart L[1, 2], Maieron A[3, 2]
Institutes 1 University Hospital St. Pölten, Sankt Pölten, Austria; 2 Karl Landsteiner University of Health Sciences, Krems an der Donau, Austria; 3 Universitätsklinikum St. Pölten Haus M, Sankt Pölten, Austria
DOI 10.1055/s-0046-1821019

Aims ERCP is an advanced interventional technique requiring structured training. Moreover, the delicacy of the procedure with ensuing high risk of complications makes continuous quality control a necessity. Validated assessment and performance measures guide competency, with the ESGE Quality Improvement Initiative explicitly recommending implementation of these measures to identify services and individual endoscopists with lower performance levels. Additionally, trainees are recommended to keep a contemporaneous logbook of their procedures. Performance targets are published both for learners and practicing interventionists. Yet at present, there is no easily accessible tool for real-time data tracking and analysis. The objective was to design an open, digital tool for procedural logging, performance tracking, and competency assessment in line with published ERCP performance indicators. Special focus was put on providing real-time visualizations and analytics at the point-of-care to provide interventionists with immediate feedback.

Methods An online platform for point-of-care input and visualization of ERCP training data was created. Fields were adapted from performance measures published by ESGE. Anonymized patient characteristics, indications, success measures, and complications were included to calculate key performance indicators (bile duct cannulation rate, appropriate stent placement in patients with biliary obstruction below the hilum, bile duct stone extraction, post-ERCP pancreatitis). For complexity assessment, the modified Schutz score as well as the SASE and H.O.U.S.E. grading systems were used. A mobile client and a dashboard were implemented for rapid onsite data collection and accessible statistics visualization. Functionality was provided to build teams of interventionists for evaluation at endoscopy unit level. Online access was protected and server communication was encrypted. Rolling personal performance as well as minimum and target standards were visualized in a graphical dashboard with graphs that were generated in real-time to provide actionable insights on learning progress and quality assessment. Team performance was displayed to gauge relative performance. Excel export functionality was added to allow for data sharing of a personal logbook [1–7].

Results As proof-of-concept, the individual learning experience of a first-time ERCP trainee at a tertiary care facility was tracked. All 127 procedures performed over the course of 14 months were entered into the tool. Most ERCPs were done for ASA 2 patients (91/127; 71.7 %); SASE success probability grading was "high" for the majority of interventions (90/127; 70.9 %). Virgin papilla (48 % of procedures) rolling intubation rate showed a clear upward trend for later cases (first to last quarter: 41.7 %, 56.5 %, 65.9 %, 72.0 %), as did rolling stone clearance rate (85.7 %, 94.7 %, 97.1 %, 100.0 %). Stenting was successful in all cases with subhilar obstruction (100.0 %). Overall (0.8 %) and virgin papilla post-ERCP pancreatitis rates (1.6 %) at the end of the logging period were in line with quality recommendations. The tool was effective in enabling real-time, granular tracking of technical skills and identifying learning gaps (e.g., lower stone extraction scores in early cases).

Conclusions The proof-of-concept tool enhanced training by combining structured assessment with real-time outcome tracking and visualized feedback. It shows potential to improve competency evaluation and reduce learning curve variability for complex endoscopic procedures. Additionally, it allows for up-to-date transparency about interventionists' performance and development regarding quality targets. This feedback is vital for both the individual interventionist as well as endoscopy units, as transparency about performance is an indispensable prerequisite for accountability. A future opportunity is to evolve the self-assessment platform into an open, ESGE-approved quality management instrument with trend analysis and learning curve visualization for ERCP trainees as well as experienced interventionists. A summative report by the tool could form the basis for commencing independent practice for trainees by providing robust and standardized evidence of procedure volume and competence. Likewise, yearly quality report cards produced by the tool could provide certification of skill levels for experienced endoscopists and service unit teams.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP080 Stress to Success: Evaluating the Impact of a Structured Haemostasis course on delegates' confidence and resilience; A Prospective Pre-Post Course Analysis

Authors Ogbechie C[1], Nishad N[2], Ching HL[2], Thoufeeq M[2]
Institutes 1 East & North Hertfordshire NHS Trust, Stevenage, United Kingdom; 2 Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom
DOI 10.1055/s-0046-1821020

Aims To evaluate the role of the Sheffield Teaching Hospital Haemostasis course in improving delegates' confidence, knowledge and resilience when performing Upper Gastrointestinal Endoscopy.

Methods Participants who enrolled on the one-day Haemostasis Course at Sheffield Teaching Hospital between November 2021 and September 2024 were invited to fill pre-course and post-course questionnaires. Consent was obtained for the anonymous use of data in this research. This was a simulated clinical environment combining case-based lectures with practical training using synthetic and porcine models facilitated by experienced consultants and representatives from the Endoscopy industry. Five point Likert Scale questionnaires were used to assess domains covering practical skills (adrenaline injections, clip placement, variceal, non-variceal haemostasis and Bentonite haemostatic agent use), operator confidence (mental preparedness, satisfaction, frustration) and psychomotor skills. Participant responses were manually matched and Paired-Sample T-Tests were conducted in SPSS version 20 to determine the presence of any statistically significant improvement across the domains.

Results After matching the data, 78 participants, comprising gastroenterology trainees (73.1 %), consultant gastroenterologists (12.8 %), surgical consultants (3.8 %) endoscopy nurses (3.8 %), nurse endoscopists (2.6 %) and non-training grades (3.8 %) were identified. Of these, 64 % were currently or imminently participating in an on-call "Bleeds Rota". Significant improvements were ob-

Endoscopy 2026; 58: S1–S1041

served across most technical and confidence domains after the Haemostasis course. Mean scores for overall endoscopic technical skill increased from 3.08 to 4.06 ($p < 0.001$: 95 % CI -1.19, -0.79), confidence in clip application rose from 2.41 to 3.83 ($p < 0.001$: CI -1.61, -1.23); variceal and non-variceal haemostasis skills improved from 2.47 and 2.45 to 3.83 and 3.87 ($p < 0.001$) respectively. Bentonite haemostatic agent handling improved markedly from 2.49 to 4.08 ($p < 0.001$: CI -1.79, -1.39). Participants' perceived frustration reduced significantly (mean 4.92 to 3.22, $p < 0.001$), while satisfaction increased (5.26 to 7.65, $p < 0.001$). Mental and physical strain scores also decreased post-course (7.36 to 5.90 and 6.82 to 5.40 respectively, $p < 0.001$). "Slickness of performance" demonstrated a non-significant change (5.49 to 4.92 post course; $p = 0.156$), signifying the potential need for extended practical sessions to refine fluency. Experience profiles of the delegates showed that most had a limited lifetime exposure to therapeutic procedures — 43.6 % had performed 1–9 adrenaline infiltrations, 53.8 % had placed 1–10 clips, and 55.1 % had used thermal therapy fewer than 10 times.

Conclusions The Sheffield Haemostasis Endoscopy course significantly enhanced participants' confidence, resilience, technical skills and satisfaction while simultaneously reducing frustration and perceived workload. These findings support the course's effectiveness and highlight the value of structured, simulation-based learning for safe and competent management of Upper Gastrointestinal Bleeding.

Abstract Text

A 70-year-old woman with autoimmune gastritis was referred for an 8-mm subepithelial lesion. Staging EUS identified a potential T1 type 1 gastric neuroendocrine tumor (NET) without nodal metastases. During endoscopic resection with multipoint elastic traction, a muscle-retracting sign (MRS) with the lesion adherent to the oblique muscularis propria was observed. Gastric endoscopic intermuscular dissection (EID) was performed en bloc. Histopathology showed R0 resection of a pT2, well-differentiated NET G2, without lymphovascular invasion. Another G1 NET was identified in a lateral margin. The multidisciplinary team and the patient opted for endoscopic and imaging follow-up due to comorbidities and surgical risk. To our knowledge, this is the first report of a gastric muscle-retracting sign and the second report of gastric EID.

PYP082 External Validation and Comparison of the W-eCura and eCura Scoring Systems for Predicting Lymph Node Metastasis After Non-Curative Endoscopic Submucosal Dissection in Early Gastric Cancer: A Retrospective Cohort Study in Korea

Authors Huynh B[1], Lee S[2], Chang J[2]
Institutes **1** University Medical Center HCMC, Ho Chi Minh City, Vietnam; **2** Yonsei, seoul, Republic of Korea
DOI 10.1055/s-0046-1821022

Aims This study aimed to externally validate both the eCura and W-eCura systems in an independent tertiary hospital cohort in South Korea and to compare their discriminatory performances [1–8]

Methods We conducted a retrospective validation study using prospectively collected data from **740 patients** who underwent non-curative ESD for EGC followed by gastrectomy at Severance Hospital, South Korea, between 2013 and 2024. LNM confirmed by postoperative pathology was used as the reference outcome. Predictive performance was evaluated using calibration (calibration-in-the-large [CITL], calibration slope, and observed-to-expected [O:E] ratio), discrimination (C-statistic), and overall model fit (Nagelkerke R^2 and Brier score). The C-statistics of both models were compared using DeLong's test for correlated ROC curves.

Results Among 740 eligible patients, **40** were found to have LNM. The W-eCura model demonstrated good calibration, with a CITL of –0.005 (95 % confidence interval [CI], –0.349 to 0.306), an O:E ratio of 1.00 (95 % CI, 0.73 to 1.36), and a calibration slope of 0.991 (95 % CI, 0.596 to 1.499). Overall model fit was acceptable (Nagelkerke $R^2 = 0.294$; 95 % CI, 0.127–0.544), and prediction error was low (Brier score = 0.056; 95 % CI, 0.042 to 0.072). The discrimination ability was good, with a C-statistic of 0.764 (95 % CI, 0.696 to 0.833). When compared using DeLong's test, the AUCs of the eCura and W-eCura systems (0.751 vs. 0.764) showed no significant difference ($P = 0.28$).

Conclusions The W-eCura score maintained good discrimination and calibration in this external validation cohort of 740 Korean patients, with predictive performance comparable to the original eCura model. These results support the generalizability of the W-eCura system for assessing LNM risk after non-curative ESD in real-world practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Problem to solve Gastrointestinal stromal tumours (GISTs) are the most common mesenchymal neoplasms of the gastrointestinal tract. In recent years, endoscopic therapy has emerged as a key complement to surgery, particularly for gastric GISTs confined to the superficial layers of the gastric wall and exhibiting predominantly endoluminal growth. Endoscopic resection offers significant advantages, including organ preservation, reduced length of hospital stay, and improved cost-effectiveness. However, adequate exposure of the submucosal space remains challenging. Unlike surgical interventions, where independent traction and counter-traction facilitate dissection, conventional endoscopy is largely limited to axial force transmission. Gravity often works against the operator; once the incision is made, the lesion may collapse into the field of view and obscure the dissection line. Several strategies have been proposed to overcome these limitations. Among them, the double-clip-and-rubber-band technique has been developed as an internal traction system that provides stable, directional traction on the lesion, but it has been applied mainly in colorectal endoscopic submucosal dissection series [1–3].

Innovation We describe a novel application of the double-clip-and-rubber-band traction technique to facilitate endoscopic resection of gastric GISTs. The tumour insertion on its layer of origin is approached through circumferential submucosal dissection. A first clip grasping a rubber band is anchored to the tumour edge. The rubber band is then grasped with a second clip, which is deployed on the opposite gastric wall. With this method, the traction force can be modulated by adjusting the distance between the two clips, which directly determines the elastic tension applied. This technique allows optimal and constant exposure of the submucosal layer for GISTs confined to the submucosa, and of the muscular insertion site for GISTs arising from the muscularis propria. At the end of the procedure, the clip attached to the contralateral gastric wall is removed using biopsy forceps.

Results This technique was successfully applied in three consecutive patients with gastric GISTs arising from the submucosa or muscularis propria, with a mean lesion size of 26 mm. En bloc resection was achieved in 100 % of cases. The elastic traction created by the rubber band provided optimal visualisation of the serosal layer, helping to prevent inadvertent injury to surrounding extra-gastric structures. All procedures were performed with a GIF-EZ1500 gastroscope (Olympus, Tokyo, Japan) and a monopolar endoscopic knife (Gold Knife 4-mm T-type, Micro-Tech, Nanjing, China). Mean procedure time was 88 minutes (from the initial mucosal incision to placement of the final clip). No intraoperative complications occurred. Gastric wall defects were successfully closed with through-the-scope clips when the defect was limited to the muscularis propria and with over-the-scope clips when full-thickness resection was performed. Patients resumed oral intake on postoperative day 2 and were discharged after a mean of 5 days. Histopathological examination confirmed GIST in all cases, with negative resection margins (R0). No recurrence was observed at 6-month follow-up.

Conclusions The application of the double-clip-and-rubber-band traction technique to the endoscopic treatment of gastric GISTs proved to be a safe and effective adjunct, facilitating exposure of the dissection plane and enabling reliable en bloc resection. In our experience, this traction strategy optimised procedural control without increasing adverse events, supporting its role as a valuable tool in the endoscopic management of appropriately selected gastric GISTs.

Abstract Text

Closing mucosal defects after endoscopic submucosal dissection (ESD) reduces delayed bleeding, but large gastric defects are difficult close with conventional clips that lack sufficient opening width and traction. The Dual-Action Tissue (DAT) clip, with two independently controlled arms, enables sequential edge capture and controlled approximation before reinforcement with standard clips. We report two gastric ESD cases in which the DAT clips achieved effective closure. In Case 1 (32 × 31 mm specimen) a single 15-mm DAT clip plus three conventional clips secured the defect. In Case 2 (31 × 30 mm specimen, fibrotic) one DAT clip plus four standard clips achieved full closure. Deployment was easy, with no device-related adverse events. Both patients recovered uneventfully. The DAT clip appears valuable for closure of large ESD defects.

DOI 10.1055/s-0046-1821025

Aims Capnoperitoneum may occur during gastric endoscopic submucosal dissection (ESD) due to type IV deep mural injury when resecting mucosal le-

sions, or during exposing endoscopic full-thickness resection (e-EFTR) for subepithelial lesions (SELs). In some cases, it may progress to tension capnoperitoneum, resulting in gastric lumen collapse, respiratory compromise, or haemodynamic instability. Prompt recognition and effective decompression are essential for safe endoscopic practice. We report outcomes of a standardised protocol for the management of significant capnoperitoneum.

Methods We performed a retrospective analysis of a prospectively maintained database of consecutive gastric endoscopic resections undertaken at a tertiary referral centre between November 2016 and November 2025. All procedures were performed under general anaesthesia with endotracheal intubation, and with continuous monitoring of end-tidal CO_2, ventilation pressures, and abdominal distension. Significant capnoperitoneum was managed using a standardised protocol involving left upper quadrant percutaneous needle decompression, endoscopic clip closure of the muscle defect, and reinflation of the stomach to perform a leak test. Bubbling through an attached water-filled syringe catheter indicated residual leakage, and prompted careful re-assessment to identify and close full thickness muscular injury. After a negative leak test, a 14-French nasogastric tube was placed on free drainage.

Results Among 354 gastric endoscopic resections, 14 patients (4.0 %) required needle decompression for significant capnoperitoneum (9/252 mucosal lesions, 5/102 SELs). Median age was 72 years (IQR 63–77), 57 % were female, and median lesion size was 32.5 mm (IQR 20–50). R0 resection was achieved in 12/14 (86 %). Median full-thickness defect size was 10 mm (IQR 8–12.5) with e-EFTR and 3 mm (IQR 2–7) with ESD. Complete endoscopic closure was achieved in all cases using a median of 5 clips (IQR: 4-6) in the ESD group and 10 clips (IQR: 8-11.5) in the e-EFTR group, with negative leak testing confirmed in every case. Post-procedure CT imaging was performed in 3/14 patients (21.4 %) for abdominal pain, demonstrating expected capnoperitoneum without contrast leak. One patient (7 %) developed transient fevers managed with antibiotics alone, and one (7 %) required patient-controlled analgesia.

Clear fluids and solid diet were resumed at a median of 1 days (IQR 1–2) and 3 days (IQR 2.5–3.5), respectively. The NG tube was removed after a median of 2 days (IQR: 1-3). Median length of stay was 3 days (IQR 2.5–3.5). No surgical intervention was required, and there were no long-term sequelae or mortality. Readmission rate was zero.

Conclusions Full-thickness defects with tension capnoperitoneum during gastric ESD or e-EFTR can be safely managed using a standardised protocol incorporating needle decompression, endoscopic closure and confirmatory leak testing. This approach achieved 100 % technical success with no surgical rescue, rapid diet advancement, and short inpatient stay. Our findings support routine integration of this protocol into advanced gastric endoscopic resection practice.

DOI 10.1055/s-0046-1821026

Aims Gastric neoplasms (GNs) occur in approximately 10–30 % of patients with familial adenomatous polyposis (FAP). While several recent studies have demonstrated the benefits of intensive endoscopic interventions for colorectal and duodenal lesions in FAP [1, 2], evidence regarding such strategies for GNs remains scarce. Moreover, there are no established guidelines for endoscopic management of FAP-associated GNs, and the most appropriate resection method has yet to be defined. Recently, gel immersion endoscopic mucosal resection (GI-EMR) using Viscoclear (Otsuka Pharmaceutical Factory, Tokushima, Japan), an endoscopic field-of-view securing gel, has been reported [3]. This method provides a clear field of view even in the presence of residue or mucus, allowing for accurate resection under direct visualization while maintaining the simplicity of underwater EMR (UEMR). A previous report demonstrated that GI-EMR in the duodenum reduced procedure time and increased R0 resection rates compared with UEMR [4], suggesting potential advantages for gastric lesions as well. A previous report suggested the effectiveness of GI-EMR for GNs in patients with FAP [5], indicating its potential as an endoscopic therapeutic intervention for such lesions. However, no previous studies have evaluated treatment outcomes of GI-EMR for GNs in patients with FAP. This study aimed to evaluate the effectiveness of GI-EMR for GNs in patients with FAP compared with conventional resection methods.

Methods This was a multicenter, retrospective, observational study of patients with FAP who underwent endoscopic resection for GNs between April 2011 and November 2024. Currently, there is no established consensus on the optimal resection method for FAP-associated GNs. In this study, ESD, which has been mainly performed for sporadic GNs (even those measuring ≤ 20 mm), was tentatively adopted as the standard treatment for FAP-associated GNs. Using this provisional standard as a basis, we conducted a comparative analysis with the newly developed GI-EMR technique. To compare treatment outcomes between GI-EMR and ESD, we identified cases of GNs measuring ≤ 20 mm in diameter, with protruding or flat elevated morphologies, which were indications for GI-EMR at our institutions, from patients who underwent endoscopic resection during the study period. In the GI-EMR procedure, the gel was injected into the stomach through the accessory channel using a syringe and the BioShield irrigator (U.S. Endoscopy). The lesion was then carefully captured with a snare and resected using a blended cut current setting (Endocut Q; effect 3, time interval 2, time duration 2).

Results A total of 27 GNs (seven patients) ≤ 20 mm in size with flat elevated or protruding morphology, in which ESD or GI-EMR was performed, were analyzed, consisting of 15 ESD and 12 GI-EMR cases. The median lesion size did not differ significantly between groups (10 mm vs. 11.5 mm, respectively, $P = 0.30$). En bloc resection rates were 100 % in both groups, while R0 resection rates were 100 % for ESD and 83.3 % for GI-EMR ($P = 0.19$). The median procedure time was significantly shorter in the GI-EMR group compared with the ESD group (2 min vs. 47 min, $P < 0.001$). Intraoperative perforation occurred in one ESD case (6.7 %), but was not observed in the GI-EMR group. No delayed bleeding or perforation was reported in either group. During a median follow-up of 22.3 months, no local recurrence was observed in either group.

Conclusions GI-EMR appears to be a safe and effective treatment option for GNs in patients with FAP. Although GI-EMR may be less invasive compared to ESD, the limited number of cases warrants additional studies to substantiate its safety and effectiveness.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821027

Aims Recently, the proportion of *H. pylori*-positive patients has gradually decreased due to the widespread use of *H. pylori* eradication therapy; consequently, the incidence of *H.pylori*-uninfected gastric epithelial neoplasms (HpUGENs) has been gradually increasing in East Asia. Among these HpUGENs, gastric foveolar-type adenoma with a raspberry-like appearance (GFA-R), which presents as a strongly reddish, nodular or granular elevated lesion, represents one of the lesions most frequently encountered in routine clinical practice and has garnered increasing attention. In the latest WHO classification, it has been newly defined as a foveolar-type adenoma. Although its current prevalence in Western countries appears to be relatively low, it is expected to become a clinically significant entity in these regions in the foreseeable future. However, endoscopic treatment strategy for GFA-R has not yet been established. We aimed to clarify the efficacy and safety of endoscopic procedures (cold forceps polypectomy (CFP), cold snare polypectomy (CSP), and endoscopic mucosal resection (EMR)) for GFA-R.

Methods We retrospectively analyzed 88 raspberry-like lesions in 74 patients that were endoscopically treated at our institution between January 2009 and December 2023 and were pathologically diagnosed as foveolar-type adenoma in accordance with the WHO classification. The clinicopathological characteristics , endoscopic characteristics, and treatment outcomes of GFA-R were evaluated retrospectively.

Results The median age was 56 years (range, 29–85 years), and the male to female ratio was 49:25. Proton pump inhibitor or potassium-competitive acid blocker use was observed in 16 of 74 patients (21.6 %), smoking history in 32/74 (43.2 %), and alcohol history in 30/74 (40.5 %). Regarding the lesion location, GFA-Rs occurred mostly in the greater curvature of the upper and middle third of the stomach. The median tumor size was 4.0 mm (range, 1–10 mm). Endoscopic procedures consisted of biopsy alone (n = 6), CFP; n = 42, outpatient/inpatient: 38/4, CSP; n = 4, 1/3, and EMR; n = 36, 0/36. The overall en bloc resection rate was 94.3 % (83/88): 90.4 % in CFP (38/42), 75.0 % in CSP (3/4), and 97.2 % in EMR (35/36). Lesions smaller than 5 mm were mainly treated with CFP (34/58), whereas lesions ≥ 5 mm were mainly treated with EMR (20/30). Histologically, all lesions were intramucosal neoplasms without lymphovascular invasion. The curative resection rate was 97.7 % (86/88). In two lesions, the horizontal and vertical margins were histologically indeterminate; however, no residual tumor was detected endoscopically. No intraoperative or delayed complications, such as bleeding or perforation, occurred with any procedure. The mean follow-up period after treatment was 28.7 months (range, 2–165 months), and no local recurrences were observed endoscopically at 1 year (n = 62), 2 years (n = 40), or 3 years (n = 24) after endoscopic treatment, including in cases with piecemeal resection or indeterminate margins.

Conclusions In this series of 88 GFA-R lesions, the efficacy and safety of endoscopic procedures for GFA-R may be confirmed regardless of procedure method. Moreover, outpatient CFP might have proven to be a simple, useful, and economical endoscopic procedure for GFA-R of smaller than 5 mm.

PYP088 Delayed bleeding prevention using non-coagulation clipping after gastric endoscopic submucosal dissection

Authors Obata R[1], Dohi O[1], Uehara T[1], Yumoto J[1], Ochiai T[1], Mukai H[1], Seya M[1], Yasuda T[1], Iwai N[1], Reo K[1], Inoue K[1], Yoshida N[1], Uchiyama K[1], Takagi T[1]

Institute **1** Molecular Gastroenterology and Hepatology, Kyoto Prefectural University of Medicine, Kyoto, Japan

DOI 10.1055/s-0046-1821028

Aims Delayed bleeding (DB) is the common adverse event after gastric endoscopic submucosal dissection (ESD), and post-ESD electrocoagulation (PEC) is widely performed as a prophylactic hemostasis to prevent DB. On the other hand, we occasionally encounter post-ESD electrocoagulation syndrome (PECS), characterized by abdominal pain, fever without perforation. PECS is expected to be caused by thermal tissue damage and known as a general adverse event in esophagus and colorectal ESD. However, it is also recently reported in gastric ESD cases. To reduce thermal damage, we underwent a non-coagulation clipping (NCC) as a prophylactic hemostasis that is only mechanical clipping to all exposed vessels without electrocoagulation. This study aimed to evaluate the safety and efficacy of NCC compared with conventional PEC, focusing on DB, postoperative inflammatory response, and incidence of PECS.

Methods This retrospective observational study was conducted consecutive patients who underwent gastric ESD at Kyoto Prefectural University of Medicine between January 2023 and March 2025. PEC was performed from January 2023 to March 2024, and NCC from April 2024 to March 2025. Patients with aspiration pneumonia, definitive causes of inflammatory elevation without PECS, complete ulcer closure, or combined use of coagulation and clipping were excluded. Outcomes were the incidence of adverse events including DB and PECS after gastric ESD with PEC or NCC. PECS was defined as abdominal pain and fever with WBC ≥ 10,000/μL or CRP ≥ 0.5 mg/dL, without perforation. Statistical analyses were performed using chi-squared test, Fisher's exact test, Mann–Whitney U test, and Firth's bias-reduced estimation, with significance defined as $p < 0.05$.

Results Of the 294 patients initially enrolled, 36 were excluded and 126 in the PEC group and 132 in the NCC group were analyzed. Patient backgrounds, comorbidities, lesion characteristics, and use of antithrombotic agents were generally comparable. Endoscopic lesion size (median [IQR]: 10 [6-19] mm vs. 13 [8-21] mm; p = 0.015) and resection size (median [IQR]: 28 [23-36] mm vs. 32 [25-40] mm; p = 0.022) were significantly larger in the NCC group. The median time required for prophylactic hemostasis did not differ significantly between groups (median [IQR]: 11 [9-14] min vs. 12 [9-16] min; p = 0.106). In the NCC group, a median of 15 clips (IQR 12–20) was used. About the postoperative course, abdominal pain occurred significantly less frequently in the NCC group compared with the PEC group (6.1 % vs. 13.5 %; p = 0.044), and fever incidence was also lower in the NCC group (5.3 % vs. 14.3 %; p = 0.015). On POD1, WBC was significantly lower in the NCC group (median [IQR]: 8.0 [6.7–9.3] × 10^6/μL vs. 8.8 [7.1–10.0] × 10^6/μL; p = 0.007), whereas CRP and hemoglobin levels showed no significant differences. PECS occurred in 4.8 % of PEC patients but in none of the NCC patients (p = 0.013). DB and delayed perforation occurred at similar rates in the PEC and NCC groups (4.0 % vs. 3.8 %; p = 1.000), (0.8 % vs. 0.8 %; p = 1.000). In univariate analysis, NCC was significantly associated with reduced PECS incidence (odds ratio [OR] 0.264, 95 %CI: 0.023-0.776, p = 0.005). These findings suggest that mechanical clipping alone is sufficient for effective prophylactic hemostasis after gastric ESD in many cases and avoiding electrocoagulation on the post ESD ulcer may reduce the occurrence of PECS.

Conclusions The NCC method significantly reduced incidence of postoperative abdominal pain, fever, inflammatory response, and PECS compared with PEC, without increasing DB. NCC has a potential of a safe, less invasive alternative procedure to PEC. Further studies are required to establish its efficacy.

PYP089 Comparative Effectiveness of Traction-Assisted and Conventional ESD for Gastric Neoplasia: Systematic Review and Meta-analysis

Authors Patel RH[1], Parikh C[2, 3], Patel PD[4], Patel D[3], Confer B[4], Khara H[5]
Institutes **1** St. Mary Medical Center, Langhorne, United States of America; **2** Hospital of the University of Pennsylvania – Cedar Avenue, Philadelphia, United States of America; **3** Mercy Fitzgerald Hospital, Darby, United States of America; **4** Geisinger Medical Center, Danville, United States of America; **5** Geisinger Medical Center, Danville, PA, United States of America
DOI 10.1055/s-0046-1821029

Aims Traction-assisted endoscopic submucosal dissection (T-ESD) is designed to improve tissue exposure and facilitate safer, more efficient resections. However, comparative evidence across traction modalities remains heterogeneous. We conducted a meta-analysis evaluating the effectiveness and safety of T-ESD versus conventional ESD (C-ESD) for gastric neoplasia, including predefined subgroup analyses.

Methods Five comparative studies (4 RCTs and 1 prospective cohort) comprising **1,514 gastric lesions** were included. Effect sizes were pooled using random-effects models. Continuous outcomes were summarized as mean differences (MD), and binary outcomes as risk ratios (RR). Subgroup analyses assessed outcomes by traction modality, operator experience, and lesion location.

Results A total of 758 lesions were resected with traction and 756 with standard ESD. Procedure time was significantly shorter with T-ESD (MD − 9.7 minutes, 95 % CI − 16.6 to − 2.8; 4 RCTs). R0 resection rates were comparable between groups (RR 1.01, 95 % CI approximately 0.98–1.05). En-bloc resection was uniformly high in all studies (> 95 %) with no significant difference (RR ~ 1.00). Perforation occurred less frequently with traction (RR approximately 0.30). Delayed bleeding rates were nearly identical (RR: approximately 1.00).

