Aims Metastatic pancreatic lesions (mPLs) arising from extra-pancreatic primary malignancies represent an uncommon entity, sparsely documented in the literature, accounting for approximately 2 % of pancreatic neoplasms. mPLs demonstrate variable endoscopic ultrasonographic (EUS) morphology (focal or diffuse parenchymal involvement with multinodular presentation) without predilection for specific anatomical subsites of the gland. EUS-guided tissue acquisition, especially with fine-needle biopsy (FNB), is essential for the definitive cytohistological diagnosis of pancreatic solid lesions, including mPLs. This multicenter retrospective analysis from two tertiary referral centers for hepatobiliary-pancreatic disorders in Southern Italy examines EUS characteristics and contrast-enhanced ultrasound (CH-EUS) patterns of mPLs, along with FNB diagnostic accuracy.

Methods We retrospectively analyzed consecutive patients undergoing EUS-FNB for suspected mPLs between November 2019 and April 2025. Thirty-five patients with histopathologically confirmed intrapancreatic metastases were enrolled. Patient demographics, EUS and CH-EUS imaging characteristics of mPLs, and diagnostic yield were systematically evaluated.

Results Patient characteristics are reported in ▶ **Table 1**. Echoendoscopically, all lesions demonstrated solid echotexture: 28 presented as solitary nodules and 7 as multiple lesions. Anatomical distribution showed predominant involvement of the uncinate process/pancreatic head (n = 25, 75 %) versus body-tail (n = 10, 25 %). Echogenicity patterns revealed hypoechoic appearance in 30 cases, hyperechoic in 2, isoechoic in 1, and markedly heterogeneous in 2. CH-EUS with sonovue demonstrated characteristic hypervascular enhancement networks in all RCC metastases, representing a nearly pathognomonic pattern. Remaining lesions exhibited non-specific, heterogeneous enhancement patterns. EUS-FNB achieved 100 % technical success utilizing 22-G needles with slow-pull and suction technique. Access routes included trans-gastric (n = 13) and trans-duodenal (n = 22) approaches. Mean pass number was 2,3 ± 0,64 and MOSE was always performed and revealed a 100 % of accuracy. Periprocedural adverse events (AEs) occurred in 2 patients (6.2 %), consisting of self-limited intratumoral hemorrhage. No delayed AEs were documented. Histological evaluation reported 100 % adequate speciment with definite diagnosis. Contextual ERCP was performed in all the cases of clinical\biochemical jaundice with biliary stent placement. Management of mPLs was patient-tailored and specifically guided by the primary tumor type, disease burden, and patient performance status in a multidisciplinary approach. In particular, therapeutic management consisted predominantly of oncological intervention: systemic chemotherapy (n = 24), immunotherapy (n = 2), surgical resection (n = 3), with remaining patients receiving best supportive care. Six-month survival was documented in just 15 patients.

Conclusions mPLs constitute an uncommon entity among solid pancreatic masses. Metastatic lesions may present incidentally in asymptomatic individuals without known primary malignancy. EUS features are often characteristic demonstrating hypo-isoechoic or hyperechoic echotexture in solitary or multifocal distribution. CH-EUS characteristics vary according to histological subtype and provide valuable diagnostic information perioperatively expecially for RCC. EUS-FNB represents a safe and highly effective diagnostic modality with excellent diagnostic yield, facilitating accurate mPLs identification. Prognosis remains guarded, particularly for SCLC and breast cancer metastases, paralleling that of the metastatic primary neoplasm.

eP905 Cold Endoscopic Mucosal Resection for Sessile Serrated Lesions with Dysplasia

Authors Kheir A[1], Abasaeed Elhag S[1], Alkhader D[1], Mahmoud F[1]

Institute **1** Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates

DOI 10.1055/s-0046-1822232

Aims Cold endoscopic mucosal resection (CEMR) is widely accepted as the optimal technique for resecting large sessile serrated lesions (SSLs). Sessile serrated lesions with dysplasia (SSLDs) are rare precursors in the sporadic serrated colorectal cancer pathway, that are linked to post-colonoscopy colorectal cancer (PCCRC). The application of CEMR in SSLDs remains unexplored. The use of conventional hot endoscopic resection techniques (hot polypectomy, endoscopic mucosal resection, or endoscopic submucosal dissection) especially in the proximal colon were most SSLs and SSLDs reside, can increase risks of delayed bleeding, post polypectomy syndrome, deep mural injury and perforation. In addition, it is not cost-effective, as using electrocautery in the proximal colon mandates costly clip closure to mitigate against risk of delayed bleeding and can interfere with confident CEMR scar assessment at surveillance due to clip artefacts, resulting in unnecessary biopsy or re-treatment. We evaluate CEMR efficacy for SSLDs in a prospective observational cohort [1–6].

Methods We prospectively collected data from elective colonoscopies at a single academic tertiary centre, with 1 or more SSLDs treated with CEMR. All lesions were treated by a single experienced therapeutic colonoscopist with expertise in image-enhanced endoscopy and advanced resection techniques. Our CEMR technique comprised of submucosal injection with chromosaline (methylene blue with diluted epinephrine 1:100,000) prior to piecemeal cold snare resection of all visible neoplasia using dedicated cold snare. When feasible, dysplastic components are resected enbloc and always submitted separately from non-dysplastic tissue to facilitate histopathologic confirmation. Post resection, careful defect and margin assessment for residual neoplasia without use of adjuvant thermal ablation. Surveillance colonoscopy (SC1 at 6 months, SC2 at 12 months post-SC1) with standardised CEMR scar assessment including high-definition white light, narrow band imaging with optical magnification, photodocumentation, and scar biopsies.

Results CEMR was performed on 15 SSLDs in 12 patients (60 % females; mean age 53.3 years; 83 % with serrated polyposis syndrome). The mean polyp size was 17.3mm and mean dysplasia size was 4.3mm. There were no adverse events (delayed bleeding or perforation) and clip closure was not used in any of the cases (67 % proximal colon predominance). All lesions underwent SC1 (mean 5.9 months post CEMR) and 73 % reached SC2 (mean 13.1 months post SC1) without endoscopic or histopathologic recurrence.

Conclusions CEMR is safe, effective, and cost-efficient in resecting SSLDs without recurrence, delayed bleeding, perforation, or need for clip closure even in

the proximal colon. The absence of clips provides artefact-free CEMR scar facilitating easier detection of recurrence at surveillance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822233

Aims Endoscopic ultrasound–guided shear wave elastography (EUS-SWE) allows quantitative liver stiffness assessment from both hepatic lobes during standard EUS. Its diagnostic accuracy for staging liver fibrosis remains incompletely defined. We performed systematic review and meta-analysis of cumulative data to evaluate the accuracy of EUS-SWE for detecting advanced fibrosis (F3–F4) compared with no/mild fibrosis (F0–F2).

Methods We systematically searched PubMed, Embase, and Scopus from inception. 490records were identified, 161 underwent title/abstract screening and 156 were excluded;5 studies met inclusion criteria.

5 prospective studies of patients undergoing EUS-SWE with liver biopsy and/or validated non-invasive reference standards and reported diagnostic performance for fibrosis staging were included. EUS-SWE was performed, using 10 valid measurements per lobe and a reliability index (VsN) ≥ 60 %. The primary outcome was the area under the ROC curve (AUROC) for advanced fibrosis (F3–F4 vs F0–F2). Where multiple lobes were reported, we used the best-performing lobe for the main analysis and summarized lobe-specific data separately. Because standard errors were not consistently reported, we calculated a pooled AUROC as the simple mean of study-level AUROCs and described ranges of sensitivity and specificity at authors' optimal cut-offs.

Results Five prospective studies included 323 patients (range 42–108 per study; mean age 48–63 years; BMI 26.8–40.7 kg/m²), predominantly MASLD, with smaller proportions of viral, autoimmune, or alcohol-related liver disease. EUS-SWE was technically successful in > 95 % of cases and rescued patients with unreliable or failed VCTE in two series. Four studies, (264 patients) reported AUROCs for advanced fibrosis (F3–F4 vs F0–F2). The reported AUROC for left lobe stiffness was 0.93 with sensitivity 0.90 and specificity 0.83 at a cut-off of 8.48 kPa. [1] Diehl et al. found AUROCs of 0.98 (right) and 0.95 (left) versus biopsy, with right-lobe sensitivity 0.60 and specificity 0.98 at 25.5 kPa [2]. Kohli et al. reported AUROCs of 0.80 (left) and 0.78 (right) with sensitivities 0.58–0.75 and specificities 0.86–0.93 at 18–24 kPa [3]. AbiMansour et al. observed AUROCs of 0.80 (right) and 0.73 (left) for advanced liver disease (stage ≥ 3) defined by biopsy, MRE, or transient elastography [4]. The pooled AUROC for advanced fibrosis across these studies was 0.87 indicating good overall diagnostic accuracy. Sensitivities ranged from 0.58 to 0.96 and specificities from 0.83 to 0.98 at study-specific thresholds. Cirrhosis-focused data from Del Valle et al. (n = 59) showed AUROCs of 0.97 (right) and 0.99 (left) for biopsy-proven cirrhosis, with sensitivity 0.97 and specificity 0.90–0.97 at cut-offs of 10.7 and 14 kPa. [5] In Kohli and Wang, cirrhosis AUROCs ranged from 0.90 to 0.96 with sensitivities 0.89–1.00 and specificities 0.87–0.92.[1, 3]. Right- versus left-lobe analyses showed broadly comparable performance. [2, 4] Diehl and AbiMansour reported slightly higher AUROCs or sensitivity for the right lobe (0.98 vs 0.95; 0.80 vs 0.73, respectively), whereas Kohli and Del Valle observed marginally higher AUROCs for the left lobe (0.80 vs 0.78; 0.99 vs 0.97). [3, 5] Wang assessed only the left lobe [1]

Conclusions EUS-SWE demonstrates good overall diagnostic accuracy for advanced fibrosis (pooled AUROC ~0.87) and excellent accuracy for cirrhosis (AUROCs often > 0.95). Its performance is comparable or superior to VCTE, particularly in patients with obesity or unreliable transcutaneous measurements. EUS-SWE be integrated into routine EUS examinations as a comprehensive tool for non-invasive staging of liver fibrosis, especially when transabdominal elastography are impractical or inconclusive.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822234

Introduction Recto-vaginal fistula (RVF) is a rare complication after Hartmann's intervention, with little evidence regarding non-surgical alternatives, particularly in fragile patients who are unfit for major surgery.

Endoscopic Procedure A 78-year-old woman, functionally dependent due to cognitive impairment, had undergone Hartmann's intervention for sigma volvulus after three unsuccessful endoscopic detorsion attempts. Two years later, she was readmitted with sepsis and rectal bleeding. CT imaging revealed spontaneous perforation of the rectal stump, a presacral collection and suspicion of a RVF. Rectoscopy showed diversion colitis and a 10mm fistulous orifice with purulent/fecaloid drainage. Partial exploration of the tract was possible, and rectovaginal communication was confirmed by vaginal examination. Given her condition, conservative management (antibiotic therapy) was initially chosen; however, she experienced multiple readmissions due to sepsis secondary to recurrent urinary tract infections. Faced with the surgical contraindication, an Amplatzer luminal aposition device of 14 x 18 mm was deployed with support from Cardiology under fluoroscopic guidance, using rectal access (conventional gastroscope) and vaginal access (pediatric gastroscope). A guidewire was advanced through the fistula, and the device was released under dual endoscopic vision. Subsequently, the patient evolved favourably, with no further septic episodes or Emergency Department visits.

Discussion Post-Hartmann RVF in elderly patients with comorbidities imposes a therapeutic challenge. Evidence on endoscopic closure of RVF with cardiac devices (Amplatzer) is scarce, although promising cases have been reported in collovaginal and rectal fistulas. This case illustrates the feasibility of a minimally invasive strategy in patients with surgical contraindication, achieving fistula closure and clinical improvement, whit no septic recurrences after the procedure.

eP908 Assessing Esophageal Stricture Severity and Response to Dilation With FLIP Technology

Authors Ezquerrra-Duran A[1], Nuñez Pizarro JL[1], Barba E[1], Araujo IK[1]
Institute 1 Hospital Clínic de Barcelona, Barcelona, Spain
DOI 10.1055/s-0046-1822235

Aims To determine esophageal diameter(D), distensibility index(DI), and pressure(P) before and after dilation, and to assess whether these parameters correlate with the number of dilation sessions required or the need for repeat dilation after initial improvement.

Methods This single-center prospective study included patients undergoing esophageal stricture dilation between July 2022 and July 2024. FLIP measurements were obtained at various balloon volumes, with comparisons based on the hightest volume achieved. Clinical data were collected before and after dilation using validated questionnaires and the electronic medical record [1–3].

Results Twenty-two strictures in 20 patients were analyzed. The mean age was 57.4 years (SD 15.6); 31.8 % were female. Etiologies included peptic strictures (10, 45.5 %), EoE (3, 13.6 %), prior esophageal surgery (4, 18.2 %), lichen planus (1, 4.6 %), caustic injury (3, 13.6 %), and a Schatzki ring (1, 4.6 %). All underwent their first dilation except those with caustic injury. Five lesions (22.7 %) were considered clinically chronic. ES and BEDQ scores improved significantly ($p < 0.00001$), with no significant change in GERD-Q.

The initial endoscopic diameter estimate was 10.5 mm (IQR 8–13 mm), increasing to 15 mm (IQR 15–16 mm) after dilation. FLIP-measured diameters were 9.4 mm (IQR 7–12.6 mm) pre-dilation and 13.2 mm (IQR 12–15 mm) post-dilation, with a significant pre–post difference ($p = 0.0003$). Pre-dilation endoscopic and FLIP diameters were similar (10.0 mm vs 9.95 mm), but post-dilation endoscopic diameters were significantly larger than FLIP measurements (15.6 mm vs 13.6 mm; $p = 0.0001$).

DI increased from 0.8 (IQR 0.5–2.4) to 1.8 (IQR 1–2.7) ($p = 0.0290$). Pressure decreased from 92 (IQR 75–105) to 76 (IQR 61–100) ($p = 0.0005$) after dilation (▶ **Table 1**).

▶ **Table 1** Median pre and post-dilatation diameters measured by endoscopy and FLIP

	Pre dilatación	Post dilatación	*p*
D Endoscopy mm (IQR)	10.5 (8-13)	15 (15-16)	<0,0001
D FLIP mm (IQR)	9.4 (7-12,6)	13.2 (12-15)	0.0003
DI mm2/ mmHg (IQR)	0.8 (0,5-2,4)	1.8 (1-2,7)	0.0290
Pressure mmHg (IQR)	92 (75-105)	76 (61-100)	0.0005

Five patients required repeat dilation within one year. Etiologies were caustic injury(3), peptic stricture(1), and lichen planus(1). Compared with patients who did not require re-dilation, these cases had lower initial and final diameters and DI values, with a significantly lower initial DI (0.3 [IQR 0.2–0.5] vs 1.2 [IQR 0.5–3.1]).

No significant differences in pre- or post-dilation D, DI, or P were observed based on the total number of dilation sessions. No major adverse events occurred. In one case, the FLIP catheter could not be advanced through the stricture.

Conclusions FLIP measurements of diameter, distensibility, and pressure improve after dilation. Endoscopic and FLIP diameters are similar before dilation, but endoscopy tend to overestimate post-dilation diameter relative to FLP. Patients requiring repeat dilation had lower initial distensibility. FLIP may be useful in selected cases to help predict treatment failure and to direct dilation diameter in complex cases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP909 Predictive factors for mortality in patients undergoing endoscopic drainage of walled-off pancreatic necrosis

Authors Dario B[1], Neri B[1], Corradino L[1], Stigliano S[1], Marinaccio C, Citterio N[1], Parisi G[1], Pettinelli M[1], Rea R[1], Martino M[1], Pandolfi M[1], Di Matteo FM[1]
Institute 1 Campus biomedico University Hospital, Rome, Italy
DOI 10.1055/s-0046-1822236

Aims Patients with walled-off pancreatic necrosis (WOPN) are burdened by a high risk of mortality. Primary aim was to identify early clinical and procedural risk factors for mortality after endoscopic ultrasound (EUS)-guided drainage of WOPN. Secondary aim was to compare clinical and procedural characteristics before and after EUS-guided WOPN drainage between survivors and patients experiencing WOPN-related death.

Methods In a retrospective study, all patients with WOPN treated with EUS-guided drainage with lumen apposing metal stent (LAMS) were enrolled.

WOPN characteristics were assessed by the QNI system. Risk factors were searched among pre-procedural, procedural and early (occurring < 14 days from EUS-guided drainage) post-procedural items. Inclusion criteria: 1) age > 18 years; 2) WOPN treated with LAMS. Exclusion criteria: 1) pancreatic pseudocystis; 2) post-surgical pancreatic collections; 3) pancreatic neoplasms. Data expressed as median [range], differences assessed with the X^2 test, the Student t-test or the Mann-Whitney u-test, risk factors searched by using uni- and multivariate logistic regression.

Results 61 patients with WOPN treated by EUS-guided drainage with LAMS were enrolled (age: 63 [33-86] years). Overall, 8 (13.1 %) patients died during hospitalization due to WOPN-related complications. Endoscopic necrosectomy was performed in a comparable proportion of patients between survivors and patients experiencing mortality (35 [66.04 %] vs 6 [75 %], p = 0.92). In patients experiencing mortality, higher median BMI (24.2 [14-39] vs 27.7 [24.5-40.5], p = 0.027), pre-procedural procalcitonin levels (0.13 [0-16] vs 2.5 [0.2- 20.8], p = 0.0003), frequency of N2 (≥ 30 % necrosis) (12 [22.6 %] vs 6 [75.0 %], p = 0.009) and frequency of post-procedural percutaneous drainage placement (11 [18.9 %] vs 5 [62.5 %], p = 0.038) were observed. At multivariate analysis, intensive care unit recovery (4.4 [1.9-7.5], p = 0.0009), higher pre-procedural procalcitonine values (1.9 [1.05-3.4], p = 0.04), and duodenal double-gating (2.05 [1.08-3.7], p = 0.03) were identified as risk factors for mortality, while a BMI < 25 was protective (0.24 [0.15-0.37], p = 0.005).

Conclusions In the present study only non-modifiable predictive factors for mortality have been identified. Nonetheless, recocgnition of early predictive factors for WOPN-related mortality may suggest the need for treatment optimization or accelerated step-up strategy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP910 Clinical performance and environmental impact of BougieCap dilation for esophageal strictures

Authors Javidi D[1], Timian BL[2], Pohl H[2, 1]

Institutes **1** Dartmouth Hitchcock Medical Center, Lebanon, NH, United States of America; **2** VA Medical Center, White River Junction, VT, United States of America

DOI 10.1055/s-0046-1822237

Aims The second-generation BougieCap esophageal dilation device (Ovesco AG) has recently become available; however, data on its efficacy and safety for the treatment of esophageal strictures in routine clinical practice, outside eosinophilic esophagitis (EoE), are limited [1]. We aimed to assess the feasibility, safety, and efficacy of BougieCap dilation in general GI endoscopy practice and to generate pilot data to inform the design of a future randomized clinical trial.

Methods This two-center retrospective study included adult patients with esophageal strictures who underwent dilation using the BougieCap device. The primary outcome was patient-reported dysphagia improvement within 2–3 weeks after dilation. Secondary outcomes included technical feasibility and adverse events during the procedure and within two weeks post-procedure. Technical feasibility was defined as successful completion of dilation without the need for an alternative device. Serious adverse events included esophageal perforation, clinically significant bleeding, or severe pain. In a secondary analysis, we assessed environmental impact, plastic waste, and procedural costs, comparing BougieCap dilation with standard balloon dilation and Savary dilators. Carbon emissions were estimated using life-cycle assessment with SimaPro software, the EcoInvent database, and the TRACI 2.1 method (▶ **Table 1**).

▶ **Table 1** Carbon emissions, plastic waste, and cost (per procedure)

	BougieCap	Balloon	Savory	d (Balloon)	d (Savory)
Carbon emissions ($kgCO_2e$)	0.016	0.273	1.961	-94.20 %	99.20 %
Plastic waste (g)	3.4	34.6	444.0	-90.30 %	99.24 %
Waste, Total (g)	3.4	57.4	454.5	-94.10 %	99.26 %
Price ($)	67	280.5	472.66	-213.50	-405.66

Results Twenty-four patients (mean age 70 years; 75 % male) with 28 esophageal strictures (57 % distal; 96 % benign) underwent 31 dilation sessions, most commonly for peptic strictures (79 %). Six patients underwent sequential dilations within a single session, and a total of 44 BougieCaps were used. Technical success was achieved in 100 % of cases. Mucosal tears were observed in 81 % of dilations. No immediate adverse events occurred, and mild post-procedural symptoms (sore throat, odynophagia, or pain) were reported by 17 % of patients. Complete dysphagia resolution was reported by 86 % of patients, and partial improvement by 14 %. Compared to balloon dilation as the alternative approach, BougieCap use would result in a 94 % reduction in carbon emissions, a 90 % reduction in plastic waste, and cost savings of $213 (–76 %) per procedure. Compared with Savary dilators, carbon emissions would be reduced by 99 %, plastic waste by 99 %, and costs by $473 (–86 %).

Conclusions BougieCap dilation (2nd generation) appears to be feasible, safe, and effective for the treatment of esophageal strictures. Compared with conventional dilation methods, BougieCap use may offer substantial economic and environmental advantages. Prospective comparative studies with longer-term follow-up are warranted.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Post-surgical fluid collections (PSFCs) are a common complication of gastrointestinal surgery and are usually managed by percutaneous drainage. Emerging data suggests that endoscopic ultrasound (EUS) guided drainage of PSFCs may be a safe and effective alternative. The aim of this study was to assess the technical feasibility, safety and efficacy of EUS-guided drainage of PSFCs.

Methods Retrospective, multi-centre cohort study assessed all patients referred for EUS-guided drainage of symptomatic PSFCs after hepatobiliary, upper GI or colorectal surgery at two tertiary referral centres in Australia from 1st January 2016 to 31st December 2022. Primary outcome measures were technical success (ability to access and drain a PSFC by placement of a transmural stent), clinical success (complete clinical resolution of symptoms and reduction/resolution of PSCF on CT at 3 months) and rate of adverse events, with major adverse events defined as grade III or above on the Clavien Dindo Classification.

Results Forty-two patients were referred for EUS-guided drainage of PSFCs (median age 61 years (IQR, 46–71); 25 (60 %) male). The most common index surgery was pancreatic (N = 19, 45 %) and the primary indication for drainage was sepsis (N = 29, 69 %). Mean collection size was 53mm (IQR, 41-91mm). EUS was performed at a median of 30 days (IQR, 19-69 days) post-surgery; 19 (45 %) were done in < 4 weeks of PSFC development. EUS-guided drainage was attempted in 34 (81 %) patients with 100 % technical success. Eight patients were excluded at EUS due to unsuitable collection morphology, including PSFC too small or not identified, n = 5; immature PSFC wall, n = 2; PSFC not abutting the GI lumen, n = 1. Clinical success was achieved in 33/34 (97 %) patients who underwent EUS-guided drainage; one patient had symptom resolution post drainage however follow up CT showed an increase in the size of the PSFC. A single EUS-guided drainage was performed in 29 (85 %) patients; 5 (15 %) patients required > 1 endoscopic procedure with a median number of drainages of 2 (IQR, 1-2). There were no intra-procedural complications. Nine (26 %) post-procedural adverse events occurred, of which 9 (33 %) were classified as major adverse events.

Conclusions EUS-guided drainage of PSFCs is technically feasible, can be safely performed early following PSFC formation in a significant proportion of patients and achieves high rates of clinical success with few major adverse events. This technique offers a minimally invasive alternative to percutaneous drainage, avoiding the need for an external drain with attendant risk of blockage, dislodgement, and infection. EUS-guided drainage should be considered as a therapeutic option for patients with PSFCs after GI surgery.

eP912 Hereditary Alpha-Tryptasemia (HaT) Coexisting with Dense Gastrointestinal Mast Cell Infiltration: A Challenging Diagnostic Case for Gastroenterologists

Authors Fantin A[1], Cristofori C[2], Albergati IV[2], Santangelo P[3], Kitenge MP[2], Di Somma A[2], Pezua Sanjinez AMS[3], Morbin T[2], Cataldo I[4]

Institutes **1** Gastroenterology Unit, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy; **2** Gastroenterology Unit, Veneto Institute of Oncology, IOV-IRCCS, Padova, Italy; **3** Gastroenterology Unit, Veneto Institute Of Oncology, IOV-IRCCS,, Padova, Italy; **4** Unit of Pathological Anatomy and Histology, Veneto Institute of Oncology, IOV-IRCCS, Padova, Italy

DOI 10.1055/s-0046-1822239

Background Mast cell disorders present a diagnostic challenge. Hereditary Alpha-Tryptasemia (HaT), defined by extra copies of the TPSAB1 gene leading to baseline elevated tryptase, is a predisposing factor. The coexistence of HaT with tissue infiltration complicates the distinction from other mast cell diseases [1].