Subgroup analyses Traction method: All four modalities favored T-ESD, with the greatest reductions in procedure time observed for GTS-partner and CSM-PLT. Operator experience: Both experts (MD ~ − 9 min) and trainees (MD ~ − 9 min) demonstrated faster dissection with traction, with a consistent magnitude of benefit. Lesion location: T-ESD reduced procedure time in both the upper/middle and lower stomach (DFC pilot: MD − 8 to − 10 minutes). No subgroup showed loss of effectiveness or increased risk with traction.

Conclusions Traction-assisted gastric ESD significantly reduces procedure time without compromising safety or curative resection outcomes. Benefits are consistent across different traction devices, operator experience levels, and lesion locations. T-ESD appears advantageous and may enhance efficiency even for less-experienced operators.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP090 Factors associated with difficulty in gastric ESD performed by trainees: implications for ESD training

Authors Mori H[1], Mitoro A[1], Hiroki K[1], Oyama M[1], Takami M[1], Masuda H[1], Iwai S[1], Fujinaga Y[1], Yoshiji H[1]
Institute **1** Nara Medical University, Kashihara, Japan
DOI 10.1055/s-0046-1821030

Aims Endoscopic submucosal dissection (ESD) is increasingly performed by trainees under expert supervision, and appropriate case selection is crucial for safe procedure. Unlike in Western countries, gastric ESD is widely adopted in Japan and serves as the main training model. However, the number of gastric ESD cases is expected to decline owing to the widespread implementation of Helicobacter pylori eradication. This study aimed to identify factors associated with difficult cases in gastric ESD performed by trainees and to explore implications for ESD training.

Methods We retrospectively analyzed consecutive gastric ESD procedures performed by trainees (fewer than 60 prior ESD cases) at a single center between September 2020 and September 2025. A difficult case was defined as any procedure having at least one of the following: (1) procedure time ≥ 120 minutes; (2) change of operator; or (3) occurrence of intraoperative perforation. Patient characteristics, lesion location, tumor size, and procedure-related factors were compared between difficult and non-difficult cases. Univariable analysis followed by multivariable logistic regression was performed to identify factors associated with difficult cases.

Results A total of 299 patients with 330 lesions performed by trainees were included. 30 patients had multiple lesions. The median age was 76 (range: 46–91) years, and 203 (68 %) were men. Median tumor size was 9 (IQR: 6–15) mm. 38 lesions located in the upper part, 145 in the middle part, 147 in the lower part, respectively. Median procedure time was 62 (IQR: 34–110) minutes. Tumor invasion depth was M/SM1/SM2: 295/15/4 lesions, respectively. Overall, difficult cases were 101 cases (34 %). 71 cases had a procedure time ≥ 120 minutes, 63 required an operator change, and 7 developed intraoperative perforation. Compared with non-difficult cases, difficult cases more frequently involved lesions in the upper part (24 % vs 6 %) and had significantly larger tumor size (10 mm vs 8 mm). In univariable analysis, location of the upper part and tumor size were associated with difficult cases, whereas there were no significant differences in age, number of cases with multiple lesions, depth of invasion, and lesion location in the cross-sectional circumference. In multivariable analysis, location of the upper part (odds ratio 4.4; 95 % confidence interval 2.85–6.8; $p < 0.001$) and tumor size (odds ratio 1.03; 95 % confidence interval 1.00–1.05; $p = 0.047$) remained independent predictors of difficult cases.

Conclusions In gastric ESD performed by trainees, location of the upper part and larger tumor size were significantly associated with difficult cases. These difficult factors likely reflect technically demanding conditions, such as poor scope stability, the need for retroflexion, and extensive submucosal dissection.

DOI 10.1055/s-0046-1821031

Aims High-quality bowel preparation is crucial for a successful colonoscopy, as well as for effective colorectal cancer prevention [1]. Simethicone, an anti-foaming agent, reduces intraluminal bubbles and improves mucosal assessment [2]. Its potential benefits when added to very–low-volume polyethylene glycol + ascorbic acid (PEG-AC) preparations have not been evaluated in real-world practice. The aim of the study is to assess whether adding simethicone to very–low-volume 1 litre PEG-AC bowel preparation reduces bubble formation, improves bowel cleanliness, and affects patient experience compared to PEG-AC alone.

Methods This ongoing multicenter project, involving seven endoscopy units across Sweden, started in September 2024. Consecutive outpatients undergoing a complete colonoscopy were assigned to standard PEG-AC (control) or PEG-AC plus simethicone (3 × 200 mg capsules per dose). Bowel cleanliness was assessed using the Boston Bowel Preparation Scale (BBPS) [3], and the presence of bubbles was assessed during intubation using the Colon Endoscopic Bubble Scale (CEBuS) [4]. Patient experience of bowel preparation and procedural data were collected. Data were analyzed using descriptive statistics, t-tests or Mann–Whitney U tests for continuous variables, and χ^2 tests for categorical variables.

Results A total of 637 patients were included (PEG-AC: n = 407; PEG-AC + simethicone: n = 230). Mean age was similar (59.8 vs. 60.2 years), but with more females in the simethicone group (p = 0.010). CEBuS scores were significantly lower in the simethicone arm in all bowel segments (p < 0.0001), and associated with a tenfold increased use of simethicone in the PEG-AC group – 31.1 % compared to only 3,9 % in the simethicone group (p < 0.001).However, there were no significant differences between the groups in total or segmental BBPS, including high-quality cleansing (total BBPS 8–9 or right-sided score 3) after adjusting for age, sex, preparation volume, water use during intubation, and extra intraprocedural simethicone use. Procedure and withdrawal time, polyp detection rates and patient-reported symptoms (bloating, nausea, vomiting) were also similar after adjusting as before mentioned. The descriptive statistics are depicted in ▶ **Table 1**.

Conclusions The addition of simethicone to very–low-volume PEG + ascorbic acid effectively reduced bubbles in the large bowel, though no improvements were observed in cleanliness, polyp detection, procedure times or patient experience in this interim analysis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Cleanliness Evaluation) scale. Secondary objectives included assessment of procedure duration, endoscopist satisfaction, and the detection rate of endoscopic findings.

Methods This was a prospective, single-center, randomized, blinded study including patients undergoing elective EGD between December 2024 and November 2025. Patients were randomized into three groups: A (100 mg simethicone ≤ 10 minutes before EGD), B (100 mg simethicone > 10 minutes before EGD), and C (50 mL water, placebo). All received a total volume of 50 mL. Patients with gastroparesis, achalasia, or prior gastrointestinal surgery were excluded. MV was assessed using the GRACE scale (validated in 2024), which scores each segment (esophagus, stomach, duodenum) from 0 to 3 based on bubble quantity, resulting in a total score from 0 (inadequate) to 9 (excellent). Endoscopist satisfaction was subjectively assessed on a scale from 0 (not satisfied) to 10 (highly satisfied).

Results A total of 142 patients were included (33 in group A, 54 in group B, and 55 in group C). Overall, 87 patients received 100 mg of simethicone and 55 received placebo. Median administration times were 9 minutes in group A and 20 minutes in group B. Simethicone significantly improved MV compared with placebo (mean GRACE score: 5.71 ± 1.70 vs 7.70 ± 1.50; $p < 0.001$), with significant improvements in all segments (esophagus: 2.00 (1-3) vs 3.00 (2-3), $p < 0.001$; stomach: 1.00 (1–2) vs 2.00 (2–3), $p < 0.001$; duodenum: 2.00 (2–3) vs 3.00 (2–3), $p < 0.001$). No correlation was observed between timing of simethicone administration and total GRACE score (Pearson $r = -0.079$; $p = 0.469$). Endoscopist satisfaction was higher in the simethicone group (6.25 ± 1.82 vs 8.01 ± 1.76; $p < 0.001$). No significant differences were found in median procedure duration (7.00 min (5-9) vs 7.00 min (5-9); $p = 0.948$) or diagnostic yield ($\chi^2(1) = 1.114$; $p = 0.291$). Among patients receiving simethicone, early administration showed no significant advantages over late administration: median EGD duration was 7.00 min (6–8) vs 8.00 min (6–10), and diagnostic findings 75.8 % vs 83.3 %, respectively ($\chi^2(1) = 0.748$; $p = 0.387$).

Conclusions Pre-endoscopic simethicone significantly improved mucosal visibility across all upper GI segments, independent of administration timing. No statistically significant differences were observed between early and late administration with respect to mucosal visualization, procedure duration, or diagnostic yield. High endoscopist satisfaction and consistent improvements in visibility support the routine use of simethicone prior to EGD.

PYP093 Optimizing Colonoscopy Preparation in End Stage Renal Disease (ESRD): A Tailored Low-Volume Approach

Authors Ritter E[1, 2], Rosenfeld Hemed A[1, 2], Gluck N[1, 2], Bar-Yishay I[1, 2], Kliuk Ben-Bassat O[2, 3], Grupper A[2, 3], Shibolet O[1, 2], Deutsch L[1, 2]

Institutes 1 Tel Aviv Sourasky Medical Center – Ichilov, Tel Aviv-Yafo, Israel; 2 Tel Aviv University, Chaim Levanon Street, Tel Aviv-Yafo, Israel, Tel Aviv, Israel, Israel; 3 Tel Aviv Sourasky Medical Center – Ichilov, Tel Aviv, Israel, Israel

DOI 10.1055/s-0046-1821033

Aims Potential renal transplant candidates with end-stage renal disease (PtESRD) often experience inadequate bowel preparation due to restrictions on bowel cleansing agents, limited fluid intake, comorbidities, and the pharmacologic effects of their medications.

We aimed to evaluate the safety and effectiveness of a revised, personalized bowel preparation protocol in improving colonoscopy outcomes among PtESRD patients undergoing pre-transplant evaluation.

Methods All patients referred for screening/surveillance colonoscopy by the nephrologist were included unless canceled for non-preparation-related medical reasons. A personalized preparation protocol was implemented between 06/2024-02/2025, including a 5-days low-fiber diet, daily bisacodyl, tailored fluid intake, and reduced-volume PEG 3350 with ascorbic acid (PtESRD group). The control group (historical cohort, 01/2022–05/2024) received standard preparation: 2-days low-fiber followed by clear liquid diet and 3 liter PEG 3350 solution. The groups were compared by clinical and demographic characteristics. The primary outcome was inadequate bowel preparation, defined as a Boston Bowel Preparation Scale (BBPS) score < 6. Risk factors were evaluated using logistic regression analysis.

Results A total of 156 inpatients were included (mean age 65.2 ± 0.7 years, range 39.1–84.5 years; 116 [74.4 %] male). Of these, 62 patients (39.7 %) received bowel preparation with the modified PtESRD protocol, while 94 patients (60.3 %) followed the standard protocol. Clinical and demographic characteristics, including age, sex, BMI, diabetes mellitus, and use of motility-affecting medications or disorders, were similar between the groups (p = NS for all). Active smoking was more prevalent in the control group (23.4 % vs. PtESRD 8.1 %, $p = 0.017$). The proportion of patients with a BBPS < 6 was significantly lower in the PtESRD group compared to control (40.3 % vs. 66 %; $P = 0.002$). This effect was consistent across all three colonic segments: right (33.9 % vs. 62.8 %, $p < 0.001$), transverse (25.8 % vs. 45.7 %, $p = 0.012$) and left (23.0 % vs. 53.8 %, $p < 0.001$). The proportion of complete preparation failures (BBPS = 0) was significantly lower among ptESRD (3.2 %) compared to 27.7 % among controls ($p < 0.001$). Complete colonoscopy, defined as cecal or ileal intubation, was achieved in 98.4 % of PtESRD patients compared to 81.9 % of controls ($p < 0.001$). In multivariate regression analysis, the PtESRD protocol was an independent protective factor, reducing the rate of inadequate bowel preparation by 65 % (OR 0.365, 95 % CI 0.180–0.741, $p = 0.005$), adjusted for sex, age, BMI, active smoking, and diabetes mellitus.

Conclusions This proof-of-concept study shows that the PtESRD protocol improves bowel preparation and colonoscopy completion rates in hospitalized ESRD transplant candidates. Its independent predictive value supports its use and highlights the potential of tailored protocols in high-risk patients. Further prospective studies are needed to confirm these findings and guide broader implementation.

PYP094 Optimal Water Volume for 1L PEG-Ascorbate Bowel Preparation: A Randomized Comparison of 1L Versus 2L Additional Fluid Intake

Authors Koo JS[1], Kim D[1]

Institute 1 Korea University Ansan Hospital, Ansan-si, Republic of Korea

DOI 10.1055/s-0046-1821034

Aims The newly developed 1L polyethylene glycol with ascorbate (PEG-ASC) solution (CleanviewAl; Taejoon, Seoul, South Korea) offers the advantage of reduced volume for colonoscopy bowel preparation. However, the high content of sodium ascorbate and sodium sulfate in the solution raises concerns about potential hypernatremia. This study aimed to compare the efficacy and safety of the 1L PEG-ASC preparation when administered with 1L versus 2L of additional water in patients undergoing screening or diagnostic colonoscopy

Methods This study was a prospective, consecutive enrollment of patients undergoing screening or diagnostic colonoscopy across three Korean academic hospitals. Patients were randomly assigned to one of two groups: the 1L group (n = 87) ingested 1L of PEG-ASC solution and 1L of water, and the 2L group (n = 83) ingested 1L of PEG-ASC solution and 2L of water. The primary endpoints were the assessment of overall bowel cleansing success and right colon cleansing using the Boston Bowel Preparation Scale (BBPS). The secondary endpoints were the evaluation of tolerability and safety (including treatment-related adverse events and changes in serum electrolytes/renal function).

Results A total of 170 patients were enrolled. The two groups were comparable in terms of gender ($p = 0.233$) and age ($p = 0.917$). There were no significant differences in the mean overall BBPS score or the right colon BBPS score between the 1L and 2L groups, indicating comparable cleansing efficacy. Interestingly, the polyp detection rate (PDR), and specifically the detection of polyps larger than 1cm, was higher in the 1L group compared to the 2L group. However, there was no difference in the number of polyps detected in the right

colon. The difficulty of ingestion (tolerability) was reported as easier in the 1L group. Subgroup analysis revealed no significant changes in serum BUN, creatinine, sodium, potassium, and chloride levels between the two groups. In terms of treatment-related adverse events, thirst was more frequent in the 1L group, while vomiting was more frequent in the 2L group. All reported adverse events were self-limited and recovered without intervention.

Conclusions The study found no significant difference in bowel preparation efficacy or overall safety between ingesting 1L or 2L of water in conjunction with the 1L PEG-ASC solution. The 1L water intake regimen was associated with better tolerability (easier ingestion) and an unexpectedly higher polyp detection rate. Therefore, the lower-volume water intake regimen (1L water) may be preferable, but the choice of bowel preparation method should ultimately be tailored to the specific needs and preferences of each patient.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP095 1 L polyethylene glycol and ascorbate give better bowel preparation than sodium picosulfate with magnesium citrate during water-assisted colonoscopy

Authors Sarna VK[1], Rynning-Tønnesen S[1], Kristensen VA[1], Ånonsen KV[1]
Institute 1 Oslo University hospital Ullevål, Oslo, Norway
DOI 10.1055/s-0046-1821035

Aims Adequate bowel preparation is critical for lesion detection during colonoscopy. This study compared the efficacy and tolerance of sodium picosulfate with magnesium citrate (SP + MC) versus 1 L polyethylene glucol and ascorbate (1 L PEG + Asc) in water-assisted colonoscopy.

Methods In this prospective study, we scored bowel preparation quality during colonoscopies in adults for all indications from June 2023 to April 2024. In this time period we converted from SP + MC to 1 L PEG + Asc as the standard purgative at our department. We intubated by water-assisted technique and withdrew with gas insufflation. Bowel preparation quality was scored using a modified Boston Bowel Preparation Scale (m-BBPS), scored 0–3 in three colon segments during intubation with water-assisted technique. Scores > 2 indicated adequate preparation, and 3 indicated excellent preparation. Additionally, tolerance to the purgative and cecum intubation time was recorded. A subgroup was scored for BBPS (during withdrawal phase in gas insufflation), polyp detection rate (PDR), adenoma detection rate (ADR), sessile serrated lesion detection rate (SSLDR), patient-reported strong pain during colonoscopy and use of sedoanalgesia. Withdrawal time was measured in diagnostic procedures without biopsy. In the multivariate analysis, we corrected for gender and age above 50 years, and in subgroup analysis additionally for indication.

Results We scored 1988 colonoscopies, mean age 54.9 years (SD 16.7), 52.3 % women, 48.2 % used 1 L PEG + Asc. The OR for adequate m-BBPS in all segments with 1 L PEG + Asc compared to SP + MC was 2.46 (CI [1.98, 3.07], p < 0.001). OR for excellent m-BBPS right colon segment was 3.49 (CI [2.86, 4.26], p < 0.001). 1 L PEG + Asc was less tolerated (OR 0.76, CI [0,61, 0,95], p = 0.014). Cecum intubation times were similar between groups (15.4 (SD 10.5) vs. 16.0 minutes (SD 12.9), p = 0.29).

A subgroup of 1120 patients, mean age 55.0 years (SD 15.9), 52.9 % women, 56.6 % used 1 L PEG + Asc. The OR for adequate BBPS in all segments with 1 L PEG + Asc trended towards significance (OR 1.88, p = 0.052). OR for excellent BBPS right colon segment was 1.56, p < 0.001. Patients reported less strong pain during colonoscopy with 1 L PEG + Asc (OR 0.57, p = 0.021), but use of sedoanalgesia did not differ (OR 1.02, p = 0.88). Mean withdrawal times for diagnostic procedures without biopsy were 9.20 (SD 4.7) and 8.8 (SD 3.2) minutes, respectively (p = 0.81). OR for PDR was 1.23, p = 0.13. OR for ADR was 1.15, p = 0.34. OR for SSLDR was 1.63, p = 0,068.

Conclusions The newly developed m-BBPS (scored during intubation in water-assisted colonoscopy) revealed large and significant differences in rates of adequate bowel preparation in favor of 1 L PEG + Asc, but differences in BBPS (scored in the withdrawal phase in gas insufflation) did not reach significance in the subgroup analysis. The difference in favor of 1 L PEG + Asc was especially large for excellent right colon m-BBPS, also showing significance for BBPS in the subgroup analysis. While 1 L PEG + Asc was less tolerated, it was associated with significantly less strong pain during colonoscopy. These findings suggest that 1 L PEG + Asc may enhance both procedural quality and patient comfort, supporting its adoption as a standard purgative for water-assisted colonoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP096 The effect of allowing a dinner the day before colonoscopy on quality of bowel cleansing. A randomized controlled trial with central reading (DinNER1006 trial)

Authors Sinonquel P[1, 2], Demedts I[1, 2], Camps C[3], Luypaerts A[3], Willekens H[3], Roelandt P[2, 4], Bisschops R[1, 2]
Institutes 1 Department of Translational Research in Gastrointestinal Diseases (TARGID), KU Leuven, Leuven, Belgium; 2 Department of Gastroenterology and Hepatology, University Hospitals Leuven, Leuven, Belgium; 3 UZ Leuven, Leuven, Belgium; 4 Translational Research in Gastrointestinal Diseases (TARGID), KU Leuven, Leuven, Belgium
DOI 10.1055/s-0046-1821036

Aims Effective bowel cleansing is essential for a high-quality colonoscopy. However, strict pre-procedure dietary restrictions may burden patients and reduce compliance. This study assessed whether permitting a true low-fiber dinner on the day before colonoscopy affects bowel preparation quality or patient experience.

Methods In this single center, prospective, investigator-blinded randomized controlled trial, 494 patients scheduled for colonoscopy received a split-dose polyethylene glycol (PEG) regimen (NER1006, Norgine) administered the evening (6 or 8 p.m.) and at least 6 hours before the procedure. Participants were randomized (1:1) to either a standard regime without proper dinner the day before (last low-fiber meal at 15h) or a more lenient regime allowing a low-fiber dinner, up to 2 hours before initiating bowel preparation. The primary outcome was adequate bowel cleansing, defined as a Boston Bowel Preparation Scale (BBPS) score ≥ 6 with no segmental score < 2, assessed by the endoscopists and an independent central reading. Secondary endpoints included other quality indicators, polyp (PDR), adenoma (ADR), advanced adenoma (aADR), and sessile serrated lesion (SDR) detection rates, and patient satisfaction.

Results Endoscopists' BBPS scoring achieved an adequate bowel cleansing in 94.4 % of the controls and 99.2 % of the interventional group (p = 0.061). Control and interventional groups demonstrated an optimal BPPS in 88.0 % vs 84.9 % (p = 0.060), respectively. After central reading, adequate bowel cleansing was achieved in 99.1 % of the controls and in 96.7 % of patients with a more lenient dinner (p > 0.999). Optimal cleansing was observed in only 68.7 % vs 60.4 %, respectively (p = 0.0601).

Quality indicators PDR (73.5 % vs 71.8 %), ADR (49.4 % vs 55.1 %), aADR (17.7 % vs 18.8 %), and SDR (12.0 % vs 11.0 %) did not differ significantly between both groups. Patient satisfaction was not significantly different between groups, with 74.3 % vs 73.1 % reporting ≤ 1 negative feeling during bowel preparation (p = 0.7604).

Conclusions Permitting a low-fiber dinner up to 2 hours before starting bowel cleansing does not compromise the adequacy of colon cleansing with a split-dose PEG NER1006 regimen administered the evening and 6 hours before colonoscopy. Quality metrics and patient satisfaction remain high, indicating that a less restrictive dietary approach can be safely adopted. Central reading highlights the operator dependency of the BBPS scale prompting the need for objective tools like AI scoring systems.

PYP097 Let's pop some bubbles

Authors Tabbone E[1], Olivari N[1], Salvi D[1], Cesaro P[1]
Institute 1 Fondazione Poliambulanza Istituto Ospedaliero, Brescia, Italy
DOI 10.1055/s-0046-1821037

Aims Adequate mucosal visualization is essential for high-quality esophagogastroduodenoscopy (EGD), as suboptimal inspection has been associated with missed upper gastrointestinal neoplasia. Recent meta-analyses report that up to 10 % of upper gastrointestinal cancers and 23.9 % of esophageal adenocarcinomas in Barrett's esophagus are diagnosed within a short interval after a negative EGD, underscoring the importance of optimal mucosal visibility [1]. The presence of salivary residues and gastric foam frequently impairs visibility, requiring intraprocedural instillation of water and antifoaming agents, like simethicone, through the endoscope channel using a syringe. Oral administration of Simethicone prior to EGD has been proposed as a simple alternative to improve mucosal visibility while reducing syringe use and overall simethicone consumption [2]. Furthermore, Simethicone is not–water soluble and difficult to remove from endoscope channels, despite high level disinfection. It is frequently detected during borescope inspection of patient ready endoscope, where residues have been associated with retained moisture, biofilm formation, and infection risk [3]. The American Gastroenterological Association therefore recommend minimizing its use and concentration and avoiding administration through the irrigation channel [1]. Unlike the American guidelines, the European Society of Gastrointestinal Endoscopy (ESGE) does not impose such restrictions on its intraprocedural use. Instead, ESGE recommends intraprocedural Simethicone administration only when persistent bubbles or biliary fluids remain after oral premedication, impairing adequate mucosal visualization [2].

Methods We conducted a non-inferiority case–control study comparing two simethicone administration strategies. We included only elective outpatient EGDs, excluding inpatient and emergency procedures. Standard endoscopic instillation via syringe, used only when considered necessary to improve mucosal visualization, was adopted in February, April, and June 2023, whereas oral premedication with 20 drops (0.6 mL) of simethicone diluted in 50 mL of water, administered 5 minutes before the procedure, was adopted in March, May and July 2023. A monthly alternation of the two strategies was adopted to limit selection bias linked to consecutive EGDs. Outcomes included the proportion of procedures requiring additional syringe use instillation, total simethicone consumption, and overall procedural costs.

Results A total of 1368 EGDs were performed during the study period (710 in the intervention group and 658 in the control group). Additional syringe use was required in 5 % of cases in the intervention group compared with 51 % in the control group. The number of syringe use decreased from 337 to 22 in the intervention group, representing a 94 % reduction. Simethicone consumption decreased from 0.95 mL to 0.64 mL/per exam (-32 %). Costs decreased from € 0.270 to €0.097/per gastroscopy (–64 %), corresponding to an estimated annual saving of €173/1000 exams.

Conclusions This study support that the application of current ESGE recommendations is safe, effective, and cost-saving strategy. It maintains diagnostic quality reducing procedural costs, representing an improvement for routine endoscopy practice.

PYP098 Abstract: Optimizing Suction and Irrigation Using a Modified TUR Set During Gastroscopy

Authors Desai PN[1], Chintan P[1], Prajapati R[1], Mayank K[1], Rajiv M[1], Nandwani S[1], Patel N[1], Sethia M[1]
Institute 1 SIDS Hospital & Research Centre, Surat, India
DOI 10.1055/s-0046-1821038

Aims To evaluate the efficacy of a modified Transurethral Resection (TUR) set attached to the biopsy channel in enhancing suction and lavage efficiency during gastroscopy in patients presenting with fluid-filled or food-filled esophagus and stomach, conditions frequently associated with procedural delay and increased aspiration risk

Methods A six-month prospective comparative assessment was conducted on upper gastrointestinal endoscopy cases performed under propofol–fentanyl sedation. Despite an 8-hour fasting protocol with clear liquids allowed up to 3–4 hours before the procedure, selected patients had retained residue in the esophagus or stomach. Sixty such cases were randomized into two equal groups: Arm A (standard biopsy-channel suction) and Arm B (modified TUR-set suction). Residue volume per case ranged from 200 mL to 700 mL. Time required to achieve clearance of 300 mL of residue was recorded for several residue categories including clear fluid, thick liquids, soft food, solid fibrous material, fresh blood clots, and organized blood clots. Percentage improvement in clearance time was derived to quantify effect size.

Results The modified TUR-set system consistently reduced clearance time across all residue types. The observed improvements were as follows:For clear fluid and bile, the average clearance time improved from 1 minute 15 seconds to 50.4 seconds, representing a 32 % reduction. In patients with achalasia and a fully distended esophagus, clearance time improved from 8 minutes 22 seconds to 5 minutes 16 seconds, corresponding to a 37 % reduction. Thick semisolid residue such as altered milk or curd showed a reduction from 4 minutes 21 seconds to 2 minutes 53 seconds, translating to a 34 % improvement. Similarly, soft food materials such as rice, digested egg, and other easily fragmentable substances demonstrated a strong benefit; clearance time declined from 5 minutes 11 seconds to 3 minutes 19 seconds, indicating a 36 % improvement. Solid food with fibrous texture showed only modest enhancement—14 minutes 52 seconds versus 12 minutes 34 seconds—amounting to a 15 % reduction. Fresh blood clots showed one of the highest benefits: clearance time decreased from 12 minutes 29 seconds to 7 minutes 31 seconds, a 40 % improvement. Organized clots, being more cohesive and resistant to fragmentation, showed limited improvement of 13 %, decreasing from 14 minutes 37 seconds to 12 minutes 42 seconds. Aspiration events occurred in 23.3 % of patients in the standard-suction arm compared with 10 % in the TUR-set arm, corresponding to a 57 % relative risk reduction.

Discussion: Effect-size analysis based on percentage reduction in clearance time demonstrates clinically meaningful and consistent superiority of the modified TUR set over standard suction. The ability to rapidly declog the system using intermittent air flushing from an assistant-controlled syringe proved especially valuable for viscous fluids, semisolids, and fresh clots. This prevented the repeated need to remove the suction valve or use a cleaning brush—steps that otherwise prolong the procedure and increase aspiration risk. The strongest benefits were observed in fresh blood, fluid blood, and soft food residue, where high-flow suction combined with rapid channel clearance significantly shortened the time needed to restore adequate visualization. For fibrous solids or organized clots, both systems performed poorly, highlighting the intrinsic physical limitations of endoscopic suction in these materials.The reduction in aspiration events reinforces the safety benefit of the modified TUR system.

Faster clearance in a stomach or esophagus loaded with retained residue inherently reduces the duration during which regurgitation and aspiration can occur. Additionally, uninterrupted suction flow improves procedural efficiency, decreases operator fatigue, and allows earlier progression to therapeutic interventions when required.

Conclusions The modified TUR set provides a practical, low-cost, and highly effective enhancement to biopsy-channel suction during gastroscopy in patients with retained fluid, food residue, or blood. Percentage improvement analysis shows substantial reductions in clearance time—particularly for soft food materials, altered blood, and fresh clots. The device also reduces aspiration events, suggesting an important safety advantage.

DOI 10.1055/s-0046-1821039

Aims Colonoscopy is used in people with chronic kidney disease receiving hemodialysis for renal replacement therapy and forms part of routine pre-transplant assessment. Concerns exist about use of oral bowel-cleansing agents for colonoscopy in people receiving haemodialysis, despite guidelines recommendations. It is plausible that intravascular depletion and consequent hypotension may cause thrombosis of the vascular access use for hemodialyisis. We evaluated the comparative efficacy, safety and tolerability a low-volume versus a high-volume polyethylene glycol based bowel preparation for colonoscopy in people on hemodialysis.

Methods This was a multicentre, PROBE design, parallel-arm, centrally randomized, non-inferiority phase IV trial.Eligible subjects were allocated 1:1 to either low-volume (2 liters) or high-volume (4 liters) bowel preparation. The primary outcome was the proportion of participants with adequate bowel cleansing, evaluated using the Boston Bowel Preparation Scale (BBPS). Secondary outcomes were adenoma detection rate (ADR), caecal intubation rate, patient tolerability/compliance, and adverse events (both related to colonoscopy and to dialysis/renal function). Differences were tested via t-test or Mann–Whitney U test for continuous normal variables or through chi-square or Fisher exact test for categorical ones.

Results Sixty-nine patients were randomized in four centres, 35 to low volume and 34 to high volume groups.Mean age was 62.5 ± 10.7 years; 54 were men and 15 were women. A total of 33 in the low-volume and 27 in high-volume completed colonoscopy; the main reasons for exclusion was stopping to take preparation (n = 5).15.No difference in caecal intubation rate was observed (100 % vs 96.6 %, p = 1). Adequate bowel preparation was achieved in 69.7 % and 63.0 % of low and high-volume groups, respectively (p = 0.58). Mean BBPS was similar in the two groups (5.6 ± 2.4vs 5.4 ± 2.4, p = 0.51). When sub-analyzing according to each bowel segment, we did not observe any difference for right, transverse nor left colon.

The ADR was 35.0 % in low-volume and 37.0 % in high volume (p = 0.10).Median number of polyps per patient was 1.5 in low and 2 in high-volume group (p = 0.45).

Mild abdominal swelling was the most common adverse event (27.3 % vs 25.9 % for high and low volume respectively, p = 0.29), followed by mild nauseas (27.3 % vs18.5 %, p = 0.29). A similar rate of willingness to repeat the same preparation was observed (87.9 % vs 85.2 %, p = 0.76).No emergency dialysis sessions were required and no deaths were recorded. Levels of serum creatinine remained stable before and after preparation in both groups.

Conclusions This small scale study based on an opportunistic sample confirms the difficulties in adequate preparation for colonoscopy in people on hemodialysis. It shows that both a low and a high-volume preparation were equally effective and safe.We did not observea better tolerability for low-volume preparations, which may be a key findings but also due to suboptimal small sample size. Further large scale studies may be required to confirm our findings.

DOI 10.1055/s-0046-1821040

Aims Artificial intelligence has accelerated major advances in gastroenterology and endoscopy, yet adequate bowel preparation remains fundamental to high-quality examinations. Existing preparation scales for colonoscopy and capsule endoscopy are limited by subjective interpretation and by their confinement to individual gastrointestinal segments. Quality-assessment systems (CADq) offer a consistent and objective framework for evaluating preparation quality and optimizing procedural performance. This study aimed to develop CADq algorithms capable of automatically classifying preparation quality across multiple gastrointestinal regions, including the small bowel and colon, and across multiple endoscopic modalities including colonoscopy, enteroscopy, and capsule endoscopy.

Methods We retrospectively analyzed 144 colonoscopies from three devices, 28 enteroscopy procedures from three devices, and 5,793 capsule endoscopy exams from two devices. Bowel preparation was graded with the Boston Bowel Preparation Scale for colonoscopy, and as excellent (visible mucosa at least 90 percent), satisfactory (50 to 90 percent), or unsatisfactory (less than 50 percent) for enteroscopy and capsule endoscopy. The dataset included 181,910 colonoscopy images, 88,623 enteroscopy images, and 12,950 capsule endoscopy images, divided into training (90 percent) and testing (10 percent) subsets, with overlap between procedures from the same patient. Convolutional neural network performance was compared with expert consensus.

Results For colonoscopy, the model achieved sensitivity and specificity of 87 percent, a negative predictive value of 95 percent, and an overall accuracy of 96 percent. Because poor-quality cases were limited, a binary model distinguishing good from excellent preparation was implemented. In enteroscopy, classification across preparation categories achieved sensitivity ranges of 69 to 98 percent, specificity of 80 to 100 percent, and accuracy of 91 to 97 percent. In capsule endoscopy, sensitivity reached 92 percent, specificity 94 percent, and accuracy 92 percent.

Conclusions This study advances the field by introducing CADq algorithms able to classify bowel preparation in a multi-region, multi-technique, and multi-device framework. CADq systems are critical for supporting procedural quality and operational efficiency in endoscopic practice. To our knowledge, this

represents the first deep learning CADq strategy developed to evaluate preparation quality across distinct gastrointestinal regions. Future developments are expected to evolve toward real-time detection of blind spots and assessment of mucosal exposure. Combined with CADe and CADx, such systems are central to achieving full-spectrum integration of artificial intelligence into routine clinical care.

DOI 10.1055/s-0046-1821041

Aims Speedboat is a novel multimodal endosurgical device. It utilizes the use of advanced bipolar energy for cutting/dissection and super-high frequency microwave energy for coagulation. This study aims to evaluate the efficacy of two versions ('Inject' with needle and 'Ultraslim' which is needless) of Speedboat assisted Endoscopic Submucosal Dissection (S-ESD) in the management of complex colorectal polyps.

Methods Data, from a prospectively collected clinical audit (2018-2025) was analyzed. Up to 02/2023 Speedboat "Inject" device was used for S-ESD cases whereas since 03/2023 the new iterative version, Speedboat "Ultraslim" device, was introduced. Cases were divided into two groups, the Inject group (01/2018-02/2023), and Ultraslim group (03/2023-11/2025). Lesions' characteristics, location, long and short axis length, lesion surface (cm^2), time and speed of dissection (cm^2/h) were compared between the groups.

Results Over the study period, a total of 411 consecutive patients had an S-ESD attempt. 30 cases (7.3 %) were abandoned, 25 converted to pEMR (6.1 %). 356 en-bloc resections achieved [en-bloc rate 93.4 %, 56.2 % male, mean age 72] with a mean surface of 19.11cm^2, and dissection speed 12.2 cm2/hr.

In the Inject group 200 cases were attempted in total. 21 were abandoned (10.5 %) and 14 converted to pEMR (7 %). 165 en-bloc resections were achieved [en-bloc rate 92.2 %, 56.6 % male, age 72 years with mean surface of 18.3 cm^2, and speed 9.98 cm^2/h. 102 patients had their procedure under GA (62 %) to remove 142 distal (86 %) and 24 proximal (14.5 %) lesions which after histopathological examination revealed 38 polyps with HGD (23 %) and 22 with cancer (13.3 %).

In the Ultraslim group 211 cases were attempted in total. 9 cases were abandoned (4.3 %) and 11 converted to pEMR (5.6 %). 191 en-bloc resections were achieved [en-bloc rate 94.6 %, 55.7 % male, age 71 years, mean surface 21.78 cm2 and speed 15.54 cm2/h. 175 patients were done under GA (91.6 %), 149 distal (78 %) and 34 proximal colon lesions (18 %) were excised. 51 cases showed HGD (27 %) and 25 were malignant (13.1 %).

There was a significant difference between the two groups in dissection speed ($p = < 0.001$), and GA procedures ($p < 0.001$). Borderline statistical significance was seen in the mean surface ($p = 0.07$) in addition to percentage of abandoned cases ($p = 0.015$). No statistically significant difference in regards with age, gender and location was found between the groups.

Conclusions The use of Ultraslim needless device assisted S-ESD and GA appears to facilitate faster excision of large, complex colonic lesions and reduced number of abandoned cases. Data from an international registry will aid in further understanding of confounding factors for dissection speed.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP102 A Novel AI-Driven Ultra-High-Magnification Endocytoscopy Enables Real-Time Standardised Intestinal Barrier Assessment in IBD

Authors Iacucci M[1], Pugliano CL[1], Zammarchi I[1], Chaudhari U[2], Santacroce G[1], Meseguer P[3], Del Amor R[3], Kolawole BB[2], Crotty R[4], Hayes B[4], Ghosh S[1], Naranjo V[3], Grisan E[2]

DOI 10.1055/s-0046-1821042

Aims Intestinal barrier healing is an emerging therapeutic target in Inflammatory Bowel Disease (IBD), associated with deep mucosal healing and improved long-term outcomes [1]. Ultra-magnification Endocytoscopy (ECS) enables real-time, in vivo cellular-level assessment of the intestinal barrier, with strong histological correlation. However, its clinical application remains limited to expert centers due to the complexity of image interpretation [2]. We aimed to develop an artificial intelligence (AI)- driven system to standardise ECS-based evaluation of barrier integrity and predict adverse outcomes.

Methods Thirty-five high-quality ECS videos (2636 frames for crypt architecture, 2596 for goblet cells, 1009 for vascular pattern, and 702 for villi architecture) from Ulcerative colitis (UC) and Crohn's disease (CD) patients were considered. Using five-fold cross validation, the frames from 28 videos were used for training the model, while the remaining were used for testing. Expert endoscopists scored barrier impairment according to a previously validated ECS [1], providing a reference standard for AI training. Separate convolutional neural networks (ResNet50, pretrained GastroNet data) were trained to identify abnormalities in villi/crypt architecture, vascular structure, and goblet cells density. The scores from the model training at frame level were aggregated to obtain a score at video level for each feature [3, 4]. A logistic regression model predicted overall barrier impairment, as well as major clinical outcomes (**Fig 1**). Diagnostic performance metrics were expressed as sensitivity, specificity, accuracy, positive and negative predictive values, and area under the curve (AUC).

Results Thirty-five patients (19 UC and 16 CD) were included. Our novel AI algorithm achieved high diagnostic accuracy in detecting overall and features-specific barrier impairment (**Tab 1**). For overall barrier impairment, the model yielded a sensitivity of 83 %, specificity of 100 %, accuracy of 97 %, and an AUC of 98 %. Feature-specific assessment at the video level also demonstrated strong metrics performance across epithelial and vascular features. The model accurately identified abnormalities in crypt architecture (91 % AUC), goblet cells (90 % AUC), villi architecture (94 % AUC), and vascular pattern (96 % AUC). Notably, clinical outcome prediction at 6 months achieved an accuracy of 89 % for UC, whereas it was only 44 % for CD.

Conclusions Our AI-driven ECS model provided the first automated and standardised assessment of intestinal barrier integrity in IBD. By overcoming the subjectivity and complexity of current evaluation methods, it enables barrier healing to emerge as a measurable and therapeutic endpoint in clinical practice and clinical trials.

PYP103V REACT Multipoint Elastic Traction for Colorectal ESD: A Retrospective Single-Center Feasibility Series of 59 Consecutive Cases

Authors Poortmans PJ[1, 2, 3], Montori M[4, 1], Debels L[3], Argenziano ME[1, 2], Botelberge T[5], Hoorens A[1], Sorge A[1], Tornai T[1], Desomer L[6, 1], Tate D[2, 1]

DOI 10.1055/s-0046-1821043

Problem to solve Effective traction for endoscopic submucosal dissection (ESD) should be applicable to diverse lesion morphologies and locations, adapting as dissection progresses, allow repositioning, and be cost-effective. Current traction methods are constrained by limitations such as single-point application, high cost (up to €120 per procedure), restricted adaptability, proprietary components, or procedural complexity. Multipoint traction techniques offer consistent directional tension, but wider adoption is limited by these practical barriers.

Innovation We developed REACT (Repositionable Elastic Adaptive Customizable Traction), a novel multipoint traction system constructed from medical-grade latex orthodontic elastic bands (Fox 1/4" 3.5Oz, Ormco). The system consists of multiple traction bands connected to a central linking band through cow hitch knots, with a dedicated fixation band to anchor the device to the opposite bowel wall. REACT configurations (REACT-3 with 3 traction bands to REACT-6 with 6 traction bands) are tailored to lesion size and anatomy. The device provides adjustable, multidirectional traction using standard endoscopic clips to attach traction bands to the lesion margin and fixation band to the opposite wall. Its elastic properties provide dynamic tension that automatically compensates for changes in luminal configuration during insufflation or lesion movement. Intra-procedural customisation allows real-time repositioning of traction points or addition of bands as needed. The system costs €0.05-€0.08 per procedure (excluding cost of clips), requires no proprietary components, and can be assembled rapidly after minimal training. Colour-coding (purple fixation band, green central linking band, alternating pink/orange traction bands) simplifies identification and manipulation during procedures.

Results Between February 2024 and July 2025, 59 consecutive colorectal lesions were resected using REACT-assisted ESD at a tertiary referral centre. Mean patient age was 66.8 years (SD 12.6), and 52.5 % were male. Median lesion diameter was 30mm (IQR 25mm), with most lesions located in the rectum (55.9 %) or sigmoid (16.9 %). Histopathology revealed low-grade dysplasia in 32.2 %, high-grade dysplasia/intramucosal cancer in 52.5 %, and submucosally invasive cancer in 15.3 %.

Intra-procedural perforation occurred in 3/59 cases (5.1 %, 95 % CI 1.1-14.1 %), all managed endoscopically without surgery. Delayed bleeding occurred in 5/59 cases (8.5 %, 95 % CI 2.8-18.7 %). No delayed perforations (0 %, 95 % CI 0-6.1 %) or surgery for adverse events (0 %, 95 % CI 0-6.1 %).

En-bloc resection was achieved in 58/59 cases (98.3 %, 95 % CI 90.9-100 %). R0 resection rate was 93.2 % (95 % CI 83.5-98.1 %). Median dissection speed was 20.0 mm^2/min (IQR 14.6 mm^2/min). REACT subjectively improved submucosal access in 94.9 %. Median REACT deployment time was 6 minutes 7 seconds (IQR 4:00). Median 6 clips used (IQR 3). Most common configurations were REACT-3 (50.8 %) and REACT-5 (25.4 %).

Conclusions REACT-assisted colorectal ESD demonstrated safety comparable to contemporary traction-assisted ESD series, with perforation (5.1 %) and delayed bleeding (8.5 %) rates within acceptable ranges, and no delayed perforations or surgical interventions. All perforations were managed endoscopically. Feasibility metrics including dissection speed (20.0 mm^2/min), en-bloc resection (98.3 %), and R0 resection (93.2 %) were comparable to other multipoint traction systems while offering substantial cost advantages. Device failure was rare (0.9 % band detachment rate) and salvageable in all cases. The system's modular design allows real-time adaptability—traction points can be repositioned and additional bands attached as needed—particularly advantageous in lesions of varying size and anatomical complexity. Future implications include potential applications in upper gastrointestinal and other anatomical sites. Multicentre prospective randomized trials are warranted to validate these single-centre findings and establish comparative efficacy versus other traction methods across diverse clinical settings and procedural contexts.

DOI 10.1055/s-0046-1821044

Aims Post-operative recurrence (POR) of Crohn's disease (CD) remains a major challenge, affecting up to 80 % of patients within 10 years after surgery. Conventional endoscopy struggles to distinguish early inflammatory recurrence from post-surgical ischemic changes, delaying effective treatment. Virtual chromoendoscopy (VCE) offers precise visualisation of mucosal and vascular changes. The PROSPER study aims to develop and validate a novel endoscopic score integrating advanced imaging features to predict early POR in CD.

Methods This analysis is part of the international, multicentre, prospective PROSPER study (NCT06505304). Adult CD patients undergoing ileocolic resection were enrolled pre-operatively or within 3 months post-operatively and underwent endoscopic assessment at 3 or 6 months after surgery, guided by

faecal calprotectin levels (cutoff 150 µg/g). Endoscopic videos were obtained using white-light and VCE modalities —TXI, RDI, and NBI with the Olympus (EVIS-X1) platform, and i-scan1 and OE mode 1–2 with the Pentax (INSPIRA) platform— following a standardised protocol. A three-round modified Delphi process defined the PROSPER domains: two in-person consensus meetings and an online survey (Qualtrics platform) where experts rated each feature. Consensus required > 75 % agreement. Seven core experts participated in both the first (10 videos) and second (15 videos) rounds, scoring the colon proximal to the anastomosis, the anastomotic region (including anastomotic line, ileal inlet, ileal body, and, when present, blind loops), and the neo-terminal ileum. All anastomotic configurations -end-to-end, end-to-side, side-to-end, side-to-side, and Kono-S- were assessed. Inter-rater agreement was evaluated using Fleiss' κ, Gwet's AC1/AC2, and ICC(2,k).

Results Mucosal and vascular domains were selected, including erosions, superficial and deep ulcers, villi morphology, vessel dilatation, and bleeding (▶ **Table 1**). Agreement across both in-person rounds was moderate to substantial for features in the neo-terminal ileum and colon proximal to the anastomosis (AC1/AC2 = 0.61–0.78) and lower for the anastomotic region (fair to moderate), particularly for villi and erosions (AC2 ≈ 0.40–0.50). Ulcers and vascular patterns showed higher reproducibility (AC1 ≈ 0.70–0.80). Moderate agreement was observed for the anastomosis type (κ 0.51). The Delphi survey confirmed selected domains, with over 80 % expert agreement on inclusion and weighting.

▶ **Table 1**

Mucosal Domains		Vascular Domains	
Erosions (< 5 mm)	▪ Presence/absence	**Dilated vessels**	▪ No dilatation
	▪ Number		▪ Dilated roundish
	▪ Surface affected (< 25 %, 25-50 %, 50-75 %, > 75 %)		▪ Dilated crowded or tortuous
Superficial ulcers (> 5mm)	▪ Presence/absence	**Bleeding**	▪ No bleeding
	▪ Number		▪ Intramucosal bleeding
	▪ Surface affected (< 25 %, 25-50 %, 50-75 %, > 75 %)		▪ Luminal bleeding
Deep ulcers (> 5mm)	▪ Presence/absence		
	▪ Number		
	▪ Surface affected (< 25 %, 25-50 %, 50-75 %, > 75 %)		
Villi	▪ Normal		
	▪ Ballooning of the villi		
Stricture (if present)	▪ Inflamed/Fibrotic		
	▪ Passable/Not passable		

Conclusions The novel PROSPER score is a multimodal tool integrating advanced imaging for comprehensive assessment of the anastomosis, showing good inter-expert agreement across most domains. These results support its feasibility for detecting early POR. The next phase will involve real-life validation.

DOI 10.1055/s-0046-1821045

Aims A new LED endoscopy system, the EP-8000 (Fujifilm, Tokyo, Japan), was launched in 2024, featuring Triple Noise Reduction (TNR) and Extended Dynamic Range Image Processing (EDRIP). We previously demonstrated that this system provides low-noise, bright images with minimal halation compared with the previous system (VP-7000) [1]. In addition, the EP-8000 includes a novel observational mode, amber-red color imaging (ACI), which enhances the visibility of blood vessels and active bleeding points in the mucosa and submucosa. Several case reports have shown that ACI improves visualization of vessels, the submucosal layer, and the muscle layer during endoscopic submucosal dissection (ESD), suggesting that safer dissection under ACI may be possible [2]. However, no studies have evaluated the efficacy of ACI specifically in colorectal ESD. This study assessed the visibility of vessels and the submucosal layer using ACI during colorectal ESD.

Methods This international, multicenter study retrospectively reviewed consecutive patients who underwent colorectal ESD at a single institution between January 2021 and June 2025. Therapeutic outcomes of 72 cases performed using ACI were compared with those of 505 cases performed using white-light imaging (WLI). The primary outcome was the mean number of intraoperative bleeding (IB) events during ESD in the ACI and WLI groups. Secondary outcomes included additional therapeutic outcomes of ESD. Furthermore, fifteen endoscopists (seven experts and eight non-experts) from four countries (Japan, Malaysia, Singapore, and Chile) evaluated the visibility of vessels, submucosa, and muscle layer under ACI and WLI using a four-point scale (1 = poor, 4 = excellent).

Results Among 72 cases (mean age: 67.3 ± 11.9 years, male proportion: 48.6 %), the en bloc resection rate was 98.6 %. The ACI group showed fewer IB events than the WLI group (2.1 ± 2.5 vs 2.8 ± 3.4, p = 0.040), significant only among non-experts (1.3 ± 1.2 vs 2.7 ± 3.2, p = 0.032). Regarding image evaluations, ACI achieved higher visibility scores for vessels (3.54 ± 0.67 vs 2.81 ± 0.77, p < 0.001), submucosa (3.60 ± 0.60 vs 2.96 ± 0.75, p < 0.001), and muscle layer (2.99 ± 0.78 vs 2.45 ± 0.85, p < 0.001). Significant differences in ACI scoring between Japanese and other international endoscopists were observed for vessels and submucosa among experts, and muscle layer visibility among both groups.

Conclusions ACI facilitated safer colorectal ESD by reducing perioperative bleeding and improving visualization of vessels, subkmucosa, and the muscle

layer. Further randomized controlled trials are warranted to confirm these findings.

Conflicts of Interest Yoshida N, Dohi O, and Takagi T received research grant from Fujifilm Co. The other authors declare no conflicts of interest. Novel endoscopic systems and scopes were lent by Fujifilm Co.

DOI 10.1055/s-0046-1821046

Problem to solve Colorectal polyp size is important for determining surveillance intervals, how to resect the polyp and whether to resect-and-discard the polyp. However, currently used polyp size measurement techniques are inaccurate and difficult to perform, highlighting the need for novel techniques. This international multicenter study evaluated the precision of visual assessment (VA) and biopsy forceps (BF)-assisted measurement compared to a novel laser-based measurement system during real-time colonoscopy.

Innovation AccuMeasure (VTM Technologies, Haifa, Israel) is a novel laser-based measurement system to sub-mm–accurately perform 3D measurements during real-time colonoscopy. A previous ex vivo animal study showed this system to be more precise compared to VA with and without use of a BF. The system consists of a reusable through-the-scope (TTS) probe and a medical grade personal computer. The TTS probe inserted through the endoscope working channel projects a laser line across the polyp, enabling size measurement.

Results A total of 137 polyps was successfully measured in 110 patients (56.4 % male; median age 68 years (interquartile range (IQR): 18)). Colonoscopy indications were screening in 47 patients (42.7 %), surveillance in 34 (30.9 %), and diagnostic in 29 patients (26.4 %). Most polyps were adenomas (n = 91) or hyperplastic (n = 23) and were equally distributed through the colon. The polyps were measured with the laser measurement system, VA, and BF in randomized order. The laser-based system achieved successful measurements in 68.8 % of polyps, with a mean measurement time of 120 seconds (standard deviation (SD): 109.9). As shown in ▶ **Table 1**, failed measurements were due to technical malfunctions or difficulty aligning the laser with the polyp surface. Moderate agreement (Cohen kappa (k) = 0.514) was observed between the laser-based system and VA, with VA wrongly assigning a polyp size to > 5 mm (instead of ≤ 5 mm) in 10 polyps (7.3 %) and ≥ 10 mm (instead of < 10 mm) in 2 polyps (1.5 %). Moderate agreement (k = 0.534) was also observed between the laser system and BF, with BF wrongly assigning a polyp size to > 5 mm (instead of ≤ 5 mm) in 11 polyps (8.0 %) and ≥ 10 mm (instead of < 10 mm) in 1 polyp (0.7 %). Based on VA, two patients were assigned a 3- and 5-year surveillance interval, respectively, whereas based on the laser-based measurements these patients should have returned to screening at 10 years, in accordance with ESGE recommendations. Bland-Altman plots indicated that VA resulted on average in an underestimation compared to laser measurement, specifically in polyps of around 5 mm (-0.11 mm, 95 % confidence interval (CI) [-0.39 to 0.17]). In contrast, for polyps over 6 mm, VA showed an average overestimation of 0.29 mm (P = 0.012). BF also resulted in an average underestimation compared to laser measurement (-0.16 mm, 95 % CI [-0.38 to 0.06]) but showed no significant overestimation for polyps over 6 mm (P = 0.118). During the study, no adverse events related to the laser measurement system were reported.

▶ **Table 1** Laser-based measurement system summary statistics on performance

Polyps, n	
Polyps identified	276
Polyps attempted for measurement	199
Polyps successfully measured	137
Failed laser-based measurement reasons, n (%)	
Software malfunction	14 (22.6)
Technical difficulties	17 (27.4)
Anatomical interference	25 (40.3)
Unknown	6 (9.7)

Conclusions Although mechanical difficulties during colonoscopy limited successful measurement to only two-thirds of cases, the novel laser-based system demonstrated greater precision than VA and BF reducing size misclassification. Our findings indicate that laser-based measurement may offer a more reliable approach for determining polyp size, ensuring more appropriate surveillance intervals.

Conflicts of Interest The study was sponsored by VTM Technologies. Data analysis and drafting of the abstract was performed by the authors.

PYP107V ClipTack: A Cost-Effective Method for Closing Large Endoscopic Resection Defects

Authors Htet H[1], Lim MS[1], Bhandari P[2]

Institutes **1** Queen Alexandra Hospital, Portsmouth, United Kingdom; **2** Department of Gastroenterology, Portsmouth Hospitals University NHS Trust, Portsmouth United Kingdom

DOI 10.1055/s-0046-1821047

Problem to solve Closing large endoscopic resection defects is often challenging. Helical tack systems can facilitate closure but are costly. Each device kit contains four tacks. When additional tacks are needed, opening a new kit substantially increases expense, particularly if only one or two extra tacks are required instead of all four tacks.

Innovation To address this, we developed **ClipTack**, a cost-saving technique that uses threaded hemostatic clips to complete the closure without the need to open additional helical tack kits.

Results A 76-year-old patient underwent endoscopic mucosa resection (EMR) for a polyp at the hepatic flexure many years ago. A JNET 2a lateral spreading tumour (LST) had regrown at the same location, in keeping with post-EMR recurrence. Underwater piecemeal EMR was performed for this LST. The resulting defect after pEMR was large, with extensive fibrosis seen at the resection base, and its position over a fold made it challenging to securely close the defect with standard hemostatic clips. Hence a helical tack system was used to initiate closure.

The resection base was still inadequately closed after all four tacks in the helical tack kit were deployed. The remaining suture line was threaded through an opening in the phalange of a standard hemostatic clip. The clip was well lubricated and then advanced along the suture line, which was held under constant gentle tension. Once positioned just lateral to the resection edge, the clip was closed and deployed in the usual fashion. A second hemostatic clip was similarly threaded and advanced, allowing approximation of most of the resection

base. The amount of clinical expertise needed in closing the clip is lesser than the deployment of the helical tack. The suture line was then gently pulled so as to draw the tacks and clips closer and then cinched in the standard manner. We named this hybrid, cost-efficient method as **ClipTack**.

Conclusions ClipTack is a simple reproducible, and cost-effective approach for managing large endoscopic resection defects. By using threaded hemostatic clips in place of additional helical tacks, it significantly reduces procedural costs while still achieving secure and reliable closure. This technique underscores practical innovation, ease of adoption, and resourcefulness in the closure of challenging endoscopic defects.

PYP108 Utility of crystal violet staining and magnifying endoscopy in diagnosing SMIC and determining resectability a western setting

Authors Campion JR[1], Olabintan O[1], Lim A[1], Eqbal A[1], Judge C[1], Ayubi H[1], Noreillie MA[1], Adeyeye A[1], Gulati S[1], Hayee B[1], Haji A[1], Emmanuel A[1]

Institute **1** King's College Hospital, London, United Kingdom

DOI 10.1055/s-0046-1821048

Aims As endoscopic resection (ER) is routinely offered to patients with large non pedunculated colorectal polyps (LNPCP), diagnosing submucosal invasive cancer (SMIC) and differentiating resectable (adenomas and T1 SMIC) from unresectable LNPCP (≥T2 cancer) can be crucial. Crystal violet (CV) staining and magnifying endoscopy to delineate Kudo type V pit patterns may be useful for distinguishing such lesions but is almost never used in western practice and most endoscopists remain sceptical of its efficacy. We aimed to determine the value of magnifying endoscopy with CV staining compared to indigo carmine in diagnosing SMIC and determining resectability in patients with LNPCP referred to a tertiary centre.

Methods All patients referred with LNPCP deemed suitable for ER but without confirmed invasive cancer from January 2018 to September 2025 were included. Patients with biopsy proven adenocarcinoma prior to referral were excluded. Patients were divided into a CV staining cohort after the introduction of this technique between September 2021 and September 2025 and compared to a cohort of patients referred between January 2018 and August 2021 when lesions were assessed with indigo carmine alone. Lesions were stained with crystal violet 0.05 % for one minute or indigo carmine 0.2 % and then examined in detail with magnifying endoscopy at 80-100x magnification. Sensitivity and specificity of CV staining and indigo carmine with magnifying endoscopy in diagnosing HGD or SMI on subsequent biopsy or examination of a resected specimen were calculated.

Results 1448 lesions were referred for consideration of ER and assessed with magnifying endoscopy, 898 in the crystal violet staining cohort and 550 in the indigo carmine alone cohort. Patients in both cohorts were similar in terms of age, mean lesion size, sex, location, and incidence of SMIC. 82 % of diagnoses of type Vi high grade (HG) pit pattern were made using CV and diagnosing any type V pit was more common in the CV cohort (p = 0.02). Using CV, type Vn had a positive predictive value (PPV) for SMIC of 89 % and type Vi HG pit had a PPV of 58 % for SMIC. Vi HG had a PPV 83 % for determining resectability (≤T1 cancer). Vn pit had a PPV of 57 % for ≥T2 cancer. Vi HG was rarely diagnosed in the indigo carmine cohort where Vn pit had a PPV of 91 % and Vi undifferentiated pit had a PPV of 27 % for SMIC. JNET 2b had a PPV of only 23 % for SMIC.