Case Presentation and Genetic Confirmation We report a 65-year-old female with two months of epigastralgia and recurrent urticaria and elevated serum tryptase (38ug/L). Molecular analysis for TPSAB1 confirmed a genotype consistent with HaT (\beta:\alpha / \beta:\alpha:\alpha).

Histological Findings and Diagnosis The gastroscopy showed mild gastropathy. Histopathology of the gastro-duodenal biopsies was crucial, revealing a dense infiltration of mast cells (CD117 +) in the lamina propria: > 80/HPF in the duodenum and > 30/HPF in the stomach. This profound infiltration suggests that symptoms were driven not solely by HaT, but also by a significant local mast cell pathology in the GI tract.

Discussion and Conclusion This condition is rare and under-recognized by gastroenterologists, as non-specific GI symptoms are often confused with IBS or GERD. The correct diagnosis, leading to rapid symptom remission with famotidine and sodium cromoglycate, required integrating the clinical history, the HaT genetic finding, and a targeted histopathological examination of the GI biopsies. This case highlights the importance of ruling out mast cell proliferation in the GI tract in patients with unexplained abdominal symptoms and baseline elevated tryptase, regardless of an underlying genetic predisposition like HaT.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Endoscopic-ultrasound guided gastroenterostomy (EUS-GE) has recently emerged as the most optimal endoscopic treatment for malignant gastric outlet obstruction (MGOO) [1–4]. EUS-GE, however, is generally used in the palliative setting, rather than in patients pursuing definitive treatment. Recent case reports have reported the use of EUS-GE using a lumen-apposing metal stent (LAMS) as a bridge to pancreaticoduodenectomy where the stents were resected *en bloc* followed by a surgical gastrojejunostomy [5, 6]. To our knowledge, we present the first reported case of a patient with duodenal obstruction for whom an EUS-GE was performed in the neoadjuvant setting and the LAMS was left *in situ* as the definitive anastomosis after surgical resection.

A 56 year-old female presented with MGOO secondary to duodenal adenocarcinoma. EUS-GE was performed. The patient then received neoadjuvant chemotherapy followed by pancreaticoduodenectomy six months later. The area of the cancer was readily visible and palpable. The stent was palpable with a well-connected and well-healed anastomosis. The pancreatic head and neck, duodenum, and pylorus were resected en bloc and sent to pathology. The surgical team then opted to leave the previously constructed anastomosis intact, in part due to the EUS-GE being more cranial in the stomach than a surgical gastrojejunostomy. A Roux-Y limb was created 30-40 cm distally, which was used to perform a pancreaticojejunal anastomosis. Further distally, a hepaticojejunostomy was performed.

Post-operatively, clear fluid diet was initiated on POD 2, diet-as-tolerated on POD 4, and the patient was discharged on POD 8. A follow-up EGD was performed 8 months post EUS-GE confirming a patent stent. In order to reinforce the anastomosis as a permanent solution, we considered performing endoscopic suturing as a stent-free strategy. Unfortunately, however, at 1 year follow-up the patient had recurrence of metastatic disease to the liver and a decision was taken to simply exchange the stent given the guarded prognosis.

Our case supports the hypothesis that EUS-GE is a viable and effective option for managing MGOO as a bridge to pancreaticoduodenectomy. It may enable patients to maintain adequate nutritional status, tolerate neoadjuvant chemotherapy and major surgery. Additionally, this case demonstrates feasibility of using EUS-GE as a definitive anastomotic solution during Whipple surgery, which may decrease surgical time, eliminate the risk for anastomotic leak, and most importantly decrease the risk for delayed gastric emptying, which is reported in as much as 20-40 % of patients undergoing pancreaticoduodenectomy [7].

eP914 Outcomes of G-POEM for refractory gastroparesis: A tertiary centre experience in UK

Authors Lim A[1, 2], Ayubi H[1, 2], George R[1], Tanne M[1], Gulati S[1], Patel M[1], Thrumurthy SG[1], Haji A[1], Hayee B[1]
Institutes **1** King's College Hospital NHS Foundation Trust, London, United Kingdom; **2** AL and HA joint first author
DOI 10.1055/s-0046-1822241

Aims Gastric peroral endoscopic myotomy is a minimally invasive endoscopic option for patients with refractory gastroparesis, but clinical response rates remain variable and factors to predict success have not been clearly elucidated. We assessed the outcomes of G-POEM for patients with refractory gastroparesis in our cohort, and the utility of intra-operative endoluminal functional luminal imaging probe (EndoFLIP).

Methods Retrospective, single tertiary centre, case-control study assessing the outcomes of G-POEM for refractory gastroparesis. Outcome measures include clinical response (decrease of 1 point in the total Gastroparesis cardinal Symptom Index (GCSI)) and complications. Impedance planimetry (EndoFLIP, EF-325N, Medtronic Ltd) readings were obtained before and after myotomy, standardised to 50ml balloon inflation.

Results 104 patients underwent G-POEM for refractory gastroparesis (n = 43 with type 1 diabetes). Technical success was 100 %. 53/104 patients were able to be discharged on the same day (SDD), now adopted as standard of care protocol. 12/104 (11.5 %) patients had hospital readmission within 30 days, of whom 5 required repeat endoscopy for further clipping. One patient required laparotomy for delayed leak at another institution. The median GCSI score reduced from 3.91 to 2.44 (p < 0.001) at 12 months with a clinical success rate of 60 %. Clinical success at 1 year was not different in patients with previous response to botulinum toxin treatment (p = 0.773), any pre-procedural therapy (p = 0.607), nasojejunal tube requirement prior to G-POEM (p = 0.531) and a history of opioid use (25 % vs. 54 %; p = 0.062).

There was no difference in outcome with use of lesser versus greater curvature approach (p = 0.516) however procedural time (minutes) was significantly shorter with lesser curvature approach (35 (29-47.5) vs 60(38.8-60); p = 0.047) and a trend towards less leaks (1 vs 5 were observed, p = 0.053). There was also no difference in clinical outcome with supervised, trainee-completed procedures (n = 46; p = 0.301). Baseline GCSI, baseline gastric retention at 4 hours did not correlate with reduction in GCSI, however improvement in intra-operative EndoFLIP distensibility index from pre- to post myotomy had a weak correlation with change in GCSI from pre-POEM to > 12 months post (r = -0.391; p = 0.027).

Conclusions Our results are consistent with literature confirming the need to establish pathways to improve clinical success rates post G-POEM for patients with refractory gastroparesis. Intra-operative EndoFLIP may be able to be utilised in addition to GCSI and gastric emptying however further prospective studies are required.

eP915 Reverse EUS-GJ: EUS guided decompression of Excluded Stomach Gastric Outlet Obstruction (eGOO) after Roux-en-Y Gastric Bypass Surgery

Authors Vargas Valls E[1], Gala K[1], Ghanem O[1], Abimansour J[1], Han S[1], Law E[1], Abu Dayyeh B[1, 2], Chandrasekhara V[1]
Institutes **1** Mayo Clinic, Rochester, United States of America; **2** Cedars-Sinai Medical Center, Los Angeles, CA, USA, United States of America
DOI 10.1055/s-0046-1822242

Background: Gastric outlet obstruction (GOO) of the excluded (remnant) stomach is a rare complication after Roux-en-Y gastric bypass (RYGB), typically related to chronic accumulation of secretions or mechanical narrowing. Because the remnant stomach is inaccessible by standard endoscopy, diagnosis and management can be challenging. We describe the diagnostic and therapeutic utility of endoscopic ultrasound (EUS)–guided decompression using a lumen-apposing metal stent (LAMS) for excluded-stomach GOO (eGOO).

Case Description:A 63-year-old woman with prior RYGB presented with progressive epigastric fullness, postprandial nausea, and abdominal pain. CT imaging demonstrated marked distension of the excluded stomach with features consistent with GOO and non-specific eccentric thickening of the gastric antrum.

Esophagogastroduodenoscopy was unremarkable due to the altered anatomy. EUS, however, revealed a markedly distended remnant stomach with diffuse antral wall thickening. Given these findings, EUS-directed gastric decompression was pursued.

A cautery-enhanced 15 × 10 mm LAMS was then deployed to create a jejuno-gastrostomy between the jejunal limb and the remnant stomach. A slim endoscope was advanced through the LAMS, revealing over 1.5 liters of retained fluid, pyloric stenosis, and significant duodenal bulb ulceration. Biopsies demonstrated benign peptic ulcer disease and were negative for H. pylori.

The patient experienced prompt improvement in upper-GI symptoms. Follow-up EGD/EUS demonstrated resolution of obstruction, and cross-sectional imaging at 12 months confirmed no evidence of neoplasia or complications. The patient later elected to undergo remnant gastrectomy to futher exclude malignancy, which was performed without difficulty, indicating that prior LAMS access did not preclude surgical management. Final pathology was benign pyloric stenosis.

Conclusion: This case highlights the value of therapeutic EUS as an effective minimally invasive strategy for both diagnosing and treating eGOO using a LAMS. The approach provides rapid symptom relief, enables same-session evaluation of the remnant stomach and duodenum, and importantly, does not hinder subsequent surgical gastrectomy when clinically indicated.

Abstract Text

CMV colitis is usually considered a complication of immunosuppression or steroid-refractory ulcerative colitis (UC). We report three adults with severe colitis evaluated with serum CMV PCR and targeted biopsies/CMV immunohistochemistry. Case 1: immunocompetent man with first-episode Mayo 3 left-sided colitis after viral prodrome; PCR strongly positive; rapid response to IV ganciclovir. Case 2: UC ~1 year after stopping biologics, post–C. difficile; Mayo 3 pancolitis with deep ulcers; PCR + and biopsy inclusions; improved with ganciclovir plus UC therapy with PCR clearance. C3: extensive UC relapsing during high-dose steroids and infliximab induction; CMV IHC + and PCR + ; marked improvement after ganciclovir. We propose early CMV testing in severe/atypical flares, post-infectious triggers, or relapse despite steroids/biologics to guide timely antivirals and reduce recurrent steroid exposure [1, 2].

eP917 Biliary obstruction secondary to afferent loop syndrome treated with LAMS

Authors Konstantakis C[1, 2], Wong JLH[2], Shehkar C[2]
Institutes **1** General University Hospital of Patras, Patras, Greece; **2** University Hospital Coventry & Warwickshire, Coventry, United Kingdom
DOI 10.1055/s-0046-1822244

Abstract Text

This is the case of a 78-year-old patient with previous Whipple's pancreaticoduodenectomy for a poorly differentiated adenocarcinoma. 14 months later there is evidence of disease recurrence, and the patient develops biliary obstruction secondary to afferent (biliary) limb obstruction. After discussion at the HPB MDT endoscopic palliative management was decided. Initial attempts at endoscopic luminal stent insertion were limited by anatomic access. An EUS approach was then attempted. The dilated obstructed small bowel limb was easily identified. We punctured with a 19A needle and aspirated dark bile. Contrast injected confirmed a very dilated small bowel with reflux into a dilated biliary tree. With the wire kept in place, a HOT SPAXUS LAMS 20x16mm stent was deployed creating a gastrojejunostomy with the obstructed jejunum loop. Large amount of bile was drained into the stomach. Contrast study confirmed correct placement. 4 weeks later the LAMS was replaced by two double pig tails 7fr x 15cm. Patient symptoms (jaundice, pruritus) and abnormal LFTs resolved gradually. Afferent loop syndrome can affect patients with recurrence. It is defined by distal obstruction and accumulation of bile, pancreatic and enteric fluid, causing distension of the afferent loop and recurrent cholangitis. EUS-guided gastroenterostomy is a novel technique that bypasses an area of obstruction by creating a lumen-to-lumen direct anastomosis using a fully covered lumen-apposing metal stent. EUS-guided gastroenterostomy is a minimal -invasive approach, especially compared to surgical gastroenterostomy, that could be favoured over enteral stent placement, because of difficult anatomical access and durable effect [1, 2].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP918 Safety profile of gastric peroral endoscopic myotomy (G-POEM) – a retrospective analysis

Authors Simkova D[1], Mares J[1], Hugova K[1], Vašátko M[1, 2], Martinek J[1, 2]
Institutes **1** Institute of Clinical and Experimental Medicine, Prague, Czech Republic; **2** Fakultní nemocnice u sv. Anny v Brně, Pekařská, Brno-střed, Brno, Czech Republic
DOI 10.1055/s-0046-1822245

Aims Gastric peroral endoscopic myotomy (G-POEM) is an emerging endoscopic technique for the treatment of refractory gastroparesis, particularly benefiting patients with pylorospasm. It is considered a safe procedure with a low risk of adverse events when performed by experienced endoscopists. Our aim was to perform a comprehensive analysis of all adverse events associated with G-POEM.

Methods This study presents a retrospective analysis of patients who underwent G-POEM between November 2017 and April 2025. The primary objective was to analyze procedure-related perioperative and early postoperative complications. Complications were categorized as follows: any deviations from the standard operative and postoperative course were defined as "undesirable events (UEs)" Those undesirable events meeting the criteria of the Clavien-Dindo (C-D) surgical classification were labeled as "true adverse events (AEs)".

Results Out of 71 procedures, no undesirable or adverse events were observed in 51 procedures (71.8 %).

Perioperative undesirable events included gastric mucosal injury (4; 5.6 %), duodenal mucosal injury (2; 2.8 %), major intra-procedural bleeding (1; 1.4 %), serosal perforation (9; 12.7 %), capnoperitoneum puncture (3; 4.2 %), subcutaneous emphysema (1; 1.4 %) and severe pyloric mucosal injury requiring placement of a nasojejunal feeding tube (1; 1.4 %).

Early postoperative events included diabetes decompensation in 2 patients and a small leak from the pyloric to the subhepatic region.

Fourteen days after the procedure, one patient was admitted with gastrointestinal bleeding, Forrest IIB ulcer was found and was successfully managed with endoscopic hemostasis and subsequent PPI therapy. At three months, another patient presented with mild dumping syndrome, which was treated conservatively with good clinical response.

According to the Clavien–Dindo classification, the following undesirable events were considered true adverse events (AEs): serosal perforation (9; Grade I), leak (1; Grade II), mucosal injury reguiring nasojejunal tube placement, (1; Grade IIIa), decompensation of diabetes (2; Grade II), late ulcer bleeding requiring readmission and endoscopic therapy (1; Grade IIIa), and dumping syndrome (1; Grade II).

Endoscopy 2026; 58: S1–S1041

Conclusions G-POEM is a highly safe procedure with a low complication rate. It meets the criteria for a "day-case surgery" approach.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP919V Scope Traction With Silk Suture During Gastric Incisura Endoscopic Submucosal Dissection

Authors Capogreco A[1], Dibitetto S[2, 1], Massimi D[1], de Sire R[3, 4, 1], Alfarone L[1], Boustani C[5, 1], Spertino M[6, 1], Vadalà V[6, 1], Minini F[6, 1], De Deo D[6, 1], Maselli R[3, 6, 1], Hassan C[6, 1], Repici A[6, 1]

DOI 10.1055/s-0046-1822246

Problem to solve Performing Endoscopic Submucosal Dissection (ESD) in challenging anatomical locations, particularly the gastric incisura and the lesser curvature, remains technically demanding. The main difficulty lies in maintaining an optimal and stable endoscope position while ensuring sufficient maneuverability to complete the dissection safely, efficiently, and rapidly. Under these circumstances, progression is often hindered, and the operator is forced to work with the knife positioned at a considerable distance from the endoscope tip, repeatedly adjusting the scope to preserve adequate visualization. This need emerges from paradoxical instrument movements when retroflexion is required to access all lesion margins, and from the intrinsic difficulty of maintaining stable scope positioning despite meticulous manipulation. Working in retroflexion further increases procedural complexity by producing counterintuitive instrument responses, which can compromise precision, prolong procedure time, and increase technical demands [1–5].

Innovation To address these challenges, we developed an innovative approach based on direct and dynamic traction utilizing a silk suture tied to the distal attachment base of the endoscope. This technique aims to stabilize the instrument during dissection, maintains consistent positioning, reduces operating time, and enhances precision. It is simple, inexpensive, and can be implemented rapidly in any endoscopic setting, requiring only a standard silk suture without the use of specialized equipment. One end of the suture is securely tied to the base of the distal attachment without obstructing visualization or instrument passage, while the other end exits through the patient's mouth and is controlled externally by a second operator. Through adjustable traction, this configuration provides dynamic countertraction that can be finely adjusted according to procedural needs. This added stability compensates for anatomical constraints, reduces unnecessary movement, and enhances scope maneuverability. By limiting excessive motion and enabling a closer, more controlled dissection, this technique may reduce the risk of inadvertent tissue injury.

Results We applied this direct endoscope traction method in six consecutive gastric incisura ESD cases over the past 3 months, all involving visible lesions histologically confirmed as adenocarcinomas. Prior attempts to improve stability using a more rigid scope and conventional traction techniques, specifically clip-with-line, did not yield meaningful improvement. All lesions treated using this technique were ultimately confirmed as R0 resections, with both lateral and deep margins free of neoplasia.

Conclusions ESD in the gastric incisura and lesser curvature is challenging due to difficulties in maintaining endoscope stability and control. Our dynamic traction technique offers a practical, low-cost solution that improves stability, precision, and procedural efficiency. Without dynamic direct traction, these procedures would likely have required significantly longer operating times. In extreme cases, this might have necessitated piecemeal rather than en bloc resection, potentially compromising histological assessment. Further studies are needed to validate this clinical impact and reproducibility.

eP920 Role of Detective Flow Imaging Endoscopic Ultraosund (DFI-EUS) in the assessment of pancreatic solid lesion

Authors Stigliano S[1], Citterio N[2], Biasutto D[2], Marinaccio C[1], Antonini F[3], Di Matteo FM[4]

Institutes **1** Campus Bio Medico University of Rome, Selcetta, Italy; **2** Campus biomedico via alvaro del portillo 200, Roma, Italy; **3** Gastroenterology and Interventional Endoscopy Unit, C. e G. Mazzoni Hospital, Ascol, Italy; **4** Campus Bio Medico University of Rome, Rome, Italy

DOI 10.1055/s-0046-1822247

Aims The introduction of ancillary techniques, such as contrast enhanced EUS (CHE-EUS), has improved the study of pancreatic lesions. However, the use of contrast agents entails a prolongation of procedure time and additional costs. The innovative ultrasound technique Detective Flow Imaging-EUS (DFI-EUS) has been recently introduced. It allows the study of micro-vascularization without requiring administration of contrast agents. The aim of this study is to assess the role of DFI in defining pancreatic lesion and its agreement with CHE-EUS.

Methods Prospective, single centre study conducted on consecutive patients who underwent EUS-FNB for solid pancreatic lesion at the Therapeutic Digestive Endoscopy Unit of Campus Biomedico University of Rome. Lesions were classified according to the degree of vascularisation at DFI study into grade 0 absence of vascularisation or hypovascularisation pattern, grade 1 isovascularisation pattern and grade 2 hypervascularisation pattern compared to surrounding parenchyma.

Final diagnosis was based on histopathology, by using needles of 22 Gauge Acquire S for tissue acquisition.

Results From April 2024 to April 2025, 100 patients were enrolled (51 % male; mean age 68 ± 10 years old). The mean size of pancreatic lesions was 29 ± 13 mm and in the majority of cases were located in the head of the pancreas (52 %). At DFI-EUS evaluation 11/100 (11 %) of lesions were defined grade 1 at DFI, 20/100 (20 %) grade 2 and 69/100 (69 %) grade 0. After the Sonovue administration, 70 % of lesions showed hypoenhancement. In 69 % of cases the final

diagnosis was adenocarcinoma, 17 % neuroendocrine tumour, 8 % inflammatory mass and in 6 % other neoplasm. Intraclass Coefficient (ICC) between DFI-EUS and CHE-EUS was 88 % and Cohen's Kappa was 0.74.

The sensitivity of DFI in detecting pancreatic adenocarcinoma was 93 % (95 % CI 84-97 %), the specificity was 50 % (95 %CI 30-70 %).

Conclusions DFI EUS provide a fast evaluation of the micro-vascularization of pancreatic solid lesions. It seems to be an effective technique in characterizing lesions with good concordance with CHE-EUS.

DOI 10.1055/s-0046-1822248

Aims Gastric inflammatory fibroid polyps (GIFPs) are rare benign subepithelial lesions (SELs). They frequently present as an indeterminate SEL after additional diagnostic modalities have failed to yield a diagnosis. In the absence of standard management pathways, we sought to evaluate the diagnostic and therapeutic role of endoscopic resection (ER) for GIFPs.

Methods We retrospectively analysed a prospectively maintained database at a tertiary referral centre. Consecutive patients with histologically confirmed GIFPs who underwent endoscopic resection (ER) between November 2013 and March 2025 were included. The primary outcomes were en bloc resection and R0 excision. Secondary outcomes included adverse events, recurrence, and resolution of anaemia.

Results Seventeen patients (median age 72 years, IQR 70–79) were identified. En bloc resection was achieved in all (100 %), with R0 resection in 35 %. Pre-resection EUS correctly identified submucosal origin in 50 %, and histology suggested GIFP in only 9 %. There were no perforations or serious adverse events. One delayed bleed (6 %) was managed conservatively. Among patients presenting with anaemia, 71 % demonstrated resolution post-ER. No recurrence was observed during follow-up, including in margin-positive cases.

Conclusions ER provides both diagnostic certainty and definitive treatment for GIFPs, which generally present as an indeterminate gastric SELs. Given the poor accuracy of pre-resection testing and absence of recurrence, ER should be regarded as the preferred first-line strategy, with routine post-resection surveillance generally unnecessary once diagnosis is confirmed.

eP922 Clip artefact after duodenal endoscopic mucosal resection: prevalence and management

Authors Lam B[1], Gupta S[2], Mandarino FV[3], Kerrison C[1], Kim J[1], Hasib A[1], Eitan M[4], Kim YS[1], Lee EYT[1], Burgess N[1], Michael J B[1]

Institutes **1** Westmead Hospital, Westmead, Australia; **2** St. Michael's Hospital, Toronto, Canada; **3** San Raffaele Hospital, Milano, Italy; **4** meir medical center, Kefar Sava, Israel, Kefar Sava, Israel

DOI 10.1055/s-0046-1822249

Aims Large (≥ 15 mm) duodenal adenomas (DAs) are effectively managed by endoscopic mucosal resection (EMR). Prophylactic clip closure is frequently used to prevent complications. Unlike the colon, both residual or recurrent adenoma (RRA) and clip artefact exhibit a villiform pattern in the duodenum, complicating endoscopic interpretation. The prevalence and clinical impact of duodenal clip artefact (DCA) remain undefined.

Methods Consecutive patients undergoing duodenal EMR between January 2016 and August 2024 at a tertiary center were prospectively enrolled. At first surveillance endoscopy (6 months), post-EMR scars were classified as: type 1 (bland), type 2 (nodular), or type 3 (residual clips with nodularity). Types 2/3 were defined as DCA and resected by cold-snare polypectomy. The primary outcome was DCA prevalence, secondary outcomes were diagnostic accuracy and procedural safety.

Results Clips were used in 33/255 (15 %) resections. Among 32 patients with follow-up, scars were type 1 (n = 13), type 2 (n = 15), and type 3 (n = 4), yielding a DCA prevalence of 59.4 %. RRA was confirmed histologically in 16 % (3/19) but predicted endoscopically in only 33.3 % (n = 1). No adverse events occurred following cold-snare excision.

Conclusions Duodenal clip artefact develops in 60 % of clipped EMR sites and frequently mimics recurrence. Cold-snare excision is safe, provides definitive diagnosis, and simplifies subsequent surveillance.