Conclusions This study suggests that the use of CV increases the likelihood of identifying any form of type V pit pattern and particularly type Vi pit pattern. Differentiating type Vi HG pit pattern is useful for diagnosing invasive cancer compared to JNET 2b vascular pattern and is highly predictive of lesions being resectable regardless of potential SMIC with a high NPV for ≥T2 cancer. Vn pit pattern is reasonably predictive of ≥T2 cancer. These findings support longstanding Japanese recommendations to use CV to further delineate surface characteristics when JNET 2b is identified.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP109 Vessel Coagulation in Third Space Endoscopy: a Randomized Controlled Trial

DOI 10.1055/s-0046-1821049

Aims Third-space endoscopy is the standard of care for neoplastic and motility disorders; however, it is technically challenging because of the high risk of intraprocedural bleeding. Such a risk may be reduced by prophylactic coagulation of the submucosal vessels, but it requires instrument exchange. A new approach involves pre-sealing the submucosal vessels using standard electrocautery settings under brief saline immersion using the same knife. The aim of this randomized trial was to further assess the efficacy of underwater pre-sealing in the prevention of intraprocedural bleeding and the overall efficiency of third-space endoscopy.

Methods Patients undergoing third space procedures (ESD or POEM) were randomized to receive either targeted saline-immersion pre-sealing (study group) or conventional coagulation (CO_2 insufflation, control group) for prophylactic management of vessels ≥ 1.2 mm. Dissection settings were identical (HybridKnife, SWIFT COAG mode). Rate of intraprocedural bleeding requiring retreatment for vessels ≥ 1.2 mm was the main outcome. Both *per-patient* and *per-vessel* analyses were also performed. The use of an adjunctive device and coagulation time were also assessed.

Results Seventy patients (37 immersion, 33 control) with 864 ≥ 1.2 mm vessels were included. Saline-immersion pre-sealing significantly reduced bleeding rates both at *per patient* (32.4 % vs 75.8 %, RR 0.43, 95 % CI 0.26-0.71; NNT 2.3; p = 0.01) and at *per vessel* analysis (6.3 % vs 29.9 %, RR 0.21; 95 % CI 0.14-0.31; NNT 4.2; p < 0.01). The use of coagulation forceps for bleeding treatment also decreased (0 % vs 24.2 % and 0 % vs 8.3 %; p < 0.01). A significant reduction in coagulation time was reported in the saline-immersion group (22.7 ± 26.4 seconds vs 29.6 ± 49.8 seconds; p < 0.01).

Conclusions A substantial reduction in the risk of intraprocedural bleeding was achieved by saline-immersion pre-sealing in per-patient and per-vessel analyses, prompting its implementation in clinical practice.

DOI 10.1055/s-0046-1821050

Aims Initial reports have described rectal endoscopic knife-assisted full-thickness resection (kFTR) as a novel technique for achieving R0 resection in deeply invasive rectal cancer or technically challenging rectal lesions, offering a potential alternative to surgery and reducing associated morbidity and mortality. [1, 2] This study aimed to evaluate the feasibility, safety, and technical outcomes of rectal kFTR in an international, multicenter cohort.

Methods We conducted an observational cohort study of consecutive patients undergoing rectal kFTR at 16 centers across 5 continents between April 2017 and April 2025. Eligible patients had rectal lesions with suspected deep submucosal invasion, severe submucosal fibrosis, or subepithelial pathology. Primary outcomes were technical success, en-bloc and R0 resection rates, and adverse events (AEs). Secondary outcomes included length of hospital stay, rectal preservation, and recurrence. Risk factors for AEs were assessed using univariate and multivariate logistic regression.

Results 97 patients (mean age 66 years [IQR 58-74]; 57.7 % male; 79.1 % ASA I/II) were included. The median lesion size was 35 mm [IQR 25-50].

kFTR was performed for suspected deep invasion (59; 60.8 %), severe fibrosis (30; 30.9 %), and subepithelial lesions (8; 8.2 %).

The technical success rate was 97.9 % (95/97), while en-bloc and R0 resection rates were 96.9 % and 79.4 %, respectively. 31 (32.0 %) lesions were T2 adenocarcinomas, 27 (27.8 %) non invasive/T1 adenocarcinomas, 28 (28.9 %) T1 sm2-3 adenocarcinomas, 8 subepithelial lesions (8.2 %), 3 (3.1 %) T3 adenocarcinomas (▶ **Table 1**).

▶ **Table 1** Technical outcomes of endoscopic knife-assisted full-thickness resection across different histopathological groups.

Histology	Non invasive/T1 sm1 n = 27	T1 sm2-3 n = 28	T2 n = 31	Subepithelial lesions n = 8
Technical success	96.3 % (26)	100 %(28)	100 % (31)	100 % (8)
En bloc	92.6 % (25)	100 %(28)	96.8 % (30)	100 % (8)
R0	88.9 % (24)	85.7 % (24)	67.7 % (21)	100 % (8)

Overall, 19 adverse events occurred in 15/97 (15.5 %) patients: 12 grade I, 2 grade II, and 5 grade III per AGREE classification. Delayed bleeding occurred in 4 (4.1 %) patients, and post-procedural pain in 7 patients (7.2 %). One patient required surgery for a recto-vaginal fistula. Increasing lesion size was the only risk factor independently associated with a higher risk of adverse events (OR 1.05, 95 % CI 1.02–1.09, $p = 0.003$).

Median procedural time was 135 minutes (IQR 100–180), and median hospital stay was 1 day (IQR 0.5–3). Rectal preservation was achieved in 75.9 % (22/29) of patients with T1 adenocarcinoma and 45.2 % of T2 (14/31) adenocarcinomas. Among 59 patients with adenocarcinoma and available follow-up (median 12 months (IQR 6 – 23.5)), 3 (5.1 %) experienced loco-regional recurrences, and 1 (1.7 %) had distant metastasis. There were no cancer-related deaths.

Conclusions kFTR appeared to be a feasible and safe technique for excising deeply invasive adenocarcinomas and complex fibrotic or subepithelial rectal lesions in expert centres. Rectal kFTR may serve as an alternative to device-assisted endoscopic full-thickness resection and local surgical excision, potentially avoiding radical surgery in highly selected patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821051

Aims Although peroral endoscopic myotomy (POEM) is performed worldwide for achalasia, the use of intraoperative endoluminal functional luminal imaging probe (EndoFLIP) is debated. Given the lack of consensus, we sought to compare our local outcomes following intraoperative EndoFLIP in guiding myotomy to standard myotomy in our centre.

Methods A retrospective, single-centre, case-control study was conducted, comparing consecutive patients undergoing POEM without or with EndoFLIP guidance (FLIP- or FLIP +). Outcome measures included clinical remission (Eckardt score of ≤ 3), presence of reflux (GERD-HRQL questionnaire), complications and the requirement for further treatment. FLIP readings were obtained before and after myotomy, standardised to 40ml balloon inflation.

Results 100 FLIP + (F: 50; median age: 47.5) were compared to 145 FLIP- (F:65; median age: 49). Intraoperative measurements resulted in extension of myotomy in 9 % of procedures. There was no difference in clinical remission at > 6 months (84 % vs 75 %; p = 0.09).

The length of myotomy (cm) was shorter in FLIP + (7 (5-10) vs 11 (9-13); p = < 0.001). Procedural time (minutes) was also shorter (median 60 (60-79) vs 75 (60-100); p < 0.001), with fewer adverse events recorded in the FLIP + group (1 vs 5, p = 0.041). Neither post-myotomy FLIP measurements, nor change in readings, correlated with clinical outcome. Long-term PPI use was not significantly different in the two groups (30 % vs 43 %; p = 1.61).

Conclusions Intra-procedural use of EndoFLIP during POEM is associated with shorter procedure time, shorter myotomy and fewer adverse events, without negatively impacting clinical success or PPI use long-term. FLIP-guided extension of myotomy is a possible marker of clinical utility, preventing early recurrence and re-do procedures. FLIP + POEM has been adopted as standard of practice in our institution.

PYP112 Esophageal Motility Disorders After Pulsed Field Ablation for Atrial Fibrillation – Prospective Data from High-Resolution Manometry

Authors Kasparian K[1, 2], Neven K[1], Fueting A[3, 2], Reinsch N[1, 2], Hartl S[1, 2], Schaefer A[1], Schramm C[4], Jochheim L[4], Zeller A[4], Schmidt H[4], Gerges C[5], Rahe G[4]

Institutes 1 Alfried Krupp Hospital Ruettenscheid, Essen, Germany; 2 Witten/Herdecke University, Witten, Germany; 3 Helios St. Anna Klinik Duisburg, Duisburg, Germany; 4 Essen University Hospital, Essen, Germany; 5 Helios HMU Clinic Krefeld, Krefeld, Germany

DOI 10.1055/s-0046-1821052

Aims Atrial fibrillation (AF) is considered one of the major health problems in Western societies, with a prevalence of more than 10 % of the population older than 65 years in Europe and North America. Approximately 100,000 catheter ablations are performed annually in German hospitals, according to data provided by the German Cardiac Society. Until 2021, standard methods for cardiac ablation included radiofrequency ablation and cryoballoon ablation. Despite their effectiveness, these methods are associated in a small number of cases with major and potentially life-threatening complications such as esophageal injury and atrio-esophageal fistulas. Since its first certification in 2021, pulsed field ablation (PFA) has demonstrated an improved safety profile in this regard. To date, no esophageal injuries or atrio-esophageal fistulas have been reported, likely due to the highly tissue-selective, non-thermal mechanism of irreversible electroporation by which PFA achieves myocardial ablation. However, animal models have demonstrated potential injury to the esophageal muscular layers after PFA, presumably due to the close anatomical proximity of the esophagus to the left atrium. To date, no clinical studies investigating a potential association between PFA and esophageal motility disorders have been conducted. Therefore, we performed a prospective study using high-resolution manometry (HRM) to address this unanswered question.

Methods We conducted a prospective observational cohort study including patients with AF referred to the electrophysiology outpatient clinic of the Alfried Krupp Hospital in Essen, Germany, who were scheduled for PFA from March 2024 until the time of submission. Each participant underwent HRM in our Gastroenterology Department one day before and one day after PFA. HRM was performed according to the Chicago Classification v4.0 for esophageal motility disorders, including ten swallows in the semi-recumbent and five swallows in the sitting position. Participants were also evaluated for dysphagia, and the Eckardt Score was calculated for each individual before and after PFA. The primary endpoint was the change in HRM parameters based on the Chicago Classification v4.0, specifically the mean integrated relaxation pressure (IRP), mean distal contractile integral (DCI), mean distal latency (DL), and mean intrabolus pressure (IBP) before and after PFA. Patients who showed significantly altered manometric parameters after PFA underwent repeat HRM three months later. Secondary endpoints included the persistence or resolution of altered HRM findings at the three-month follow-up, patient-reported dysphagia and changes in the Eckardt Score before PFA, directly after and at the three-month follow-up [1–4]

Results From March 2024 until submission, 40 of the planned 50 patients were enrolled in the study, and 11 patients had completed the three-month follow-up. Eight patients were lost to follow-up. In the remaining patients, no significant long-term differences in manometric parameters were observed after PFA. The mean age of the participants was 68.4 years, and 70 % were male. A significant reduction in DCI was observed one day after PFA in both the supine (p = 0.01) and sitting positions (p < 0.0005). The mean DCI decreased by approximately 25.4 % in the supine and 38.4 % in the sitting position, with a maximal DCI-reduction of 87.5 % in one individual. Approximately 55 % (22/40) of the patients developed focal areas of reduced pressure in the distal third of the tubular esophagus. Among the patients who completed the three-month follow-up, DCI values had returned to baseline, despite the transient reduction observed at day one. However, five participants still exhibited focal areas of reduced esophageal pressure in isolated swallows at three months. No changes in patient-reported symptoms or Eckardt Scores were detected at any time point.

Conclusions Patients undergoing PFA may develop transient reductions in esophageal motility one day after the procedure. These alterations largely resolve within three months and appear to have no clinical impact on symptoms. However, the presence of persistent focal pressure abnormalities in a subset of patients suggests subtle long-term motility effects of PFA, highlighting the need for additional research.

PYP113 Same-day discharge for oesophageal POEM without investigations is feasible and safe

Authors Ayubi H[1, 2], Lim A[1, 2], George R[1], Gulati S[1], Patel M[1], Thrumurthy S[1], Haji A[1], Hayee B[1]
Institutes **1** King's College Hospital, London, United Kingdom; **2** HA and AL joint first aurthor
DOI 10.1055/s-0046-1821053

Aims Same-day discharge (SDD) after oesophageal per-oral endoscopic myotomy (POEM) for achalasia is variably applied in clinical practice. Many centres still adopt at least overnight admission (ONA) and patient discharge is dependent on investigations such as oesophago-gastro-duodenoscopy (OGD) or contrast swallow (CS). Many series describing SDD (achieving 41-70 % rates) still advocate same-day CS, a highly resource-intensive strategy. In our institution, we introduced a step-wise protocol change to SDD from ONA, phasing out both OGD and CS [1].

Methods A retrospective, single-centre, case-control study was conducted, comparing consecutive patients undergoing SDD protocol to a consecutive age- and sex-matched group following the original ONA protocol. For SDD, patients were observed for 4 hours post-procedure and admitted if they met any of the following criteria: 1) unstable vital signs 2) persistent chest pain or dyspnoea requiring more than one dose of opioid analgesia 3) severe complications or endoscopic concerns 4) unable to swallow secretions or 5) social reasons.

Results The ONA group (n = 123; F = 57; mean age 48) were compared to SDD (n = 124 F: 55; mean age: 47; median duration of admission: 2; IQR 1-2 days). N = 102 (83 %) had successful SDD. Median procedural time (minutes) was shorter for SDD (60 (60-84) vs 75 (60-100); p = 0.01) and median myotomy length (cm) was also shorter (7 (5-10) versus 12 (9-14), p < 0.001). There was no difference in 30-day readmission rate (4.2 % vs. 5.4 %; p = 0.648).

There was no correlation between 30-day readmission and age (p = 0.456), ASA score (p = 0.453), opioid analgesia in recovery (p = 0.523), fellow performing procedure (p = 0.763), baseline Eckardt score (p = 0.816), or long term outcome (> 12 month Eckardt score).

Of those SDD patients admitted overnight, we identified n = 8 where a prolonged period of same-day observation may have safely prevented admission (total 89.4 %).

Conclusions The protocol for SDD following oesophageal POEM can be feasibly and safely refined to increase rates of SDD (83 %) without the need for routine imaging or endoscopy. Prospective studies should assess whether patients with minor complications managed endoscopically may also be safely discharged on the same day.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP114 Anterior Versus Posterior Myotomy Orientation in POEM: A Comprehensive Meta-analysis of Efficacy, Safety, GERD, and Procedural Outcomes

Authors Patel RH[1], Parikh C[2, 3], Patel PD[4], Patel D[3], Confer B[4], Khara H[5]
Institutes **1** St. Mary Medical Center, Langhorne, United States of America; **2** Hospital of the University of Pennsylvania – Cedar Avenue, Philadelphia, United States of America; **3** Mercy Fitzgerald Hospital, Darby, United States of America; **4** Geisinger Medical Center, Danville, United States of America; **5** Geisinger Medical Center, Danville, PA, United States of America
DOI 10.1055/s-0046-1821054

Aims To compare anterior versus posterior myotomy during POEM across all major clinical, safety, physiologic, and procedural outcomes using the latest available time points from randomized trials and high-quality comparative studies.

Methods A systematic review and meta-analysis of RCTs and cohort studies was performed. Outcomes included clinical success (Eckardt score ≤ 3), adverse events (overall and mucosotomy-specific), GERD (pH, endoscopy, symptoms), manometric response, and procedural metrics (total procedure time, closure time, hospital stay). For binary outcomes, pooled odds ratios (OR) were calculated; for continuous outcomes, mean differences (MD) were synthesized using random-effects models. Long-term data from RCT extensions were incorporated when available.

Results A total of four RCTs and multiple cohort studies (≈ 1,200 patients) were included.

Clinical success: No significant difference between anterior and posterior POEM at 12 months (OR ≈ 1.02; RR ≈ 0.98). Long-term RCT follow-up (≥ 2 years) also showed similar results (85 % vs 79 %, p > 0.40).

GERD: Incidence of GERD by pH, endoscopy, and symptom scores was similar across orientations (pooled OR ~ 1.0 across modalities).

Adverse events: Posterior POEM demonstrated significantly fewer overall adverse events (RR ≈ 0.63) and markedly reduced mucosotomy risk (RR ≈ 0.42).

Procedural outcomes: Posterior POEM was associated with shorter incision-closure time (MD − 2.28 minutes) and, in observational datasets, shorter overall procedure duration. Anterior POEM demonstrated a statistically shorter but clinically negligible hospital stay (MD + 0.31 days).

Manometry: LES pressure and IRP reduction were equivalent between approaches (MD ≈ 0), with similar normalization rates.

Conclusions Anterior and posterior POEM achieve equivalent clinical success, similar GERD rates, and comparable physiologic improvement. Posterior myotomy offers procedural advantages: reduced adverse events and faster closure time without compromising clinical efficacy. These findings support the routine use of posterior orientation, particularly in centers prioritizing efficiency and mucosal safety, while affirming that either approach yields excellent therapeutic results.

PYP115 Pre-procedure Risk Stratification for POEM Failure: Comparative Evaluation of the Urakami and Abe Scores

Authors Inês S[1], Lima PA[1], Mascarenhas A[1], Rodrigues JP[1], Cristina C[1], Barreiro P[1, 2]
Institutes **1** Hospital Egas Moniz, Lisboa, Portugal; **2** Lusíadas Hospital, Advanced Endoscopy Center of Lisbon, Lisbon, Portugal
DOI 10.1055/s-0046-1821055

Aims Peroral endoscopic myotomy (POEM) is a safe and effective treatment for achalasia; however, a notable proportion of patients experience therapeutic failure. Urakami et al. and Abe et al. developed pre-procedure scores to predict POEM failure at 12 and 6 months, respectively. The aim of this study was to evaluate the applicability of these scores in our patient population.

Methods We conducted a retrospective cohort study with prospectively collected data, including patients who underwent POEM for achalasia between January 2017 and February 2023, with at least 12 months of follow-up. Therapeutic failure was defined as an Eckardt score > 3 or the need for additional intervention. After calculating and stratifying the scores, their discriminative ability, sensitivity, and specificity were assessed [1, 2].

Results Eighty-three patients (mean age 55 years, range 17–79; 56 % female) underwent POEM, predominantly with type 2 achalasia (n = 50). Thirty-seven percent had undergone prior treatment. Initial clinical response was achieved in 98 % of patients (n = 81). During long-term follow-up (median 49 months), 11 patients developed symptomatic recurrence, occurring at a median of 24 months after the procedure (range: 6–48 months). Aside from the pre-proce-

dure Eckardt score (p = 0.04), no statistically significant association was observed between age, sex, manometric diagnosis, esophageal transit characteristics or prior treatment and therapeutic failure. The Urakami score demonstrated an AUC of 0.725, stratifying patients into low (n = 41), intermediate (n = 35), and high-risk (n = 8) groups, with a sensitivity of 7.7 % and specificity of 90 %. The Abe score showed an AUC of 0.737, stratifying patients into low (n = 70) and high-risk (n = 13) groups, with a sensitivity of 30.8 % and specificity of 87 %.

Conclusions Both scores demonstrated acceptable discriminative ability (AUC > 0.7), indicating they can statistically distinguish patients at higher versus lower risk of POEM failure. The Urakami score had very low sensitivity but high specificity (90 %), meaning it reliably identifies patients who are unlikely to fail POEM and may help avoid unnecessary interventions in low-risk individuals. In contrast, the Abe score showed higher sensitivity (30.8 %) but lower specificity (87 %), reflecting a trade-off between detecting at-risk patients and overestimating risk. These findings highlight that while pre-procedure scores can aid risk stratification, their clinical application should be complemented by careful patient evaluation and follow-up, and further refinement of predictive tools is needed.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP116 Long-Term Outcomes of Per-Oral Endoscopic Myotomy (POEM) for Achalasia: Clinical Efficacy and Gastroesophageal Reflux in a Real-World Cohort

Authors Inês S[1], Pereira B[1], Lima PA[1], Mascarenhas A[1], Cristina C[1], Barreiro P[1, 2]

Institutes **1** Hospital Egas Moniz, Lisboa, Portugal; **2** Lusíadas Hospital, Advanced Endoscopy Center of Lisbon, Lisbon, Portugal

DOI 10.1055/s-0046-1821056

Aims Achalasia is a primary esophageal motility disorder characterized by impaired lower esophageal sphincter relaxation and absent peristalsis. Although no treatment is curative, interventions aim to reduce esophagogastric junction obstruction and improve symptoms. Pneumatic dilation, laparoscopic Heller myotomy and per-oral endoscopic myotomy (POEM) have comparable efficacy in type I and II achalasia, whereas POEM is preferred for type III. Long-term outcomes of both POEM and Heller myotomy demonstrate symptom control rates between 80–90 %. Post-POEM gastroesophageal reflux (GERD) is common, with esophagitis reported in up to 65 % of patients, though severe disease is less frequent and often improves over time. Regular surveillance is recommended to detect silent esophagitis and guide management. Our aim was to evaluate long-term clinical efficacy of POEM and GERD-related outcomes in a real-world cohort.

Methods This retrospective single-center study included all patients undergoing POEM for achalasia at a tertiary Portuguese referral center between January 2017 and November 2023, with ≥ 24 months of follow-up. All procedures were performed by a single experienced endoscopist. The primary outcome was clinical success, defined as a post-POEM Eckardt score ≤ 3 without additional intervention. Secondary outcomes included perioperative adverse events (AEs), post-POEM GERD assessed through patient-reported symptoms, long-term proton pump inhibitor (PPI) therapy and endoscopic findings. AEs were classified according to the AGREE system [1–4].

Results A total of 143 patients underwent technically successful POEM. Of these, 113 patients had ≥ 24 months of follow-up. Median age was 55 years (range 17–81), and 57 patients were female (50.4 %). Achalasia types were: 72 type II, 28 type I and 13 type III. Only one significant post-procedure AE occurred (aspiration pneumonia requiring ICU admission, Grade IV). Clinical response at 1 year was 97.3 % (n = 110), with long-term clinical success in 88.5 % (n = 100) with a median follow-up of 44 months (range 21–96). Thirteen patients experienced symptomatic recurrence at a median of 24 months (range 0–48), four underwent re-POEM and two underwent endoscopic dilation with sustained success, while two are awaiting endoscopic retreatment. Higher pre-POEM Eckardt scores were significantly associated with recurrence (p = 0.027), with a median of 9 points in the recurrence group versus 6 points in responders. No significant association was observed between clinical success and achalasia type, age, gender, previous treatment or myotomy approach.

Regarding GERD, 29 patients reported frequent or daily reflux symptoms at some point during follow-up, but only 15 (13 %) remained symptomatic at last evaluation, all responding to PPI therapy. Long-term PPI therapy (> 6 months) was required in 95 patients (84 %), and 79 (70 %) remained on daily PPI at last follow-up. First post-procedure endoscopy (median 7 months) was available for 85 patients: esophagitis was found in 42 (49 %), including severe reflux esophagitis in 13 % (10 LA-C, 1 LA-D) and ischemic ulcers in five patients. Last endoscopy (median 32 months, n = 70) revealed esophagitis in 31, severe in only 1 patient (1.4 %, LA-C). Eleven patients were on PPI at the time of last endoscopy, one twice daily. At least one patient had documented refractory reflux esophagitis (LA-B despite twice-daily PPI). No patient required additional endoscopic or surgical intervention for GERD. Reported symptomatic reflux was significantly associated with clinical failure (p = 0.017), with 62 % of patients with long-term failure reporting symptoms (without severe esophagitis in endoscopy) versus 21 % of responders. No associations were found between symptoms or severe esophagitis and age, gender, achalasia type, diabetes, alcohol use, smoking, BMI or myotomy approach.

Conclusions POEM is a safe and highly effective treatment for achalasia, achieving excellent long-term clinical success. Post-POEM GERD is common but usually manageable with long-term PPI therapy, and no patient in our cohort required additional interventions. Higher reported reflux symptoms among patients with clinical failure may reflect overlapping symptomatology between uncontrolled achalasia and GERD, highlighting the importance of monitoring and managing reflux symptoms during follow-up.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP117 Post-POEM Care Optimization: Evidence Supporting Soft-Diet Initiation on Day 2

Authors Inês S[1], Bruno R[1], Lima PA[1], Cristina C[1], Barreiro P[1, 2]

Institutes **1** Hospital Egas Moniz, Lisboa, Portugal; **2** Lusíadas Hospital, Advanced Endoscopy Center of Lisbon, Lisbon, Portugal

DOI 10.1055/s-0046-1821057

Aims Peroral endoscopic myotomy (POEM) has become a first-line therapeutic option for achalasia and other esophageal motility disorders, offering high effectiveness and a favorable safety profile. Most adverse events are identified and managed intraprocedurally, while severe post-procedural complications such as leak, perforation or bleeding are uncommon, occur in ≤ 1 % of cases. Despite this, post-POEM care lacks standardization. Current ESGE guidelines advise against routine esophagram in asymptomatic patients and recommend gradual diet advancement – fluids on day 1, soft diet on day 3, and normal diet on day 7 – along with single-dose prophylactic antibiotics and empiric acid suppression. AGA acknowleges that same-day discharge may be feasible and supports early initiation of oral fluids in clinically stable patients without intraprocedural complications, hours after the procedure, although no uniform post-procedure diet protocol exists. Growing clinical experience suggests that early oral intake is safe in appropriately selected patients, as most complications are detected during POEM and early feeding does not appear to increase adverse events.

Our aim was to describe our post-procedural management protocol and demonstrate the safety of introducing a soft diet as early as 48 hours after POEM.

Methods This retrospective single-center study included all patients undergoing POEM at a tertiary Portuguese referral center between January 2017 and October 2025. All procedures were performed by a single experienced endoscopist. The primary outcome was perioperative adverse events (AEs). AEs were classified according to the AGREE system [1, 2].

Results A total of 204 patients underwent 211 POEM procedures, 51 % were male (n = 104) with a median age of 55 years. Most patients had achalasia (n = 195), including 101 with type II, 52 with type I, 24 with type III and 18 unclassified. Six patients had other esophageal motility disorders, most commonly esophageal spasm (n = 4).

Technical success was achieved in 209 of the 211 procedures. Intra-procedural adverse events occurred in seven cases (some with more than one event): six minor bleedings and two perforations, all endoscopically managed, three pneumoperitoneums drained during the procedure, and two anesthetic complications (aspiration and pneumonia). One aspiration pneumonia required ICU admission, constituting a grade IV adverse event according to the AGREE classification.

Most patients were admitted for 48-hour surveillance, during which prophylactic ceftriaxone was administered. Thirty-eight patients reported post-procedural pain controlled with analgesics (grade I), and two experienced fever requiring one additional day of hospitalization (grade II).

A barium swallow was performed on day one in 146 patients, with no clinically significant findings. Since September 2024, this examination is no longer performed routinely and is now reserved for technically complex procedures with higher perceived risk.

A liquid diet was initiated on day 1 (24 hours after POEM) in 200 patients, followed by a soft diet on day 2 in 198 patients, with no diet-related complications observed. Patients maintained a soft diet for six days, progressing to a light general diet from day 7 onward. All patients received double-dose PPI therapy during admission, continued until at least the first outpatient follow-up. Aside from GERD and symptomatic failure, no other late complications were recorded.

Conclusions POEM remains a highly safe therapeutic modality, with most adverse events occurring intraprocedurally and effectively managed endoscopically. Post-procedural clinical surveillance is sufficient to guide patient management, without the need for routine contrast studies in asymptomatic individuals. Our data indicate that early diet advancement is feasible and safe, supporting the initiation of a soft diet on day 2 after POEM.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP118 The Impact of Per Oral Endoscopic Myotomy on Patient Quality of Life

Authors Amine M[1], Mrabti S[2], Benhamdane A[1], Azammam S[1], Hiji C[1], Addajou T[1], Elkoti I[1], Fedoua R[3], Seddik H[1]

Institutes **1** Mohammed V Military Training Hospital, Rabat, Morocco; **2** Mohammed V Military Teaching Hospital Rabat, Morocco, Rabat, Morocco; **3** Mohamed V Military training hospital, Rabat, Morocco

DOI 10.1055/s-0046-1821058

Aims Per Oral Endoscopic Myotomy(POEM) is the treatment of choice for achalasia.Beyond clinical efficacy, evaluating quality of life and symptom progression is a crucial indicator of the real benefit to patients.This study aims to analyze the effectiveness of POEM using symptom scores(GerdQ,achalasia-specific questionnaire)and different dimensions of the SF-36,three months after the procedure.

Methods A prospective, descriptive, and analytical study was conducted on 28patients,evaluated before and three months after POEM. Participants completed three questionnaires:

1-GerdQ,

2-Achalasia-specific questionnaire,

3-SF-36, covering its main dimensions: physical functioning, physical and emotional role limitations, vitality,mental health,social functioning,bodily pain,general health,and health change.Statistical analyses were based on paired **t-tests** to compare pre- and post-procedure scores. Correlations between score **changes (Δ)** were studied using **Pearson's r**. The significance threshold was set at **$p < 0.05$**.

Results Twenty-eight patients were evaluated before and three months after POEM. Analysis of symptom scores and quality of life revealed a significant improvement in all parameters studied.**The GerdQ score** significantly decreased from **10.89 ± 2.1 to 5.46 ± 1.8** at **3 months** post-POEM (**$p < 0.001$**).**The achalasia-specific questionnaire** also showed a marked reduction in symptoms, from **26.3 ± 5.2 to 15.7 ± 4.9** (**$p < 0.001$**).Regarding **quality of life (SF-36)**, all dimensions improved significantly:

- Physical functioning: **46.1 → 80.0; $p < 0.001$**
- Physical role limitations: **16.1 → 75.9; $p < 0.001$**
- Emotional role limitations: **19.0 → 73.8; $p < 0.001$**
- Vitality: **32.0 → 64.1; $p < 0.001$**
- Mental health: **41.4 → 72.7; $p < 0.001$**
- Social functioning: **39.5 → 69.7; $p < 0.001$**
- Bodily pain: **27.3 → 71.3; $p < 0.001$**
- General health: **31.3 → 68.5; $p < 0.001$**
- Health change: **18.6 → 64.3; $p < 0.001$**

The overall SF-36 components showed significant improvement: the physical component summary (PCS) increased from 30.2 ± 9.4 to 50.2 ± 9.0 ($p < 0.001$), and the mental component summary (MCS) from 27.1 ± 11.6 to 46.0 ± 12,6 $p < 0.001$).Correlation analysis between score changes (Δ) at 3 months showed:

- A **moderate** and **significant correlation** between the decrease in reflux symptoms **(ΔGerdQ)** and the reduction of achalasia-specific symptoms **(ΔAchalasia): $r = 0.497$; $p = 0.008$**.
- The change in the **achalasia-specific score** was **strongly negatively correlated** with the improvement in the **physical component (ΔPCS)**: $r = -0.595$; $p = 0.001$, indicating that a substantial reduction in achalasia symptoms is associated with significant physical quality-of-life gains.

- **No significant correlation** was observed between the **mental component (ΔMCS)** and other scores **(ΔGerdQ, ΔAchalasia, ΔPCS),** suggesting that short-term mental improvement is independent of symptom changes.

Conclusions Our study confirms the **effectiveness** of POEM in improving reflux symptoms, achalasia manifestations, and all dimensions of quality of life, both physical and psychosocial. The mental component at three months, however, may require more time to show improvement.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP119 Precisect Mode vs Spray coag Mode for Submucosal Tunneling in Peroral Endoscopic Esophageal Myotomy: A Randomized Trial

Authors Shehab H[1], Fadloon I[1], Ahmed E[1], Kaddah M[1], Omran S[1], Nafee A[2], Mohamed H[2], Elhendawy R[2], Khafagy A[2]

Institutes **1** Cairo University, Cairo, Egypt; **2** Zagazig University, Zagazig, Egypt

DOI 10.1055/s-0046-1821059

Aims Peroral endoscopic esophageal myotomy (POEM) has become a primary therapeutic modality for Achalasia. Precisect is a newly developed electrosurgical current mode with proposed advantages over standard modes in POEM procedure. The aim of this study was to evaluate the performance of precisect mode vs spray coag mode in submucosal tunneling during POEM.

Methods 52 patients diagnosed with Achalasia were randomized to have POEM procedure performed with either Precisect mode or Spray coag mode for submucosal tunneling using an ERBE VIO3 generator and Hybrid knife.

Results Technical success occurred in all patients. Submucosal tunneling duration (17 minutes (8-41) vs 15.5 (7-76), p:0.5), submucosal tunneling speed (0.64 cm/minute (0.21-1.5) vs 0.73 (0.2-1.43), p:0.34) and whole procedure duration (44 minutes (27-77) vs 38.5 (21-130), p:0.19) were similar in Precisect and Spray coag groups respectively. Bleeding requiring change to a coagrasper (1 (0-3) vs 0 (0-1), p:0.01) and need to change electrosurgical mode to coagulate non-bleeding vessels (3 (0-9) vs 1 (0-5), p:0.002) were higher in the Precisect group. However, the occurrence of mucosal injury was higher in the Spray coag group (7.7 % vs 34.6 %, p: 0.05).

Conclusions Using a hybrid knife, Precisect mode is associated with more frequent switching to coagrasper to coagulate bleeding vessels as well as a more frequent need to shift to another mode to coagulate non-bleeding vessels in comparison to Spray coag mode. On the other hand, Spray coag mode is associated with a higher incidence of mucosal injury. Both modes seem to have the similar speed of submucosal dissection.

DOI 10.1055/s-0046-1821060

Aims To compare technical, clinical success, adverse events rate and incidence of post-procedural pain of conventional PerOral Endoscopic Myotomy (POEM) versus underwater POEM (u-POEM) in consecutive patients treated for achalasia at a tertiary referral centre.

Methods We retrospectively analysed POEM and u-POEM performed in our centre between February 2024 and July 2025 with at least 3 months of follow-up. In u-POEM, CO_2 insufflation was suspended during tunnelling and myotomy and the submucosal space was filled with room-temperature saline. Pre-procedural (demographics, achalasia subtype, previous treatments, Eckardt score, laboratory exams), procedural (tunnel and myotomy length, tunnelling and myotomy speed, procedure time, anterior or posterior approach) and post-procedural (pain, laboratory exams, analgesics administration, adverse events evaluation) data were recorded. Statistical analysis was made using Student's t-test or Wilcoxon rank-sum for continuous variables and Fisher's exact test for categorical variables; two-sided $p < 0.05$ was considered significant (▶ **Table 1**).

▶ **Table 1**

Characteristic	POEM Group (n = 13)	u-POEM Group (n = 12)	p-value
Age (mean ± SD)	62.6 ± 11.8 years	61.8 ± 15.2 years	0.887
BMI (mean ± SD)	24.1 ± 3.4 kg/m²	22.1 ± 3.4 kg/m²	0.154
Pre-op Haemoglobin (g/dL, mean ± SD)	14.5 ± 0.9	13.4 ± 1.3	0.019
Procedure Duration (min, mean ± SD)	56.2 ± 12.5	68.8 ± 16.0	0.038
Myotomy Speed (cm/min, mean ± SD)	1.44 ± 0.54	0.85 ± 0.28	0.003
Technical success, n (%)	13 (100 %)	12 (100 %)	N/A
Pain Score (NRS, median [IQR])	3 [3, 4]	1 [0, 2.25]	0.004
Patient-Reported Pain, n (%)	13 (100.0 %)	8 (66.7 %)	0.039
Δ Haemoglobin (g/dL, mean ± SD)	-0.48 ± 0.91	-0.45 ± 1.25	0.937
Minor Adverse Events, n (%)	4 (30.8 %)	1 (8.3 %)	0.322
Post-operative Fever, n (%)	2 (15.4 %)	0 (0.0 %)	0.480
Pre-op Eckardt Score (mean ± SD)	7.7 ± 2.5	6.7 ± 2.1	0.272
Post-op Eckardt Score (mean ± SD)	0.92 ± 0.95	0.83 ± 0.72	0.794
Clinical success (Eckardt score ≤ 3 at 3 months), n (%)	13/13 (100 %)	12/12 (100 %)	N/A
Hospital Stay (days, median [IQR])	3 [3, 4]	3 [3, 3.75]	0.723

Results Twenty-five consecutive patients were included (POEM n = 13; u-POEM n = 12). Baseline demographics, BMI, ASA and Eckardt score were comparable. Technical success was reached in all patients. Clinical success (Eckardt score ≤ 3 at 3 months) was 100 % in both groups. Mean total procedure time was significantly longer for u-POEM (68.8 ± 16.0 vs 56.2 ± 12.5 min; p = 0.038), driven by

a slower myotomy speed (0.85 ± 0.28 vs 1.44 ± 0.54 cm/min; p = 0.003), while tunnelling speed and tunnel/myotomy lengths were similar between the two groups. Postoperative pain, measured 24 hours after the procedure using an NRS scale, was less intense in the group of patients who underwent u-POEM (median NRS 1.0 [IQR 0.0–2.25] vs 3.0 [IQR 3.0–4.0]; p = 0.004) and 4/12 patients in u-POEM group reported no pain versus 0/13 in POEM (p = 0.039). No major adverse events occurred; minor adverse events rate was lower with u-POEM (1/12, 8.3 % vs 4/13, 30.8 %; p = 0.322) but without statistical significance [1, 2].

Conclusions u-POEM is feasible and achieved the same outcomes of POEM. This new technique is associated to a reduction of postoperative pain. This result is probably due to the less intense thermal effect on tissues. On the other hand, u-POEM is associated with reduced myotomy speed. These findings support u-POEM as a safe, effective and less painful alternative to conventional POEM.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP121 Updated Meta-analysis of Gastric and Duodenal Cancer Incidence and Upper Endoscopy Surveillance in Lynch Syndrome

Authors Ausina Pous V[1], Baile S[2], Sala-Miquel N[1], Mangas Sanjuán C[3], Sáez M[1], Compañy Catalá L[3], Jover R[4]

Institutes **1** University General Hospital Dr. Balmis, Alicante, Spain; **2** University General Hospital Dr. Balmis, 03010s3, Spain; **3** General University Hospital of Alicante, Alicante, Spain; **4** GASTROENTEROLOGY, ALICANTE, Spain

DOI 10.1055/s-0046-1821061

Aims Individuals with Lynch syndrome (LS) are at increased risk for gastric cancer (GC) and duodenal cancer (DC), particularly those with specific mismatch repair (MMR) gene mutations or a family history of GC. However, the benefit of upper gastrointestinal surveillance with esophagogastroduodenoscopy (EGD) remains unclear, with heterogeneous recommendations among international guidelines. This study aimed to estimate the incidence of GC and DC in LS patients, assess the risk in high-risk subgroups, and evaluate the effect of EGD surveillance.

Methods We conducted a systematic review and meta-analysis of cohort studies and clinical trials identified in PubMed and EMBASE (inception to April 2025). Cancer incidence rates per 1,000 person-years (p-y) were calculated overall and stratified by gene mutation and family history. When applicable, relative risks (RRs) and 95 % confidence intervals (CIs) were computed to compare patients undergoing EGD surveillance with those without surveillance. Random-effects meta-analyses were performed, and heterogeneity was assessed using the I^2 statistic.

Results Thirty-four studies were included, comprising 36,402 LS patients. Among studies with calculable person-years, the pooled incidence rate of GC was 1.13 per 1,000 p-y (95 % CI, 0.62–1.63) and 1.92 per 1,000 p-y (0.78–3.05) for DC. By MMR gene, GC incidence rates were 0.62 (MLH1), 1.25 (MSH2), and 0.12 (MSH6) per 1,000 p-y. In supplementary proportion-based analyses, overall GC and DC incidences were 2.71 % (95 % CI, 2.21–3.21) and 1.71 % (95 % CI, 1.30–2.12), respectively; GC incidences were 2.66 % for MLH1, 4.05 % for MSH2, 0.40 % for MSH6, and 10.38 % (95 % CI, 3.25–17.51) in patients with a family history of GC. DC incidences by gene were 1.65 % for MLH1, 1.75 % for MSH2, and 0.64 % for MSH6. In analyses by mode of diagnosis, incidence rates were higher in screen-detected than in symptom-detected cohorts (GC 1.35 vs 0.74 per 1,000 p-y; DC 2.70 vs 0.67 per 1,000 p-y). In sensitivity analyses, the pooled GC incidence was 0.76 per 1,000 p-y when restricting to studies with ≥ 250 participants and 0.73 per 1,000 p-y in prospective-only cohorts. In two comparative studies of surveillance, EGD was associated with a lower risk of both GC (RR 0.31; 95 % CI, 0.14–0.69) and DC (RR 0.29; 95 % CI, 0.16–0.52).

Conclusions Patients with LS, particularly MSH2 carriers and those with a family history of GC, have an increased incidence of upper gastrointestinal cancers. EGD surveillance was associated with a lower incidence of both GC and DC in selected patients, although evidence is based on a limited number of comparative cohorts. Further prospective studies are needed to define optimal surveillance strategies [1–12].

PYP122 Upper GI Cancer Risk After Positive FIT in a Population-Based Screening Program: A Retrospective Cohort Study

Authors Frazzoni L[1], Baldacchini F[2], Giuliani O[2], Gibiino G[3], Fabbri C[4], Falcini F[2], Fuccio L[5]

DOI 10.1055/s-0046-1821062

Aims Occult blood detected by fecal immunochemical testing (FIT) could originate from upper gastrointestinal (GI) lesions. We aimed to assess whether individuals with a positive FIT in a colorectal cancer (CRC) screening program – even without colorectal advanced neoplasia (AN) – have increased risk of esophagogastroduodenoscopy-detectable upper GI cancers (EUGIC) within three years after screening.

Methods Subjects aged 50–69 who underwent FIT-based CRC screening from 2005 to 2018 in Romagna were included. FIT positivity was defined as ≥ 20 µg hemoglobin/g feces. According to the last screening round result, subjects were classified as: FIT-positive with advanced neoplasia (FIT + /AN + ; colorectal cancer or advanced adenoma), FIT-positive without AN (FIT + /AN −), or FIT-negative (FIT −). All esophageal, gastric, or duodenal cancers diagnosed within three years of the FIT were identified via linkage with the regional cancer registry. Incidence of EGD-detectable upper GI cancers was compared across FIT + /AN + , FIT + /AN − , and FIT − groups. In a sub-analysis, we evaluated a lower fecal hemoglobin cutoff (≥ 10 µg/g) for association with upper GI cancer. Multivariable logistic regression (adjusting for age, sex, and screening round) estimated odds ratios (OR) for EUGIC, and ROC analysis assessed the predictive performance of FIT. The number of screenees needed to scope (NNS) to find one EUGIC was computed [1, 2].

Results A total of 281,370 individuals were included (FIT-positive: 7.8 % [2.4 % with AN]; FIT-negative: 92.2 %). EUGIC were identified in 0.20 % of FIT − participants, compared to 0.34 % of FIT + /AN − and 0.38 % of FIT + /AN + participants ($p < 0.001$). Lowering the FIT positivity threshold to ≥ 10 µg/g increased sensitivity with decrease in specificity. At multivariable analysis, FIT ≥ 10 µg/g (OR 1.67, 95 %CI 1.34-2.08), increasing age (OR 1.05, 95 %CI 1.04-1.07), male sex (OR 1.74, 95 %CI 1.46-2.08) and first-round screening (OR 1.46, 95 %CI 1.20-1.77) were associated with EUGIC, with fair predictive performance (ROC 0.64). The predicted three-year EUGIC risk ranged from 0.09 % (lowest-risk category) to 0.6 % (highest-risk category). Corresponding NNS was 1111 for lowest-risk category and 167 for highest-risk category.

Conclusions FIT-positive screening participants showed a 1.7-fold higher incidence of esophageal, gastric and duodenal GI cancers than FIT-negatives within three years from last screening round – although the absolute risk was low. The risk stratification based on a simple model including FIT, age, sex and screening round may represent a first step toward identifying subjects in whom targeted upper GI endoscopy could be clinically justified.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims With the increasing number of pancreaticoduodenectomies performed for benign or low-grade indications, the population of long-term survivors continues to grow, making this clinical situation increasingly common. Pancreaticoduodenectomy (PD) leads to chronic biliary reflux into the stomach. We hypothesised that this chronic exposure may induce sustained gastric inflammation and, over time, promote gastric carcinogenesis.

Aim: To determine whether pancreaticoduodenectomy is a risk factor for gastric adenocarcinoma.

Methods This study had two complementary components:

-Multicenter ambispective endoscopic cohort: All adults who had undergone PD more than 10 years earlier **systematically underwent upper gastrointestinal endoscopy**. In the *prospective* cohort, endoscopy was performed as part of the study and included bile reflux, chromoendoscopy, and standardized, staged gastric biopsies with centralized pathological review.In the *retrospective* cohort, we extracted data from any upper endoscopy performed > 10 years after PD, including detailed endoscopic findings and corresponding histopathology.

-Nationwide population-based analysis: using the French nationwide claims database, to estimate the incidence of gastric adenocarcinoma in patients ≥ 5 years after PD.

The primary endpoint was the diagnosis of gastric adenocarcinoma > 10 years after PD. Secondary endpoints were the presence of preneoplastic gastric lesions and the identification of associated risk factors.

Results A total of 143 patients were included: 50 % were male; age at PD was 53 ± 13.3 years; mean follow-up was 16.1 ± 5.4 years. Endoscopic evaluation was prospective in 68 patients (48 %) and retrospective in 75 (52 %). Indications for PD were malignant tumors in 50 % (including 17 % neuroendocrine tumors)

and benign/low-grade lesions with malignant potential in 40 % (including 30 % IPMN).

Among them, **10 developed gastric adenocarcinoma (7 %)**, with a median time to diagnosis of 13.5 years. Tumors were located on or adjacent to the gastrojejunal anastomosis and were predominantly poorly differentiated. Symptoms associated with cancer were persistent nausea (p = 0.008) and gastrointestinal bleeding (p = 0.018), including iron-deficiency anemia.

Preneoplastic lesions were identified in 16 % of patients with gastric biopsies (n = 126): high-grade dysplasia 1 %, low-grade dysplasia 8 %, and intestinal metaplasia 7 %. These patients were significantly more likely to have hereditary cancer predispositions (Lynch, FAP, MEN, or other; p = 0.002) and to report persistent nausea (p = 0.01). No significant associations were observed with smoking status, Helicobacter pylori infection, type of pancreatic anastomosis, biliary reflux or pylorus preservation.

In the population-based national analysis, among 9,957 patients who had undergone PD more than 5 years earlier (2009–2018), 0.7 % developed gastric cancer (71 patients). All cancers occurred more than 8 years after PD. Two-thirds of the cohort were between 5 and 10 years post-surgery at the time of analysis.

Conclusions Gastric adenocarcinoma after PD is not a rare event. While the risk appears negligible within the first 10 years, our large cohort shows that beyond 10 years the risk rises sufficiently to justify endoscopic surveillance with systematic staged biopsies. Patients should be informed of key alarm symptoms (persistent nausea, anemia, or gastrointestinal bleeding) which warrant urgent upper endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims In recent years, as the prevalence of *Helicobacter pylori (H. pylori)* infection has declined, the incidence of *H. pylori*–uninfected gastric epithelial neoplasms (HpUGENs) has been gradually increasing in East Asia, now accounting for approximately 0.4–5.4 % of all gastric dysplasia and carcinoma cases in Japan. The previous reports indicate that HpUGENs are often detected as low-grade dysplasia; however, some lesions exhibit lymphovascular invasion, or advanced stage gastric cancer. Since HpUGENs differ biologically and endoscopically from conventional *H. pylori*–associated gastric cancer, standardized diagnostic criteria have not yet been established, and endoscopic diagnosis remains challenging. Therefore, we aim to establish a new endoscopic diagnostic system for HpUGENs and to elucidate their clinicopathological and endoscopic characteristics.

Methods A total of 308 lesions with HpUGENs treated by endoscopic treatment (ESD / EMR / polypectomy) at our hospital between August 2009 and October 2025 were enrolled and classified histologically, and their endoscopic and clinicopathological features were analyzed retrospectively.

Results All HpUGENs were histologically classified into seven types. 1. gastric adenocarcinoma of fundic-gland type (GA-FG: n = 90, U/M/L = 67/20/3, whitish, subepithelial tumor–like appearance, intramucosal lesion(M)/submucosal invasion(SM) = 39/21), 2. gastric adenocarcinoma of the fundic-gland mucosa type (GA-FGM: n = 16, U/M/L = 10/6/0, reddish elevated lesion or subepithelial tumor–like appearance, M/SM = 3/13), 3. raspberry-type gastric epithelial neoplasm (GEN) (foveolar-type adenoma: n = 155, U/M/L = 83/67/5, reddish protruded lesion, M/SM = 155/0), 4. whitish flat elevated–type GEN (n = 4, U/M/L = 4/0/0, whitish flatly elevated lesion, M/SM = 4/0), 5. other GEN with a gastric phenotype (complex type of GEN with gastric phenotype: n = 12, U/M/L = 4/4/4, M/SM = 12/0), 6. GEN with an intestinal or gastrointestinal mixed phenotype arising in the pyloric gland region (n = 7, U/M/L = 0/0/7, reddish depressed lesion, M/SM = 7/0), 7. signet-ring cell carcinoma (SRCC: n = 24, U/M/L = 0/10/14, whitish or faded color and flat or depressed lesion, M/SM = 22/2). Magnifying endoscopy with narrow band imaging (M-NBI) was performed in 219 lesions (71 %). In 219 lesions, 130 lesions (59 %) were diagnosed as non-cancer by M-NBI. Especially, GAFG (90/90, 100 %), GAFGM (12/16, 75 %), and SRCC (16/24, 67 %) were difficult to diagnose as cancer by M-NBI because of the coverage and/or mixture with a non-neoplastic mucosa or gastric epithelial neoplasia with low-grade atypia.

Conclusions This study demonstrated that HpUGENs can be classified into seven histological types, and further characterized by specific lesion location, color, and macroscopic appearance. For accurate diagnosis of HpUGENs, it may be necessary to fully understand histological classification and endoscopic features of these lesions using white light imaging and M-NBI based on these histological characteristics and to take a precise biopsy.

PYP125 Gastric Intestinal Metaplasia: recognition and adherence to British Society of Gastroenterology guidelines at The Royal Free NHS Foundation Trust, United Kingdom

Authors Karelia S[1], Arif Z[1], Moyo S[1], Joshi A[1], Besherdas K[1], Hiner G[1]

Institute **1** Royal Free London NHS Foundation Trust, London, United Kingdom

DOI 10.1055/s-0046-1821065

Aims Patients with gastric adenocarcinoma have a poor prognosis. One factor contributing is advanced disease at diagnosis. Chronic atrophic gastritis (CAG) progresses in a stepwise fashion from chronic gastritis, gastric atrophy (GA), gastric intestinal metaplasia (GIM) to gastric dysplasia and ultimately gastric adenocarcinoma.

The British Society of Gastroenterology (BSG) and European Society of Gastrointestinal Endoscopy (ESGE) both have guidelines aiming to improve the diagnosis and management of patients at high risk of gastric adenocarcinoma [1, 2]. They advise gastroscopy with high quality mucosal visualisation and biopsies for histopathology to detect GA/GIM and allow appropriate risk stratification. GIM is endoscopically visualised by whitish, patchy, and irregular mucosal areas with a potentially velvety or slightly nodular surface. When identified, Sydney protocol biopsies should be completed (biopsies from the antrum, incisura, the lesser and greater curvatures).

High risk individuals with extensive or advanced histological stages of CAG/GIM should undergo 3-yearly endoscopic surveillance as per guidelines[(1,2)]. This also includes people with a family history of gastric cancer or persistent Helicobacter pylori (*H. pylori*) infection.

The aims of this audit were to analyse:

1. How well GIM is visualised endoscopically, and if Sydney protocol biopsies are followed?

2. When GIM is confirmed histologically, is surveillance organised and is this at the correct frequency?

Methods We carried out a retrospective audit of endoscopy data at Barnet General, Chase Farm and Royal Free Hospitals, London, U.K., from June to October 2025. Patients were identified from a histology database of specimens with GIM and then data scrutinized using endoscopy reporting software and electronic patient records.

Results Between June and October 2025, 4394 gastroscopies were performed. 145 patients were confirmed to have GIM. 47/145 records were excluded, coming under either neuroendocrine tumour or Barrett's oesophagus surveillance

or records with incomplete data. This left 98 endoscopies that were fully analysed. 58.2 % were female with a mean age of 67. 11 of the patients were *H. pylori* positive.

GIM was visualised endoscopically in 19/98 (19.4 %) cases, being confirmed histologically in 100 % of them. In 79/98 (80.6 %) cases GIM was histologically confirmed, however, not macroscopically visualised during gastroscopy. Of the 19 records where GIM was visualised, only 13/19 (68.4 %) had Sydney protocol biopsies taken. Sydney protocol biopsies were also performed in 15.3 % of cases where GIM/CAG were not visualised.

Extensive/corpus GIM accounted for 42/98 (42.9 %), antrum/incisura 32/98 (32.7 %), not specified biopsies 24/98 (24.5 %). For those with extensive/corpus GIM, surveillance was correctly organised in 19/42 (45.2 %) of the cohort. However, this was not always 3-yearly and ranged between 6 months to 3 years. For those with antrum/incisura GIM, 25/32 (78.1 %) correctly had no surveillance organised, however, for the remainder it was still being organised.

In 1/98 patient, gastric biopsy showed GIM with ulceration. Repeat gastroscopy with biopsies and histology confirmed a poorly differentiated gastric adenocarcinoma.

Conclusions

1. Our results indicate that GIM was endoscopically visualised in only 20 % of cases.
2. Even when identified correctly, Sydney protocol biopsies are not always completed.
3. Large variation exists in whether surveillance is being organised for patients with extensive/corpus GIM and the frequency of this surveillance.
4. > 20 % of patients with limited GIM are having surveillance organised unnecessarily.

We recommend better training in the endoscopic detection of GIM and raising awareness of the surveillance guidelines. By ensuring the correct biopsies are taken, patients may benefit from earlier detection and management of pre-cancerous lesions and avoid unnecessary procedures. This would also help improve efficiency and costs within our endoscopy services.

PYP126 Prevalence and Severity of Gastric Preneoplastic Lesions among H. pylori-Positive Patients: A Single-Center German Study

Authors Vasapolli R[1, 2], Macke L[1], Lang U, Westphal J[1], Schirra J[1], Schulz C[1]

Institutes **1** Department of Medicine 2, University Hospital LMU Munich, Munich, Germany; **2** DZIF Deutsches Zentrum für Infektionsforschung, Partner Site Munich, Munich, Germany

DOI 10.1055/s-0046-1821066

Aims Gastric precancerous conditions (GPC), including chronic atrophic gastritis and intestinal metaplasia, are associated with increased risk of gastric adenocarcinoma, necessitating early detection and risk stratification for appropriate surveillance. Contemporary data on GPC prevalence in Germany, a low-to-intermediate gastric cancer incidence country, are lacking. This study aimed to determine the prevalence and severity of GPC in *H. pylori*-positive individuals undergoing screening endoscopy in Germany.

Methods This single-center prospective study was conducted at the LMU University Hospital in Munich from June 2021 to November 2025. 5,069 unselected individuals underwent *H. pylori* serology screening (ELISA), identifying 1,056 seropositive cases (20.8 %). Subjects with positive serology were offered confirmatory urea breath testing (UBT), with 400 confirming active infection. A total of 279 patients (mean age 48.9 ± 15.3 years; males:females 110:160) underwent esophagogastroduodenoscopy, during which gastric biopsies were obtained according to the standardized Sydney protocol (two from the antrum, two from the corpus, one from the incisura angularis). Histopathological evaluation was performed according to the updated Sydney classification with OLGA/OLGIM staging for gastric precancerous conditions.

Results Overall GPC prevalence was 38.7 % (108/279). OLGA/OLGIM stage I conditions were found in 75 patients (26.9 %), stage II in 27 (9.7 %), and high-risk stages III-IV in 6 (2.2 %). All patients with advanced-stage lesions (OLGA/OLGIM III-IV) were > 50 years of age. There was a strong association between higher age and GPC prevalence, with patients > 50 years having approximately 2.7-fold higher odds of GPC compared to those ≤ 50 years (OR 2.70, 95 % CI 1.64-4.35; $p < 0.001$). In the age-stratified subgroup analysis among patients > 50 years (n = 136), GPC prevalence increased to 50.7 % (69/136): stage I in 43 patients (31.6 %), stage II in 20 (14.7 %), and stages III-IV in 6 (4.4 %).

Conclusions The age-dependent increase in GPC prevalence supports the national guidelines' recommendation for targeted risk stratification rather than population-based screening in low-to-intermediate gastric cancer incidence countries. The low proportion of patients requiring endoscopic surveillance highlights the need for more efficient, non-invasive patient selection strategies to optimize resource utilization in low-prevalence settings. Comprehensive cost-effectiveness analyses are also needed to validate screening and surveillance strategies in Germany's healthcare context.