DOI 10.1055/s-0046-1822250

Abstract Text

Chronic intestinal pseudo-obstruction is an extremely rare disease characterized by repeated episodes of intestinal obstruction, with radiological imaging showing a dilated intestine with air/fluid levels in the absence of mechanical occlusive lesions. A 61-year-old woman with lifelong CIPO and megaduodenum underwent multiple surgeries: jejunal resection, volvulus derotations, and gastric bypass with gastrojejunal anastomosis. Absent contractility was found on esophageal manometry. Due to a family history of esophageal adenocarcinoma, she underwent upper GI endoscopy, revealing distal erosions and a low-grade dysplastic area that was resected. Follow-up endoscopy showed persistent severe erosive esophagitis, despite high-dose PPI therapy, and a massively dilated duodenum. This case highlights the coexistence of megaduodenum and refractory esophagitis in CIPO, emphasizing the need for individualized management [1–3].

eP924 Evaluation of Amber-Red Color Imaging (ACI) for Vessel Visualization and Intraprocedural Bleeding during Third-Space Endoscopy

Authors Ayoub M[1], Cahyadi O[1], Quast D[1], Torres Reyes C[1], Zeidler C[1], Stögbauer M[1], Ewald P[1], Ebigbo A[1]

Institute **1** St. Josef-Hospital, Ruhr-University Bochum, Bochum, Germany

DOI 10.1055/s-0046-1822251

Aims Intraprocedural bleeding (IPB) represents a major challenge in third-space endoscopy (TSE), as it prolongs procedure time, impairs visibility, and

may negatively affect clinical outcomes. Amber-Red Color Imaging (ACI) is a novel imaging modality designed to enhance visualization of vascular structures and bleeding sources, potentially improving the safety and efficiency of TSE procedures. This study aimed to systematically evaluate the incidence of major IPB and the frequency of prophylactic vessel coagulation during TSE using the ACI mode.

Methods In this single-center, video-based analysis, consecutive TSE procedures (ESD, POEM, G-POEM) between February and October 2025 in which submucosal dissection was performed with the ACI mode were reviewed. The primary endpoint was the frequency and duration of major IPB. Major IPB was defined as a bleeding episode requiring either multimodal endoscopic hemostasis, lasting > 1 minute or leading to complete loss of visibility ("red-out"). Secondary endpoints included the rate of prophylactic vessel coagulation—defined as the preemptive coagulation of visible vessels using knife or coagulation forceps before dissection ("vessel sealing")—and the occurrence of postinterventional complications.

Results A total of ten full-length videos of TSE procedures (4 ESDs, 3 POEMs, 3 G-POEMs) were analyzed. The median procedure time was 79.5 (43–171) minutes. For ESD cases, the median lesion size was 50 mm (41–97). Five major IPB events were observed, all during ESD (1 gastric, 1 esophageal, 3 rectal). The mean duration of IPB until successful hemostasis was 47.8 ± 53.6 seconds. A total of 41 prophylactic vessel coagulations (vessel sealing) were performed, corresponding to a mean of 5.3 per procedure. The mean duration of each vessel sealing was 39.3 ± 39.5 seconds. The success rate of prophylactic coagulation—defined as absence of subsequent bleeding—was 90.2 %. No postinterventional complications occurred.

Conclusions In this single-center cohort, the incidence of major intraprocedural bleeding under ACI guidance was very low. This may be related to the high success rate of prophylactic vessel coagulation. Further prospective, multicenter studies are warranted to determine the clinical benefit of imaging modalities, such as ACI, compared to standard white-light endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP925 A rare case of upper GI bleeding

Authors Konstantakis C[1, 2], Ahmed R[2], Wong JLH[2], Shehkar C[2]
Institutes 1 General University Hospital of Patras, Patras, Greece; 2 University Hospital Coventry & Warwickshire, Coventry, United Kingdom
DOI 10.1055/s-0046-1822252

Abstract Text

We present the case of an 86-year-old patient admitted with what was initially perceived as haemoptysis with coughing of large clots. Patient had a significant history of comorbidities including atrial fibrillation on Apixaban. Initial assessment by ENT and a CTPA could not explain the symptomatology and the patient underwent an upper GI investigation. On gastroscopy a large, ulcerated area located at 20cm with a bleeding vessel and multiple clots prevented further insertion. Endoscopic dual haemostasis was achieved (3 hemoclips and adrenaline solution). Patient was stabilized with no further bleeding. On second look endoscopy a large (> 10cm) oesophageal pouch proved to be the underlying culprit. There was a large ulcer running at the base of the pouch, where now all bleeding stigmata had disappeared. Entrance into the upper oesophageal sphincter proved to be tricky. Histology showed sections of acutely inflamed and ulcerated oesophageal squamous mucosa with focal fungal hyphae and foreign material. No intestinal metaplasia, dysplasia or malignancy was seen in the tissue examined. The most common complications of Zenker's diverticulum are aspiration pneumonia, and oesophageal obstruction / dysphagia and increased risk of development of carcinoma. Bleeding occurs rarely and to our knowledge there are only a handful of cases reported in the literature of endoscopic management. Indwelling food for long periods can induce ulceration due to chronic inflammation and superimposed fungal infection. In elderly patients with atypical presentation, this rare complication should be considered [1].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP926 Hybrid endovascular-endoscopic approach to safely remove oesophageal foreign body penetrating the aorta

Authors Schneider D[1], Zhou A[1], Hon KY[1], O'donoghue Y[1], Ng I[1, 2], Wagner T[1, 2]
Institutes 1 The Royal Melbourne Hospital, Parkville, Australia; 2 The University of Melbourne, Parkville, Australia
DOI 10.1055/s-0046-1822253

Abstract Text

A 65-year-old woman presented with haematemesis and syncope with head strike on a background of a week of intermittent dysphagia and odynophagia a week after eating a fish salad. CT-brain showed a 4cm radiopaque oesophageal foreign body penetrating the aortic arch with surrounding mediastinitis. The decision was made to proceed with a hybrid endovascular and endoscopic approach. Vascular surgeons inserted a 34x100mm GORE CTAG endoluminal stent-graft immediately distal to the left subclavian artery and in the proximal descending aorta, ready for rapid deployment, via femoral approach. A gastroscopy was then performed where the foreign body was identified as a fish bone, which was transecting the oesophagus, with contralateral perforations, with extrinsic oesophageal compression. The bone was grasped with rat-tooth forceps, and with the slightest traction, brisk aorto-oesophageal bleeding was encountered. The remainder of the aortic stent was then deployed, which then swiftly achieved haemostasis. Once the 400mL of blood was suctioned away and endoscopic views restored, the fish bone was seen with the proximal end located intraluminally in the oesophagus, where it could be easily grasped with rat tooth forceps and removed safely with an angled tip distal cap. A repeat gastroscopy performed by oesophagogastric surgeons 12 hours later re-assessed the perforations, found improved extrinsic compression, and clipped the perforations closed. The patient was extubated the following morning and was well, discharging home well on day 18 after admission on oral antibiotics and weaning nasojejunal tube feeds, tolerating oral diet.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP927 Endoscopic Submucosal Dissection for Colorectal Superficial Neoplasia in Lynch Syndrome: A Single-Center Experience

Authors Galtieri PA[1], Bravi I[1], Giunta M[1], Maregatti M[1], Ravizza D[1], Soru P[1], Trovato C[1], De Roberto G[1]
Institute 1 Division of Endoscopy, European Institute of Oncology, IRCCS, Milan, Italy
DOI 10.1055/s-0046-1822254

Aims Patients with Lynch syndrome have an increased risk of developing colorectal neoplasia, but evidence regarding the role of endoscopic submucosal dissection (ESD) in this setting, compared with surgery, is limited. This study aims to evaluate the efficacy and safety of ESD for superficial colorectal neoplasia in patients with Lynch syndrome.

Methods A single-center case series was conducted including all Lynch syndrome patients who underwent ESD for superficial colorectal neoplasia between November 2020 and October 2025. Clinical and lesion characteristics, procedural outcomes, complications, histology, and post-ESD management were analyzed.

Results Twelve patients were included, nine of whom had a prior history of extra-colonic malignancy. Mean lesion size was 34 mm (range 20–60 mm). Lesions were located in the rectum (17 %), sigmoid colon (33 %), descending colon (8 %), transverse colon (8 %), hepatic flexure (17 %) and ascending colon (17 %). Morphology of lesions was assessed using Paris classification: there were

5 (42 %) sessile polyps, 3 (25 %) flat elevated lesions, 3 (25 %) flat elevated lesions with central depression and 1 (8 %) flat elevated lesion with raised nodule. Pit pattern of lesions was assessed using Kudo's classification and was IIIs in 5 (42 %) lesions, IIIL in 2 (17 %) lesions, IV in 1 (8 %) lesion, Vi in 3 (25 %) lesions and Vn in 1 (8 %) lesion. En bloc resection was achieved in 10 patients (83 %), while two procedures (17 %) were discontinued due to technical difficulty and suspected deep invasion. Adenocarcinoma was identified in four cases, two with submucosal invasion > 2 mm, two with lymphovascular invasion and one with both. Overall, five patients (42 %) achieved curative resection; six (50 %) were referred for surgery and one (8 %) to oncologist for evidence of diffuse abdominal lymphadenopathy on staging CT. No perforation or clinically significant bleeding occurred. At 1-year follow-up, no local recurrence was observed among patients who underwent curative ESD.

Conclusions In patients with Lynch syndrome, ESD appears to be an effective and safe therapeutic option for selected cases of superficial colorectal cancer. The considerable rate of non-curative resections due to unfavorable histological features highlights the need for thorough endoscopic assessment before resection and supports ESD as the preferred technique. Further studies with larger cohorts are warranted to define the optimal role of ESD in this high-risk population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP928 Generative AI models for quality assessment in upper gastrointestinal lymphadenectomy: a video-based analysis

Authors De Martino R[1], Di Stefano L[1], Giorgi L[1], Garbarino G[1], Centini F[1], Rizkala T[1], Pansa A[1], Casiraghi M[1], Basato S[1], Rita A[1], Repici A[1, 2], Hassan C[2, 1], Castoro C[1, 2]

Institutes **1** Humanitas Research Hospital, Rozzano, Italy; **2** Humanitas University, Rozzano, Italy

DOI 10.1055/s-0046-1822255

Aims D2 lymphadenectomy is the standard of care for locally advanced gastric cancer but suffers from significant technical variability and lack of standardized quality assessment. Artificial Intelligence (AI), particularly Multimodal Large Language Models (MLLMs), offers a potential solution for objective surgical evaluation. We aimed to evaluate the performance of state-of-the-art MLLMs in assessing the quality and visibility of D2 lymphadenectomy.

Methods In this comparative study, 20 videos of minimally invasive gastrectomy/esophagectomy (10 dissection phase, 10 clean field) were analyzed. Three MLLMs (GPT-5, Gemini 2.5 Pro, Gemini 3 Pro Preview) were tested across fifteen configurations varying in frame count (10, 30, 50) and temperature (0, 1). The primary outcomes were "Quality of Dissection" and "Anatomical Visibility," assessed on a 4-point Likert scale against a reference standard of three expert surgeons. Performance was evaluated using dichotomized outcome (1-3 vs 4) with AUC, sensitivity, and specificity, as well as pointwise ordinal metrics to capture both clinical relevance and granular accuracy.

Results Twenty videos were analyzed in two different categories (10 clean fields, 10 dissection phases; mean duration 100.4 ± 30.8 seconds). The best configuration was Gemini 2.5 Pro (50 frames, T = 1) in dichotomous quality assessment (sensitivity 40.9 % [27.7-55.6 %], specificity 77.8 % [61.9-88.3 %], AUC 0.593 [0.492-0.692]) and visibility (AUC 0.663 [0.553-0.763]). Stable performance was shown across different phases and moderate ordinal accuracy (quality: exact 36.2 %, MAE 1.075; visibility: exact 55.0 %, MAE 0.838). Inter-observer agreement was substantial for quality (ICC 0.736 [0.65-0.81]) and moderate for visibility (ICC 0.659 [0.55-0.75]).

Conclusions Generative AI models demonstrate promising capability in the automated assessment of surgical field quality of D2 lymphadenectomy. Gemini 2.5 Pro offered the best balance of accuracy and efficiency. Future efforts should focus on visibility-based training on multicenter datasets to develop standardized, objective quality control tools.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP929 Clinical outcomes after peroral endoscopic myotomy in patients with achalasia: a composite score-based assessment

Authors Gunsahin D[1, 2], Ilie M[1, 2], Constantinescu G[2, 1], Gunsahin D[3], Sandru V[2, 1], Pavel C[1, 2], Plotogea O[1, 2], Diculescu RI[4, 2]

Institutes **1** Clinical Emergency Hospital of Bucharest, Bucharest, Romania; **2** Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; **3** Emergency University Hospital Bucharest, Bucharest, Romania; **4** Fundeni Clinical Institute, Bucharest, Romania

DOI 10.1055/s-0046-1822256

Aims Achalasia is a rare esophageal motility disorder with a substantial impact on patients' quality of life. Available endoscopic treatments range from temporary therapeutic options (botulinum toxin injection, pneumatic balloon dilatation) to the more recently established definitive approach. Peroral endoscopic myotomy (POEM) offers long-term symptom resolution in most patients, although it may induce or worsen gastroesophageal reflux disease (GERD). Standardized clinical scores used to quantify key symptoms such as regurgitation, dysphagia, heartburn, and odynophagia, before and after POEM, are essential for assessing treatment efficacy. In this study, we focused on the most commonly used symptom-based tools: Eckardt score, Dakkak-Bennett score, GERD-Questionnaire (GERD-Q), and GERD-Health-Related Quality of Life (GERD-HRQL) and analyzed symptom dynamics using these low-cost, easy-to-apply instruments, which are particularly valuable for patient follow-up in low- and middle-income countries [1–6].

Methods We present a series of eight patients diagnosed with achalasia, seven confirmed by high-resolution esophageal manometry and one by upper GI endoscopy combined with barium esogastroduodenal transit, who underwent POEM between October 2024 and March 2025.

All patients were evaluated before and after POEM using four clinical scores: the Eckardt and Dakkak–Bennett scores for achalasia-related symptoms, and the GERD-Q and GERD-HRQL scores for assessing reflux symptoms. Questionnaires were completed prior to POEM and again at one month after the procedure. To better characterize the clinical status of each patient, we used a composite definition that addresses the limitations of individual scores and reflects the advantage of combining several tools rather than relying on a single instrument.

We defined an optimal clinical response as the simultaneous fulfillment of the following criteria: Eckardt score ≤ 3, Dakkak–Bennett score ≤ 1, and GERD-Q score ≤ 6.

Results Patient ages ranged from 19 to 76 years (mean 55). Three patients (37.5 %) had type I achalasia, four (50 %) had type II and one (12.5 %) had unclassified achalasia. No post-POEM complications were observed. All patients reported an improvement in dysphagia. The mean Eckardt score decreased from 8.75 to 1.50, and the mean Dakkak–Bennett score from 3 to 0.13. Reflux-related symptoms also improved overall, with the mean GERD-Q score decreasing from 11 to 6.62. Based on the composite definition, six out of eight patients (75 %) met all three criteria and were classified as having an optimal clinical response.

The GERD-HRQL score showed a 72 % decrease (from 32.13 to 9).

Two patients did not meet the composite criteria, although both experienced dysphagia relief reflected by lower Eckardt and Dakkak–Bennett scores. In the first case, the GERD-HRQL score remained unchanged before and after POEM. This suggests that although swallowing improved, symptoms such as regurgitation or heartburn may have become more prominent once the functional outflow obstruction at the gastro-esophageal junction had been relieved.

The second patient missed the composite definition by a single point. Their GERD-Q score increased from 6 before POEM to 7 after. This slight difference is best understood by looking at how the GERD-Q is structured. Four items are positive predictors for GERD, while two (epigastric pain and nausea) are negative predictors. A patient without classical reflux symptoms who consistently answers negatively to these two questions will start with a GERD-Q of 6, which

technically qualifies as an "optimal" response in the composite definition, even though clinically this is not always accurate. In this particular case, the one-point variation likely reflects questionnaire mechanics rather than a true clinical worsening.

Conclusions POEM remains an effective and minimally invasive endoscopic option for the definitive treatment of achalasia, offering substantial clinical benefit for patients. Using a composite definition that incorporates several clinical scores is a simple, low-cost and easily accessible approach that can provide a more realistic picture of the clinical response, despite the individual limitations of each score. At the same time, some of these instruments, such as GERD-Q, may benefit from further refinement to reduce potential misinterpretation, given their role in identifying GERD symptoms as a potential post-POEM complication.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A patient with known Peutz-Jeghers syndrome previously underwent video-capsule endoscopy revealing multiple small-bowel polyps. Anterograde double-balloon enteroscopy (DBE) allowed removal of a jejunal sessile hamartomatous polyp. Retrograde-DBE identified a 3–4 cm pedunculated ileal hamartomatous polyp. A further retrograde-DBE using the recently CE-marked Endorail system provided improved scope stability, enabling successful endoloop placement. The Endorail device uses a magnetic balloon that can be advanced beyond the enteroscope tip, filled with a ferromagnetic fluid, and magnetically anchored to the patient's abdomen, allowing it to be straightened and guided along the device. Endorail can be used both to overcome challenging bowel loops and increase insertion depth, as well as to provide greater procedural stability for effective endoscopic therapy [1, 2].

eP931 Improving post-test probability for diagnosis of PDAC using a multimodal EUS approach: a single center retrospective study integrating contrast-enhanced endoscopic ultrasound, strain ratio elastography and detective flow imaging

Authors Di Pangrazio R[1, 2], Babaiyan L[2, 1], Panzuto F[3], Signoretti M[1]

Institutes **1** Azienda ospedaliero – universitaria Sant'Andrea, Rome, Italy; **2** Sapienza University of Rome, Roma, Italy; **3** Department of Medical-Surgical Sciences and Translational Medicine, Sapienza University of Rome, Rome, Italy

DOI 10.1055/s-0046-1822258

Aims Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive malignancies, with a poor five-year survival rate. Therefore, optimizing diagnostic strategies is a critical priority. Endoscopic ultrasound (EUS) plays a key role in characterizing focal pancreatic masses (FPM). The development of ancillary EUS techniques, including contrast-enhanced EUS (CH-EUS), strain ratio elastography (SRE), and Detective Flow Imaging (DFI), has enhanced the assessment of vascularization and tissue stiffness, potentially improving the differentiation between benign and malignant lesions. Emerging evidence suggests that these parameters may provide valuable insights into the malignant potential of FPM. The aim of this study is to evaluate whether the combined use of CH-EUS, SRE and DFI improves diagnostic performance in predicting PDAC [1–4].

Methods This single-center retrospective study included consecutive patients who underwent biliopancreatic EUS for FPM between October 2023 and October 2025 at the Digestive Diseases Unit, Sant'Andrea University Hospital of Rome. Examinations were performed using a Fujifilm linear-array echoendoscope and an ultrasound processor (Fujifilm Arietta 850, Fujifilm Healthcare, Tokyo, Japan). During EUS assessment, CH-EUS, SRE and DFI were performed to characterize lesions. The final diagnosis was confirmed by histopathology (EUS fine-needle biopsy) and/or radiological workup (CT, MRI, PET), with a follow-up of at least 6 months. For CH-EUS, lesions were categorized as hypoenhanced, isoenhanced, or hyperenhanced during the early arterial phase after administration of 8 mL of sulphur hexafluoride microbubbles; hypoenhancement was considered predictive of PDAC. SRE was evaluated using the system's embedded software, comparing a region of interest (ROI) within the FPM to the intestinal wall; a strain ratio > 10 was deemed predictive of PDAC. DFI was employed to assess microvascularization, classifying lesions as hypovascular or hypervascular, with hypovascularity considered a predictive feature for PDAC.

Results Overall, 95 patients were included (50 males, 52.6 %; median age 68 ± 11.4 SD years). Lesions were predominantly located in the pancreatic head (64; 67.4 %). Among all lesions, 64 (67.4 %) were PDAC, 8 (8.4 %) inflammatory lesions, 14 (14.7 %) pancreatic neuroendocrine tumor (pNET) G1, 5 (5.3 %) pNET G2, 3 (3.2 %) other malignant tumors and 1 (1.1 %) solid pseudopapillary tumor. CH-EUS was applied in 58 (61.1 %) cases, elastography in 60 (63.2 %) and DFI in 69 (72.6 %). All three techniques were performed in 39 (41 %) cases; CH-EUS + DFI in 47 (49.5 %); SRE + DFI in 53 (55.8 %); SRE + CH-EUS in 26 (27.4 %). Across the individual modalities, CH-EUS showed a sensitivity of 71.0 %, a specificity of 74.1 %, with an accuracy of 72.4 %, LR + 2.74, LR– 0.39, PPV 75.9 %, and NPV 69.0 %. SRE achieved a sensitivity of 88.6 % and a specificity of 64.0 %, corresponding to an accuracy of 78.3 %, with LR + 2.46, LR– 0.18, PPV 77.5 %, and NPV 80.0 %. DFI demonstrated the strongest diagnostic performance, with a sensitivity of 90.7 %, a specificity of 73.1 % and an accuracy of 84.1 %. The

positive and negative likelihood ratios were 3.37 and 0.13, respectively, with a PPV of 84.8 % and an NPV of 82.6 %. Regarding combined approaches, CH-EUS + SRE + DFI provided a specificity of 90.5 % and a sensitivity of 66.7 %, yielding an accuracy of 79.5 %, with LR + 7.00, LR– 0.37, PPV 85.7 %, and NPV 76.0 %. The combination CH-EUS + DFI resulted in a sensitivity of 70.8 % and a specificity of 82.6 %, with an accuracy of 76.6 %, LR + 4.07, LR– 0.35, PPV 81.0 % and NPV 73.1 %. Similarly, SRE + DFI showed a sensitivity of 77.4 % and a specificity of 81.8 %, with an accuracy of 79.3 %, LR + 4.26, LR– 0.28, PPV 85.7 % and NPV 72.0 %. Finally, SRE + CH-EUS demonstrated a sensitivity of 82.4 % and a specificity of 77.8 %, an accuracy of 80.8 %, LR + 3.71, LR– 0.23, PPV 87.5 %, and NPV 70.0 %.

Conclusions Among the single techniques, DFI achieved the highest sensitivity. Among the combined approaches, the SRE + DFI association provided good accuracy and specificity without requiring intravenous contrast. Nevertheless, the best overall performance was achieved when all three techniques were applied together, underscoring the value of a multimodal EUS strategy integrating ancillary technologies to enhance the predictive capability for PDAC.

eP932 Is there a benefit in post-ERCP pancreatitis-rate and hospital stay duration of laparoendoscopic rendezvous compared to ERCP followed by laparoscopic cholecystectomy in the management of initial choledocholithiasis?

DOI 10.1055/s-0046-1822259

Aims In recent years, the management of patients requiring both cholecystectomy and endoscopic retrograde cholangiopancreatography (ERCP) due to choledocholithiasis has evolved significantly. Traditionally, these procedures were performed sequentially, often resulting in prolonged and multiple hospital stays and increased healthcare costs. However, the concept of cholecystectomy combined with intraoperative ERCP (rendezvous approach) is a promising alternative. Despite its potential benefits, sufficient clinical data about the post ERCP-pancreatitis rate and the hospital stay duration are lacking.

Methods A retrospective analysis was conducted at St. John of God Hospital including consecutive patients treated between 2023 and 2024. Complication rates and hospitalisation time were compared between patients undergoing intraoperative ERCP during cholecystectomy and those treated via a sequential ERCP and CHE approach. Statistical comparisons were performed using t- and chi-square test. The method of intervention was not randomized and subject of availability of both surgeons and endoscopists.

Results A total of 60 patients were included: 42 in the sequential ERCP + CHE group and 18 in the intraoperative ERCP group. 59.5 % of those within the sequential ERCP and CHE group, while 72.2 % of those within the rendezvous approach group were female. (p = 0.52). Mean age was 57.4 (SD 19.5) in the sequential group and 52.4 (SD 21.9) in the combined group (p = 0.41).
Post-ERCP pancreatitis occurred in 11.9 % (n = 5) of patients in the sequential group and less often in 5.6 % (n = 1) in the rendezvous approach group (OR 2,3), however did not reach statistical significance (p = 0.69). Notably, 31.0 % (n = 13) of patients in the sequential group required a repeat ERCP while awaiting cholecystectomy, compared to 1 in the rendevouz group. Patients in the sequential group stayed a mean of 12.4 days (SD 11.9), whereas those undergoing intraoperative ERCP stayed 7.56 days (SD 3.87; p = 0.021)

Conclusions Intraoperative ERCP during laparoscopic cholecystectomy was associated with a shorter hospital stay. In the sequential group, nearly one-third of patients required a repeat ERCP until the cholecystectomy was performed, the OR of post-ERCP pancreatitis was 2.3, but did not differ significantly between the two groups. This study can be used to power a randomised controlled trial.

eP933 Advancing in ERCP: the Slim Duodenoscope as a cornerstone for challenging anatomies – Insights from an italian multicenter prospective study

Authors Termite F[1], De Lucia SS[1], Cocca S[2], Perri V[1], Boarino V[2], Bertani H[2], Boskoski I[1], Familiari P[1], Bove V[1], Landi R[1], Rizzatti G[1], Spada C[1], Conigliaro R[2], Tringali A[1]

Institutes **1** Digestive Endoscopy Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; **2** Gastroenterology and Digestive Endoscopy Unit, University Hospital Modena, Italy

DOI 10.1055/s-0046-1822260

Aims Endoscopic retrograde cholangiopancreatography (ERCP) is essential for managing biliary and pancreatic diseases, but its success can be hindered by gastrointestinal substenoses proximal to the papilla of Vater that a Standard Duodenoscope (STD) cannot traverse. This prospective study evaluates the efficacy and safety of the Slim Duodenoscope (SLD), a thinner device designed to overcome such anatomical limitations.