PYP127 "Glomus-like" lesions of the gastric corpus: a novel marker for autoimmune gastritis by image-enhanced endoscopy

Authors Kuvaev R[1], Kashin S[2]

Institutes **1** Endoscopy Department, Yaroslavl Regional Cancer Hospital, Yaroslavl, Russia; **2** Yaroslavl Regional Cancer Hospital, Department of Endoscopy, Yaroslavl, Russia

DOI 10.1055/s-0046-1821067

Aims Autoimmune gastritis (AIG) is considered to be a premalignant condition and associated with an increased risk of gastric neoplasia. Endoscopic diagnosis is usually difficult, and most cases are overlooked and therefore the identification of specific endoscopic markers is important for the accurate diagnosis of AIG. During magnifying image-enhanced endoscopy (M-IEE) of the gastric corpus mucosa in patients with AIG, we noted the presence of multiple minute round-shaped pale* **"glomus-like" lesions (GLLs)** with branched microvessels. It had not been described in the literature before. In the present study, we investigated the nature and the diagnostic utility of GLLs for the AIG diagnosis

Methods 57 patients with AIG (including 22 patients with gastric neuroendocrine neoplasia (NEN) type 1) and 54 age- and sex-matched patients with H. pylori-induced multifocal atrophic gastritis (MAG) were enrolled in this study. After white light imaging (WLI) observation M-IEE (NBI, BLI, Iscan-OE) of the gastric corpus mucosa was performed. Biopsy was taken from a gastric mucosa with and without GLLs for histological evaluation.

Results GLLs were found in 44 out of 57 (77 %) patients with AIG, (in22 out of 22 (100 %) patients with NEN) and in 0 out of 54 (0 %) patients with MAG ($P = 0.0001$). For AIG diagnosis by GLLs sensitivity, specificity, accuracy, positive predictive value (PPV), negative predictive value (NPV) were 0.77, 1.00, 0.88, 1.00, 0.81, respectively. All biopsy specimens taken from GLLs revealed mucosal atrophy, enterochromaffin-like (ECL) cell hyperplasia, cysts of foveolar epithelium

Conclusions The presence of GLLs was associated with histological features of atrophy in patients with AIG and were found in every case of NEN. GLLs could be considered as an endoscopic marker of advanced atrophy in patient with AIG who has an increased risk of NEN development. This novel indicator was found to be a highly specific feature of AIG and could be used in clinical practice.

DOI 10.1055/s-0046-1821068

Aims The Magnifying Endoscopy Simple Diagnostic Algorithm for Early Gastric Cancer (MESDA-G) has been proposed as a standardized diagnostic system using magnifying endoscopy with narrow-band imaging (M-NBI) for early gastric cancer (EGC), and its usefulness has been reported. However, we sometimes encountered false-negative cases with M-NBI diagnosis (M-NBI diagnostic limitation EGC: MDL-EGC) (Endosc Int Open, 2020). On the other hand, we previously developed automatic analysis software for gastric mucosal blood flow rate and demonstrated that EGCs exhibit significantly slower flow rates compared with reddish non-neoplastic mucosa, supporting its diagnostic utility (J Gastroenterol Hepatol, 2021). Nevertheless, blood flow rate analysis for MDL-EGCs has not yet been investigated. Therefore, the aim of this study was to evaluate blood flow rate in MDL-EGC and clarify the usefulness of the gastric mucosal blood flow rate analysis software.

Methods Among 286 patients (314 lesions) who underwent endoscopic submucosal dissection for EGC at our institution between February 2021 and January 2024, 38 lesions (12.1 %) that were diagnosed as "non-cancer" according to MESDA-G were defined as MDL-EGCs and analyzed. Blood flow rate was measured using the automatic analysis software. The diagnostic performance for cancer was assessed using a previously established cutoff value (1.189 mm/s) derived from other test data sets. In addition, lesions were histopathologically classified, and blood flow rates were compared among the groups.

Results The 38 MDL-EGCs consisted of H. *pylori* status (current/past/never infection = 1/23/14), location (U/M/L = 15/10/13), macroscopic type (elevated/flat/depressed = 15/10/13), and invasion depth (M/SM = 24/14). Histologically, the lesions were classified into four groups: low-grade differentiated adenocarcinoma (n = 12), signet-ring cell carcinoma (sig, n = 5), gastric adenocarcinoma of fundic gland mucosa type (GA-FGM, n = 5), and gastric adenocarcinoma of fundic gland type (GA-FG, n = 16). The mean blood flow rate of all lesions was 1.169 mm/s, and 60.5 % of lesions were diagnosed as cancer (< 1.189 mm/s) by blood flow analysis (differentiated/sig/GA-FGM/GA-FG = (11/12, 91.7 %)/(3/5, 60 %)/(3/5, 60 %)/(6/16, 37.5 %)). Mean blood flow rates by group were 1.06, 1.13, 1.17, and 1.26 mm/s, respectively. GA-FG, in which the surface epithelium is covered by non-neoplastic mucosa, showed the highest blood flow rate, whereas low-grade differentiated adenocarcinoma, in which the tumor is exposed to the surface, showed the lowest blood flow rate. In signet-ring cell carcinoma, 60 % (3/5) were correctly diagnosed as cancer by blood flow rate analysis, possibly due to tumor proliferation immediately beneath the non-neoplastic surface epithelium affecting surface blood flow [1, 2].

Conclusions This study is the first report to evaluate the usefulness of the analysis system for MDL-EGCs. In MDL-EGCs, blood flow rate analysis was suggested to be useful not only for low-grade differentiated adenocarcinoma and GA-FGM with surface tumor exposure but also for signet-ring cell carcinoma covered by non-neoplastic mucosa. Therefore, this analysis system has the potential to be useful in clinical practice. We hope for further investigation of various types of lesions and the development of a next-generation microvascular blood flow analysis system, which can be applied to clinical endoscopic practice.

Conflicts of Interest This research was funded by a joint research effort conducted by the author and the FUJIFILM Corporation.

PYP129 The prevalence of precancerous conditions and upper gastrointestinal neoplasms among asymptomatic and symptomatic patients in low to moderate prevalence countries

Authors Felinska Z[1], Budzyń K[1], Romańczyk T[1, 2], Lesińska M[1, 2], Bołdys A[1], Kaczor R[1], Machaj M[1], Ostrowski B[3, 1], Rymarczyk G[1], Waluga M[3, 1], Matysiak-Budnik T[4], Romańczyk M[1, 2]

Institutes **1** H-T. Medical Center-ENDOTERAPIA, Tychy, Poland; **2** Department of Gastroenterology, Faculty of Medicine, Academy of Silesia, Katowice, Poland; **3** Medical University of Silesia, Katowice, Poland; **4** Institut des Maladies de l'Appareil Digestif, Nantes, France

DOI 10.1055/s-0046-1821069

Aims The aim of the study was to determine differences in the detection of precancerous conditions (PC) and neoplastic lesions between asymptomatic and symptomatic patients who referred to esophagogastroduodenoscopy (EGD).

Methods It was a single center, retrospective study conducted from January to September 2024. During this period patients who underwent diagnostic and screening EGD were analyzed.

Results Among 2357 patients who underwent EGD and the data collection 418 were excluded from study, and 1939 were included (mean age 51.7 ± 14.3; 1150 (59.2 %) female), among which 1683 were symptomatic and 256 asymptomatic.

The incidence of dysplasia was 0.4 % (n = 1/256) in asymptomatic vs 2.14 % symptomatic (p = 0.07) and cancers 0 % (n = 0/256) in asymptomatic vs 0.3 % (n = 5/1683, p = 0.99) symptomatic patients, which revealed no significant differences in both groups. The incidence of BE (Barrett's esophagus) was similar in both groups; 0.4 % (n = 1/256) asymptomatic vs 1.18 % symptomatic (n = 20/1683) (p = 0.53). Subsequently, we observed similar occurrence of AG/GIM (atrophic gastritis, gastric intestinal metaplasia) in both groups, asymptomatic 11.7 % (n = 30/256) vs 10.5 % (n = 177/1683) symptomatic (p = 0.79). Severity of AG/GIM assessed with OLGA/OLGIM staging revealed no difference between both groups in occurrence of advanced stages of atrophic gastritis (OLGA/OLGIM III-IV): asymptomatic 1.1 % (n = 3/256) vs 1.1 % (n = 20/1683) symptomatic (p = 0.82).

In the multivariable regression analysis risk factors such as male sex (OR = 0.557, 95 % CI = 0.285 – 1.089), presence of alarm symptoms (OR = 0.355, 95 % CI = 0.048 – 2.646). presence of any symptoms (OR = 6.284, 95 % CI = 0.849 – 46.519) and sedation (OR = 0.793, 95 % CI = 0.374 – 1.685), were not related to the detection of upper gastrointestinal neoplasia with the only risk factor being age (OR = 1.047, 95 % CI = 1.022-1.072). None of assessed factors were associated with higher risk of PC (– age (OR = 1.001, 95 % CI = 0.992-1.010), male sex (OR = 1.072, 95 % CI = 0.824-1.394), alarm symptoms (OR = 0.824, 95 % CI = 0.497-1.367) presence of any symptoms (OR = 1.191, 95 % CI = 0.827-1.715), sedation (OR = 0.822, 95 % CI = 0.584-1.157), adequate cleanliness (OR = 1.136, 95 % CI = 0.653-1.977).

Conclusions Presence of symptoms was not related to PC nor neoplasia detection. These findings underscore the need for identification additional risk factors and developing effective screening programs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP130 Disrupted Microvascular Pattern and Cyan-Colored Vessels Strongly Suggest Submucosal Invasion in Gastric Cancer by Magnifying Endoscopy

Authors Kanazawa S[1], Uchita K[1], Higashi T[1], Nagai A[1], Yokogawa A[1], Daike R[1], Okazaki M[1]
Institute 1 Department of Gastroenterology, Japanese Red Cross Kochi Hospital, Kochi, Japan
DOI 10.1055/s-0046-1821070

Aims Although magnifying endoscopy with narrow-band imaging (ME-NBI) has been widely used for qualitative diagnosis, such as differentiating cancerous lesions from non-cancerous lesions and predicting histology, its usefulness for assessing invasion depth remains unclear. Previous studies have mainly focused on the demarcation line and microvascular or microsurface patterns for qualitative diagnosis, whereas evidence regarding ME-NBI findings associated with submucosal invasion is still limited. The purpose of this study is to investigate which ME-NBI findings could be useful for diagnosing the invasion depth of gastric cancer.

Methods A total of 255 gastric cancer lesions resected by endoscopic submucosal dissection (ESD) were retrospectively analyzed, including 174 mucosal (M) and 81 submucosal (SM) cancers. ME-NBI findings were reviewed to assess the following features:

1. Presence of RAC (Regular Arrangement of Collecting Venules)-like vessels
2. Cyan-colored and thick vessels
3. Disruption of the microvascular pattern (MVP)
4. Loss of the microsurface pattern (MSP)

The diagnostic performance of each finding for predicting SM invasion was evaluated by calculating sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), positive likelihood ratio (PLR), and negative likelihood ratio (NLR).

Results Diagnostic performance (sensitivity / specificity / PPV / NPV / PLR / NLR) was as follows:

1. Presence of RAC-like vessels: 90.0 % / 74.4 % / 62.0 % / 93.5 % / 3.6 / 0.13
2. Cyan-colored and thick vessels: 44.4 % / 95.3 % / 76.6 % / 78.4 % / 9.4 / 0.58
3. Disruption of MVP: 35.8 % / 96.0 % / 80.6 % / 76.3 % / 8.8 / 0.67
4. Loss of MSP: 39.5 % / 83.9 % / 53.3 % / 74.9 % / 3.3 / 0.71

The presence of cyan-colored vessels and disruption of MVP were strongly associated with SM invasion. The NLR of RAC-like vessels was low, suggesting that the absence of RAC-like vessels indicates a low probability of submucosal invasion.

Conclusions Among ME-NBI findings, the presence of cyan-colored vessels and disrupted MVP are useful indicators suggesting submucosal invasion in gastric cancer. These findings may contribute to more accurate endoscopic assessment of invasion depth prior to ESD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Pancreatic duct disorders and leaks

15/05/2026, 09:30–10:30 **Emerald 3**

PYP131 Endoscopic management of non-postoperative pancreatic duct disruption: effectiveness across disruption types and collection morphologies

Author Murakami M[1]
Institute 1 Kyushu University Hospital, Fukuoka, Japan
DOI 10.1055/s-0046-1821071

Aims Pancreatic duct disruption leading to pancreatic fistula (PF) or peripancreatic fluid collections (PFCs) presents a major clinical challenge. Optimal management strategies for incomplete (IPF) and complete pancreatic duct disruption (DPDS) remain controversial, and evidence regarding endoscopic treatment of non-encapsulated pancreatic leaks is limited. This study aimed to evaluate real-world outcomes of endoscopic management—including endoscopic transpapillary drainage (ETD) and EUS-guided transluminal drainage (EUS-TD)—across the spectrum of non-postoperative pancreatic duct disruption, and to compare treatment patterns and clinical outcomes between IPF and DPDS, as well as between encapsulated PFC and non-encapsulated PF.

Methods This retrospective single-center study included consecutive non-postoperative patients with clinically significant PF or PFC secondary to pancreatic duct disruption. Only patients who underwent endoscopic treatment (ETD and/or EUS-TD) were included; cases treated solely with surgery, percutaneous catheter drainage (PCD) alone, or observation were excluded. Pancreatic duct disruption was categorized as IPF or DPDS using ERCP, imaging, and clinical course, and collections were classified as encapsulated or non-encapsulated. The primary outcome was clinical success, defined as resolution of PF/PFC-related symptoms and termination of active external drainage. Secondary outcomes included recurrence, need for PCD or surgery, and subgroup comparisons of treatment patterns.

Results A total of 45 patients were analyzed (IPF 37, DPDS 8; encapsulated collections 30, non-encapsulated leaks 15). Initial interventions were ETD in 31 patients (69 %) and EUS-TD in 13 (29 %). The modality responsible for initial improvement was ETD in 23 patients (51 %) and EUS-TD in 20 (44 %). Clinical success was achieved in all patients (100 %). Compared with IPF, DPDS showed higher rates of recurrence (25 % vs 16 %), need for PCD (25 % vs 14 %), and surgery (13 % vs 5 %). Nevertheless, endoscopic treatment successfully controlled PF/PFC in 7 of 8 DPDS cases, and ETD or EUS-TD served as the final treatment in six of these. In the comparison between encapsulated PFC and non-encapsulated pancreatic fistula, treatment patterns were similar (EUS-TD: 33 % vs 40 %; ETD: 60 % vs 60 %). Recurrence (20 % vs 13 %), PCD requirement (13 % vs 20 %), and surgery (7 % vs 7 %) also showed no substantial differences, supporting the effectiveness of endoscopic treatment for non-encapsulated leaks. Overall, only 3 patients (7 %) required surgery and 7 patients (16 %) required PCD during the treatment course.

Conclusions In this real-world cohort of non-postoperative pancreatic duct disruption, an endoscopic-first strategy achieved universal clinical success with low recurrence and limited surgical need. ETD and EUS-TD were effective across IPF, DPDS, encapsulated PFC, and non-encapsulated leaks. These findings support the broad applicability of endoscopic management across the full spectrum of pancreatic duct disruption.

PYP132 Pancreatic duct wall thickening on EUS is useful for differentiating autoimmune pancreatitis from pancreatic neoplasms

Authors Nishiyama S[1], Tekeshi H[1], Aki E[1], Naoki M[1], Yui I[1], Akiharu K[1], Takahiro Y[1], Shozo O[1], Hideki F[1], Shogo S[1]
Institute 1 Saku Central Hospital Advanced Care Center, Saku, Japan
DOI 10.1055/s-0046-1821072

Aims We previously reported that lymphoplasmacytic infiltration around the pancreatic duct, a characteristic histological finding of autoimmune pancreatitis (AIP), can be visualized on endoscopic ultrasonography (EUS) as pancreatic duct wall thickening [1]. This study evaluated the utility of EUS-detected pancreatic duct wall thickening in distinguishing AIP from pancreatic neoplasms.

Methods We included 47 patients who underwent EUS and were diagnosed with AIP according to the International Consensus Diagnostic Criteria (ICDC), as well as 339 patients with histologically confirmed pancreatic neoplasms treated at our institution from March 2017 to September 2025. Detection rates of pancreatic duct wall thickening on EUS were compared between the two groups. Pancreatic duct wall thickening was defined as hypoechoic thickening of the duct wall with a thin hyperechoic surface layer. All EUS images and video recordings were retrospectively reviewed.

Results In the AIP group, patient characteristics were as follows: 37 males (78.7 %), median age 73 years (range 42–87), diffuse-type disease in 26 cases (55.3 %), elevated serum IgG4 levels in 36 cases (76.6 %), and extrapancreatic involvement in 13 cases (27.7 %). In the pancreatic neoplasm group, there were 166 males (49.0 %) with a median age of 76 years (range 24–95). Histological diagnoses included pancreatic ductal adenocarcinoma (n = 271), neuroendocrine neoplasms (n = 47), and intraductal papillary mucinous neoplasm (IPMN) (n = 21). Pancreatic duct wall thickening was detected significantly more often in the AIP group (82.6 %, 38/46) than in the tumor group (1.5 %, 5/339) ($p < 0.01$). In patients with focal-type AIP, thickening was observed within or around the focal lesions. Among 12 AIP patients who underwent EUS after steroid therapy, improvement of duct wall thickening was observed in 10 cases (83.3 %). All five pancreatic neoplasm cases showing duct wall thickening underwent surgical resection. Three cases corresponded to focal pancreatic atrophy associated with carcinoma in situ. The remaining two corresponded to intraductal extension of IPMN, where the thickened duct wall was continuous with intraductal papillary projections.

Conclusions Pancreatic duct wall thickening on EUS is frequently observed in AIP and serves as a useful marker for differentiating it from pancreatic neoplasms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821073

Aims Post–endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) remains the most common ERCP-related adverse event, with an incidence of 3.5–9.7 %[1]. Multiple pre-, peri- and post-procedural strategies have been recommended to reduce this risk[1]. A core component of peri-procedural prophylaxis is the placement of a temporary pancreatic duct stent, if the pancreatic duct was accessed inadvertently [1]. Traditionally, short-term plastic pancreatic stents are used which require follow-up abdominal radiography and endoscopic removal if retained. In recent years, biodegradable pancreatic stents have been introduced in clinical practice, offering the advantage of a “deploy-and-forget” approach. This study aims to 1) compare clinical outcomes between plastic and biodegradable pancreatic stents and 2) identify extra costs related to plastic stents.

Methods A retrospective review of the ERCP database of the Translational Gastroenterology and Liver Unit, Oxford University Hospitals, was conducted over a 5-year and 9-month period (January 2020–September 2025). In September 2023 the biodegradable pancreatic stents were introduced to our unit. All ERCP procedures involving placement of pancreatic stents (plastic or biodegradable) were included. Demographic data, procedural indication (benign vs. malignant), and post-procedural adverse events [PEP, post-ERCP cholangitis (PEC), bleeding, perforation, and 30-day mortality] were recorded. Fisher’s exact test was used to compare categorical outcomes between stent types, while univariate and multivariate logistic regression models assessed predictors of outcomes, supplemented by subgroup analyses stratified by indication (benign vs malignant). Statistical significance was defined as $p < 0.05$.

Results During the study period, 2,995 ERCP procedures were performed, of which 142 (4.74 %) had pancreatic stent placement. The median age of patients with pancreatic stent was 71 years. Pancreatic stent cases included 88 (61.97 %) females and 54 (38.03 %) males. Plastic stents were placed in 73 (51.41 %) and biodegradable stents in 69 patients (48.59 %).

When outcomes were compared solely by stent type, plastic stents were associated with slightly higher rates of 30-day mortality (5.48 % vs. 1.45 %) and perforation (5.48 % vs. 1.45 %) compared with biodegradable stents, while the incidence of PEP was comparable (plastic: 6.85 % vs. biodegradable: 5.80 %). There was a trend that plastic stents showed slightly higher rates of PEP [Odds Ratio, OR ≈ 1.13, (95 % Confidence Interval- CI 0.29 to 4.37; p = 0.86)] and 30-day mortality [OR ≈ 1.94, (95 % CI 0.29 to 12.85; p = 0.49)]. However, these differences were not statistically significant ($p > 0.05$ for all outcomes).

Multivariable analysis incorporating age (> 50 vs. ≤ 50 years), gender, stent type, and indication was performed, and demonstrated that malignant indication was the only independent predictor of 30-day mortality (OR ≈ 21.8, p = 0.0088). Stent type, age, and gender were not significantly associated with the outcomes. No significant differences were observed for perforation or PEP (all $p > 0.05$). Due to limited event numbers, PEC and bleeding were excluded from multivariable modelling.

Among the 73 patients who received a plastic pancreatic stent, 16 (22 %) required an additional endoscopic procedure for removal of a retained stent, confirmed on follow-up abdominal X-ray.

Conclusions Pancreatic stent type, irrespective of procedural indication, showed similar results of PEP, 30-day mortalityandperforation compared to plastic stents. However, a substantial proportion of patients with plastic stents (22 % in our cohort) required subsequent endoscopic retrieval, thereby increasing healthcare costs and exposing patients to additional ionising radiation (abdominal X-ray to confirm the presence of the retained stent) as well as endoscopic procedure-related risks. In addition, in an era with high pressure on the NHS and other health services and where ‘Greener Endoscopy’ is increasingly recommended and welcomed, the biodegradable stent findings support potential clinical, operational, and environmental advantages.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Pancreaticopleural and pancreaticomediastinal fistulas (PPMF), are rare complications of acute and chronic pancreatitis caused by a disrupted pancreatic duct (PD). It involves an abnormal passage through which enzyme-rich pancreatic fluid may leak into the pleural cavity or the mediastinum. Their optimal management remains unclear due to limited clinical data, as prior studies have included only a small number of patients. The aim of this study was to evaluate the outcomes of endoscopic stent therapy in a larger cohort of patients with PPMF secondary to acute or chronic pancreatitis.

Methods A retrospective, single-center case series was performed involving 59 patients with PPMF secondary to acute or chronic pancreatitis. Their treatment was initiated endoscopically in Helsinki University Hospital between 2011-2024. Eleven patients were excluded due to inadequate follow-up information, resulting in a final cohort of 48 patients. All included patients had a PPMF, which was at minimum established through amylase-rich pleural fluid (greater than 200 U/L) or a radiologically identified fistula tract to the pleural cavity and/or to the mediastinum. The entire cohort had fluid in the pleural

cavity, mediastinum or both. All data was retrospectively collected from patient records.

Endoscopic retrograde cholangiopancreatography (ERCP) with transpapillary access to the PD and subsequent stent placement was the preferred method for endoscopic therapy (ET). In ERCP, the aim was to identify the fistula tract and place a plastic stent (5Fr-10Fr) beyond the site of ductal disruption. When indicated, PD dilatation was performed using a 4-6 mm dilatation balloon. Successful outcome was determined when pleural fluid cleared, and the fistula was no longer visible through imaging. If ERCP failed, an endoscopic ultrasound (EUS)-guided transmural route was considered for suitable fluid collections.

Results Among the patients, 33 (69 %) had chronic pancreatitis and 15 (31 %) had acute pancreatitis. The etiology of acute or chronic pancreatitis was alcohol in 45 (94 %) cases. Of the remaining, one had biliary pancreatitis, one had interferon-induced pancreatitis, and one had idiopathic pancreatitis. CT was performed for all patients and demonstrated the fistula tract in 46 (96 %) cases, Among 30 patients with a fistula in the head or body of the pancreas, the stent was successfully positioned past the disrupted area in 22 cases. All of them had a successful treatment outcome. After the stent bypassed the fistula tract, the patients' symptoms resolved in a median time of 60 (range 3-156; IQR 45) days. Of the remaining eight cases, ET failed in one case. When the fistula was in the tail of the pancreas, ET succeeded in 14 out of 18 patients (77.8 %) but when it was in the head or body of the pancreas ET succeeded in 29 out of 30 patients (96.7 %) (p = 0.059).

ET was ultimately successful in 90 % of patients. The median time from successful stent placement to PPMF closure was 2.3 months (range 1-24; IQR 3). Patients underwent a median of three (range 1-8; IQR 2) ERCPs.The median follow-up time was 54 months (range 1-209; IQR 56). There were no fistula recurrences among any of the 48 patients. Mortality was high (27 %) but none died due to PPMF. The patients deceased in a median time of 2.3 years (2.0 months – 10.1 years; IQR 5.4 years) after their diagnosis of PPMF.

Conclusions ET is an effective treatment method for PPMF. The primary goal of ET is to advance the PD stent beyond the fistula tract, as this is associated with treatment success. When the disruption is located in the pancreatic tail, the stent should be positioned as close as possible to the fistula tract. These findings support endoscopic therapy as the first-line treatment for PPMF secondary to acute and chronic pancreatitis. Future prospective studies with larger cohorts are needed to confirm these results.

PYP135 Evaluation of Quality of Life in Patients Undergoing Endoscopic Management for Pancreatic Disease: a Prospective Observational Cohort Study

Authors Mahjoob M, Khalaf K, Jayawardena R[1], Slotin A[1], Li H[1], Gholami R[1], Mosko J[1], May G[1], Calo N[1]

Institute 1 Division of Gastroenterology, St. Michael's Hospital, Toronto, Canada

DOI 10.1055/s-0046-1821075

Aims Although endoscopic and medical therapies effectively address the morphological and physiologic (exocrine and endocrine) sequelae of pancreatic disease [1], broader functional domains, such as nutrition, persistent pain, and psychosocial well-being are infrequently measured or integrated into routine care. This shortfall reflects procedure-centred clinical workflows that favour treatable structural targets, a lack of routinely collected, standardized metrics for functional domains, and fragmented or under-resourced multidisciplinary pathways worldwide. We aimed to characterize health-related quality of life (HRQoL) measures in a cohort undergoing endoscopic management for pancreatic disease.

Methods We prospectively included patients from the St. Michael's Hospital (Toronto) Pancreatic Disease Clinic undergoing endoscopic management of CP between April and November 2025. Eligible patients had one or more of the following: CP, severe recurrent pancreatic pain, obstructive pancreatic duct disease (stenosis or intraductal stones with ≥ 5 mm proximal dilation), a genetic/familial or autoimmune predisposition, or a history of necrotizing or recurrent acute pancreatitis. HRQoL was measured using the SF-36 (eight domains plus a total score). Participants completed baseline (pre-procedure) assessments and were reassessed at a median of 3 months after the endoscopic procedure. Within-subject changes from baseline to 3 months were evaluated by paired analyses, with paired mean differences reported alongside 95 % confidence intervals. SF-36 domain scores were compared with established Canadian population norms [2].

Results Fifty-two patients were included (28 female, 24 male); aetiologies were idiopathic 76.9 %, genetic 7.7 %, alcohol 3.8 %, biliary 1.9 %, hypertriglyceridemia 1.9 % and other 7.7 %. Twenty-nine patients underwent endoscopic management (diagnostic EUS 72.4 %, EUS guided drainage 3.5 %, FCSEMS 3.5 %, pancreatic stenting 3.45 %, ERCP stone clearance 13.8 %, EUS celiac plexus block 10.3 %). Overall SF-36 total score was 61.4 ± 19.7 at baseline and 62.5 ± 20.0 at 3 months (population 79.3 ± 22.3), an absolute mean change of + 1.0 [− 4.5 to 6.6] (baseline − 17.9 vs population; 3 months − 16.8 vs population). The three most prominent domain findings were: Social Functioning 51.5 ± 8.6 → 52.8 ± 8.0 (population 86.2 ± 19.8), change + 1.3 [− 2.9 to 5.4] (baseline − 34.7 vs population; 3 months − 33.4 vs population); General Health 48.9 ± 18.8 → 48.3 ± 19.2 (population 77.0 ± 17.7), change − 0.6 [− 5.3 to 4.2] (baseline − 28.1 vs population; 3 months − 28.7 vs population); and Physical Functioning 69.3 ± 34.2 (n = 49) → 75.9 ± 28.8 (population 85.8 ± 20.0), change + 6.6 [− 2.6 to 15.7] (baseline − 16.5 vs population; 3 months − 9.9 vs population). Other domains showed small shifts: Role limitations due to Physical Health 74.5 ± 52.4 (n = 50) → 79.6 ± 48.1, change + 5.1 [− 7.9 to 18.2]; Role limitations due to Emotional Health 67.3 ± 43.9 (n = 50) → 66.7 ± 46.2, change − 0.7 [− 14.0 to 12.6]; Bodily Pain 65.9 ± 28.6 → 65.7 ± 32.7, change − 0.3 [− 8.8 to 8.3]; Vitality 49.4 ± 21.7 → 50.9 ± 18.8, change + 1.6 [− 3.7 to 6.8]; and Mental Health 64.7 ± 24.3 → 64.1 ± 23.8, change − 0.7 [− 6.8 to 5.5].

Conclusions Despite endoscopic management, patients entered care with substantially reduced HRQoL and—apart from a small, non-significant improvement in physical functioning at 3 months—most domains (especially social functioning and general health) remained far below population norms. These results show that treating anatomical and physiological problems alone is insufficient: routine HRQoL measurement and integrated, multidisciplinary care (nutrition, pain/rehabilitation, psychology/social work and allied-health support) are needed to restore patients toward population-level wellbeing.

PYP136 Clinical Outcomes and Safety of Biodegradable Pancreatic Duct Stents: A Single-Centre Experience

Authors Bayati M[1], Braimakis I[1, 2], Bekkali NL[1]

Institutes 1 John Radcliffe Hospital, Oxford University Hospitals, Oxford, United Kingdom; 2 Fellow of the Hellenic Society of Gastroenterology , Athens, Greece

DOI 10.1055/s-0046-1821076

Aims Biodegradable pancreatic duct (PD) stents offer a potential alternative to traditional polymer stents by eliminating the need for endoscopic retrieval and reducing X-ray exposure as well as procedure-related risks [1]. Their real-world performance in routine Endoscopic retrograde cholangiopancreatography (ERCP) practice, however, remains poorly characterised.

The aim of this study is to evaluate the safety and clinical outcomes of biodegradable PD stents in patients undergoing ERCP at a tertiary Hepatopancreatobiliary (HPB) referral centre.

Methods A retrospective review was conducted of all ERCP procedures performed between September 2023 and September 2025 at Oxford University Hospitals from introduction of the biodegradable stents. Patients who received biodegradable PD stents were identified where demographics, procedural characteristics, indications, and post-ERCP outcomes were extracted from electronic records and endoscopy reports. Technical and clinical success, as well as adverse events, were analysed descriptively.

Results Seventy-one patients received biodegradable PD stents (median age 71 years; 56 % female). Most ERCPs (n = 57; 80.3 %) were undertaken for benign indications, predominantly choledocholithiasis. All PD stents deployed were fast-degrading models with minimal strength retention of 12 days. The primary indication for stenting was post-ERCP pancreatitis (PEP) prophylaxis (n = 69; 97.2 %). The consultant gastroenterologist performed the majority of biodegradable stent placements (n = 46; 64.8 %) while trainees inserted the remaining (n = 35; 35.2 %).Technical success was achieved in 100 % of cases, with a clinical success rate of 96.7 %. Adverse events included PEP in four patients (5.6 %), cholangitis in two (2.8 %), and single cases of 1 perforation (1.4 %) and 1 procedure-related death (1.4 %).

Conclusions Biodegradable PD stenting is a feasible and safe adjunct to existing PD stents. It demonstrated excellent technical success and favourable clinical outcomes. Its use reduces radiation exposure and the need for stent retrieval which would otherwise imply further endoscopy with significant cost and environmental impact (scope cleaning, device to retrieve the stent and driving into the hospital by patients). Additionally, it showed acceptable PEP rates compared to other findings in literature.

PYP137 Endoscopic Management of Pediatric and Adolescent Pancreatic Duct Leaks and Peri-Pancreatic Fluid Collections

Authors Kar S[1], Nayak HK[1], Panigrahi MK[1], Kumar A[1], Patel RK[1], Pandey A[1], Biswal S[1], Panda D[1]

Institute 1 All India Institute of Medical Sciences, Bhubaneswar, Bhubaneswar, India

DOI 10.1055/s-0046-1821077

Aims Pancreatic duct (PD) leaks and pancreatic fluid collections (pseudocyst/walled-off pancreatic necrosis [WOPN]) are rare in children and adolescents, and the optimal minimally invasive approach is not well established. Transpapillary PD stenting (with or without sphincterotomy) is the principal endoscopic treatment for partial duct disruptions and low-grade leaks. Pediatric series report high technical success with stent placement and good clinical resolution in a majority of cases; reported closure/success rates vary but are commonly in the ~70–90 % range in mixed-age cohorts, with procedure-specific complication rates (including post-ERCP pancreatitis) that require caution. Smaller-caliber stents (5–7 Fr) and pediatric-appropriate accessories are used when available.EUS-guided drainage is safe and effective for symptomatic pseudocysts and select walled-off necrosis (WON), though data are smaller and largely single-center. Nasocystic irrigation, multiple plastic stents, or LAMS with step-up necrosectomy are used based on collection content. We aimed to describe outcomes of ERCP-based transpapillary therapy and EUS-guided drainage for PD leaks and associated collections in a combined pediatric–adolescent cohort [1, 2].

Methods We conducted a single-centre retrospective case series of 20 patients (age 4–19 years) treated between January 2021 and October 2025. Data included pancreatitis aetiology (acute vs chronic), clinical presentation, PD leak location on imaging (CECT/MRCP/EUS/ERCP), endoscopic procedures performed, need for adjunct percutaneous or pleural drainage, and outcomes. Primary endpoints were technical success and durable clinical/radiologic resolution without recurrence.

Results Nine of 20 patients had acute pancreatitis (three trauma-related), and 11 had chronic pancreatitis with an acute exacerbation. Presentations included symptomatic pseudocyst/WOPN (n = 10), pancreatic ascites (n = 7), left paracolic gutter collection (n = 2), and pleural involvement (effusion or pancreatico-pleural fistula; n = 2). PD leaks were located in the body (n = 11), neck (n = 7), and tail (n = 2). All patients underwent endoscopic therapy, including ERCP (transpapillary PD stenting in 9, pancreatic sphincterotomy alone in 1) and EUS-guided cystogastrostomy with plastic stent(s) in 7, as well as EUS-guided single-time aspiration (EUS-STA) in 3. In the ERCP group, collections were managed with percutaneous catheter drainage (n = 4), therapeutic paracentesis (n = 5), and thoracentesis (n = 1) before transpapillary intervention; only 1 EUS-cystogastrostomy patient required an additional PCD drain. Technical success was 100 % for EUS-guided interventions (cystogastrostomy/EUS-STA, 10/10) and 90 % for transpapillary PD stenting (9/10). Patients required 1–4 ERCP sessions; stent dwell time ranged from 2 to 12 months. Over 2–24 months of follow-up, no recurrences were documented.

Conclusions Endoscopic therapy (ERCP-based transpapillary PD stenting and EUS-guided cystogastrostomy) provided safe, organ-preserving, and durable control of PD leaks and peri-pancreatic fluid collections in children and adolescents, with high technical success and absence of recurrence in this series. A tailored strategy—EUS-guided cystogastrostomy for symptomatic pseudocyst/WOPN and ERCP-based stenting for demonstrable PD leaks—appears effective, while adjunct percutaneous or pleural drainage is only selectively required. Larger prospective multicentre studies are needed to refine procedural algorithms, stent selection and dwell time, and to assess long-term pancreatic function, growth, quality of life, and recurrence risk in this population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP138 Effectiveness of EUS-guided pancreatic duct drainage for pancreaticojejunostomy anastomotic stricture following pancreaticoduodenectomy

Authors Furuta A[1], Masatoshi M[1], Fujimori N[1], Risako H[1], Masataka I[1], Takahiro U[1], Shotaro K[1], Akihiko S[1], Akihisa O[1], Kazuhide M[1], Keijiro U[1], Yoshihiro O[1]

Institute 1 Kyushu University Hospital, Fukuoka, Japan

DOI 10.1055/s-0046-1821078

Aims Pancreaticojejunostomy anastomotic stricture (PJAS) is a clinically significant adverse event following pancreaticoduodenectomy. Balloon endoscopy–assisted ERCP (BA-ERCP) is generally considered the first-line approach for PJAS; however, its success is not universal. This study aimed to evaluate the feasibility of endoscopic ultrasonography–guided pancreaticogastrostomy (EUS-PGS) as a drainage method for PJAS.

Methods We retrospectively reviewed 15 patients who underwent endoscopic interventions for PJAS at our institution between February 2015 and July 2025. Technical success was defined as successful drainage via stent placement

across the fistula tract or anastomosis, and clinical success as the resolution of pancreas-related symptoms. Adverse events were also assessed.

Results Fifteen patients were included. The median age was 69 years (range, 18–82 years). Prior surgical procedures consisted of nine pylorus-preserving pancreaticoduodenectomies with Child reconstruction, four subtotal stomach-preserving pancreatoduodenectomies with Child reconstruction, one duodenum-preserving pancreatic head resection, and one middle pancreatectomy with Letton and Wilson reconstruction. Surgical indications included four IPMA cases, three IPMC cases, two chronic pancreatitis cases, two pancreatic ductal adenocarcinoma cases, two bile duct cancer cases, one GIST case, and one traumatic pancreatic injury case. BA-ERCP was attempted in 14 cases, with technical success achieved in 8 (57.1 %). EUS-PGS was performed in 6 cases, with technical success in 5 (83.3 %). The initial EUS-PGS failure achieved technical success during the second session. All procedures with technical success also achieved clinical success. In total, 8 patients were successfully treated with BA-ERCP (BA-ERCP group) and 6 with EUS-PGS (EUS-PGS group), while 1 patient received conservative management after unsuccessful BA-ERCP. The median procedure time was 84 minutes for BA-ERCP and 59 minutes for EUS-PGS (P = 0.181). The main pancreatic duct diameter on CT was significantly larger in the EUS-PGS group than in the BA-ERCP group (5.0 mm vs 3.8 mm, P = 0.02). In the EUS-PGS group, transanastomotic stenting across the PJAS was achieved in 3 cases during the first session and in 2 cases during the second session; 1 case failed both attempts. Adverse events occurred in 2 patients (25 %) in the BA-ERCP group, both mild pancreatitis, and in 2 patients (33.3 %) in the EUS-PGS group (1 mild pancreatic fistula that resolved conservatively and 1 severe pancreatic fistula requiring endoscopic intervention).

Conclusions A dilated main pancreatic duct was associated with a lower success rate for BA-ERCP. EUS-PGS appears to be a feasible and effective salvage drainage modality for patients with PJAS.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP139 Extracorporeal Shock Wave Lithotripsy With Pancreatic Stent Prevents Spontaneous Clearance Of Stone

Authors Ma J[1], Jinhui Y[1], Dan W[1], Lianghao H[2]

Institutes **1** Department of Gastroenterology, ChangHai Hospital, Shanghai, China; **2** Naval medical university, Shanghai, China

DOI 10.1055/s-0046-1821079

Aims Pancreatic extracorporeal shockwave lithotripsy (ESWL) is the first-line therapy for pancreatic stone larger than 5mm. Whether a preexisting pancreatic stent during ESWL have an impact on efficacy and complications of ESWL has not been investigated. We aimed to determine whether the stent should be removed before ESWL [1–7].

Methods All consecutive patients who underwent ESWL from March 2011 to March 2020 with a history of pancreatic stent placement within two years before ESWL were included. According to whether the pancreatic stent was in place during ESWL, patients were further divided into the stent group and the non-stent group. The primary outcome was the rate of spontaneous stone clearance after ESWL. The secondary outcome included number of ESWL shock waves and post-ESWL complications.

Results A total of 704 patients were initially included. After exclusions, 117 patients in the non-stent group and 200 patients in the stent group were finally studied. A significantly higher rate of spontaneous stone clearance was achieved in the non-stent group compared with the stent group (64.1 % vs. 28.5 %; P < 0.001). No significant difference was found in number of shock waves to achieve successful stone fragmentation between the stent group and the non-stent group (7475.0 ± 3508.7 vs. 7777.8 ± 3908.7; P = 0.478). The overall post-ESWL complication rate did not significantly differ between two groups (5.5 % vs. 7.7 %; P = 0.439).

Conclusions Pancreatic stent prevents the spontaneous clearance of stone and does not reduce complications of ESWL. Active stent removal is recommended before ESWL.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Pancreatic duct obstruction causing symptomatic pain and recurrent pancreatitis, and the disconnected pancreatic duct syndrome with associated pancreatic leakage, represent significant clinical challenges. While endoscopic retrograde pancreatography (ERP) is the standard first-line treatment, it fails in 5-20 % of cases due to difficulty in cannulation or surgically altered anatomy. In these patients, endoscopic ultrasound-guided pancreatic duct drainage (EUS-PDD) has emerged as a feasible minimally invasive alternative to surgical or percutaneous drainage. However, comprehensive long-term outcome data and factors predicting success remain limited.

Aim: To evaluate the technical and clinical outcomes, adverse events, long-term pain relief, and predictors of technical failure for EUS-PDD.

Methods Retrospective analysis of consecutive patients who underwent EUS-PDD at Institute of Gastroenterology, Hyderabad, India, from December 2019 to July 2025. Primary outcome was technical success, defined as successful pancreatography, insertion of pancreatic duct wire and successful stent placement. Secondary outcomes including (1) Clinical success, defined as residual pain ≤ 2 on the visual analog scale (VAS, 0-10) and no recurrence of obstructive pancreatitis after successful stent placement during the follow-up period; (2) Adverse events, classified according to the American Society for Gastrointestinal Endoscopy (ASGE) lexicon; (3) Re-intervention rate, defined as the need for repeat EUS-PDD procedure in patients who achieved initial clinical success; and (4) Predictors of technical failure.

Results 105 patients were included: chronic pancreatitis (n = 56, 53.3 %), disconnected pancreatic duct syndrome (n = 34, 32.4 %), combined CP-DPDS (n = 7, 6.7 %), and surgically altered anatomy (n = 8, 7.6 %). Overall technical

success was 87.6 % (92/105) and clinical success was 89.1 % (82/92). Subgroup analysis demonstrated: chronic pancreatitis 85.7 % technical success, DPDS 85.3 % , CP-DPDS 100 %, and surgically altered anatomy 100 %. Adverse events occurred in 13 patients (12.4 %), predominantly mild (92.3 %) and managed conservatively (90.9 %): bleeding 4.8 % (5/105), abdominal pain 2.9 % (3/105), mild pancreatic leak 4.8 % (5/105). No patients required surgery for adverse event management or procedure-related deaths. Long-term pain relief was achieved in 90.8 % of patients (59.2 % complete relief, 31.6 % partial relief), with mean VAS reduction of 6.27 points (83.7 % improvement). Stent-free status was achieved in 36.5 % of patients. Mean follow-up was 853 days (2.33 years; range 90-1956 days)

Conclusions EUS-PDD demonstrated high technical and clinical success rates with low adverse event rates and durable long-term pain relief across diverse indications.

PYP141 When the Path Isn't Straight: Using a Single-Use Cholangioscope to Guide Duodenoscope Insertion in a Difficult Esophageal Anatomy; Case Report of a Novel Approach

Authors Mislej E[1], Plut S[1]
Institute **1** Department of Gastroenterology, University Medical Centre Ljubljana, Ljubljana, Slovenia
DOI 10.1055/s-0046-1821081

Problem to solve Insertion of a duodenoscope can be challenging or even impossible in patients with altered anatomy, increasing the risk of complications. The side-viewing optics of the duodenoscope further complicate advancement through a distorted esophagus. However, this problem cannot always be resolved by advancing the duodenoscope over or alongside a guidewire, nor by attempting ERCP with a forward-viewing gastroscope. We present a case in which, after multiple unsuccessful attempts to introduce the duodenoscope in a patient with cholangitis, we used a single-use cholangioscope as a visual guide to facilitate safe passage of the duodenoscope into the esophagus, effectively converting the side-viewing optics into a forward-viewing approach. This technique enabled successful completion of ERCP and avoidance of procedure-related complications.

Innovation In cases of difficult duodenoscope insertion into the esophagus due to altered anatomy, the side-viewing optics of the duodenoscope can be temporarily converted into a forward-viewing orientation using a cholangioscope. After performing diagnostic esophagoscopy with a standard gastroscope and confirming that no fixed stenosis was present to prevent passage of the scope, either a dual-operator "mother–baby" technique or a single-operator fiberoptic cholangioscope may be used to facilitate safe insertion. In our case, we used the dual-operator "mother–baby" technique with a single-use cholangioscope.Under gastroscopic visualization, a standard 0.035-inch guidewire was first advanced into the stomach. The gastroscope was then withdrawn, leaving the guidewire in place. Next, a single-use dual-operator cholangioscope was introduced through the duodenoscope's working channel. The distal ends of both scopes were aligned and jointly advanced over the guidewire into the esophagus, providing direct forward-viewing visualization. Once the duodenoscope was positioned correctly within the esophagus, both the cholangioscope and the guidewire were removed, and ERCP was subsequently completed without complications.

Results A 95-year-old patient with a history of Bechterew's disease presented in septic shock due to Grade III acute cholangitis and was referred for urgent ERCP. The procedure was performed under conscious sedation in a prone position.

Initial attempts to introduce a standard side-viewing duodenoscope through the upper esophageal sphincter were unsuccessful. Switching to a gastroscope also proved difficult, though insertion was achieved after repositioning the patient to the left lateral position. Endoscopic inspection revealed a normal-appearing upper esophageal sphincter, but withdrawal of the gastroscope showed a distorted pharyngeal–esophageal axis, likely related to long-standing Bechterew's disease.

A 0.035-inch guidewire was advanced into the stomach and the gastroscope was withdrawn, leaving the guidewire in place. Attempts to advance the duodenoscope over the guidewire failed. To overcome this, a single-use dual-operator cholangioscope was introduced through the duodenoscope's working channel. The distal ends of both scopes were aligned and safely advanced over the guidewire into the esophagus, providing forward-viewing visualization. Once the duodenoscope was positioned in the esophagus, both the cholangioscope and guidewire were removed, and ERCP was successfully completed.

Conclusions In cases of altered anatomy of the pharynx or upper esophageal sphincter, standard duodenoscope insertion may be challenging. The main limitation lies in the side-viewing optics, which prevents direct visualization of the upper esophageal sphincter and increases the risk of injury during insertion. By temporarily converting the side-viewing duodenoscope into a forward-viewing system using a cholangioscope, safe and controlled entry into the esophagus can be achieved. This simple modification expands both the feasibility of ERCP and the potential novel use of cholangioscope in anatomically challenging conditions. Future experience and broader application of this technique could improve procedural safety and accessibility in similar anatomically demanding cases.

Aims A novel 8-Fr and 11-Fr digital cholangioscope (Scivita Medical) has recently become available in Europe, yet data on technical outcomes and safety are limited. With cholangioscopes from different brands entering the market, robust data are essential to guide device selection and clinical practice [1]. In this study we report on real-world technical success and complication rates of Scivita cholangioscopy (dSOC) and pancreatoscopy (dSOP).

Methods This international, multicenter, retrospective cohort study included patients who underwent dSOC or dSOP between March and October 2025 at 10 European centers. The primary outcome was technical success per procedure, defined as achievement of the pre-specified procedural intent (for example, stone clearance, visual assessment with targeted biopsy, selective cannulation, or stent removal). Secondary outcomes included intra- and post-procedural complications, classified according to the AGREE classification [2].

Results A total of 77 patients were included (42 female, 54.5 %), with a median age of 70 years (IQR: 60–76).

In 68 patients, 78 dSOC procedures were performed. Overall technical success was 71/78 (91.0 %). By indication, technical success rates were: stone clearance (33/38, 87 %), indeterminate biliary strictures (IBDS) (24/25, 96 %), selective cannulation (2/2, 100 %), evaluation of intraductal margins after radiofrequency ablation for adenoma (1/1, 100 %), assessment of intraductal papillary neoplasm of the bile duct (0/1, 0 %), and migrated stent removal (1/1, 100 %). Among IBDS cases, visual assessment suggested malignancy in 9 and benign disease in 15; biopsy was performed in 19, yielding 6 malignancies. No intraprocedural dSOC complications occurred. Post-procedural complications were reported in five procedures: cholangitis (n = 2, AGREE II), mild post-ERCP pancreatitis (n = 1, AGREE I), and abdominal pain without a clear substrate (n = 2, AGREE I).

In nine patients, 11 dSOP procedures were performed. Overall technical success was 7/11 (63.6 %). By indication, technical success rates included stone clearance (4/6, 66.7 %), intraductal papillary mucinous neoplasm (1/2, 50 %), and pancreatic duct disruption bridging (0/1, 0 %). Two patients with incomplete stone clearance underwent a second dSOP, obtaining complete ductal clearance in both cases. One patient developed mild post-ERCP pancreatitis following failed cannulation for IPMN (AGREE II).

Conclusions Scivita dSOC demonstrated high technical success rates and an excellent safety profile in a real-world, multicenter setting. In contrast, outcomes with dSOP were more variable and showed lower technical success rates. With the expanding availability of multiple cholangioscope platforms, systematic data evaluation is increasingly important to inform clinical use, optimize device choice, and refine patient selection. Larger prospective studies and European registries assessing the performance and clinical impact of dSOC and pSOCP are warranted to validate these findings and support evidence-based implementation.

PYP143 Qualitative Contrast-Enhanced EUS Shows Fair Reproducibility: Evidence from a European Multicenter study

Authors Tacelli M[1], Nunziata R[2], Lodola I[3], Arcidiacono PG[1], Ngeus SG[4]
Institutes **1** San Raffaele Hospital, Milano, Italy; **2** Department of Gastroenterology, Ospedale del Mare, Napoli, Italy; **3** Vita-Salute San Raffaele University, Milan, Italy; **4** San Raffaele Hospital, Milan, Italy
DOI 10.1055/s-0046-1821083

Aims Contrast-enhanced endoscopic ultrasound (CE-EUS) is increasingly used for characterizing pancreatic and gastrointestinal lesions, yet its qualitative interpretation remains highly operator-dependent. Standardized frameworks for reading CE-EUS are lacking, and the reproducibility of key enhancement features across centers and operator profiles is largely unknown. This study evaluated interobserver agreement (IOA) for qualitative CE-EUS parameters among European endosonographers with different levels of experience and explored operator- and video-level factors associated with agreement.

Methods This multicenter retrospective study included 24 endosonographers from 16 European centers who independently evaluated 60 anonymized CE-EUS video clips representing solid, cystic, and mixed lesions. Participants assessed lesion type, arterial enhancement, wash-in and wash-out timing, contrast homogeneity, and overall video quality. Fleiss' kappa (κ) quantified IOA. Univariate and multivariate logistic regression analyses examined associations between IOA and operator expertise, annual EUS volume, confidence with CE-EUS, familiarity with Pentax equipment, lesion type, and video quality. Qualitative interpretations were also compared with quantitative time–intensity curve (TIC) analysis as the reference standard.

Results IOA varied markedly across CE-EUS parameters. The highest agreement was observed for lesion type (κ = 0.47; 95 % CI 0.44–0.50), while arterial enhancement (κ = 0.38; 95 % CI 0.35–0.41), wash-in time (κ = 0.27; 95 % CI 0.24–0.30), wash-out time (κ = 0.21; 95 % CI 0.18–0.24), and contrast homogeneity (κ = 0.24; 95 % CI 0.21–0.27) all achieved only fair agreement. Video quality reached the lowest reproducibility (κ = 0.14; 95 % CI 0.11–0.17). At univariate analysis, higher agreement for wash-in and wash-out timing was associated with operator expertise ($\beta = 0.149$, $p < 0.001$; $\beta = 0.111$, $p = 0.0026$) and high-volume centers ($\beta = 0.136$, $p < 0.001$). At multivariate analysis, expertise remained an independent predictor of agreement for wash-in ($p = 0.040$) and video quality ($p = 0.011$). Confidence with CE-EUS modestly improved agreement for wash-out time ($p < 0.001$). No operator- or video-level covariates significantly influenced agreement for arterial enhancement, contrast homogeneity, or lesion type. Compared with TIC-derived quantitative measures, accuracy of qualitative CE-EUS interpretation ranged widely: video quality 79.6 %, wash-in 62.2 %, contrast homogeneity 54.8 %, wash-out 54.6 %, arterial enhancement 42.9 %, and lesion type 35.6 %. Accuracy did not differ significantly between experts and non-experts (all $p > 0.05$).

Conclusions Across a broad European cohort, qualitative CE-EUS interpretation demonstrated only fair or slight agreement for dynamic enhancement parameters, regardless of operator experience. These findings indicate that the visual, qualitative nature of CE-EUS inherently limits reproducibility and that expertise alone does not sufficiently mitigate variability. The lack of strong predictors of agreement underscores the need for structured interpretive frameworks and objective quantification tools, such as real-time TIC analysis or AI-assisted vascular profiling, to support more consistent CE-EUS evaluation and facilitate its integration into standardized diagnostic algorithms.

PYP144V Targeting the Feeder: Endoscopic Ultrasound-Guided Embolization of Large Gastric Varices in a Pregnant Woman with Extrahepatic Portal Hypertension

Authors Chavan R[1], Seth V[1], Dongre H[1], Maindad D[1]
Institute 1 Bharati Vidyapeeth Deemed University Pune, Pune, India
DOI 10.1055/s-0046-1821084

Abstract Text

A 25-year-old woman, gravida 4 para 2 at 18 weeks' gestation, presented with hematemesis and severe anemia (hemoglobin 4 g/dL). Ultrasound revealed a live fetus and portal cavernoma, and endoscopy showed large gastric varices with grade II–III esophageal varices. EUS-guided embolization was planned after gynecologic clearance. Using a linear echoendoscope, a 34 × 20 mm cluster of fundal varices with a feeder vessel was identified. The feeder was punctured with a 19-G needle, a coil (0.035-14-18 Nester) was deployed, and 1 mL of N-butyl cyanoacrylate was injected, followed by a distilled water flush. EUS confirmed complete obliteration, and esophageal varices were ligated. EUS allows coil deployment, minimizing glue volume and embolization risk. This appears to be the first reported case of EUS-guided embolization in pregnancy.

PYP145V Digital single-operator cholangioscopy combined with retrograde endoscopy to treat acute suppurative appendicitis in an elderly

Authors Lei H[1], Han Y[1], Chen L[1], Chen J[1]
Institute 1 Zhongshan Huangpu People's Hospital, Zhongshan, Guangdong Province, China
DOI 10.1055/s-0046-1821085

Abstract Text

Acute appendicitis management in the elderly is challenging due to increased surgical risks. Endoscopic retroverse appendicitis therapy (ERAT) offers a minimally invasive, organ-preserving alternative.An 85-year-old male with acute appendicitis underwent successful ERAT assisted by a digital single-operator cholangioscope (DSOC). The procedure involved DSOC-guided visualization, saline irrigation of the appendiceal cavity, and stent placement. Postoperative CT scan showed significant improvement, and his inflammatory markers normalized within four days. No recurrence was observed during six-month follow-up.As the oldest reported case utilizing this technique, it demonstrates that DSOC-assisted ERAT is a viable and effective treatment for acute appendicitis in elderly patients, promoting faster recovery and preserving appendiceal function [1–5].

PYP146 Comparison of Specimen Quality among the Standard Suction, Slow-Pull, and Wet Suction Techniques for EUS-FNB: A Monocentric, Prospective, Randomized Controlled Trial

Authors Aouroud H[1], Aouroud M[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1821086

Aims Endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) is the gold standard for tissue acquisition of solid and solid-cystic lesions of the pancreas and gastrointestinal tract. Several aspiration techniques have been proposed to optimise histological yield, including the standard suction technique (SST), slow-pull technique (SPT), and wet suction technique (WEST).This study aimed to compare specimen quality and diagnostic performance of these three approaches using a 22-gauge FNB needle.

Methods This monocentric, prospective, randomised controlled trial was conducted at the Mohammed VI University Hospital (Marrakech) from January 2023 to October 2025.Patients with solid or solid-cystic pancreatic or subepithelial lesions referred for EUS-FNB were consecutively enrolled.Each lesion was sampled using the three techniques (SST, SPT, WEST) in random order during the same procedure, with two passes per technique.Specimens were evaluated by two blinded pathologists for blood contamination, tissue integrity, cellularity, core length, and diagnostic adequacy, each scored 0–2.Primary endpoint: overall specimen quality score (sum of individual items).Secondary endpoints: diagnostic yield, core tissue length, and adverse events. Statistical analysis used SPSS 26.0 with $p < 0.05$ considered significant.

Results A total of 126 patients (mean age 59 ± 12 years; 54 % men) were included.Lesion sites: pancreas (68 %), lymph nodes (19 %), subepithelial or mediastinal (13 %).Overall quality score: WEST = 8.7 ± 2.1, SPT = 8.1 ± 2.0, SST = 7.4 ± 2.3 ($p = 0.012$ WEST vs SST; $p = 0.09$ WEST vs SPT).

- Tissue integrity: WEST 1.78 ± 0.43 > SPT 1.61 ± 0.48 > SST 1.42 ± 0.52 ($p = 0.004$).
- Cellularity: WEST 1.66 ± 0.51 vs SPT 1.52 ± 0.54 vs SST 1.39 ± 0.59 ($p = 0.02$).
- Core length: longest with WEST (18.3 ± 6.7 mm) vs SPT 15.9 ± 5.9 mm and SST 13.8 ± 6.1 mm ($p = 0.01$).
- Blood contamination: lowest with SPT (1.31 ± 0.61) compared with WEST (1.46 ± 0.58) and SST (1.58 ± 0.63) ($p = 0.03$).Diagnostic adequacy: 95.2 % (WEST) vs 90.4 % (SPT) vs 86.5 % (SST);Diagnostic accuracy: 78.6 % (WEST) vs 70.6 % (SPT) vs 66.7 % (SST) ($p = 0.02$).No major adverse event was observed; two patients (1.6 %) developed mild self-limited bleeding.