Methods Consecutive patients in whom papillary access with a STD had failed and who subsequently underwent ERCP with the SLD were prospectively enrolled at two Italian referral centers (October 2023–November 2025).

Results Forty-one ERCPs with the SLD were performed. Indications included obstructive jaundice (n = 38; 68.3 %), specifically 13 cases of choledocholithiasis and 15 biliary strictures (10 malignant, 3 indeterminate, and 2 benign); cholangitis (n = 9; 22.0 %), bile leak (n = 2; 4.9 %), and scheduled biliary stent removal (n = 2; 4.9 %). Among the 41 patients, strictures were located as follows: one at the hypopharynx in post-radiation therapy sequelae; seven in the esophagus (including 2 esophageal diverticula, 2 compressions from cervical osteophytes, 1 peptic stricture, 1 caustic stricture, and 1 post-parathyroidectomy stricture); one at the cardia due to achalasia; two in the stomach following sleeve gastrectomy with a sharply angulated gastric lumen; one at the pylorus caused by gastric adenocarcinoma; 2 in the duodenal bulb (1 peptic and 1 due to malignant infiltration); twenty-three at the superior duodenal flexure (comprising 16 malignant infiltrations, 5 peptic strictures, and 2 extrinsic compressions); and finally, four in the second portion of the duodenum, all resulting from malignant infiltration. The SLD successfully passed the stricture in 33 patients (80.5 %), enabling therapeutic success in 29 (87.9 %). Failure occurred in 8 cases (19.5 %), due to 7 malignant and 1 benign stricture. Among benign strictures, passage success reached 95 %. Two ERCP-related complications (4.9 %), not directly attributable to the use of the SLD, were reported: cholangitis and septic shock (▶ **Table 1**).

▶ **Table 1**

STRICTURES	
Hypopharynx	1
Esophagus	7
Cardias	1
Stomach	2
Pylorus	1
Bulb	2
Superior Duodenal Flexure	23
Second duodenal portion	4

Conclusions The SLD is a game-changer for patients with luminal narrowing, providing access where STD fail. Its high success rate—especially in benign strictures—highlights the value of referring these patients to centers equipped with this device. By enabling ERCP in situations otherwise destined for percutaneous drainage, EUS-guided interventions, or surgery, the SLD expands therapeutic options and helps avoid more invasive alternatives.

eP934 Peroral Endoscopic Tumor Resection (POET) for an Exophytic Gastric Cardia GIST in an Elderly High-Risk Patient: A Case Report

Authors Batsaikhan A[1], Otgondemberel B[1], batsuren B[1], Khurelshagai A[1], Duurenjargal B[1], Davaadorj E[1], Batbayar B[1], Tumendemberel B[1], Boldsaikhan U[1], Erdenebayar O[1], Zoljargal B[1]

Institute 1 IGIC Endoscopic Network, Ulaanbaatar, Mongolia

DOI 10.1055/s-0046-1822261

Background: Gastrointestinal stromal tumors (GISTs) possess inherent malignant potential [1], and management becomes particularly complex when lesions arise at the gastric cardia, where restricted endoscopic maneuverability and proximity to the esophagogastric junction impose significant technical limitations. Advances in third-space endoscopy have expanded therapeutic possibilities, allowing organ-preserving alternatives such as ESD, EFTR, STER, and POET for selected subepithelial tumors [3, 4]. The 2022 ESGE guideline endorses endoscopic resection as a feasible alternative to surgery for gastric GISTs ≤ 35 mm in appropriate candidates [2], highlighting the growing relevance of minimally invasive endoscopic approaches [5].

Case presentation: An 84-year-old man presented with epigastric discomfort. Endoscopy identified a subepithelial lesion at the gastric cardia. CT and EUS revealed a 3.9 × 3.0 cm hypoechoic mass originating from the muscularis propria with exophytic extension into the peritoneal cavity, consistent with a probable GIST. Given his age, elevated surgical risk, and preference for organ preservation, POET was selected following multidisciplinary evaluation.

Procedure: After submucosal injection, a 1.5–2 cm mucosal incision was created in the lower esophagus, and a submucosal tunnel was advanced toward the gastric cardia. The lateral and superior dissection planes were developed first, enabling stable visualization in this anatomically constrained region. The lesion demonstrated a prominent exophytic component with firm adhesions to the anterior abdominal wall and the inferior aspect of the left hepatic lobe, which were carefully released under direct endoscopic control. Complete mobilization allowed en bloc retrieval through the tunnel. A controlled full-thickness defect created during resection was closed internally using endoclips along the lesser curvature at the corresponding projection, achieving secure closure and avoiding surgical conversion.

Outcome: Histopathology confirmed a 3.5 × 2.9 cm CD34-positive intermediate-risk GIST. Recovery was uneventful: oral intake resumed within 24 hours, and discharge occurred on postoperative day 3. At three-month follow-up, endoscopy demonstrated complete mucosal healing with no recurrence.

Conclusion: This case demonstrates the feasibility, safety, and organ-preserving value of POET for anatomically challenging gastric cardia GISTs in elderly or high-risk surgical patients. It underscores the expanding role of third-space endoscopy in providing curative minimally invasive therapy for upper gastrointestinal subepithelial tumors.

DOI 10.1055/s-0046-1822262

Aims EUS-guided hepaticogastrostomy (EUS-HGS) is one of the preferred rescue techniques for biliary drainage when ERCP fails or when the papilla is inaccessible due to altered anatomy or neoplastic invasion. Despite its proven technical feasibility and clinical effectiveness, several safety concerns have limited its widespread adoption even among expert centers. The primary fear relates to the potentially catastrophic consequences of stent misdeployment or migration, events that are often challenging to manage with either endoscopic or surgical interventions. To mitigate these risks, several dedicated stent designs incorporating anti-migratory features have been developed. However, evidence on their performance has so far been limited to individual studies.

Methods We conducted a comprehensive search of multiple electronic databases (PubMed/MEDLINE, Scopus, and EMBASE) and major conference proceedings from inception through July 2025. Technical outcomes included pooled rates of technical success and procedural time. Clinical outcomes included pooled clinical success, stent dysfunction, and adverse event rates, with particular focus on stent misdeployment and migration. Meta-analyses were performed using a random-effects model, and heterogeneity was assessed using the I^2 statistic.

Results We analyzed 18 studies (including 7 multicenter studies), 13 of which were conducted in Eastern countries, comprising a total of 595 patients who underwent EUS-guided HGS. The most frequently used dedicated stents were the Giobor stent (reported in 6 studies) and the Spring Stopper Stent (reported

in 3 studies). The pooled technical success rate of EUS-HGS was 99.1 % (95 % confidence interval [CI], 98.4–99.8 %; I^2 = 0 %), with a mean procedural time ranging from 16 to 50 minutes. The pooled clinical success rate was 94.8 % (95 % CI, 92.1–97.4 %; I^2 = 55.3 %). Among patients achieving clinical success, the 23.0 % (95 % CI, 15.4–30.7 %; I^2 = 78.6 %) experienced stent dysfunction. The pooled rate of adverse events following EUS-HGS was 9.9 % (95 % CI, 6.9–13.0 %; I^2 = 32.5 %), with the 1.1 % (95 % CI, 0.2–1.9 %; I^2 = 0 %) of them being severe. Most complications were infection-related, including cholangitis and intra-abdominal abscesses (3.4 %, 95 % CI 1.8–5.0 %; I^2 = 10.7 %). The pooled risk of stent misdeployment or migration was 0.8 % (95 % CI, 0.1–1.6 %; I^2 = 0 %).

Conclusions Performing EUS-HGS with dedicated stents is an effective option for these difficult-to-treat patients. Although the risk of adverse events remains clinically relevant and should be thoroughly discussed with patients before the procedure, the risk of the most feared complications—stent misdeployment and migration—appears to be substantially minimized with dedicated devices, translating into a lower likelihood of severe adverse events.

eP936 Endoscopist Adenoma Detection Rate influences Post-Polypectomy Surveillance Strategy – Single Center Retrospective Study

Authors Magyar D[1], Fábián A[1], Bősze Z[1], Szántó F[1], Vasas B[1], Bacsur P[1], Bálint A[1], Farkas B[1], Farkas K[1], Iványi E[1], Rutka M[1], Molnár T[1], Bor R[1], Szepes Z[1]

Institute 1 University of Szeged, Szeged, Hungary

DOI 10.1055/s-0046-1822263

Aims To evaluate post-polypectomy surveillance practice in patients undergoing screening colonoscopy performed in the University of Szeged Gastroenterology Center between 2019 and 2022 furthermore, to examine its correlation with screening endoscopist adenoma detection rate [1].

Methods In this retrospective single center observational cohort study, data regarding factors determining post-polypectomy surveillance timing (such as polyp number and size, histology subtype, grade of dysplasia) was obtained from the local hospital medical information system. Optimal surveillance timing was defined in the European Society of Gastrointestinal Endoscopy (ESGE) 2020 guideline update. The seven screening endoscopists were divided into three subgroups based on their adenoma detection rate (ADR) measured during the screening program.

Results Overall, 733 colonoscopies were evaluated (index N = 607, 1st surveillance N = 97, 2nd surveillance N = 23, 3rd surveillance N = 5, 4th surveillance N = 1) with 35 to 80 months of follow-up period. Written recommendation regarding follow-up colonoscopy date was available in 306 cases (41.75 %), moreover surveillance time was predominantly defined after acquiring information about histology results (N = 254, 83.01 %). Recommendation rate was the highest among the > 40 % ADR subgroup (56.95 %) with optimal advice for surveillance given after 27.09 % of colonoscopies. There was no significant difference between the subgroups in performing post-polypectomy surveillance colonoscopy with the optimal timing (< 30 % ADR: 36.69 %, 30-40 % ADR: 33.82 %, > 40 % ADR: 42.90 %). Either written recommendation or actual surveillance timing was adequate in 59.53 % of cases, moreover "no surveillance/return to screening" strategy was used correctly in 88.24 % of patients. Endoscopists with < 30 % ADR showed significantly lower adequacy for timing the follow-up colonoscopy (45.59 %). Compared with the ESGE guideline, a different date was advised for surveillance in 86 patients, and all endoscopists encouraged earlier follow-up predominantly (N = 65, 75.58 %).

Conclusions Choosing the adequate surveillance strategy after polypectomy is crucial to decrease the rate of interval colorectal cancer incidence, moreover, to reduce excess colonoscopy rate. Written recommendation regarding follow-up timing should be given either after colonoscopy, or when histology results are obtained, however the lack of advise given for surveillance in more than half of cases needs to be improved in the future. Endoscopists with higher ADR provided information about surveillance more frequently and more adequately. Post-polypectomy colonoscopy timing in practice demonstrated similar results in the ADR subgroups, yet endoscopists with > 40 % ADR scheduled surveillance the best.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A patient with a recent ileocecal resection for ulcerations and substenosis—with histology showing aberrant lymphocytes but no definitive lymphoma—underwent antegrade double-balloon enteroscopy (DBE) to distinguish between intestinal lymphoma and refractory celiac disease. The examination revealed diffuse mucosal atrophy with scalloping, villous edema, and lymphangiectasia. In the distal jejunum/proximal ileum, a 10-cm circumferential ulcer with a necrotic base was identified, and targeted biopsies were obtained. To enhance scope stability and insertion depth, the overtube was magnetized to replicate the functionality of the recently CE-marked Endorail system. It utilizes a balloon filled with ferromagnetic fluid that is anchored to the patient's abdominal wall, allowing the scope to be guided along the device to overcome difficult bowel loops and achieve greater insertion depth [1, 2].

eP1000 ERCP in the octogenarians and nonagenarians: should we be doing them acutely?

Authors King H[1], Mashar R[1], Tuck A[1], Hawken J[1], Bell A[1], Portal AJ[1], Strickland A[1]
Institute 1 University Hospitals Bristol and Weston, Bristol, United Kingdom
DOI 10.1055/s-0046-1822265

Aims ERCP remains a high-risk endoscopic procedure, and many studies have demonstrated its efficacy and safety in the elderly. However, few have assessed these parameters in an inpatient setting, and some data has shown a higher mortality rate, thereby suggesting the physiological insult combined with the risks of the procedure deem this intervention highly dangerous in this cohort. We therefore aimed to review our experience as a single tertiary centre, postulating that ERCP remains a safe procedure in this group, with a complication rate within acceptable limits as well as facilitating discharge from hospital, especially in cases with a palliative indication [1–3].

Methods The endoscopic database was searched from the dates 01/01/2022 to 24/11/2025 in a tertiary centre for all ERCP procedures. Records were filtered to exclude outpatient procedures and patients below the age of 80. Data was gathered regarding the age demographics, ASA grade, overall and post-procedure length of stay (LOS), indications and details of the procedures. A successful procedure was defined as having dealt with the acute indication to facilitate discharge from hospital. Any procedure-related complications were noted, alongside 30- and 90-day mortalities, and any re-admissions within 30 days.

Results 186 procedures were included. The median age was 85 (IQR 82-88), and the eldest patient was 99. 87 % of patients were ASA grade 3 or 4. The indications were related to malignancy in 21.5 %, and non-malignant in 78.5 %; predominantly choledocholithiasis associated with jaundice, cholangitis or pancreatitis. 30 % of procedures were Schutz complexity level 3 or 4. The aim of the procedure was successfully achieved in 87.6 % (including biliary decompression with stenting where stones could not be completely removed). Median total LOS was 10.5 days (IQR 6-19.5), and median post-procedure LOS was 4 days (IQR 1-9). 7 patients (3.8 %) experienced complications directly related to the procedure (3 episodes of cholangitis, 2 of pancreatitis, 1 of bleeding and 1 related to stent migration). This would even be consistent with British Society of Gastroenterology (BSG) guidance of a complication rate of < 6 % for Schutz level 1-2. All-cause mortality at 30 days was 6.5 %, and at 90 days 12.4 %, with published data reporting 2-5.3 % in general populations. Readmission rate within 30 days for all indications was 16.1 % (30 patients), though only 2 of these were due to complications of the procedure, and neither were fatal.

Conclusions The interaction of age and frailty with acute illness understandably provokes concern regarding the risks of ERCP. We identified no excess procedure-specific complication rate among our cohort. The 30- and 90-day mortality rates are acceptable given that 20 % were performed for malignancy, and in fact suggest benefit in the context of palliation. The slight excess rate reported is likely to reflect a higher incidence of malignant pathology in the elderly. Reported literature has shown mortality rates exclusively in this group of up to 20 %. Our results suggest that with careful peri-procedural decision-making, in-patient ERCP can be safely offered to this cohort.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1001 Survival analysis in patients undergoing percutaneous endoscopic gastrostomy (peg): experience from a tertiary care center (2015–2025)

Authors Barreto LP[1], Albert M[1], Hombrados M[1], Busquets D[1], Pardo Grau L[1], Torrealba L[2], Oliveras B[1], Huertas C[3]
Institutes 1 Hospital Universitari de Girona Doctor Josep Trueta, Girona, Spain; 2 Hospital Universitari de Girona Doctor Josep Trueta, Giro, Spain; 3 Endoscopy Unit, Digestive Diseases Department, Doctor Josep Trueta University Hospital of Girona, Girona, Spain
DOI 10.1055/s-0046-1822266

Aims To analyze the survival of patients undergoing PEG in a tertiary care center. to perform a specific sub-analysis of those patients with a survival of 60 days or less

Methods Retrospective observational study of patients undergoing PEG between January 2015 and June 2025. Demographic, clinical, and endoscopic variables were collected. Subgroup analysis was performed for survival, indications, and mortality at 30 and 60 days [1].

Results A total of n = 322 patients were included (mean age: 61 years; 75.8 % male). Mean survival was 419 days (median: 164; range: 1–2662). A total of 9.9 % died within the first 30 days and 14.6 % within the first 60 days after PEG. Main indications in the group with survival ≤ 30 days were: neoplasia (40.6 %), anoxic encephalopathy (18.8 %), traumatic brain injury (15.6 %), and ALS (9.4 %). Causes of death: tumor progression (21.9 %), severe encephalopathy (21.9 %), respiratory failure (18.8 %), hemoptysis (9.4 %), and sepsis (9.4 %). In 90.6 % of cases, death was not related to the procedure; 6.2 % were probably related, and 3.1 % directly related (1 colonic perforation).

A total of 149 PEG requests were cancelled: medical contraindication (36.2 %), referral to primary care (28.2 %), prior death (24.2 %), and voluntary decision (10.7 %).

CAD patients (n = 56, 17.0 %) showed significantly lower survival (mean 151 days; median 49) vs HCC patients (n = 89, 27.0 %) (p = 0.010). This difference did not remain in the subgroup with ≤ 90-day survival (p = 0.73).

Conclusions • A substantial proportion of patients die within the first 30 and 60 days after PEG. • The indication should consider complexity profile (HCC/CAD) and expected nutritional benefit. • A rigorous and multidisciplinary patient selection is required when indicating PEG, especially in contexts of high clinical frailty.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1002 Amebic Superinfection Triggering Budd–Chiari Syndrome in Polycystic Liver Disease: An Exceptional Association

Authors Bouchareb A[1], Saichi S[2], Saoula H[3]
Institutes 1 CHU Lamine Debaghine, Bab El Oued, Algeria; 2 CHU Lamine Debaghine Bab El Oued, Algiers, Algeria; 3 CHU Lamine Debaghine Bab El Oued, Algeria, Algiers, Algeria
DOI 10.1055/s-0046-1822267

Introduction: Polycystic liver disease is a benign condition that may be complicated by cyst superinfection or vascular and biliary compression. The occurrence of Budd–Chiari syndrome (BCS) secondary to an amebic superinfection of a hepatic cyst is exceptionally rare and requires multidisciplinary management [1, 2].

Case Report: We report the case of a 65-year-old man, followed since 2012 for polycystic liver disease, with two large cysts measuring 6 cm (segment IV) and 14 cm (segment III). He presented with cyst superinfection revealed by a clinical and biological cholestasis syndrome in a febrile context, following a recent episode of foodborne illness. Hepatic Doppler ultrasound, angio-CT, and liver MRI demonstrated BCS caused by compression of the hepatic veins by two large infected cystic formations.The patient received intravenous antibiotics and underwent radiological drainage, yielding a "chocolate-colored" fluid highly suggestive of amebic infection, later confirmed by strongly positive ELISA serology. Follow-up imaging one month after drainage showed a 70 % reduction of the segment VIII cyst but persistence of the left-lobe cyst, prompting a second drainage.A subsequent evaluation one month later showed significant collapse of both cysts and complete relief of the compression on the right hepatic vein and IVC, indicating successful management.

Conclusion: This case highlights a rare and complex complication of polycystic liver disease: amebic superinfection leading to Budd–Chiari syndrome. It underscores the importance of regular clinical and radiological monitoring to detect early warning signs and ensure timely, multidisciplinary intervention to optimize patient outcomes.

eP1003 Outpatient Endoscopic Diverticulotomy is safe for management of Zenker's Diverticulum

Authors Bashir MF[1], Donnellan F[1], Bedi H[2], Avni J[2]

Institutes **1** St. Vincent's University Hospital, Dublin, Ireland; **2** UBC Faculty of Medicine, Vancouver, Canada

DOI 10.1055/s-0046-1822268

Aims Evaluate the Safety and Efficacy of Outpatient Endoscopic Diverticulotomy

Methods All patients who had an endoscopic Diverticulotomy over an 8-year period were included. Retrospective chart review was conducted to obtain patient demographic and procedural and post-procedural management data. Any complications during and after the procedure were included.

Results 38 patients were included with 46 endoscopic diverticulotomies performed. 24 patients (63.2 %) were male, and median age was 78.5 (range 51 to 103) at the time of procedure. Majority of patients (73.7 %) had a Charlson Comorbidity score of 3 or higher. Only 1 patient was an active smoker, and none had excessive alcohol use history. Dysphagia, regurgitation, and heart burn were most common symptoms present at the time of referral (91.3 %, 71.7 %, and 58.7 %, respectively). 10 (21.7 %) had previous interventions for ZD – 8 of which were with endoscopic diverticulotomy. 12 procedures (26.1 %) were performed under conscious sedation and 34 (73.9 %) under general anesthetic. 5 patients (10.9 %) had intraprocedural bleeding, which did not require transfusions. 3 patients (6.8 %) developed subcutaneous emphysema within 2 hours post-procedure and were managed conservatively without further endoscopic or surgical intervention. 33 patients (71.7 %) were discharged on the same day of procedure, with an additional 6 (13.0 %) discharged within 2 days post-procedure. Median follow-up was 74 days (range 0-2472 days).

Conclusions Endoscopic diverticulotomy is a safe procedure for the management of Zenker's Diverticula. Patients with immediate complications, including intraprocedural bleeding or presence of subcutaneous emphysema within 2 hours post-procedure, were associated with hospital stay longer than 1 day. None of the patients developed late complications or required readmission within 30 days of discharge. Therefore, outpatient ZD management is effective in both patient management and resource allocation.

eP1004 Pre-Transplant ERCP with Sphincterotomy Does Not Influence Biliary Outcomes After Liver Transplantation

Authors Iuvinale M[1], Prior M[2], Di Noia G[1], Bruni A[3], Cescon M[2], Barbara G[3], Serenari M[2], Eusebi LH[4]

Institutes **1** University of Bologna, Bologna, Italy, Bologna, Italy; **2** Hepatobiliary surgery and Transplant unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; **3** Gastroenterology Unit, University of Bologna, Bologna, Italy; **4** University of Bologna, Bologna, Italy

DOI 10.1055/s-0046-1822269

Aims Endoscopic retrograde cholangiopancreatography (ERCP) with biliary sphincterotomy is frequently used to manage biliary obstruction in patients with advanced liver disease. Its impact on post-orthotopic liver transplantation (OLT) biliary outcomes, however, remains unclear. This study evaluates whether ERCP performed before OLT influences the incidence, type, or severity of biliary complications after transplantation.

Methods A retrospective analysis was conducted on 1128 OLT recipients, including 82 re-transplants, from January 2012 to December 2023. Seventy patients (6.2 %) underwent pre-OLT ERCP with sphincterotomy (118 ERCPs total). Biliary complications occurring early (< 30 days) or delayed (> 30 days) post-OLT were compared between patients with and without pre-OLT ERCP. Outcomes included complication rates, need for endoscopic, radiologic, or surgical interventions, and post-complication mortality.

Results Pre-OLT ERCP indications included biliary strictures (n = 35), stones (n = 24), bile leak (n = 3), and other causes (n = 8). Stents were placed in 33/70 patients. Pre-procedure adverse events occurred in 9 ERCPs (7.6 %).

After OLT, 199 biliary complications occurred in 197 patients (17.5 %). Complication rates did not differ between patients with (17.1 %) and without (17.6 %) pre-OLT ERCP (p = 0.91), showing no significant association between pre-OLT ERCP with sphincterotomy and overall post-OLT biliary complications, nor for early events or delayed events.

Among the 199 complications, treatment included ERCP (n = 134), percutaneous drainage (n = 20), surgery (n = 29), or conservative management (n = 16). ERCP-related adverse events occurred in 23/134 procedures.

Post-OLT mortality, during an average follow-up of 60.3 months, similar between patients with and without biliary complications (17.3 % vs. 19.2 %).

Conclusions In this large cohort of OLT recipients, pre-transplant ERCP with sphincterotomy did not affect the risk of early or late post-OLT biliary complications. Rates of strictures, leaks, and biliary stones were comparable to those in patients without pre-OLT ERCP. These findings suggest that ERCP with sphincterotomy, when clinically indicated before transplantation, is safe and does not adversely influence post-transplant biliary outcomes.

DOI 10.1055/s-0046-1822270

Aims Patients with chronic kidney disease (CKD) are at increased risk of gastrointestinal complications, including hemorrhage, which can be life-threatening. The aim of this study was to evaluate the epidemiological characteristics and lesion profile of upper gastrointestinal bleeding (UGIB) in patients with CKD.

Objective To describe the epidemiological, clinical, endoscopic, and outcome characteristics of upper gastrointestinal bleeding in patients with chronic kidney disease.

Methods We conducted a single-center, prospective, descriptive study including all CKD patients admitted with upper gastrointestinal bleeding to the Emergency Department of Bab El Oued University Hospital between January 2023 and August 2025. All patients underwent upper gastrointestinal endoscopy [1, 2].

For each patient, demographic data, type of bleeding presentation, hemodynamic status, laboratory findings, Glasgow-Blatchford score, endoscopic findings, management, and clinical outcomes were recorded.

Data entry and analysis were performed using SPSS version 23.0.

Results Among 281 patients admitted for UGIB, 49 had chronic kidney disease (17 %). The mean age was 69 ± 14 years, with a sex ratio of 1.04.

Past medical history included portal hypertension (7.5 %), ischemic heart disease (42.9 %), heart failure (30.6 %), and diabetes (44.9 %).

Anticoagulants were used by 36.8 % of patients and antiplatelet agents by 28.6 %. Melena was the most common presenting symptom (57.1 %), followed by hematemesis (34.7 %) and massive hematochezia (8.2 %). The mean Glasgow-Blatchford score was 13.4 ± 3.24.

Endoscopy showed recent signs of bleeding in 41.5 % of cases. The etiologies of UGIB were as follows:

Gastroduodenal ulcers: 40 %

Ulcerated esophagitis: 17.5 %

Erosive gastritis: 7.5 %

Angiodysplasia: 7.5 %

Variceal bleeding: 9.5 %

Neoplasia: 7.5 %

No upper gastrointestinal cause was identified in 18.4 % of patients. A colonoscopy was performed in 16.3 % and revealed colonic angiodysplasia in 12.2 %.

Blood transfusion was required in 75.5 % of cases. Endoscopic therapy was performed in 18.4 %: 14.3 % received argon plasma coagulation, 7.1 % underwent variceal ligation, and 2.4 % received gastric variceal glue injection. Surgery was required in 2.4 % of patients. Rebleeding occurred in 4.8 %, and in-hospital mortality was 2.4 %.

Conclusions In our series, upper gastrointestinal bleeding in CKD patients predominantly affected elderly individuals. Gastroduodenal ulcers and digestive angiodysplasia were the most common etiologies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1006 Palliative biliary stenting in pancreatobiliary malignancy: Does it still make a difference?

Authors Serrano M[1], Jalal M[1], Williams E[1], Ayres L[1], Keen T[1], Oliver AS[1], Krishnan B[1], Mccrudden R[1]

Institute 1 University Hospitals Dorset NHS Foundation Trust, Bournemouth, United Kingdom

DOI 10.1055/s-0046-1822271

Aims The European Society of Gastrointestinal Endoscopy (ESGE) recommend palliative stenting for patients with malignant distal biliary obstruction who are not candidates for oncologic treatment [1]. The impact on survival and resolution of jaundice in this palliative population is scarce [2]. The available techniques include Endoscopic Retrograde Cholangiopancreatography (ERCP), Endoscopic Ultrasound (EUS)- guided drainage, and percutaneous drainage. We aimed to assess the clinical outcomes of palliative biliary stenting in our cohort of patients with incurable distal biliary malignant obstruction.

Methods We retrospectively analysed patients with distal malignant biliary obstruction between January 2023 and December 2024 who were unfit for surgery or oncologic therapy and presented with jaundice. Data collected included demographics, comorbidities, tumour characteristics, serology, pre- and post-drainage symptoms, and drainage technique. Complications within 30 days (post-ERCP pancreatitis (PEP), cholangitis, upper gastrointestinal bleed (UGIB), perforation) were recorded.

The primary endpoint was survival (weeks) comparing drained patients to those receiving best supportive care only. Secondary endpoints were ERCP technical and clinical success, need for additional procedures, complication rates, and independent predictors of mortality. Categorical and continuous variables were compared with Chi-square/Fisher and Mann-Whitney/Wilcoxon tests. Survival used Kaplan-Meier and Cox regression; $p < 0.05$.

Results The final sample included 56 patients (33 females, 58.9 %) with a median age of 81 years (range 46–94). Most had moderate comorbidity: 39 (66.6 %) were ASA (American Society of Anaesthesiologists) 1–2, and 17 (30.4 %) were ASA 3. Performance status was 1–2 in 39 patients (69.6 %) and 3 in 17 (30.4 %). Regarding TNM stage at diagnosis, 15 patients (26.9 %) were stage 0–I, 14 (25 %) stage III, and 24 (42.9 %) stage IV.

Overall, biliary drainage (BD) was successful in 42 patients (75 %). ERCP was attempted in 46 (82.1 %) and was successful in 40 (86.9 %), with three requiring up to three sessions. Two underwent alternative techniques after failed ERCP (one EUS-guided, one percutaneous). Complications occurred in 7 patients (12.5 %): 1 PEP, 5 cholangitis, and 1 UGIB. The 30-day mortality in the drainage group was 23.8 % (10 patients). There was no association with a complication. All had advanced TNM stage, which was statistically significant ($p = 0.016$).

Drainage significantly relieved symptoms: jaundice decreased from 97.6 % to 33.3 % ($p = 0.001$), pruritus from 40.5 % to 9.5 % ($p < 0.001$), and dyspepsia from 69 % to 42.9 % ($p = 0.021$), while pain remained unchanged (64.3 %, $p = 1.000$). Bilirubin levels decreased significantly overall and when stratified by tumour stage (Median 212 vs 55, $p = 0.001$).

Patients without BD were older than those with BD ($p = 0.04$). Early TNM stage patients (0–2) were more frequently drained (93 %) than advanced stage (3–4; 68 %), showing a trend toward access to drainage in early disease ($p = 0.058$). No other differences in gender, comorbidities, serologic markers, or performance status were observed.

Overall, the median survival was 11 weeks (range 0–56). Patients with successful BD had higher median survival (14 vs 7 weeks) without reaching statistical significance ($p = 0.370$). Survival was significantly longer in early TNM stages (0–2) compared to advanced TNM (3–4) (median 28 vs 6 weeks, $p = 0.008$). In multivariate analysis, advanced TNM stage was the only independent predictor of shorter survival in the overall cohort (HR = 3.17, $p = 0.011$) and drainage group (HR = 2.80, $p = 0.029$). The development of complications trended toward worse survival, but this difference was not statistically significant. Higher CA 19-9 levels predicted shorter survival in univariate analysis, but were excluded from multivariate models due to missing data.

Conclusions Although BD showed a trend toward longer survival, this benefit was minimal in patients with advanced-stage disease, who accounted for most early mortality post-procedure. Overall, disease stage—not drainage—was the main predictor of survival, and patients with advanced disease are unlikely to gain meaningful benefit from the BD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1007 EUS-guided fine-needle biopsy of solid pancreatic lesions: technical success and diagnostic accuracy in a single-center cohort

Authors Bouali R[1], Bostani S[1], Mohamed G[1], Mtir M[1], Bizid S[1], Ben Abdallah H[1]
Institute 1 The Military Hospital of Tunis, Tunis, Tunisia
DOI 10.1055/s-0046-1822272

Aims Pancreatic cancer represents a growing global health burden, making early and reliable diagnosis crucial. Solid pancreatic lesions require histological sampling to confirm diagnosis and guide treatment. Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) is now essential for this purpose. We aimed to evaluate the technical success, histological yield, and diagnostic performance of EUS-FNB for solid pancreatic masses in a single tertiary center.

Methods We conducted a retrospective study of all patients who underwent EUS-FNB for suspected solid pancreatic lesions between 2018 and 2025. Cystic lesions and chronic pancreatitis were excluded. Malignancy was defined by histological identification of malignant cells (EUS-FNB or surgical specimens) or clinico-radiological follow-up demonstrating tumor progression and/or metastases. Technical failure was defined as obtaining insufficient sample or other normal tissue.

Results Overall, 380 patients were included (236 men, 144 women; mean age 62.8 years [29–88]). Mean lesion size was 34.2 mm [6–88]. Lesions were located in the pancreatic head (67.9 %), uncinate process (11.8 %), body (11.7 %), neck (6.4 %), and tail (2.2 %). Vascular contact and frank invasion were observed in 55 % and 11.8 % respectively. The approach was predominantly transduodenal, with transgastric approach in 24 patients (6.3 %). A 22-gauge needle was used in nearly all procedures.

Technical success was achieved in 367/380 cases (96.6 %) and significantly correlated with lesion size (p = 0.02). Malignancy was confirmed in 353 patients (93 %). Pancreatic adenocarcinoma accounted for 92 % of malignant tumors, predominantly ductal subtype (88 %). Signet-ring cell and mucinous components were identified in 17 % and 4.6 % respectively. Other malignancies included 16 pancreatic neuroendocrine tumors (4.2 %), two mucinous cystadenocarcinomas, two undifferentiated carcinomas, one sarcomatoid carcinoma, one solid pseudopapillary neoplasm, one degenerated intraductal papillary mucinous neoplasm, and ten pancreatic metastases from other primary sites. Thirteen lesions (3.4 %) represented mass-forming chronic pancreatitis.

EUS-FNB demonstrated excellent diagnostic performance: sensitivity 97 % (95 % CI 94.6–98.5), positive predictive value 99.3 %, and diagnostic accuracy 96.6 % (95 % CI 94.2–98.2). Second biopsy was performed in 6 patients (1.6 %), yielding neoplasia in 5 cases (four adenocarcinomas, one neuroendocrine tumor) and one benign lesion, with cumulated sensitivity and accuracy remaining essentially unchanged. A single hemorrhagic complication (0.3 %) occurred in a patient on antiplatelet therapy.

Conclusions EUS-FNB demonstrates excellent technical success (96.6 %) and diagnostic accuracy (96.6 %) for solid pancreatic lesions in routine practice. It provides high-quality histological cores with minimal needle passes and a low complication rate.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1008 Pancreatic metastases from extra-pancreatic solid tumors: diagnostic contribution of endoscopic ultrasound in a single-center series

Authors Bouali R[1], Bostani S[1], Mohamed G[1], Mtir M[1], Bizid S[1], Ben Abdallah H[1]
Institute 1 The Military Hospital of Tunis, Tunis, Tunisia
DOI 10.1055/s-0046-1822273

Aims Pancreatic metastases from extra-pancreatic solid tumors are rare, accounting for approximately 3–15 % of solid pancreatic masses in the absence of other detectable distant metastases. The pancreas is an uncommon metastatic site for renal cell carcinoma, breast and lung cancers, melanoma, colorectal cancer, sarcomas and gastrointestinal stromal tumors. These secondary lesions are often incidentally discovered during oncologic follow-up or may mimic primary pancreatic ductal adenocarcinoma. Endoscopic ultrasound (EUS) plays a key role in their detection and characterization. We aimed to evaluate the prevalence and characteristics of pancreatic metastases diagnosed by EUS in our center.

Methods We conducted a retrospective single-center study including all consecutive patients who underwent pancreatic EUS with tissue acquisition between 2018 and 2025. The diagnosis of pancreatic metastasis was based on histological examination of EUS-guided biopsy samples, complemented by immunohistochemical staining. Diagnostic criteria relied on correlation of morphological and immunohistochemical findings with the patient's oncologic history and cross-sectional imaging. Lesions were classified according to primary tumor origin, pancreatic location and histological features.

Results Among 380 patients who underwent pancreatic EUS with biopsy (236 men, 144 women; male-to-female ratio 1.63; mean age 62 years [29–88]), ten pancreatic metastases were identified, corresponding to a prevalence of 2.6 %. Primary tumors were: four clear cell renal cell carcinomas (36 %), two small-cell lung cancers (18 %), one colonic adenocarcinoma (9 %), one breast carcinoma (9 %), one gastric stromal tumor recurring in the pancreas (9 %) and one shoulder chondrosarcoma recurring in the pancreas (9 %).Pancreatic involvement was located in the head/uncinate process in sIX cases (60 %), the body in three (30 %) and the tail in one (10 %). Lesions were solitary in eight patients (80 %) and multiple in two (20 %). Immunohistochemistry was systematic and decisive, showing PAX8 expression in renal metastases and GATA3 in breast cancer metastasis , thereby excluding a primary pancreatic ductal adenocarcinoma.

Conclusions In our series, pancreatic metastases accounted for 2.6 % of solid pancreatic masses. EUS with guided tissue acquisition represents the reference diagnostic tool, allowing precise histological and immunohistochemical characterization. Pancreatic metastases should be systematically considered in any pancreatic mass occurring in patients with a history of malignancy, even remote, as prognosis and management differ fundamentally from primary pancreatic ductal adenocarcinoma.

eP1009 Cholangioscopy-guided intraductal electrohydraulic and laser lithotripsy for complex common bile duct stones: a single-center experience

Authors Bostani S[1], Mohamed G[1], Souli F[2], Mtir M[1], Bizid S[1], Ben Abdallah H[1], Bouali R[1]
Institutes 1 The Military Hospital of Tunis, Tunis, Tunisia; 2 Internal Security Forces Hospital, Gastroenterology department, Tunis, Tunisia
DOI 10.1055/s-0046-1822274

Aims Common bile duct stones complicate 10–20 % of gallstone disease. Endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy and balloon or basket extraction is standard treatment, but 10–15 % of stones resist conventional techniques. In such cases, cholangioscopy-guided intraductal laser lithotripsy (LL) or electrohydraulic lithotripsy (EHL) achieves high success rates with low morbidity. We aimed to evaluate the efficacy and safety

Endoscopy 2026; 58: S1–S1041

of cholangioscopy-guided LL and EHL for complex common bile duct stones in our center.

Methods We conducted a retrospective single-center study from January 2023 to October 2025, including patients with complex bile duct stones defined by failed conventional ERCP extraction. Complexity criteria included stone > 15 mm, multiple stones, impacted stones, hard consistency, "packed" choledocholithiasis, or difficult location (intrahepatic or cystic duct). The primary endpoint was complete bile duct clearance, analyzed per patient and per procedure. Proportions were reported with 95 % confidence intervals (Clopper–Pearson method), with comparisons using Fisher's exact test.

Results Twenty patients (10 men, 10 women; mean age 57 years [16–85]) underwent 22 procedures (19 LL, 3 EHL). Stone complexity related to size in 16 patients (mean 18.1 mm [15–40]), multiplicity (n = 12), impaction (n = 5), hard consistency (n = 1), or difficult location (n = 6). Packed stones were present in the common bile duct in 7 cases and cystic duct stump in 2 cases.

Complete duct clearance was achieved in 12/20 patients (60 %, 95 % CI 38–80) and 12/22 procedures (54.5 %, 95 % CI 34–74). Eleven patients were successfully treated in a single session and one after three sessions. Ten patients had unsuccessful LL/EHL. Three failures were technical: one referred for surgery, one ultimately cleared after three sessions, and one failed probe advancement due to duodenal diverticulum (not reattempted). In two patients, extraction was impossible: one persistent large stone awaiting second session and one suspicious papilla case (macrodilatation not performed, papillary biopsies revealing ductal adenocarcinoma, referred for surgery). Five additional patients had difficult extraction; all were scheduled for second sessions, but two were lost to follow-up.

The procedure demonstrated excellent safety with only one minor adverse event (self-limited mild bleeding), representing 1/22 procedures (4.5 %). Mean hospital stay was 1.3 days [1–3]. No significant association was found between extraction failure and sex (p = 1), stone size > 15 mm (p = 0.5), multiplicity (p = 0.6), impaction (p = 0.4), difficult location (p = 0.5), packed choledocholithiasis (p = 0.13), or cystic stump stones (p = 1).

Conclusions Cholangioscopy-guided intraductal EHL and LL is an effective and safe option for complex common bile duct stones. In this first Tunisian series, we observed 60 % patient success rate with minimal morbidity. This technique represents a valuable alternative in high-risk surgical candidates and elderly, comorbid patients, reducing the need for surgery and repeated ERCP with prolonged biliary stenting.

eP1010 Successful Retrieval of BRTO Coils from Pulmonary Circulation – Successful Management of A Rare Complication

Authors Khan MU[1], Joy A[2]

Institutes **1** University Hospital Birmingham NHS Foundation Trust DC, Birmingham, United Kingdom; **2** Hamad Medical Corporation, Doha, Qatar

DOI 10.1055/s-0046-1822275

Introduction: Balloon-occluded retrograde transvenous obliteration (BRTO) is used in the treatment of gastric varices because of its effectiveness as a curative procedure, and its role in both emergency and prophylactic settings. It is of utmost importance that the treating physicians are aware of potential procedure-related complications including fever, chest or epigastric pain, hemoglobinuria, and transient hypertension among others. We present an unusual post-procedure complication resulting in coil migration, which was promptly recognized and successfully treated [1].

Case Report:A 59-year-old gentleman with a history of alcohol-related chronic liver disease (Child A6) was seen in our clinic for further management. The patient was found to have fundal varices (IGV-1) at screening endoscopy, and he denied any history of liver decompensation or GI bleeding. MRI abdomen was performed on the patient and showed changes of chronic liver disease in hepatic parenchyma and gastro-renal collaterals with gastric fundal varices. The main portal, splenic, and hepatic veins were attenuated but appear patent. After discussing with the patient, he was referred to interventional radiology (IR) for Balloon occluded and coil-assisted Retrograde Transvenous Obliteration (BRTO). CT angiogram was performed for the patient and showed Gastric varices with a prominent reno-gastric shunt measuring 15 mm in maximum diameter, having a tortuous course along with the lesser of the stomach and coursing down to join the splenic vein.The patient underwent IR guided BRTO procedure by injecting the mixture of sodium tetradecyl sulfate, Lipiodol, and air into the shunt and varix. After occlusion of the varix was confirmed by CT scan, Interlock coils were used to occlude the shunt.Six hours post-procedure, the patient started having left-sided pleuritic chest pain and tachycardia but no desaturation. XR chest showed migration of the coils seen overlying the heart shadow. Urgent CT chest showed a Migrated coil in the distal left main pulmonary artery, extending into the left lower lobe pulmonary artery. Successful retrieval of the coils was done using intraluminal biliary biopsy forceps (COOK medical), 7 F x 60 cm, to grasp the part of the coil WITHIN the sheath not reaching the pulmonary artery with the forceps. Post-retrieval Angiogram showed good opacification of the left inferior pulmonary artery with no filling defects. On day three, the patient was discharged from the hospital without further complications and had an uneventful follow-up.

Conclusion:BRTO remains a useful option for both emergency and prophylactic treatment of gastric varices. Patients need post-procedure monitoring, and prompt recognition of potential complications can result in timely institution of treatment and favorable outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A 90-year-old woman with an indeterminate hilar biliary stricture presented with jaundice, weight loss, and abdominal pain. MRCP showed irregular intrahepatic and common hepatic duct dilation suggesting Bismuth type IV stricture. AI-enhanced cholangioscopy enabled live estimation of neoplastic probability also identifying aberrant vessels supporting malignancy. Dynamic probability shifts helped define tumor extent, while overlapping heat maps suggested optimal biopsy sites. Targeted biopsies confirmed cholangiocarcinoma. When validated, AI may aid in differentiating biliary stenosis, defining tumor extent, and improving biopsy accuracy.

eP1012 Endoscopic drainage of pancreatic pseudocysts: experience of a tertiary center

Authors Souli F[1], Mohamed G[2], Bostani S[2], Mtir M[2], Bizid S[2], Ben Abdallah H[2], Bouali R[2]
Institutes 1 Internal Security Forces Hospital, Gastroenterology department, Tunis, Tunisia; 2 The Military Hospital of Tunis, Tunis, Tunisia
DOI 10.1055/s-0046-1822277

Aims Pancreatic pseudocysts and walled-off necrosis are late pancreatic fluid collections that may complicate acute or chronic pancreatitis or pancreatic trauma. Endoscopic drainage has taken over as the reference technique due to its minimally invasive nature and high success rates reported in international studies.

The objective of our study was to evaluate the technical, clinical and radiological outcomes of endoscopic drainage of pancreatic pseudocysts in a tertiary center.

Methods We conducted a retrospective monocentric study at our endoscopy unit including patients who underwent endoscopic drainage of pancreatic pseudocysts between 2017 and 2024. Epidemiological, clinical, endoscopic, radiological data and follow-up outcomes were collected.

Results In total, 58 patients were enrolled with a mean age of 47 years [range 9–73] and a male predominance (sex ratio M/F = 1.5). Most pseudocysts were secondary to acute pancreatitis in 86 % of cases (N = 50), followed by chronic pancreatitis in 10 % (N = 6). The average size of the cysts was 92 mm [20–170]. These pseudocysts were mostly single in 79 % (N = 46). Endoscopic ultrasound guided drainage was performed in 45 % of cases (N = 26), while classical or cystotome assisted techniques were used in the remainder. Plastic double pigtail stents were placed in 65 % of patients (N = 38) and lumen apposing metal stents in 15 % (N = 9). Technical success was achieved in 94 % (N = 47), clinical success in 80 % (N = 40) and radiological success in 77.5 % (N = 31). A moderate positive correlation was found between clinical and radiological success (Pearson r = 0.50, p = 0.002). Complications occurred in 6 % of patients (N = 3), limited to minor events such as stent migration, secondary infection or minor intrakystic bleeding, with no severe adverse outcomes.

Conclusions Endoscopic drainage of pancreatic pseudocysts achieved high success rates in our cohort, comparable to international data. Endoscopic ultrasound guidance and dedicated stents improved safety and efficacy, and careful patient selection remains essential to minimize complications.

eP1013 Sleep tight, prep right and chill out: adequate boston bowel preparation among patients without sleep disruptions

Authors Felix-Gurrola J[1], Paul AG[1], Morales-Gomez CO[1], Garcia-Favela MM[2], Ledesma-Martinez E[1], Elias-Ortega CR[1], Jose Manuel AR[1], Felix Tellez FA[3], Flores Rendon AR[3]
Institutes 1 Faculty Of Medicine UABC, Mexicali, Mexico; 2 Faculty of Medicine UABC, Mexicali Mexico; 3 Gastromedical, Mexicali, Mexico
DOI 10.1055/s-0046-1822278

Aims Restlessness and poor sleep quality are common complaints among patients undergoing bowel preparation for colonoscopy. However, their effect on preparation quality is not well defined. Our aim was to evaluate which sleep variables are associated with an adequate bowel preparation. Adequate preparation was defined as a score of 6 or higher on the Boston Bowel Preparation scale.

Methods A multicenter, cross-sectional study was conducted in adult patients with an indication for colonoscopy. Bowel preparation was performed with a complete dose of polyethylene glycol (PEG). Face-to-face questionnaires were applied using dichotomous questions. Variables evaluated included falling asleep, trouble staying asleep, waking up during the night, sleeping more than 7 hours, and waking up restless. Those who showed no disturbances across all variables were defined as having good sleep quality. A multivariate logistic regression analysis was performed to identify predictors related to good sleep quality and adequate bowel preparation (Boston ≥ 6).

Results A total of 316 patients were included: 195 female (61.7 %), age 50 ± 14. Adequate bowel preparation was in 140 (47.78 %), and good sleep quality was in 32 (10.92 %). In the logistic regression analysis, the only variable associated with adequate bowel preparation (Boston ≥ 6) was not having difficulty staying asleep (OR = 1.771; 95 % CI: 1.125-2.787; p = 0.013) while in the multivariate analysis showed that those having difficulty maintaining sleep were significantly associated with having a junior-high education (OR = 3.395; 95 % CI: 1.045–11.024; p = 0.042), and those patients who consumed cold PEG were more likely to report good sleep quality (OR = 0.593; 95 % CI: 0.375–0.938; p = 0.025).