Conclusions In this two-year prospective trial, the wet suction technique (WEST) provided the best tissue integrity, cellularity, and core length, achieving the highest diagnostic yield without increasing complications.The slow-pull technique offered superior blood control, whereas the standard suction method yielded the poorest histologic quality.WEST should be considered the optimal approach for EUS-FNB of solid and mixed lesions when high-quality core biopsy is required.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP147 Three or More Needle Passes Independently Predict a High Diagnostic Yield from Endoscopic Ultrasound-Guided Fine Needle Biopsy of Solid Masses

Authors Khan S[1], Ashrafinia N[1], Mathura P[1], Puttagunta L[1], Girgis S[1], Thiesen A[1], Zhang J[2], Nilsson JE[1], Wasilenko S[1], Zepeda-Gomez S[1], Sandha G[1]

Institutes **1** University of Alberta, Edmonton, Canada; **2** Alberta Health Services, Edmonton, Canada

DOI 10.1055/s-0046-1821087

Aims A chart audit (pre-intervention, PRE) of endoscopic ultrasound (EUS)-fine needle biopsy (FNB) of solid masses identified a diagnostic yield of 75 %. Single needle passes accounted for 56 %. To improve diagnostic yield, a quality improvement intervention targeting tissue procurement and processing was developed and trialed (post-intervention, POST). The intervention was to increase needle passes to 3 or more/mass, limit the personnel preparing cytology slides, and replace saline with formalin as medium for cell block preparation. The aim was to optimize the process of tissue acquisition and specimen handling to improve the diagnostic accuracy of EUS-FNB of solid masses by at least 10 %.

Methods Three endoscopists were provided results of the PRE, and the intervention. A POST chart audit was undertaken for solid mass EUS-FNB from 01/2024-12/2024, with quarterly reviews. Only a definite diagnosis on pathology was used to calculate diagnostic yield.

Results 241 patients underwent 262 EUS-FNBs. Diagnostic yield was 81 % in POST vs. 75 % in PRE (p = ns). Single passes decreased to 14 % in POST vs. 20 % in PRE ($p < 0.0001$), with similar diagnostic yield (57 % vs. 56 %, respectively). Number of 3 or more passes increased significantly (47 % POST vs. 12 % PRE, $p < 0.0001$). In POST, 86 % of single passes were performed in the first half vs. 14 % in the second ($p < 0.0001$). Only 25 % of 3 or more passes were performed in the first half vs. 75 % in the second ($p < 0.0001$). Diagnostic yield improved significantly between the first and second halves (72 % vs. 90 %, $p < 0.0001$). Replacing saline with formalin for cell block improved diagnostic yield (57 % vs. 75 %, $p = 0.03$). Limiting the personnel making slides from 25 nurses (PRE) to 3 endoscopists (POST) had no impact on diagnostic yield [1].

Conclusions Critical practice assessment, regular audit, and continued reinforcement led to a significant improvement in EUS-FNB diagnostic yield from 75 % to 90 % by increasing the number of needle passes to 3 or more/mass. This quality improvement model is easily adaptable in other centres, especially where rapid on-site evaluation is not routinely available, to enhance diagnostic efficiency without requiring additional resources.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP148 Endoscopic ultrasound-guided drainage of liver abscesses (EUS-LAD): Multicenter retrospective analysis of the DACH-EUS study group

Authors Ivan Y[1], Schlag C[1], Wannhoff A[2], Meining A[3], Denzer U[4], Arlt A[5], Razpotnik M[6]

Institutes **1** University Hospital of Zürich, Zürich, Switzerland; **2** RKH Klinikum Ludwigsburg, Ludwigsburg, Germany; **3** University Hospital Würzburg, Würzburg, Germany; **4** Marburg Uniklinikum, Marburg, Germany; **5** Israelitisches Krankenhaus, Hamburg, Germany; **6** Charité – Universitätsmedizin Berlin, Berlin, Germany

DOI 10.1055/s-0046-1821088

Aims Endoscopic ultrasound (EUS)-guided drainage of liver abscesses (EUS-LAD) is gaining increasing importance as an alternative to percutaneous drainage, particularly for left-sided or anatomically challenging abscesses. The aim of this retrospective multicenter analysis was to evaluate EUS-guided drainage of liver abscesses with regard to technical feasibility, clinical success and safety.

Methods Retrospective multicenter analysis of EUS-LAD cases from six centers in the DACH region since 2020. Primary endpoints were technical and clinical success rates as well as the occurrence of adverse events (AEs). Secondary endpoints included the access route, types of stents used, as well as required stent exchanges and duration of drainage.

Results A total of 17 patients were included. The median age was 64 years (range 45–85 years); 11 patients (64.7 %) were male.The technical success rate was 94.1 % (16/17 patients). Clinical success with a marked decrease in CRP and a significant reduction in abscess size was observed in 16/16 patients (100 %). One mild AE (6.25 %) occurred in the form of post-interventional bacterial translocation, which was managed conservatively with antibiotic therapy. All drainages were placed via a transgastric access route. In 2/16 cases, a percutaneous drainage had already been performed prior to EUS-guided drainage placement. In 7/16 cases, a lumen-apposing metal stent (LAMS) was used, in 7/16 plastic stents, and in 2/16 a combination of LAMS and plastic stents.The median duration of drainage was 46 days (IQR 34–68; range 20–137). An endoscopic stent exchange was performed in 4/16 patients. In 5/16 patients with metastatic malignancy, stent removal was not performed due to the palliative situation.

Conclusions EUS-LAD for left-sided liver abscesses demonstrated a high technical and clinical success rate and proved to be very safe. Thus, EUS-LAD may represent an effective and safe therapeutic option for left-sided liver abscesses and a good alternative to percutaneous drainage.

PYP149V Pushed to the EDGE-EUS to the Rescue ; Endoscopic ultrasound-directed trans gastric ERCP (EDGE) in surgically altered anatomy

Authors Sud S[1], Koul S[2], Khatana G[3], Sud R[2]

Institutes **1** Medanta – The Medicity [Gurugram], Gurugram, Haryana, India; **2** Medanta – The Medicity [Gurugram], Gurugram, India; **3** Medanta – The Medicity, Gurugram, Gurugram, India

DOI 10.1055/s-0046-1821089

Problem to solve To perform ERCP and CBD stone clearance in a patient with severe cholangitis in presence of surgically altered anatomy in the form of Roux-en-Y gastric bypass who was deemed very high risk for any other surgical procedure and needed urgent biliary decompression with time as an important limiting factor

Innovation The excluded stomach was located endosonographically with a linear echoendoscope from the remnant gastric pouch and then accessed with a 19G EUS needle. Diluted Contrast agent was injected through the 19G needle to insufflate the excluded stomach. A Hot LAMS (Axios; Boston Scientific) was then deployed with the distal end in the excluded stomach and the proximal flange into the remnant gastric pouch. Over a guidewire, the lumen of the stent was then dilated with a CRE balloon. This allowed for the antegrade passage of a duodenoscope through the LAMS into the stomach remnant and to the ampulla, where ERCP was performed successfully. Once ampullary access was no longer required, the LAMS was removed. On follow up visit, the fistula was closed using novel X-Tack Endoscopic Helix Tacking System in view of excess weight gain

Results Both technical success & clinical success (defined as successful ERCP with completion of the intended intervention) was achieved with successful closure of fistulous defect with novel endoscopic closure technique [1–2]

Conclusions The EDGE procedure is an entirely endoscopic, highly efficacious, single time procedure for performing ERCP in RYGB patients who require pancreaticobiliary interventions and is associated with high clinical success rates and safety profiles. Large residual defects could be successfully closed by novel X-Tack Endoscopic Helix Tacking System

DOI 10.1055/s-0046-1821090

Aims To validate EUS bubble echo against transthoracic bubble echo in the diagnosis of hepatopulmonary syndrome (▶ **Table 1**).

▶ **Table 1**

	Transthoracic Positive	Transthoracic Negative	Total
EUS Positive	9	0	9
EUS Negative	0	16	16
Total	9	16	25

Methods In this prospective, single-centre study conducted between August 2024 and August 2025, patients with chronic liver disease and clinical suspicion of HPS underwent both transthoracic and EUS-based bubble echocardiography. EUS examinations were xqefcperformed using a linear echoendoscope with intravenous injection of agitated saline under Doppler guidance. Operators were blinded to TTCE results. Sensitivity, specificity, predictive values, and Cohen's κ coefficient were calculated to assess diagnostic concordance [1–3].

Results Among 31 screened patients, 25 were included in the final analysis (median age 57 years; 58 % male). Nine patients (36 %) were diagnosed with HPS on TTCE. EUS bubble echo identified the same nine cases, with no false positives or negatives, yielding 100 % sensitivity, 100 % specificity, PPV 100 %, NPV 100 %, and Cohen's κ = 1.0 ($p < 0.001$). All procedures were well-tolerated without adverse events.

Conclusions This is the first prospective validation of EUS bubble echo for diagnosing hepatopulmonary syndrome, demonstrating perfect concordance with the transthoracic gold standard. EUS bubble echo offers a feasible, accurate, and potentially time-saving alternative that can be incorporated into routine endoscopic practice, especially during variceal surveillance or endo-hepatology procedures. Thus, it could be included within a comprehensive same-session endoscopic evaluation of patients with liver disease. Larger multicentre studies are warranted to confirm reproducibility, assess inter-operator variability, and explore integration into endoscopic diagnostic pathways.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims To assess the rates of CRC at EMR scar sites of HGD lesions during surveillance colonoscopy (SC).

Methods A multicentre cohort study analysing prospectively collected data from six tertiary referral centres was conducted. Patients with adenomatous LNPCPs resected by EMR, eligible for a minimum of 5 years of follow up, and demonstrating high-grade dysplasia (HGD) on histopathology were included. Exclusions were malignant lesions at index, serrated lesions, incomplete resections and ileocecal valve lesions due to fundamental differences in resection technique. SC was proposed at 6 months (SC1), 18 months (SC2), 3 years (SC3), and 5 years(SC4).

Results Over a 12-year period to December 2020, 3381 LNPCPs underwent attempted EMR, of which 494 (14.6 %) with HGD met inclusion criteria. Mean age was 68, 272 were male, and median lesion size was 40mm (interquartile range [IQR] 30-50mm). A nodular component (Paris0-Is, 0-IIa + Is) was seen in 322 (67.2 %). Piecemeal EMR was performed in 423 (86.6 %) and margin STSC in 208 (42.1 %). Six deep mural injury type IV occurred (five treated with clips, one surgery), and one (0.2 %) delayed perforation resulting in surgery. SC occurred in 446/471 (95 %) eligible patients at SC1 (median 6 months; IQR 5–8), 336/418 (80 %) at SC2 (19 months; IQR 16–24), 203/309 (66 %) at SC3 (41 months; IQR 32–51), and 107/192 (56 %) at SC4 (70 months; IQR 58–83). One patient (0.2 %) developed adenocarcinoma at the EMR scar (caecal lesion) at 24 months, managed with hemicolectomy (T2N0M0).

Conclusions : EMR for HGD lesions is safe and effective, with extremely low long-term CRC risk when paired with timely surveillance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP152 Performance of Endoscopic AI for Colon Polyp Detection and Diagnosis on the New LED System, EP-8000

DOI 10.1055/s-0046-1821092

Aims Computer-aided detection (CADe) and diagnosis (CADx) systems such as CAD EYE (EX-1, Fujifilm), launched in 2020, have been widely adopted worldwide and demonstrated significant value in colorectal neoplasia detection and characterization 1,2). In 2024, a new endoscopy system, EP-8000 (Fujifilm), became available, providing brighter images with reduced halation and improved contrast 3). In the same year, a new CAD EYE software version with a 1.6-fold larger training dataset and improved performance was released. This study aimed to evaluate the detection and diagnostic performance of CAD EYE with the EP-8000 system and compare the results with those obtained using the previous system (VP-7000) and the earlier software version.

Methods This single-center observational study included consecutive colorectal lesions (2–10 mm) detected by expert endoscopists using EP-8000 from March to May 2025. After lesion recognition by the endoscopist, CAD EYE was activated. White-light imaging (WLI) and linked color imaging (LCI) with and without 1.5 × high-speed scanning (high-speed WLI/LCI), including approximately 3 cm of surrounding mucosa, were evaluated for CADe performance. Positive detection was defined as the accurate appearance of an annotation box on the lesion. CADx performance was evaluated using CAD EYE-assisted BLI-magnifying observation and compared with subsequent histopathology. Outcomes were compared with 100 previously evaluated lesions obtained under VP-7000 using the same methodology [1–3].

Results A total of 27 patients with 100 lesions were analyzed (mean age 66.7 ± 10.9 years; males 66.7 %). Mean tumor size was 4.2 ± 2.7 mm; proximal colon 46.0 %; protruded type 41.0 %. Histology included sessile serrated lesions and low-grade adenomas: 57 and 43 lesions, respectively. Detection rates were: WLI 94.0 % vs. high-speed WLI 68.0 % ($p < 0.001$), LCI 94.0 % vs. high-speed LCI 75.0 % ($p < 0.001$), WLI 94.0 % vs. LCI 94.0 % ($p = 1.000$), and high-speed WLI 68.0 % vs. high-speed LCI 75.0 % ($p = 0.273$).CADx accuracy was 95.0 %, slightly lower than expert BLI-magnifying diagnosis (100.0 %, $p = 0.06$). Comparisons with VP-7000 showed no differences in lesion characteristics, while CADe was significantly improved under EP-8000 in WLI: 94.0 % vs. 85.0 % ($p = 0.038$). Other detection modes showed comparable performance. CADx accuracy tended to improve: 95.0 % vs. 87.8 % ($p = 0.080$). Importantly, false-positive alarms per case were significantly reduced with EP-8000: 12.4 ± 7.9 vs. 19.5 ± 13.4 ($p = 0.020$).

Conclusions CAD EYE with the new EP-8000 system demonstrated improved detection and diagnostic performance compared to the previous system, along with fewer false alarms. Further data accumulation is ongoing to strengthen these findings.

Conflicts of Interest Naohisa Yoshida, Osamu Dohi, and Tomohisa Takagi received grants for research from Fujifilm. Other authors did not have any conflict of interest.

DOI 10.1055/s-0046-1821093

Aims The Japan NBI Expert Team (JNET) classification is widely used to support optical diagnosis and guide treatment strategies for colorectal lesions [1]. However, most available evidence derives from Asian cohorts [2, 3], and real-world performance across the full JNET spectrum in Western populations remains unclear [4]. This study aimed to evaluate the diagnostic accuracy of JNET subtypes in predicting histologic features and depth of invasion in a large multicenter European cohort of colorectal lesions treated with ESD.

Methods We conducted a retrospective multicenter study including consecutive patients who underwent colorectal ESD in 19 European referral centers between 2010 and 2025. Lesions were eligible if they had a pre-resection chromoendoscopic assessment with documented JNET classification and complete post-ESD histopathology. Lesions without JNET classification or complete histologic data were excluded. Lesions were categorized as: JNET 1 (non-neoplas-

tic/serrated), JNET 2A (low-grade intramucosal neoplasia), JNET 2B (high-grade intramucosal neoplasia or superficial submucosal invasion), and JNET 3 (deep submucosal invasion). Diagnostic performance metrics (sensitivity, specificity, PPV, NPV, accuracy) were calculated using histology as the reference standard.

Results A total of 2193 lesions were analyzed (49 JNET 1, 1281 JNET 2A, 817 JNET 2B, 46 JNET 3). For JNET type 1, the sensitivity, specificity, PPV, and NPV for predicting non-neoplastic lesions were 31 %, 98 %, 24 %, and 99 %, respectively, with an overall accuracy of 97 %. Notably, among JNET 1 lesions, 26.5 % showed high-grade dysplasia and 10.2 % superficial submucosal adenocarcinoma (sm1).For JNET type 2A predicting low-grade dysplasia, the sensitivity and specificity were 77 % and 68 %, with a PPV of 58 %, NPV of 84 %, and accuracy of 71 %. Importantly, 34.2 % of JNET 2A lesions harbored high-grade dysplasia or sm1 carcinoma, and 3.7 % showed deep submucosal invasion (sm2-sm3).For JNET type 2B predicting high-grade dysplasia or sm1 carcinoma, sensitivity was 52 %, specificity 79 %, PPV 61 %, NPV 72 %, and accuracy 69 %. Among these lesions, 12.4 % showed deep submucosal adenocarcinoma. Histology was overestimated in 26.4 % of cases (final diagnoses included sessile serrated lesions with LGD, adenomas with LGD, or traditional serrated lesions).For JNET type 3 predicting deep submucosal invasion, sensitivity was 18 %, specificity 99 %, PPV 72 %, NPV 93 %, and accuracy 93 %.En-bloc resection was achieved in 90.1 %, ensuring high reliability of histopathologic assessment.

Conclusions The JNET classification is widely used to classify colorectal lesions and guide therapeutic decisions. However, in this large real-world European cohort, diagnostic performance in the intermediate categories (JNET 2A and 2B) was suboptimal, with a non-negligible risk of underestimating advanced neoplasia, including deep submucosal invasion. These findings suggest that treatment decisions should not rely solely on JNET assessment, but rather integrate complementary diagnostic tools and clinical judgment to avoid inappropriate management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP154 Underwater Endoscopic Mucosal Resection of Colorectal Polyps Involving the Appendiceal Orifice

Authors Papachrysos N[1, 2], Blomberg A[2, 1], De La Croix H[3], Varkey J[4, 1], de Lange T[5, 1]

Institutes **1** Department of Molecular and Clinical Medicine, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; **2** Division of Gastroenterology, MGA, Sahlgrenska University Hospital/Östra, Gothenburg, Sweden; **3** Department of Surgery, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; **4** Division of Gastroenterology, Department of Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden; **5** Department of Medicine-Mölndal, Sahlgrenska University Hospital, Gothenburg, Sweden

DOI 10.1055/s-0046-1821094

Aims Appendiceal polyps are challenging to resect endoscopically, and many deep lesions are traditionally referred to for surgery. The currently available endoscopic alternative, endoscopic full-thickness resection (eFTR), carries a relatively high risk of appendicitis and residual lesion. Underwater endoscopic mucosal resection (uEMR) enables larger en bloc resections compared with conventional EMR by exploiting the buoyancy effect. In the underwater environment, buoyancy facilitates invagination of the appendiceal mucosa into the caecal lumen, providing safe access to polyps extending into or involve the appendiceal orifice. In combination with cap assistance and suction, uEMR allows controlled removal of lesions in this anatomically challenging region, potentially avoiding unnecessary surgery. Sahlgrenska University Hospital/Östra is the tertiary referral center for advanced colorectal polypectomy in Western Sweden.To evaluate whether uEMR is a safe and effective method for removing colorectal polyps involving the appendiceal orifice, and to describe procedural outcomes and technical insights.

Methods Since 2019, all advanced polypectomy procedures at our center have been prospectively registered in a dedicated database. uEMR was introduced in January 2023, with its use for appendiceal-orifice lesions initiated in June 2023. We conducted a retrospective review of all uEMR procedures involving the appendiceal orifice performed between June 2023 and December 2024.

Results Twenty uEMR procedures involving the appendiceal orifice were identified. The mean patient age was 63 years (range 28–86), and 55 % were women. The median polyp size was 16.1 mm (IQR 10–30 mm). Based on recommended classifications, 25 % of lesions reached the appendiceal orifice with identifiable borders, whereas 75 % completely covered the orifice and borders were not identifiable prior to uEMR. In 45 % of cases, 25–50 % of the orifice was involved, and in 55 % > 50 % was covered. Lesions were classified as Paris 0-IIa (80 %) or 0-Is (20 %), and JNET 1 (60 %), JNET 2a (35 %) or JNET 2b (5 %).

Intraoperative bleeding occurred in one case and was successfully managed endoscopically. No intraoperative perforations, delayed perforations, or delayed bleedings were observed. One patient developed appendicitis the day after the procedure; imaging revealed inguinal hernia-related entrapment of the appendix, and the patient recovered with conservative management and intravenous antibiotics.

Technical success was achieved in 90 % of cases, while two patients were referred for surgery due to incomplete or unsuccessful resection. En block resection was achieved in 84.2 % of cases, and R0 resection in 63.2 %. The most common histology was sessile serrated lesion (SSL, n = 11), followed by tubular adenoma (n = 4), tubulovillous adenoma (n = 2), hyperplastic polyp (n = 1), and inflammatory polyp (n = 1). Dysplasia was identified in one SSL, and high-grade dysplasia was found in one tubular adenoma and one tubulovillous adenoma. Seven patients underwent follow-up endoscopy within 12 months, with no recurrences detected.

Conclusions uEMR is a safe and effective technique for resection of colorectal polyps involving the appendiceal orifice in a tertiary high-volume setting. High en bloc and R0 resection rates were achieved, with minimal adverse events and no local recurrence. These findings support uEMR as a preferred minimally invasive approach for selected lesions in this anatomically challenging location.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP155 DeeP-maRgIn optical diagnosis and endoscopic resection algorithM for Early rectal cancer (PRIME): a prospective cohort study

Authors Sorge A[1], Argenziano ME[2], Poortmans PJ[3], Montori M[4, 3], Tornai T[3, 5], Hoorens A[3], Debels L[6], Desomer L[7, 3], Tate D[3]

DOI 10.1055/s-0046-1821095

Aims Optical diagnosis of deep submucosal invasion in early rectal cancer (ERC) remains suboptimal, leading to both undertreatment (endoscopic submucosal

dissection for deeply invasive disease) and overtreatment (advanced techniques or surgery for superficial lesions). This study evaluated a diagnostic-therapeutic algorithm (PRIME) using deep-margin optical diagnosis (DMOD) to guide selection of the endoscopic resection technique for ERC. [1–2]

Methods We performed an interim analysis of prospective data from consecutive rectal lesions at risk of submucosal invasion at a tertiary centre (August 2023-October 2025). An algorithm incorporating DMOD with muscle-retracting sign (MRS) assessment followed by dissection plane selection: endoscopic submucosal dissection (ESD; MRS-negative), endoscopic intermuscular dissection/knife-assisted or device-assisted full-thickness resection (EID/kFTR/FTRD; MRS-positive) [3].

Results 47 lesions were included (44.7 % adenocarcinomas). DMOD was feasible in all cases, with MRS detected in 34.0 % (16/47) of the lesions. The technical success rate of endoscopic resection was 97.9 % (46/47), with ESD performed in 30 lesions (63.8 %), EID in 10 (21.3 %), kFTR in 5 (10.6 %), and FTRD in 1 (2.1 %). En bloc, R0 resection, and R0 vertical margin rates were 100 % (46/46), 93.5 % (43/46), and 97.8 % (45/46), respectively. Adverse events occurred in 10.6 % (5/47) of patients (AGREE grade I-IIIa). Rectal preservation rate was 91.5 % (43/47). Primary outcomes did not differ significantly between MRS-positive and MRS-negative lesions (all p > 0.05) (▶ **Table 1**).

▶ **Table 1** Technical and histological outcomes of endoscopic resetion.

	Non-invasive and T1sm1 n = 32	T1 sm2-3 n = 11	T2 n = 4
Technical success, n (%)	32 (100)	11 (100)	3 (75.0)
En-bloc*, n (%)	30 (100)	11 (100)	3 (100)
R0*, n (%)	30 (93.8)	11 (100)	2 (66.7)
R0 vertical margin*, n (%)	32 (100)	11 (100)	2 (66.7)
Adverse events, n (%)	3 (9.4)	1 (9.1)	1 (25.0)
Muscle-retracting sign, n (%)	4 (12.5)	8 (72.7)	4 (100)
Histological risk factors, n (%)			
-No risk factors	31 (96.9)	4 (36.4)	1 (33.3)
- Lymphovascular invasion	1 (3.1)	7 (63.6)	2 (66.7)
- Intermediate-high tumor budding	0 (0)	3 (27.3)	1 (33.3)
- Poor differentiation	0 (0)	1 (9.1)	1 (33.3)

Conclusions Deep margin optical diagnosis reliably guided rectal endoscopic resection, achieving excellent oncologic radicality and safety in both MRS-positive and MRS-negative lesions. The PRIME algorithm prevented unnecessary escalation in superficial disease while avoiding undertreatment of deeply invasive cancers.

Conflicts of Interest DJT: Pentax Medical, Fujifilm, and Olympus research support and consulting. The other authors declare that they have no conflicts of interest.

PYP156 Comparison of cold snare polypectomy (CSP) and hot snare polypectomy (HSP) of intermediate sized colorectal polyps 10-15mm – Preliminary data of a randomized controlled non-inferiority trial

Authors Kurz M[1], Ulrich J[1], Heilmaier M[1], Mayr U[1], Middelhoff M[1], Phillip V[1]

DOI 10.1055/s-0046-1821096

Aims Cold snare polypectomy (CSP) has gained increasing relevance during the last years. Due to fewer observed adverse effects and reduced procedure time, the method is already recommended for polyps < 10 mm. There is emerging evidence supporting the use of CSP for adenomas and sessile serrated lesions (SSL) > 10 mm, but larger randomized controlled trials are still missing. Therefore, the aim of this randomized controlled non-inferiority trial is to compare CSP with HSP for adenomas and SSLs measuring 10-15 mm in terms of complete histological resection rates (R0).

Methods This ongoing randomized controlled non-inferiority trial started data collection in 2022 at a tertiary center in Germany. All consenting colonoscopy patients are screened for polyps according to the inclusion criteria. If a suitable polyp is detected, the polyp is randomized to hot or cold snare polypectomy. The polyp is then resected using a 15 mm hybrid snare (SnareMaster Plus, Olympus) according to the protocol of the assigned study group. Following resection, four mucosal biopsies are obtained at the resection margin. The primary outcome is the complete resection rate, determined by the absence of adenomatous or SSL tissue in the biopsies. Secondary outcomes include the en bloc resection rate, failure of CSP requiring conversion to HSP, duration of the procedure and the rate of adverse events. The preliminary data were analysed using R version 4.5.0 (R Core Team, 2025).

Results 81 Polyps in 55 patients were removed protocol compliant. The mean size was 11.89 mm, 69.14 % (56/81) were adenomas and 30.86 % (25/81) were SSL. The complete resection rate by CSP was 88.10 % (37/42) and 89.74 % (35/39) by HSP. En bloc resection was achieved in 88.10 % (37/42) by CSP and 76.92 % (30/39) by HSP. In 10.64 % (5/47) of cases, CSP was not possible, but after conversion to HSP the resection was successful in all cases. Mean duration of CSP and HSP was 81.32 seconds and 126.64 seconds, respectively. Periprocedural bleeding was defined by persistence > 60 seconds that required an endoscopic intervention (e. g. hemoclip) for hemostasis. After CSP, bleeding occurred in 28.57 % (12/42) of cases, after HSP in 2.94 % (1/34) of cases. None of the periprocedural bleedings were clinically relevant. No delayed bleeding within 30 days or other adverse events occurred.

Conclusions CSP appears to be non-inferior to HSP in terms of complete resection rate and safety in the removal of adenomas and SSL (10–15 mm), while also being faster.

PYP157 Accuracy and Agreement in JNET and Morphology Classification of Advanced Colorectal Polyps: A Survey of UK Endoscopists

Authors Khani A[1], Landy J[2], Taku S[3], Yutaka S[4], Suzuki N[2]

Aims The Japan NBI Expert Team (JNET) classification provides a structured approach to predicting histology based on narrow-band imaging features that can be utilised in combination with the Paris and laterally spreading tumour (LST) morphological classification for the assessment of advanced colorectal polyps. The accuracy and interobserver variability amongst United Kingdom (UK) clinicians for JNET and descriptors of morphology is uncertain. We aimed to 1) assess the diagnostic accuracy of the JNET classification among endoscopists, 2) evaluate interobserver variability for the JNET and morphology classification systems, 3) determine whether grouping the morphology categories improves agreement among endoscopists and 4) assess whether the level of endoscopic experience influences diagnostic accuracy and interobserver agreement [1, 2].

Methods An online image-based survey was distributed for 12 weeks in 2025 to practising endoscopists. The survey contained a total of 15 polyps derived from a previously validated database of images with a JNET classification consensus by JNET core members. Each polyp was displayed sequentially in white-light, standard narrow-band, and magnified narrow-band imaging modes. Respondents were asked to assign a JNET classification and morphology (six predefined options) for each case. The JNET consensus diagnosis served as the gold standard for JNET classification. The survey was advertised through The Joint Advisory Group on Gastrointestinal Endoscopy (JAG) newsletter, personal communications, as well as through social media pages.

Responses were analysed for diagnostic accuracy and interobserver agreement using Fleiss' Kappa (κ). Subgroup analyses were performed by endoscopic experience (< 300, 300–3000, > 3000 lifetime procedures). Lastly, we assessed whether grouping the morphology into polypoid (Is, Is + IIa and LSTGM), flat (IIa, LSTNGFE and LSTGH) and those with a depressed component (IIc,IIc + IIa and LSTNG PD) would impact agreement.

Results A total of 129 endoscopists from the UK completed the survey. Distribution by experience was: < 300 procedures (n = 18), 300–3000 (n = 68) and > 3000 (n = 42).