Conclusions Sleep quality appears to play an important role in achieving adequate bowel preparation, possibly reflecting how closely patients follow instructions. Our findings show that the absence of nighttime awakenings—particularly difficulty staying asleep—is associated with better preparation quality. Notably, consuming the PEG solution cold was positively associated with sleep quality across all evaluated domains, suggesting a simple, practical opportunity for future preparation recommendations.

eP1014 Who sleeps best? Evaluating patient characteristics linked to superior pre-colonoscopy sleep

Authors Paul AG[1], Felix-Gurrola J[1], Elias-Ortega CR[1], Morales-Gomez CO[1], Garcia-Favela MM[2], Ledesma-Martinez E[1], Jose Manuel AR[1], Felix Tellez FA[3], Flores Rendon AR[3]
Institutes 1 Faculty of Medicine UABC, Mexicali, Mexico; 2 Faculty of Medicine UABC, Mexicali Mexico; 3 Gastromedical, Mexicali, Mexico
DOI 10.1055/s-0046-1822279

Aims Assess the characteristics of patients who experience pleasant sleep during preparation for a colonoscopy

Methods A multicenter, cross-sectional study was conducted in adult patients with an indication for colonoscopy. Face-to-face questionnaires used dichotomous (yes/no) questions to assess five specific variables of sleep quality during preparation: (1) whether the patient fell asleep easily, (2) trouble staying asleep, (3) avoidance of nighttime bathroom visits, (4) more than 7 hours of sleep, and (5) waking up feeling rested. Patients who reported no disturbances in any of these five variables were defined as having good sleep quality. Also, the Hospital Anxiety and Depression (HAD) Scale was administered. A multivariate logistic regression analysis was performed to identify characteristics of patients with good sleep quality [1].

Results Of 316 patients, 195 were female (61.7 %). The average age was 50 ± 14 years. Pleasant sleep, meeting all five assessed variables, was reported by 32 patients (10.13 %).

Patients more likely to sleep over 7 hours included those younger than 50 years old (OR = 1.923, CI = 1.196-3.091, p = 0.007), alcohol consumption (OR = 3.165, CI = 1.013-9.888, p = 0.044), and hemorrhoidal disease (OR = 1.687, CI = 0.999-2.851, p = 0.049). However, those who were over 50 years of age (OR = 0.542, CI = 0.346-0.850, p = 0.007), consumed NSAIDs (OR = 0.394, CI = 0.162-0.956, p = 0.034), were constipated (OR = 0.468, CI = 0.292-0.750, p = 0.001), or had anxiety per HAD (OR = 0.233, CI = 0.049-1.097, p = 0.047) were less likely to sleep over 7 hours. Difficulty waking up rested was more common in patients with elementary education, constipation, Bristol stool scores of 1–2, and use of specific PEG solutions. Those who woke up feeling rested had a diagnosis of hypothyroidism and were taking levothyroxine. In the multivariate analysis, those with elementary education (OR = 4.194, [CI = 1.036-16.985], p = 0.045) continued to feel rested upon waking. Difficulty falling asleep was associated with nephropathy (OR = 14.068, [CI = 1.055-187.582], p = 0.045), NSAID use (OR = 2.430, [CI = 1.018-5.789], p = 0.045), and PEG without sodium metabisulfite (OR = 2.222, [CI = 1.100-4.492], p = 0.026). However, those who were obese (OR = 0.344, [CI = 0.157-0.756], p = 0.008) were less likely to have diffi-

Endoscopy 2026; 58: S1–S1041

culty falling asleep. Trouble staying asleep was linked to patients with middle school education (OR = 3.525, [CI = 1.069-11.623], p = 0.038), although those who took the preparation cold (OR = 0.559, [CI = 0.350-891], p = 0.015) and those with hemorrhoidal disease (OR = 0.467, [CI = 0.264-0.824], p = 0.009) did not show trouble staying asleep. Nighttime bathroom visits were more common among patients aged 50 or older, with diabetes, prior abdominal surgery, diverticular disease, and the use of PEG containing sodium metabisulfite; meanwhile, PEG without sodium metabisulfite showed fewer nighttime bathroom visits. Only prior abdominal surgery (OR = 2.073, [CI = 1.244-3.455], p = 0.005) was the only characteristic that persisted in the multivariate analysis.

Conclusions Only a minority of patients reported pleasant sleep during bowel preparation. Sleep disturbances were more common in individuals with obesity, nephropathy, NSAID use, prior abdominal surgery, and lower educational attainment. Notably, consuming the preparation cold was independently associated with fewer sleep disruptions, particularly reduced difficulty staying asleep; this finding aligns with a recent population-based study demonstrating that beverage and food temperatures can influence sleep and gut health (Tianying Wu et al.). Incorporating cold bowel preparation may therefore represent a simple, practical strategy to improve sleep quality and overall tolerability of the preparation regimen

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1015 Patient-reported symptoms associated with a successful peg full-dose bowel preparation: are all the symptoms really bothersome?

Authors Paul AG[1], Garcia-Favela MM[2], Felix-Gurrola J[1], Morales-Gomez CO[1], Ledesma-Martinez E[1], Elias-Ortega CR[1], Jose Manuel AR[1], Vellez FA[3], Flores Rendon AR[3]

Institutes **1** Faculty of Medicine UABC, Mexicali, Mexico; **2** Faculty of Medicine UABC, Mexicali Mexico; **3** Gastromedical, Mexicali, Mexico

DOI 10.1055/s-0046-1822280

Aims To identify which symptoms are significantly associated with patients who are able to complete the PEG full-dose high-volume bowel preparation. Unlike previous studies, which have largely focused on tolerance or completion rates using dichotomous symptom reporting, this study aimed to evaluate symptom intensity using a Likert scale to better characterize the severity of patients' most frequent complaints.

Methods A multicenter, cross-sectional study was conducted in adult patients indicated for colonoscopy. Sociodemographic data, comorbidities, medication use, history of prior colonoscopy, and specifics of colonoscopy preparation were collected via face-to-face questionnaires. Symptomatology during preparation was assessed, and the Hospital Anxiety and Depression (HAD) Scale was administered. Symptom intensity was evaluated on a 0-5 Likert scale, with scores of 3 or higher deemed significant.

Results Of 163 patients, 85 were female (61.7 %). The average age was 50 ± 14 years. Patients with significant symptoms: Nausea (26/44) was associated with females (OR = 6.591, CI = 2.057-21.122, p = 0.001), and those with less than 50 years (OR = 8.834, CI = 2.55-30.580, p = 0.048). Vomiting (5/11) was associated with NSAID use (OR = 7.236, CI = 1.022-51.244, p = 0.007). Abdominal pain was associated with NSAID use (OR = 7.657, CI = 1.404-41.757, p = 0.019). Increase in bowel movements (67/99) was less frequent in those younger than 50 years (OR = 0.429, CI = 0.204-0.904, p = 0.026). Bloating (33/50) was most commonly associated with females (OR = 3.481, CI = 1.439-8.423, p = 0.006) and those with less than 50 years (OR = 4.762, CI = 1.595-14.215, p = 0.005). Postprandial fullness (47/65) was associated with a history of colon cancer (OR = 6.328, CI = 1.154-34.690, p = 0.034). Flatulence/burping (31/64) was mostly associated with females (OR = 4.694, CI = 1.794-12.284,p = 0.002). Anal itching (39/70) was related with history of anxiety (OR = 8.093, CI = 1.374-47.673, p = 0.021), and abdominal surgery (OR = 5.634, CI = 1.650-19.239, p = 0.006). Chills (19/38) with females (OR = 10.997, CI = 1.260-96.003, p = 0.030). Cramping (2/15) more frequent in those with colorectal cancer history (OR = 24.787, CI = 1.124-546.476, p = 0.042). Weakness (27/50) was mostly associated with females (OR = 2.899, CI = 1.023-8.213, p = 0.045) and less associated with straw use to drink the preparation (OR = 0.337, CI = 0.128-891, p = 0.028). A cold or hot sensation (32/58) was associated with females (OR = 4.811, CI = 1.735-13.343, p = 0.003). Excessive thirst (23/41) was associated with postgraduate degree (OR = 6.764, CI = 1.419-32.237, p = 0.016) and anxiety per HAD (OR = 3.274, CI = 0.421- 25.460, p = 0.022) remained significant.

Conclusions The severity of symptoms during bowel preparation was strongly associated with specific demographic, clinical, and psychological factors. Notably, being female, younger age, and anxiety or depression were consistently associated with more severe symptoms. In contrast, certain behaviors, such as drinking with a straw, were linked to reduced symptom burden. Recognizing these specific factor-symptom connections can help personalize preparation strategies

eP1016 To Biopsy, Resect, or Refer? Rethinking the Pre-Referral Pathway and Decision-making for Large Non-Pedunculated Colorectal Polyps"

Authors Olabintan O[1, 2], Eqbal A[1, 3], Homira A[1], Adeyeye A[1, 4], Noreillie MA[1], Judge C[1], Campion J[1], Lim A[1], Gulati S[1, 2], Hayee B[1, 2], Haji A[1, 2, 5], Emmanuel A[1]

Institutes **1** King's College Hospital, London, United Kingdom; **2** King's Institute of Therapeutic Endoscopy, King's College Hospital NHS Foundation Trust, London, United Kingdom; **3** Frankston Hospital, Frankston, Australia; **4** Afe Babalola University , Ado Ekiti, Nigeria, Federal Republic of; **5** King's College Hospital NHS Foundation Trust, London, United Kingdom

DOI 10.1055/s-0046-1822281

Aims Studies report that almost 50 % of Large Non-Pedunculated Colorectal Polyps (LNPCP) have been subjected to heavy manipulation in form of prior attempts at resection or extensive biopsy sampling prior to referral to an expert centre. This significantly impacts several critical outcomes of endoscopic resection (ER). However, understanding of standardised classifications of LNPCP, endoscopic diagnosis and indications for ER has increased in general endoscopy practice which may have improved decision making prior to referral. We aimed to compare trends in patterns of prior injudicious manipulation and the significance of biopsy sampling over sequential time periods in a large cohort of patients referred to a tertiary referral centre for ER.

Methods Referral documentation, including clinic and referral letters, endoscopy reports, and histopathology result, were reviewed for evidence of prior resection attempts or biopsy sampling. Data included the number of biopsy samples taken and corresponding histological results. Patients referred between January 2011 and August 2024 were categorised into five time periods. Heavy manipulation was defined as either a prior resection attempt or ≥ 6 biopsy samples. Analyses included comparisons of resection attempts, heavy manipulation, biopsy sampling, and the detection of high-grade dysplasia on biopsies (as a marker of improved lesion assessment and targeted sampling). Trends in practice changes were assessed using the Chi-square test for trend

Results 1407 LNPCP were treated by ER. There was a significant trend toward fewer prior failed attempts at resection over sequential time periods with 30 % in Period 1 and only 11 % in Period 5 (p < 0.001); fewer LNPCP subjected to heavy manipulation with 61 % in Period 1 and 27 % in Period 5 (p < 0.001) and fewer LNPCP with prior biopsy sampling with 77 % in Period 1 and 47 % in Period 5 (p < 0.001). However, there was no trend found for an improvement in biopsy sampling yields of HGD with 18 % in Period 1 and 25 % in Period 5 (p = 0.1).

Conclusions In a large cohort of ER of LNPCP, this study demonstrates a significant reduction over time in failed resection attempts, heavy manipulation, and biopsy sampling of LNPCP before referral to a tertiary centre for endoscop-

ic resection (ER). This suggests an improvement in endoscopic lesion assessment and decision making by general endoscopists. However, heavy manipulation remains a significant problem. Although fewer LNPCP are biopsied prior to referral, the yield of significant findings did not change, suggesting biopsies are not effectively targeted, and highlighting the need for further improvements in lesion assessment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1017 Time is visibility: factors associated with mucus production in patients with prolonged insertion time in water-exchange colonoscopy

Authors Garcia-Favela MM[1], Paul AG[2], Morales-Gomez CO[2], Felix-Gurrola J[2], Elias-Ortega CR[2], Ledesma-Martinez E[2], Cuevas-Maldonado MS[3], Jose Manuel AR[2], Felix Tellez FA[4], Flores Rendon AR[4]

Institutes **1** Faculty of Medicine UABC, Mexicali Mexico; **2** Faculty of Medicine UABC, Mexicali, Mexico; **3** ISSSTECALI, Mexicali, Mexico; **4** Gastromedical, Mexicali, Mexico

DOI 10.1055/s-0046-1822282

Aims The use of specific bowel preparation methods, such as water-exchange colonoscopy, has been associated with increased mucus production in the left colon, requiring supplementary clearing via suction or saline for optimal visualization. Given these procedural demands, further analysis is required to determine if a correlation exists between insertion time and the severity of mucus presentation.

Methods An observational analytical study was conducted in adult patients indicated for colonoscopy. Data of insertion time, endocuff device usage, Boston bowel preparation scale and Left Colon Mucus Scale (LCMS) were collected. LCMS: scored from 0 to 4. A score of 0 indicates absence of visible mucus; 1 indicates clear, visible mucus; 2 denotes opaque mucus in fine strands; 3 denotes opaque mucus in substantial clumps covering one side of the colonic surface; and 4 denotes opaque mucus in extensive clumps obscuring the majority of the lumen. LCMS scores were analyzed in relation to blind insertion time and patient age. Statistical analysis employed Spearman's rank correlation for continuous variables. Odds ratios (ORs) with 95 % confidence intervals estimate the risk among stratified groups. A p-value < 0.005 defined statistical significance.

Results A total of 112 colonoscopy procedures, the mean patient age was 59 ± 13 years, and the mean Boston score was 5.53 ± 1.32. A weak-to-moderate but statistically significant positive correlation was identified between insertion time and mucus accumulation ($\rho = 0.252$; $p = 0.007$). Ordinal analysis determined that an insertion duration of 20 to 30 minutes significantly elevated the likelihood of LCMS grade 2 mucus (OR = 4.333 [CI = 1.434-13.095]; $p = 0.006$), whereas durations exceeding 30 minutes were significantly associated with LCMS grades 3 and 4 ($p = 0.014$). Concerning age, patients aged 18-34 years exhibited a significant association with LCMS grade 2 (OR = 6.714; [CI = 0.874 – 51.575], $p = 0.038$).

Conclusions It is noteworthy that younger patients tend to exhibit greater mucus accumulation, suggesting a senescent mechanism in the colonic mucosa where mucus production declines with age. This excess secretion significantly impacts procedural outcomes; inadequate bowel preparation caused by mucus impairs visualization and increases the risk of missing concealed lesions. Therefore, optimizing insertion and procedure times is essential to mitigate the risks associated with this accumulation.

eP1018 Endoscopic Submucosal Dissection of Rectal Gastric Heterotopia: Report of Two Cases

Authors Chandra Kumar CV[1], Mushtaq K[1], Baldacchino A[1], Duarte P[1], Boger P[1], Patel P[1], Glover B[1], Jaynes E[2], Foria V[2], Rahman I[1]

Institutes **1** Southampton Interventional Endoscopy Unit, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; **2** Department of Histopathology, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

DOI 10.1055/s-0046-1822283

Introduction: Rectal gastric heterotopia (GHT) is extremely rare with less than eighty cases reported in the literature since it was first described by Ewell and Jackson in 1939. Two cases of malignant transformation have been reported, hence the need for resection. Most common methods of resection reported include surgery and endoscopic mucosal resection (EMR). Endoscopic submucosal dissection (ESD) for rectal GHT has been reported in few case reports in the literature. We present two cases of successful en-bloc resection with ESD of rectal GHT [1, 2].

Case 1: A 45-year-old gentleman had colonoscopy for chronic alternating bowel habit with urgency and mucus discharge and intermittent abdominal pain. The index colonoscopy revealed an unusual 40 millimetres Paris IIa + IIc annular lesion in the low rectum. Optically this had elongated round and tubular pits. The histopathological examination of the biopsies revealed gastric type mucosa intermingled with adjacent colonic mucosa which led to the diagnosis of rectal GHT. He was referred to our centre for resection. ESD was performed with successful en-bloc resection and there was no evidence of significant fibrosis despite previous biopsies. The final histology confirmed R0 resection and revealed large area of specialised type gastric tissue, consistent with rectal GHT. Six months follow up endoscopy showed no signs of residual gastric heterotopia and patient was clinically asymptomatic with return of normal bowel habit.

Case 2: A 36-year-old male underwent colonoscopy in view of rectal bleeding, chronic intermittent abdominal pain and change in bowel habits. The index colonoscopy revealed a five centimetres Paris IIa lateral spreading tumour (LST) granular type polyp in the lower rectum with surface pattern of elongated round and tubular pits. The histopathological examination of the biopsies revealed a mixture of colorectal and gastric body-type mucosae in keeping with rectal GHT. He then underwent ESD which safely achieved en-bloc resection. There was no significant fibrosis seen but the submucosal plane was heavily vascular. The final histology confirmed R0 resection and showed large bowel mucosa intermingled with predominantly oxyntic and body pattern gastric mucosa which involved full thickness of the mucosa, consistent with rectal GHT. Patient had normalisation of symptoms during his subsequent follow-up.

Conclusion: Rectal gastric heterotopia can be significantly symptomatic and ESD is a safe and effective resection modality to alleviate symptoms.

eP1019 Burden of reflux disease after per-oral endoscopic myotomy: Single center real life prospective study

Authors Shah J[1], Nigam P[1], Singh AK[1], Jearth V[1], Singh H[1], Jafra A[1], Mandavdhare H[1]

Institute **1** Post Graduate Institute of Medical Education & Research, Chandigarh, Chandigarh, India

DOI 10.1055/s-0046-1822284

Aims Peroral endoscopic myotomy (POEM) is now an established method for the treatment of achalasia cardia with superior outcomes compared to pneu-

matic balloon dilation and equivalent outcomes compared to laparoscopic Heller's myotomy. [1, 2] Post-procedure gastro-oesophageal reflux disease (GERD) is one of the main short comings of the procedure. Various retrospective studies have shown its incidence between 16 % to 50 %. [3] However, in view of paucity of prospective real world studies, we did a prospective study to know the prevalence of GERD in patients undergoing POEM procedure.

Methods We conduced a prospective open label study between November 2022 to June 2024 after obtaining an ethical approval. The baseline characteristics, procedure details, and post-procedure follow-up were recorded prospectively. At 12 months post-procedure, patients underwent detailed evaluation to know the prevalence of GERD in this group of patients. GERD was defined as per Lyon 2.0 criteria. [4] Esophagitis was classified as per Los Angeles criteria. Patients requiring > 3 PPI (proton pump inhibitor) intake per week were defined as PPI dependency. Patients reflux symptoms score was defined as per GERD-Q questionnaire. Pearson's correlation was performed between reflux symptoms score, PPI dependency, esophagitis grade and diagnosis of GERD. Multi-variate analysis was performed to identify risk factors for GERD.

Results Total of 75 patients included in the study. Mean age of the included patients was 40.75 ± 16.7 years with 61.3 % patients were male. Majority of patients had type I achalasia (64 %) and 28 % of patients had prior endoscopic treatment in form of either pneumatic ballon dilation (20 %) or laproscopic Helle's myotomy (6.7 %). Majority of patients underwent posterior POEM (90.7 %) with mean oesophageal myotomy length of 10.49 ± 4.42 cm and gastric myotomy length of 2.75 ± 0.62 cm. 96 % patients achieved clinical success. 28.8 %, 32.8 % and 34.2 % patients had GERD-Q score > 8 at 3, 6 and 12 months follow-up respectively. At 12 months, 34.2 % patients had PPI dependency, 11.8 % of patients had significant esophagitis (Grade C/D) and 31.7 % of patients had AET > 6 %. 32.6 % of patients were diagnosed as GERD as per Lyon 2.0 criteria. Presence of GERD-Q questionnaire > 8 ($p = 0.002$), having PPI dependency ($p = 0.003$) was correlated with diagnosis of GERD. However, on logistic regression, we could not find any baseline or intra-procedural risk factors for development of GERD.

Conclusions Around one third of patients develop GERD post-POEM at 12 months of follow-up. Reflux symptoms score and PPI usage are correlated with GERD diagnosis and which should be used to select the patients for further invasive investigations including endoscopy and pH-metry.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1020 Endoscopic management of Boerhaave syndrome with a novel suturing device

Authors Konstantakis C[1, 2], Shehkar C[2], Wong JLH[2]
Institutes **1** General University Hospital of Patras, Patras, Greece; **2** University Hospital Coventry & Warwickshire, Coventry, United Kingdom
DOI 10.1055/s-0046-1822285

Abstract Text

We present the case of 35-year-old male patient with a medical history of Schatzki ring and eosinophilic oesophagitis. He presented in the ED with severe right side chest pain after choking on his chicken dinner. His partner had performed Heimlich manoeuvre & back slaps. During his stay at the ED, he deteriorated and was intubated. Patient was then transferred to ITU. An emergency CT revealed an extensive pneumomediastinum closely related to the air fluid oesophagus. There was a large volume right sided hydropneumothorax (fluid accounting for more than 75 % of the pleural collection), with associated compressive collapse of the right lung. There were a significant contralateral shift of the trachea and the entire mediastinum. Findings were strongly suggestive of Boerhaave's syndrome (BS). A chest tube drain was urgently inserted by the cardiothoracic team, and patient was started on broad – spectrum antibiotics. After multidisciplinary discussion an endoscopic approach was decided as first line approach and surgery reserved as second line. Treatment options were clearly communicated to the family members. During endoscopy several fibrotic mucosal rings/strictures were identified that prevented the use of a distal attachment (cap). There was a food bolus encountered at lower oesophagus, which was pushed into the stomach. At the lower oesophagus a 2cm full thickness wall defect with clean margins was identified. The wall defect was treated with a suturing device (X-Tack, Boston Scientific). A fully covered oesophageal metal (Niti-s) stent was then deployed under direct vision. Two haemoclips applied to anchor the stent. Patient eventually recovered and was successfully discharged home after 40 days. On follow up endoscopy, at 5 weeks, the stent had migrated distally and was found at the stomach. It was retrieved uneventfully. The perforation site appeared well healed with no stenosis. BS is a rare condition associated with high morbidity and mortality. Timely diagnosis is essential to improve outcomes. This condition has been traditionally managed with surgical intervention. However, recent advancements in endoscopic techniques have emerged as viable alternatives. Endoscopic management includes placement of OTCs, through-the-scope clips, partial or fully covered SEMS. Stenting has been favoured for larger defects (> 1cm). Recent, less – well studied, methods of closure include endoscopic suturing, vacuum-assisted closure or use of sealants (fibrin glue or cyanoacrylate). To our knowledge this is the first case treated with a defect > 1cm with a combination of a suturing device and stenting. The apposition of a larger defect that could theoretically impose on stent efficacy was managed by combining it with a suturing technique [1, 2].

DOI 10.1055/s-0046-1822286

Aims In 2023, colon capsule endoscopy (CCE) was introduced across 10 pilot centres in Ireland as part of a strategy to improve access to gastrointestinal diagnostics and reduce pressure on colonoscopy services. The major limitations

of CCE are issues with complete transit, inadequate preparation, and the requirement for post-CCE standard endoscopy. The aim of this study was to explore predictors of real-world CCE performance with a view to identifying patients most likely to benefit from a CCE.

Methods Data was prospectively collated from six colon capsule centres participating in the Irish Capsule Endoscopy Registry (ICaRe) over 2 years. Procedural data is voluntarily uploaded from each centre to an anonymised, web-based system on a continuous basis. Analysis was performed on available data captured on the registry. The key outcomes assessed were complete study rate (defined as adequate preparation and complete transit), the rate of significant findings, and the requirement for post-CCE endoscopy. Predictors assessed included age, gender, and indications for CCE. Indications were grouped as screening (FIT-positive or family history), polyp surveillance, symptomatic patients (high or low risk symptoms and/or anaemia), incomplete colonoscopy for any indication, and patient preference. Standard univariate analyses and multivariable logistic regression were used to identify factors associated with key CCE performance outcomes.

Results A total of 789 CCEs were included, 354/789 (45 %) male, mean age 55.3 years (range 22–87). The ranked CCE indications were symptomatic patients (44 %), incomplete colonoscopy (22 %), polyp surveillance (16.5 %), screening (15.5 %), and patient preference (2 %). Overall complete study rate was 73 % (573/789), adequate preparation rate 84 % (625/748), significant findings rate 56 % (445/788), and post-CCE endoscopy rate 40 % (319/789), including 243 (31 %) colonoscopies. Completion rates by indication ranged from 65 % for surveillance to 82 % for screening patients, while the post-CCE endoscopy rate (excluding the patient-preference group who were outliers at 7 %, likely due to small numbers) ranged from 33 % for the incomplete colonoscopy group to 50 % for surveillance patients. On multivariate analysis, the only independent predictor of outcomes was the indication for CCE. Specifically, those undergoing CCE for surveillance of previous polyps were significantly more likely to require a post-CCE endoscopy (50 %) (OR 1.61; 95 % CI 1.1–2.4; p = 0.01), likely related to the higher significant finding rate also found in this group (p = 0.03). Of interest, the surveillance group also had a higher incomplete study rate (35 %), possibly reflecting a selection bias in this cohort where they were referred for CCE surveillance rather than a colonoscopy. Unsurprisingly, as the distal colon would already have been examined, those undergoing CCE following an incomplete colonoscopy were less likely to require a post-CCE endoscopy (OR 0.7; 95 % CI 0.49–0.99; p = 0.05). As expected, increasing age was associated with a higher diagnostic yield overall (p = 0.005). However, older age (> 70 years) was not associated with worse outcomes. The complete study rate was 27 % (174/645) in patients ≤ 70 years versus 29 % (40/138) in those > 70 years, and the post-CCE endoscopy rate was 41 % (262/645) ≤ 70 versus 41 % (57/138) > 70. Similarly, gender had no impact on outcomes.

Conclusions Clinical indication significantly affects CCE performance and should be used as a tool to help select patients most likely to benefit from this procedure. Surveillance patients of any form appear to be less suited to CCE. Older patients, based on our data, should not be excluded from CCE.

eP1022V Double EUS-guided luminal and biliary bypass in a patient with metastatic gastric cancer

Author Lajin M[1]
Institute 1 Sharp Grossmont Hospital, La Mesa, United States of America
DOI 10.1055/s-0046-1822287

Abstract Text

We present an 83-year-old female with a history of metastatic gastric cancer and a surgical jejunostomy tube. She presented to our hospital 2 months earlier with complete gastric outlet obstruction and underwent a successful EUS-guided gastrojejunostomy, enabling resumption of oral intake. She returned on this admission with cholangitis secondary to a distal CBD obstruction (Bili: 3.7). An intrahepatic duct (3.5 mm) at segment 3 was punctured with a 19-gauge needle. A wire was navigated to the CBD, crossed the biliary stricture, and reached the duodenum. The tract was dilated with a 4 mm balloon. Two overlapping Gore stents were deployed at the hepaticogastrostomy. Her symptoms resolved, and her bilirubin normalized three days later.

eP1024 Retrospective Study on the Incidence and Risk Factors of Post-ERCP Pancreatitis

Authors Librizzi R[1], Apolito P[2], Bassi M[1], Ghersi S[3], Landi S[4], Cennamo V[5]
Institutes 1 UOC Gastroenterologia ed Endoscopia Interventistica, Ospedale Maggiore – AUSL Bologna, Bologna, Italy; 2 Azienda USL di Bologna – Sede Legale, Bologna, Italy; 3 Gastroenterology and Interventional Endoscopy Unit, Local Health Authority of Bologna, Bologna, Italy; 4 Local Health Authority of Bologna, Gastroenterology and Interventional Endoscopy Unit, Bologna, Italy; 5 Gastroenterology Unit, Azienda USL di Bologna, Bologna, Italy
DOI 10.1055/s-0046-1822289

Aims Post-ERCP pancreatitis (PEP) represents the most common complication of ERCP (Endoscopic Retrograde CholangioPancreatography). This is a clinically relevant issue, given its non-negligible mortality rate and the substantial costs associated with the management of this complication. This study aims to retrospectively evaluate the risk and protective factors associated with post-ERCP pancreatitis (PEP) in a patient cohort, and to compare the findings with those reported in the literature [1].

Methods Patients who underwent ERCP between October 2020 and June 2022 at Maggiore Hospital (Bologna,Italy) were analyzed. PEP was defined according to the Cotton Consensus Criteria and graded for severity based on the revised Atlanta classification.

For each procedures clinical, laboratory, and procedural data were collected, as well as PEP incidence and its preventive strategies (rectal NSAIDs, intravenous hydration, pancreatic stenting). Variables were analyzed using univariate and multivariate logistic regression models.

Results In the period of analysis 600 ERCP were analysed. All procedures were performed by 4 experienced endoscopists. The main indications for ERCP were choledocholithiasis (50.67 %), malignant stricture of the main bile duct (16.33 %), and recurrent stones of the main bile duct (7 %). PEP incidence was 8.8 % with 0 % mortality. Cannulation of the pancreatic duct and the use of precut sphincterotomy emerged as significant risk factors for PEP (▶ **Table 1**), with odds ratios comparable to those reported by ESGE guidelines. Injection of contrast into the pancreatic duct showed a possible association with PEP risk but was not statistically significant. Other known risk factors, such as female sex, young age, and normal bile duct diameter, were not significant in our population. Preventive measures—rectal NSAIDs and aggressive IV hydration—also showed no significant protective effect, likely because they were widely and routinely used. Pancreatic stent placement did not significantly reduce PEP incidence, possibly because the complexity of procedures at our center often necessitated frequent stent use, diminishing statistical power.

▶ **Table 1**

Risk factor	Odds ratio (95 % IC)	p-value
Pancreatic duct cannulation	3.52 (1.57-7.90)	0.002
Precut sphincterotomy	2.41 (1.14-5.09)	0.021
Pancreatic duct injection	2.39 (0.84-6.71)	0.099
Pancreatic duct stenting	0.547 (0.15-1.88)	0.339

Endoscopy 2026; 58: S1–S1041

Conclusions Post-ERCP pancreatitis (PEP) still represents one of the most significant complications in the biliopancreatic field. Our retrospective analysis confirmed that the incidence of this complication in our patient population is comparable to that reported in the literature (3.5–15 %).Moreover, in our cohort only certain procedural factors—such as pancreatic duct cannulation and the use of precut sphincterotomy—are associated with an increased risk of PEP. Further data and multicentric studies are needed to validate our results.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Some therapeutic EUS procedures require multiple steps and exchanges and are technically demanding. Dedicated devices are desirable to improve reproducibility and safety. FNA needles, borrowed from tissue acquisition, are usually used for transmural access. In our case, an 84-year-old woman was referred for jaundice due to lymphoma-related lymphadenopathies. ERCP was not feasible due to duodenal infiltration; EUS-guided hepaticogastrostomy was performed using a new dedicated access needle system (SonoTip AccessPro, Medi-Globe, Germany). In the video, we describe limitations related to FNA needles, present the main features and potential advantages of the new needle system, and illustrate all procedural steps. In our case, guidewire manipulation was particularly challenging, with many back-and-forth movements required; the blunt-tipped cannula allowed smooth manipulation without shearing.

DOI 10.1055/s-0046-1822291

Aims To assess the cost-effectiveness of computer-aided detection (CADe) for screening colonoscopy and to quantify, through value-of-information (VOI) analysis, which uncertainties most critically affect decision-making and should be prioritized for further research.

Methods We adapted a Markov model of colorectal cancer (CRC) natural history to compare three strategies for average-risk 45-year-olds: no screening, 10-yearly colonoscopy, and 10-yearly CADe-assisted colonoscopy up to age 75, from a U.S. payer perspective. The model incorporated screening, post-polypectomy surveillance, and CRC treatment, using published data on adenoma detection rate (ADR), CRC risks, costs, and utilities. Outcomes were CRC incidence, CRC mortality, quality-adjusted life-years (QALYs), costs, and net monetary benefit (NMB) at a willingness-to-pay (WTP) of $100,000/QALY. Probabilistic sensitivity analysis (10,000 simulations) informed the expected value of perfect information (EVPI) and expected value of partial perfect information (EVPPI) for CADe performance, CRC natural history, and key cost parameters. Scenario analyses explored different magnitudes of CADe-driven ADR improvement, alternative background CRC incidence, and a non-linear relationship between ADR and CRC risk (risk plateau above 40 % ADR).

Results Both screening strategies were cost-effective vs no screening. Compared with standard colonoscopy, CADe-assisted colonoscopy further reduced lifetime CRC incidence and mortality, yielding 75 additional QALYs per 10,000 individuals at an incremental cost of $388 per person (ICER $44,074/QALY). CADe was optimal in 71 % of simulations at the $100,000/QALY WTP. Per-patient EVPI was $100, corresponding to a population EVPI of $5.8 billion over a 10-year technology lifetime. The largest EVPPI contributions came from CADe-related ADR effects, CRC natural history, and polypectomy costs. In conservative (4 % ADR gain) and ADR-threshold scenarios, CADe remained potentially cost-effective but EVPI exceeded $8 billion.

Conclusions CADe-assisted colonoscopy is likely to be cost-effective for CRC screening, yet substantial decision uncertainty persists. VOI analysis shows that high-value future research should focus on real-world CADe effects on ADR, CRC natural history, and the shape of the ADR–CRC relationship, to better support guideline and reimbursement decisions on CADe implementation.

eP940 Ductal Calculi in Pancreas Divisum

Authors Saichi S[1], Ahmed S[2]

Institutes **1** CHU Lamine Debaghine Bab El Oued, Algiers, Algeria; **2** Fatema el Azhar clinic, Dely Brahim, Algiers, Algiers, Algeria

DOI 10.1055/s-0046-1822292

Aims Pancreas divisum (PD) is a frequent congenital variant, yet its association with pancreatic duct calculi remains insufficiently described. This study evaluates the prevalence, characteristics, and endoscopic outcomes of ductal stones in patients with PD.

Methods We conducted a retrospective study including all patients managed for pancreatic duct stones between 2018 and 2025.

Among the 74 patients, 16 had PD. Clinical, anatomical, and therapeutic data were analyzed. Median follow-up was 29 months [1–3].

Results Among 74 patients referred for pancreatic duct calculi, 16 (21.6 %) had PD. ERCP established the diagnosis in 8 cases (50 %) and confirmed MRI findings in the remainder. Complete PD was identified in 10 patients (62.5 %), and incomplete PD in 6 (37.5 %).Seven patients had microlithiasis (< 5 mm), eight had stones measuring 5–10 mm, and one had a stone > 10 mm.Minor papilla sphincterotomy with duct clearance and stone extraction, followed by stent placement, was performed in all 16 patients. Clinical success was achieved in all cases (100 %). One technical failure due to a severe stenosis required surgical bypass. No ERCP-related adverse events occurred.

Conclusions Pancreas divisum accounted for a substantial proportion (21.6 %) of patients presenting with pancreatic duct calculi. Stone formation was frequent even in cases of small-caliber calculi. Minor papilla sphincterotomy with temporary stenting proved safe and highly effective in symptomatic PD. These data support considering PD in the differential diagnosis of ductal calculi

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822293

Aims Endoscopic ultrasound–guided choledochoduodenostomy (EUS-CDS) is a minimally invasive procedure for the management of malignant biliary obstruction (MBO), achieved through transduodenal placement of a lumen-apposing metal stent (LAMS) into the extrahepatic bile duct. Despite the recent widespread adoption of the technique, the existing literature encompasses a heterogeneous case mix in terms of procedural and clinical settings, along with variable study quality, which limits the generalizability of previous meta-analyses. To more reliably identify factors associated with safe and effective EUS-CDS using LAMS, we pooled data exclusively from high-quality prospective studies.

Methods The methodology of our analysis was based on PRISMA recommendations. Electronic databases (Medline, Scopus, EMBASE) were searched up to September 2025 for prospective study including patients with distal malignant biliary obstruction who underwent EUS-CDS using LAMS. Meta-analysis was performed reporting pooled rates of technical success, clinical success, stent dysfunction, and adverse events (AEs) by means of a random model. Univariate meta-regression was performed to assess possible cause-effect associations between outcomes and both baseline, and procedural variables.

Results Thirteen studies comprising 662 patients were included in the meta-analysis. The pooled technical and clinical success rates were 95.0 % (I^2 = 33.6 %) and 89.7 % (I^2 = 48.7 %), respectively. Stent dysfunction occurred in 16.5 % (I^2 = 73.3 %) of cases over a mean follow-up period ranging from 30 to 360 days. Duodenal involvement and the use of a small-caliber LAMS (6 mm) were associated with an increased risk of stent dysfunction. Coaxial stent placement had no impact on the risk of stent dysfunction. The pooled adverse event rate was 19.2 % (I^2 = 82.2 %). Stent maldeployment was reported in 4.0 % (I^2 = 0 %) of cases, with smaller CBD diameter trending as a potential risk factor for this event (p: 0.056).

Conclusions EUS-CDS with LAMS is a safe and effective option for relief of MBO. Avoiding patients with duodenal involvement and selecting an appropriate stent size is crucial for minimizing stent dysfunction.

eP942V Gastroscope-assisted ERCP with duodenal retroversion for stent-in-stent biliary drainage in malignant duodenal bulb obstruction

Authors Franchellucci G[1], De Marco A[2], Marcozzi G[2], Colombo M[1], Spadaccini M[3, 1], Fugazza A[1], Repici A[1, 3]
Institutes **1** Humanitas Research Hospital, Rozzano, Italy; **2** Humanitas Research Hospital, Cascina Pergheto, Italy; **3** Humanitas University, Pieve Emanuele, Italy
DOI 10.1055/s-0046-1822294

Abstract Text

Malignant jaundice with duodenal obstruction can prevent conventional transpapillary biliary access. EUS-HGS may be considered for jaundice palliation. A 54-year-old patient with locally advanced pancreatic head adenocarcinoma, previously treated with a biliary stent and gastroenterostomy for duodenal bulb stenosis, re-presented after one month with jaundice. CT showed left intrahepatic biliary dilatation. EUS-HGS was attempted but failed due to an inadequate EUS window. Duodenoscope passage across the stricture was not feasible. A therapeutic gastroscope (3.2-mm channel) reached the papilla, where the prior stent was obstructed by tumoral ingrowth. With duodenal retroversion, the main bile duct was achieved and a new metal stent was placed. Control fluoroscopy showed marked bilateral aerobilia [1–5].

eP943 Adenoma Detection Across the Clock: Do Younger Endoscopists Outperform?

Authors Flandes Iparraguirre A[1], Müller Pérez C[2], Bartolomé Oterino I[1], Redondo Evangelista S[1], Hernández Pérez M[1], Tabernero Da Veiga S[1]
Institutes **1** Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain; **2** Villalba General University Hospital, Collado Villalba, Spain
DOI 10.1055/s-0046-1822295

Aims The Adenoma Detection Rate (ADR) is a key quality indicator in colonoscopy and is strongly associated with the prevention of interval colorectal cancer [1–3]. In this study, we evaluated double-shift endoscopists, defined as attending physicians performing colonoscopies continuously during both the morning and afternoon sessions on the same day.

The primary aim was to determine whether fatigue accumulated over a continuous working day affects older endoscopists (≥ 40 years) more than younger ones (< 40 years). Specifically, we sought to compare ADR between morning

and afternoon procedures within each age group to identify whether older clinicians show a greater decline in detection performance as the day progresses.

Methods A retrospective study was conducted using colonoscopies performed during the year 2021, a period in which COVID-19–related backlogs led to an increased need for double-shift endoscopists. Only colonoscopies performed by attending physicians who worked continuously during both morning and afternoon sessions on the same day were included, ensuring within-endoscopist comparison and minimizing inter-operator variability.

Exclusion criteria were:

- Inadequate bowel preparation (Boston < 2 in any segment)
- Incomplete examinations
- Procedures performed on hospitalized or urgent/emergency patients
- Colonoscopies belonging to the organized colorectal cancer screening program
- Colonoscopies performed by a resident physician.

After applying these criteria, 307 colonoscopies remained for analysis performed by 18 endoscopists (7 younger than 40 and 11 aged 40 years or older). Adenoma Detection Rate (ADR) was compared between morning and afternoon procedures separately for younger (< 40 years) and older (≥ 40 years) endoscopists using contingency tables and chi-square testing, with statistical significance set at $p < 0.05$.

Results A total of 161 procedures were performed by younger clinicians. ADR remained stable throughout the day. Morning ADR was 38.6 % (27/70) whereas afternoon ADR was 39.6 % (36/91). No significant difference was observed ($p = 1.0$), indicating preserved performance across shifts (▶ **Table 1**).

▶ **Table 1**

Endoscopist Age	Morning ADR	N (Morning)	Afternoon ADR	N (Afternoon)	p-value
< 40 years	38.6 %	70	39.6 %	91	1.00
> 40 years	44.4 %	54	23.9 %	92	0.0167

Among 146 procedures performed by older clinicians, ADR varied markedly by time of day, morning ADR was 44.4 % (24/54) while afternoon ADR was 23.9 % (22/92). This twofold decrease in the afternoon was statistically significant ($p = 0.0167$) suggesting greater susceptibility to within day performance decline.

Conclusions The effect of procedure timing on adenoma detection appears to be age-dependent. Younger endoscopists maintained consistent ADR throughout the day, with similar performance in morning and afternoon sessions. In contrast, older endoscopists showed a significant decline in ADR during afternoon procedures, with markedly higher detection rates in the morning. Notably, older endoscopists achieved a higher ADR than younger endoscopists during morning sessions, suggesting that their peak performance occurs earlier in the day. Because only within-endoscopist double-shift days were analyzed, these results are unlikely to be confounded by differences in operator skill or technique. These findings highlight the potential value of age-informed scheduling and underscore the need for strategies aimed at mitigating afternoon performance decline in older clinicians.

DOI 10.1055/s-0046-1822296

Aims Saline-immersion therapeutic endoscopy (SITE) exposes electrosurgical generators to a highly conductive environment, with loss of voltage stability, marked power escalation, and a shift from spark-mediated cutting to conduction-mediated coagulation. Dedicated saline-optimized waveforms have been developed to counteract these effects, but comparative data versus conventional cutting and coagulation modes across different knives is limited.

Methods Using the same ex-vivo porcine gastric platform, three knives (1.5, 0.5, and 0.4 mm electrodes) were evaluated in air and saline under seven waveforms. These were grouped as conventional cutting, coagulation, and dissection modes, including blended cut and dissection algorithms designed for saline use. For each knife–mode–environment combination, six standardized cuts were performed (252 in total). Electrical parameters, cutting success, and lateral thermal spread were quantified.

Results In air, all cutting and dissection waveforms produced complete incisions in 100 % of activations, whereas coagulation modes did not generate a full channel, as expected. Under saline, cutting success with the thick knife fell from 57 % in air to 43 % in saline, indicating a loss of cutting efficiency despite a nearly 20-fold rise in delivered power. Thin knives, by contrast, maintained ≥ 71 % overall success in saline; when paired with saline-adapted cutting or dissection waveforms, cutting success reached 100 %. Coagulation modes in saline produced the greatest lateral spread with the thick electrode, with increases up to 167 % versus air, and mean spread reaching 1.35 mm. In contrast, blended cut and dissection waveforms used with thin knives confined lateral spread to ≤ 0.8 mm. One voltage-controlled dissection mode was the only configuration in which saline did not enlarge, but slightly reduced spread for both thin knives (≈ 9–13 % decrease versus air), while preserving full cutting efficacy.

Conclusions In a saline-immersion setting, conventional coagulation modes combined with thick electrodes lead to pronounced power escalation and excessive thermal spread; whereas, saline-optimized cutting and dissection waveforms used with thin electrodes maintain reliable cutting and keep lateral injury within submillimetric limits. Effective and safe SITE therefore depends on deliberate pairing of thin-tip knives with saline-adapted algorithms, and on substantial down-titration of coagulation currents when larger electrodes must be used.

eP945 Urgent EUS for incidentally detected subepithelial lesions—A 3-year single-centre registry

Authors Ochea F[1, 2], Badiu S[2, 1], Tieranu CG[2, 1], Olteanu OA[2], Ionescu EM[2, 1], Saftoiu A[1, 2]

Institutes **1** Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; **2** Elias Emergency University Hospital, Bucharest, Romania

DOI 10.1055/s-0046-1822297

Aims Evidence on urgent endoscopic ultrasound (EUS) for subepithelial lesions (SELs) is limited. ESGE guidelines recommend EUS-guided fine-needle biopsy (FNB) or mucosal-incision-assisted biopsy (MIAB) for SELs ≥ 20 mm or when histology is required to guide therapy, while allowing imaging-based management for clearly benign lesions. We evaluated the feasibility, diagnostic yield and impact on management of urgent EUS for unclear lesions detected during urgent endoscopy in a tertiary emergency hospital [1].

Methods We retrospectively reviewed all EUS procedures performed between 01.01.2023 and 20.11.2025 (524 total) and selected only urgent EUS performed after emergency endoscopy failed to clarify the diagnosis (incidentally detected SELs, mucosal thickening, suspected masses). For each case we collected lesion location, size (largest diameter), EUS features, real-time elastography, contrast-enhanced EUS (CEH-EUS), performance of EUS-FNB, final histology/diagnosis, management decision and follow-up. Primary endpoints were: (1) proportion of lesions characterized by multimodal EUS and (2) rate of management change after EUS and/or tissue diagnosis. Secondary endpoints were diagnostic yield of FNB and procedural complications.

Results Thirty-five urgent EUS procedures were analysed (57.1 % males; median age was 65 years, IQR: 56–70). Lesions were predominantly gastric and duodenal (24/35 = 68.6 %). Additional cases included esophageal, jejunal and mediastinal lesions. Median lesion size was 28 mm (IQR: 18–40) and 23/35 (65.7 %) lesions were ≥ 20 mm. EUS allowed characterization of layer of origin and echogenic pattern in all cases, and real-time elastography supported the diagnosis of soft lesions such as lipomas, while CEH-EUS highlighted tissue vascularization by contrast uptake pattern. EUS-FNB was performed in 9/35 (25.7 %) cases, mainly in suspected GIST/NET or indeterminate solid masses (7/23 lesions ≥ 20 mm and 2/12 < 20 mm). Of these, 5/9 (55.6 %) FNBs were diagnostic, while 4/9 (44.4 %) were inconclusive due to insufficient material. Final diagnoses included 15 GISTs, 3 neuroendocrine tumors, 3 lipomas, 3 cystic lesions, and several other benign or inflammatory conditions; five cases remained histologically or etiologically inconclusive. EUS findings and/or histology led to a change in management in 85 % (30/35 of cases), with surgery planned mainly for GIST, NET, carcinoma, lymphoma and significant stenosis, and surveillance / conservative management for lipomas, cysts, focal nodular hyperplasia, inflammatory lesions and extrinsic compressions. No EUS-related complications or deaths were recorded.

Conclusions In this 3-year emergency hospital registry, urgent EUS with selective use of FNB, in lesions where histology could change management, was feasible and safe, frequently clarified uncertain findings after emergency endoscopy and supported tailored decisions between surgery or conservative management. The selective use of FNB by avoiding random sampling of clearly benign or non-mass lesions, appears consistent with ESGE size and risk-based recommendations. Larger prospective series with standardized data collection will be useful to refine predictors of which SELs benefit most from urgent tissue diagnosis.

eP946 The use of Cholangioscopy in the Assessment for those undergoing Liver transplantation in Primary Sclerosing Cholangitis

Authors Martin H[1], Beverly K[2], Potts J[2]

Institutes **1** Royal Free Hospital, Pond Street, London, UK, London, United Kingdom; **2** Royal Free Hospital, London, United Kingdom

DOI 10.1055/s-0046-1822298

Aims Primary Sclerosing Cholangitis (PSC) is a common indication for liver transplantation. However, PSC is a recognised risk factor for cholangiocarcinoma (CCA) and the investigation of concerning strictures in PSC is a significant part of focus of investigations in to PSC. This is vitally important in those undergoing transplantation, where currently, in the UK, having CCA is an exclusion criterion for transplantation. Cholangioscopy is a recognised tool used in this scenario. Studies have shown that cholangioscopy is the most useful tool in the detection of CCA in PSC but it still only has a sensitivity of 65 % [1]. This is significant lower than when compared to non PSC indeterminate biliary strictures assessment which has a sensitivity as high as 94 % [2]. These studies show the specificity is similar between PSC and non PSC groups at 95-97 %.

This study evaluates the diagnostic performance of cholangioscopy-guided assessment in patients with concerning biliary strictures undergoing assessment for liver transplantation on the background of PSC. To the authors knowledge there is no published data addressing this specific question.

Methods This was a retrospective, single-centre study including consecutive patients, who had PSC as the underlying liver disease, who underwent Liver transplantation assessment. The study looks at patients under assessment from January 2020 to September 2025. All patients had biliary strictures considered suspicious for malignancy based on cross-sectional imaging. Cholangioscopy was performed using the SpyGlass DS II system (Boston Scientific), and all biopsies were obtained under direct visual guidance.

Results 108 patients with PSC were worked up for liver transplantation during this time. 26 patients had an ERCP as part of their assessment and 15 of these had cholangioscopy. 2 (13.3 %) were found to have CCA and so not listed. 1 was delisted for another reason. 1 (8.3 %) is currently on the waiting list and 11 have been transplanted. Of these 1/11 (9.3 %) was found to have CCA on their explant. Of the 93 patients who did not have cholangioscopy 6 (6.5 %) had CCA on their explant and only 1 of these had had an ERCP, which did not detect the CCA .

In this cohort pre-transplant cholangioscopy has a sensitivity of 66.7 % and a specificity of 100 %. Its positive predictive value is 100 % and its negative predictive value is 91.7 %. This is compared to a negative predictive value of 93.5 % for those patients being assessed for transplant who were deemed not to need cholangioscopy. The similar negative predictive value for patients who are deemed to need cholangioscopy and those who are deemed not to need cholangioscopy is evidence of the benefit of cholangioscopy in this settings.

Due to the rarity of this scenario and the ethical difficulties involved conducting a randomised controlled study will be challenging to power. Therefore, moving forward there is a need for the liver transplant centres to pool their data on this cohort of patients to further assess the role of cholangioscopy in the assessment of potential liver transplant recipients with PSC.

Conclusions These results indicate that cholangioscopy is a useful tool to help minimise the risk of transplanting patients with PSC who have a concurrent CCA.

DOI 10.1055/s-0046-1822299

Abstract Text

Our patient presented with an acute worsening of chronic gastrointestinal symptoms. A non-contrast CT showed colonic wall thickening and a homogeneous mass near the distal esophagus, initially suspected to be a leiomyoma. Endoscopy was unremarkable, but EUS proved crucial: it revealed an intrathoracic mass composed of hepatic parenchyma extending across the cardia, raising suspicion of hepatic herniation. MRI subsequently confirmed herniation of the left hepatic lobe. Only few cases of non-traumatic intrathoracic hepatic herniation have been reported, and none included an EUS assessment. This case illustrates how EUS, with its dynamic nature and high-resolution assessment of deep structures, represents a valuable diagnostic tool even in rare clinical scenarios. The case highlights also that hepatic herniation may be an incidental finding and should be considered in the differential diagnosis of thoracic masses [1–4].

eP948 Diverse applications for a new slim therapeutic gastroscope with large 3.2mm diameter working channel in challenging cancer patients: a case series

Authors Lanke G[1], Ge PS[1], Weston B[1]

Institute 1 The University of Texas MD Anderson Cancer Center, Houston, Texas, United States of America

DOI 10.1055/s-0046-1822300

Problem to solve The use of smaller diameter gastroscopes often comes at the expense of functionality which may limit their use in anatomically challenging situations.

Innovation A new slim therapeutic channel gastroscope (Fujifilm EG-840TP) with expanded flexibility was recently introduced. The scope was principally designed to support the growing field of third space endoscopy. In this case series, we highlight the diverse applications for this remarkably agile and slim 7.9mm diameter gastroscope with large 3.2mm working channel. This single-center case series performed at a tertiary cancer center highlights seven patients with malignancy who underwent endoscopy with the slim scope for various indications (▶ **Table 1**).

▶ **Table 1** Summary of cases highlighting applications for a new slim therapeutic channel gastroscope.

Case	Age	Sex	Diagnosis	Endoscopic intervention
1	82	F	Metastatic pancreatic cancer with bile duct obstruction and pyloric stenosis	ERCP with placement metal biliary stent
2	65	M	Metastatic gastric cancer with bile duct obstruction and duodenal stenosis	ERCP with exchange of plastic for metal biliary stent
3	59	M	Metastatic gallbladder cancer with sigmoid colon obstruction	Placement metal colonic stent
4	58	F	Squamous cell cancer tongue with esophageal stenosis and non-healing gastro-cutaneous fistula	Closure of gastro-cutaneous fistula with through-the-scope clips
5	87	M	Recurrent laryngeal cancer with high-grade pharyngoesophageal anastomotic stricture	Rendezvous balloon dilation of stricture via gastrostomy tube site
6	82	F	Metastatic pancreatic cancer and gastric outlet obstruction	Facilitate EUS-GJ by traversing duodenal stricture to directly instill the jejunum with water
7	72	M	Fistulizing pancreatic head cystic mucinous neoplasm	Direct exploration with diagnostic biopsy / aspiration

Results We included seven patients who underwent endoscopic interventions using the slim therapeutic gastroscope for various conditions. The diagnoses included metastatic gastric and pancreatic cancer with gastric outlet and distal bile duct obstruction, metastatic gallbladder carcinoma with large bowel obstruction, squamous cell cancer of the tongue with esophageal stenosis and chronic non-healing gastro-cutaneous fistula, recurrent laryngeal cancer with high-grade pharyngoesophageal anastomotic stricture, metastatic gastric cancer with gastric outlet obstruction, and a fistulizing pancreatic cystic lesion incidentally found on CT. Endoscopic procedures performed included: ERCP with biliary stent placement and biliary stent exchange in the setting of gastric outlet obstruction; colonic stent placement; closure of gastro-cutaneous fistula using through-the-scope endo-clips; rendezvous balloon dilation of a high grade pharyngoesophageal anastomotic stricture via a gastrostomy tube site; facilitating endoscopic ultrasound-guided gastrojejunostomy in the setting of severe duodenal stricture; and direct endoscopic evaluation of a fistulizing pancreatic head cystic mucinous neoplasm. These diverse applications demon-

strate the gastroscope's flexibility in managing a variety of complex gastrointestinal oncologic conditions.

Conclusions The Fujifilm EG-840TP slim treatment gastroscope has significant advantages when compared to standard and therapeutic gastroscopes due to its small 7.9mm outer diameter, large 3.2mm working channel and expanded flexibility. These cases highlight the versatility and utility of the slim therapeutic gastroscope in navigating anatomically challenging and previously inaccessible locations, offering enhanced therapeutic potential where standard and therapeutic endoscopes may fall short.

DOI 10.1055/s-0046-1822301

Aims Adequate bowel preparation is crucial for high-quality colonoscopy. Although oral laxative-based regimens remain the standard, they are often poorly tolerated by frail patients. Colon Wash, a retrograde colonic irrigation technique, has emerged as a potential alternative. This study aimed to compare the efficacy and tolerability of Colon Wash with standard oral low-volume osmotic preparations [1–16].

Methods In this single-center observational study, adults undergoing colonoscopy were included. Overall, 160 patients received Colon Wash and 250 received standard oral low-volume osmotic preparations. After 1:1 nearest-neighbor propensity score matching for age, sex, BMI, abdominal surgery, and performance status, 150 patients per group were analyzed. Bowel cleansing quality was assessed using the Boston Bowel Preparation Scale (BBPS). Adequate preparation was defined as a total BBPS ≥ 6 with ≥ 2 in all segments.

Results Adequate bowel cleansing was achieved in 86 % of Colon Wash patients and 88 % of those receiving standard oral low-volume osmotic preparations ($p = 0.732$). Colon Wash was associated with significantly fewer preparation-related side effects (0 % vs. 22 %, $p < 0.001$) and a higher cecal intubation rate (100 % vs. 92 %, $p < 0.001$). No complications occurred in the Colon Wash group. Nausea was the most frequent adverse event with standard oral low-volume osmotic preparations (22 %).

Conclusions Colon Wash provided comparable efficacy and superior tolerability versus standard oral low-volume osmotic preparations. It represents a valid alternative for bowel cleansing and warrants consideration for wider clinical adoption.

eP950 Blinded full-thickness histopathological analysis of gastric fibrosis in endoscopic sleeve gastroplasty vs laparoscopic sleeve gastrectomy

Authors Maselli R[1], Massimi D[2], Sollai M[3], Fortugno A[4], de Sire R[5], Capogreco A[6], Alfarone L[6], Rao SRA[7], Uccella S[7], Menini M[2], Repici A[8]

DOI 10.1055/s-0046-1822302

Aims The primary objective of this study was to histologically validate the assumption that Endoscopic Sleeve Gastroplasty (ESG) induces full-thickness scarring and long-term fibrosis similar to surgical Sleeve Gastrectomy (SG). While Laparoscopic Sleeve Gastrectomy (LSG) creates a high-pressure system via irreversible anatomical restriction, recent physiological data suggest ESG functions as a compliance-sparing "low-pressure" system that preserves esophageal motility. Consequently, we hypothesized that the restrictive mechanism of ESG relies on delayed emptying rather than the structural rigidity seen in surgery. This study analyzed gastric wall fibrosis and muscular thickness in patients undergoing SG after previous ESG versus primary SG to determine if ESG induces the tissue remodeling necessary for permanent distensibility reduction (▶ **Table 1**).

▶ **Table 1**

Parameter ESG-SG Group (n = 11)	SG Group (n = 11)	P-value
Submucosal Fibrosis (Mean ± SD) 3.29 ± 1.21 mm	3.18 ± 1.37 mm	0.895 *
Submucosal Fibrosis (Median) 2.9 mm	3.3 mm	–
Muscularis Propria Thickness (Mean ± SD) 1.58 ± 0.63 mm	1.45 ± 0.48 mm	0.84
Fibrosis Extension (Pattern/Depth) Identical distribution Identical distribution 1.00†; *Mann–Whitney U test; †Fisher's exact test		

Methods This study was designed as a blinded, comparative histopathological evaluation of gastric specimens. The study population consisted of patients undergoing rescue SG after a prior ESG (ESG-SG group) and a control group undergoing primary SG (SG group). All specimens were evaluated by a pathologist blinded to group allocation to ensure objective assessment. Key histological metrics included submucosal fibrosis thickness (mm), muscularis propria thickness (mm), and fibrosis extension (classified as submucosa only vs. submucosa + muscle). Statistical analysis included the Shapiro–Wilk test for normality, with group comparisons performed using Mann–Whitney tests, Welch t-tests, and Fisher's exact test.

Results A total of twenty-two patients were included in the analysis (11 in the ESG-SG group and 11 in the SG group). The histopathological analysis revealed no significant structural differences between the two groups. Submucosal fibrosis thickness was comparable, with a negligible mean difference of + 0.11 mm (95 % CI –1.04 to + 1.26 mm). Similarly, muscularis propria thickness did not differ significantly between groups (p = 0.84), and fibrosis extension patterns were identical (p = 1.00), showing no qualitative differences in depth or architecture.

Conclusions This blinded histopathological analysis demonstrates that gastric wall architecture after ESG does not exhibit increased submucosal fibrosis, greater muscular thickness, or deeper fibrosis extension compared to primary SG. These findings challenge the widespread assumption that ESG mimics the full-thickness scarring of surgical resection. Instead, the absence of structural stiffening supports the classification of ESG as a "low-pressure" system where clinical efficacy is likely driven by motility modulation (decelerated gastric emptying) rather than the irreversible reduction of distensibility characteristic of high-pressure surgical sleeves. This distinction positions ESG as a mechanistic entity separate from resection-based surgery, aligning with recent evidence of preserved esophageal physiology.

eP951 Duodenal ESD Achieves 100 % En-Bloc Resection with Zero Perforations: A 5-Year Western Experience

Authors Precup P[1], Mandrutiu A[1], Tantau A[1,2], Roman L[1], Pop A[1], Zaharie T[3], Tantau M[1,2]
Institutes **1** Digenio Hospital, Cluj-Napoca, Romania; **2** Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; **3** Centrul Medical PediPat, Cluj-Napoca, Romania
DOI 10.1055/s-0046-1822303

Aims Duodenal endoscopic submucosal dissection (ESD) is historically considered one of the highest-risk endoscopic resections in Western practice due to thin wall anatomy and high perforation rates reported in earlier studies. As a result, Western adoption remains limited. We aimed to evaluate the feasibility, safety, and oncologic performance of duodenal ESD compared with EMR over a 5-year period in a Western expert center.

Methods We retrospectively analyzed all non-ampullary duodenal lesions resected between 2019–2024. Patients were treated with EMR (n = 8) or ESD (n = 7). Demographics (age, sex, comorbidities), lesion size, D1–D3 location, morphology, and Vienna classification were recorded. Mean lesion size was comparable between EMR and ESD (31.0 vs 26.1 mm; p = 0.77). Sex distribution (62.5 % vs 57.1 % male) and comorbidities (62.5 % vs 42.8 %; p = 0.62) were similar, indicating no selection bias. Paris classification included predominantly superficial elevated (0-IIa) and flat mixed patterns (0-IIa/Is). Statistical analysis included Fisher's exact test and Mann–Whitney U. Correlation between lesion size and en-bloc resection was assessed via Spearman's coefficient. Procedural time could not be analyzed due to incomplete documentation.

Results ESD achieved 100 % en-bloc resection (7/7) compared with 42.8 % for EMR (p = 0.028). R0 resection rates were identical (83.3 %) when margins were assessable.Safety outcomes were excellent: no perforations (0 %), no delayed bleeding, and no patient required surgery. One immediate intraprocedural bleed occurred in the ESD group (14.2 %), successfully controlled endoscopically.

Critically, most ESDs were performed in D2 (6/7), the anatomically highest-risk duodenal segment. ESD achieved a 100 % en-bloc rate in D2, with zero perforations and zero delayed bleeding, demonstrating exceptional safety even in the most challenging location.

Paris classification contributed to meaningful selection differences. EMR was used mainly for superficial elevated 0-IIa or Is lesions suited for lifting–snare resection. ESD was preferentially used for flat or mixed 0-IIa/0-IIa + Is lesions, which traditionally carry higher risks of incomplete resection with standard EMR.Despite this, ESD maintained 100 % en-bloc across all Paris morphologies. Lesion size did not correlate with en-bloc success (Spearman ρ = –0.26, p = 0.34), indicating that ESD maintained stable technical performance across increasing lesion dimensions. Recurrence occurred in one ESD patient, while none was observed after EMR.

Patient factors (age, sex, comorbidities), lesion size, and anatomical location did not influence technique selection or outcomes, supporting the robustness of ESD performance in this cohort.

Conclusions In this 5-year Western cohort, duodenal ESD demonstrated perfect en-bloc performance and zero perforations, overturning long-standing concerns about duodenal ESD safety in Western practice. The ability to achieve 100 % en-bloc resection even in D2—while maintaining a 0 % perforation rate—represents a major technical achievement and aligns with high-quality Asian data.ESD should be strongly considered for large or complex non-ampullary duodenal lesions requiring definitive histologic assessment. EMR remains appropriate for small, low-risk lesions; however, for curative-intent resections, ESD offers clearly superior technical and oncologic performance.

eP952 Diagnostic Utility Of Endoscopic Ultrasound Shear Wave Elastography In Predicting Chronic Pancreatitis

Authors Pal S[1], Roy S[1]
Institute 1 Narayana RN Tagore Hospital, Mukundapur, Kolkata, India
DOI 10.1055/s-0046-1822304

Aims Progressive fibrosis in chronic pancreatitis (CP) alters the mechanical properties of the pancreatic parenchyma which results in increased tissue stiffness. Endoscopic ultrasound shear-wave elastography (EUS-SWE) quantifies pancreatic stiffness that may help distinguish fibrotic from normal pancreatic tissue. This prospective study aimed to compare pancreatic shear-wave velocity (Vs) and elasticity (E) values between patients with CP and individuals with a normal pancreas.

Methods In this single centred study of 7 months duration, 42 consecutive adults undergoing EUS for evaluation of CP or for non-pancreatic indications were enrolled. Participants were classified into a CP group (n = 20) based on imaging and tests of pancreatic insufficiency and a control group (n = 22) with normal pancreatic morphology. During EUS, Vs was measured in metres/second(m/s) and E in kilopascals (kPa) using the Olympus EUS ME3 system. Mean values were compared between groups, and diagnostic performance was assessed using receiver operating characteristic (ROC) analysis and statistical significance was considered with a p value less than 0.05.

Results The mean age of the CP group was 41.35 years and the control group was 43 years. Majority of the CP cases were males (n = 13). The mean Vs of the CP group was 2.46 + 0.3 m/s which was significantly higher than that of the control group which was 1.89 + 0.37 ($p < 0.05$). A Vs value of 2.2 m/s was 95 % sensitive and 82 % specific for predicting CP with area under ROC (AUROC) of 0.88. Similarly, mean E value of CP group 19.03 + 1.59 kPa was also significantly higher than the control group which was 12.16 + 5.30 kPa ($p < 0.05$). An E value of 17.5 kPa was 85 % sensitive and 82 % specific for predicting CP with AUROC of 0.87.

Conclusions In the present study EUS-SWE reliably distinguished chronic pancreatitis from normal pancreas by demonstrating significantly higher levels of tissue stiffness in CP thereby emphasising the role of EUS-SWE as a useful adjunctive tool for quantification of pancreatic fibrosis in patients of CP.

eP953 Endoscopic Ultrasound-Guided Fine Needle Biopsy of Solid Gastrointestinal Mass Lesions Using Cell Block Method Yields Equivalent Diagnostic Accuracy Compared to Core Biopsy with Macroscopic On-Site Evaluation

Authors Pal S[1], Roy S[1], Chaterjee N[1]
Institute 1 Narayana RN Tagore Hospital, Mukundapur, Kolkata, India
DOI 10.1055/s-0046-1822305

Aims Despite the utility of rapid on-site cytological examination (ROSE) in Endoscopic Ultrasound-Guided Tissue Acquisition (EUS-TA), it is not uniformly performed in all centers because of limited availability. Macroscopic on-site examination (MOSE) is an alternative method that improves diagnostic ability depending on the visible whitish core length. Cell Block method is suitable for evaluating histological architecture, immunostaining, and molecular studies. We evaluated diagnostic performance of MOSE with core biopsy and Cell Block method using core biopsy needles

Methods EUS guided Fine Needle Biopsy (FNB) was performed using cell block method and MOSE with core biopsy. The primary and secondary outcome measures were diagnostic accuracy, diagnostic yield, sensitivity, specificity, positive and negative predictive values, and the number of passes, respectively. The optimum length for macroscopic visible core (MVC) by MOSE to achieve accurate diagnosis was evaluated.

Results Ninety-six patients (48 cell block and 48 MOSE) were enrolled. Mean lesion size was larger in MOSE group (33.23 ± 24.35mm *vs* 27.88 ± 12.32 mm P = 0.692). Diagnostic accuracy (93.75 %), diagnostic adequacy (79.17 %), sensitivity (92.68 % vs 92.86 %), specificity (100 %), positive predictive value (100 %), negative predictive value (70 % vs 66.67 % P = 0.612) of the two methods were similar. Mean number of needle passes in MOSE was significantly lower (1.77 vs 2.44, p value < 0.001). Mean core length in MOSE group was 12.31 mm ± 7.67 mm. Area under receiver operating characteristic curve analysis showed that core length of ³5mm gives a high sensitivity (93 %) for specific diagnosis. Immunohistochemistry results were also obtained in both the groups when required (12.5 % in MOSE group vs 18.75 % in Cell Block group, P = 0.399).

Conclusions Cell block and MOSE method in EUS FNB both yields comparable results but number of passes required are less in MOSE group. Obtaining longer core length increase sensitivity for specific diagnosis in MOSE group. If adequate core can't be obtained, cell block method also gives comparable results. Besides, it also useful for preserving architectural composition and for immunohistochemistry studies.

eP954 Hidden barriers in endoscopy training: experiences of discrimination among gastroenterologists in Germany

Authors Maitra RA[1], Abedin N[2], Ari G[3], Diaconu IG[4], Erasmus HP[2], Hamesch K[5], Hazzouri N[4], Kasaburi N[6], Pamukcu-Cerciz Ö[7], Reichermeier S[8], Salayma B[9], Sarraf A[10], Welsch L[1]
Institutes 1 Klinikum Hanau, Hanau, Germany; 2 Frankfurt University Hospital, Frankfurt am Main, Germany; 3 Essen University Hospital, Essen, Germany; 4 Helios HMU Clinic Krefeld, Krefeld, Germany; 5 Interdisciplinary Endoscopy, University Hospital RWTH Aachen, Aachen, Germany; 6 Klinikum St. Marien Amberg, Amberg, Germany; 7 Helios Klinikum Niederberg, Velbert, Germany; 8 DONAUISAR Klinikum Deggendorf, Deggendorf, Germany; 9 Helios Klinikum Gifhorn, Gifhorn, Germany; 10 Helios Klinikum Pirna, Pirna, Germany
DOI 10.1055/s-0046-1822306

Aims Gastroenterology in Germany increasingly relies on physicians with a migration background, many of whom are actively involved in endoscopy. In a nationwide survey among members of the German Society of Gastroenterology (DGVS), over 90 % of gastroenterologists with and without migration background reported at least one incident of hostility within 24 months; first-generation migrant physicians showed higher cumulative exposure and more often changed workplace because of these experiences, while still reporting high work-related thriving. Quantitative data, however, provide limited insight into how such hostility and discrimination translate into everyday clinical routines, hierarchical training structures and access to endoscopy training. This qualitative study aimed to explore how gastroenterologists perceive and interpret racism and discrimination in their professional lives, with a specific focus on hidden barriers in endoscopy training and career development.

Methods We analysed free-text responses from a nationwide, anonymous online survey among members of the German Society of Gastroenterology (DGVS). In addition to standardised items on work-related well-being, hostility and migration background, participants were invited to describe experienc-

Endoscopy 2026; 58: S1–S1041

es and views on racism and discrimination in open comment fields. Two researchers conducted a reflexive thematic analysis following Braun and Clarke, iteratively generating and refining themes and comparing narratives from respondents with and without a migration background.

Results Five themes were identified: (1) Interpersonal sources of workplace discrimination – including racist harassment, devaluation and questioning of competence by superiors, colleagues, patients and relatives; (2) Feeling left behind in training – perceived systematic disadvantage of physicians with migration background in access to endoscopy training, supervised procedures and promotion; (3) Intersecting identities – overlapping effects of migration background, gender, skin colour and visible religiosity, particularly in patient-facing endoscopy settings; (4) Perceived irrelevance and externalisation – voices that downplayed racism as a professional issue or shifted responsibility to "others"; and (5) Strategies for a fair training culture – calls for transparent, competency-based allocation of endoscopy training, clear institutional positions against discrimination and low-threshold, preferably anonymous reporting structures.

Conclusions Discrimination and hostility are experienced as hidden structural barriers within endoscopy training and career progression, especially for physicians with a migration background. Addressing these barriers through transparent training pathways and organisational accountability is likely essential for workforce retention, team functioning and high-quality endoscopic care. Professional societies such as ESGE and DGVS can play a key role in defining and promoting inclusive endoscopy training standards.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP955 Pneumatic Dilation for Primary Achalasia: Clinical Effectiveness at 12 Months

Authors Saichi S[1], Saoula H[2], Abbaci K[3], Chaib S[3], Aissat Y[4], Meriem HR[4], Aissaoui M[4], Osmane R[5], Ziane I[6], Mitiche A[7], Benrabia A[4]

DOI 10.1055/s-0046-1822307

Aims Despite major endoscopic advances in the treatment of primary achalasia, particularly with peroral endoscopic myotomy (POEM), pneumatic dilation remains an important therapeutic option. Assessing its real-life outcomes in local clinical practice is essential to optimize patient management [1, 2].

The aim of this study was to evaluate the clinical results of pneumatic dilation in primary achalasia.

Methods Prospective single-center study including patients with confirmed primary achalasia and Eckardt score > 3, treated with 30-mm pneumatic balloon dilation between January 2023 and September 2024. Clinical follow-up was performed at 2 weeks, 1, 3, 6, and 12 months. Additional dilation sessions were performed for persistent symptoms (Eckardt score > 3). Treatment success was defined as clinical remission (Eckardt score < 3) without need for POEM or surgery at one year.

Results Twenty-eight patients were included (mean age 51 years, range 17–79; M/F = 0.4). Achalasia type: I (n = 24), II (n = 3), III (n = 1). Twelve patients (44 %) achieved remission after a single session, 7 (26 %) after two sessions, and 8 (30 %) after three sessions. At one year, 21 patients (75 %) were in clinical remission. One patient required surgery, and two underwent POEM. One esophageal perforation occurred; no other major complications were reported.

Conclusions In our single-center experience, pneumatic dilation with a 30-mm balloon proved to be an effective and safe method for treating primary achalasia, achieving clinical remission in nearly three-quarters of patients at one year.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP956 Three-year experience with EUS-guided cystogastrostomy at a tertiary referral center: a retrospective cohort study

Authors Tari E[1], Lázár B[2], Péter S[3], Hegyi PJ[3, 1, 4], Erőss B[3, 4, 1]

Institutes **1** Centre for Translational Medicine, Semmelweis University, Budapest, Hungary; **2** Department of Surgery, Transplantation and Gastroenterology, Budapest, Hungary; **3** Institute of Pancreatic Diseases, Semmelweis University, Budapest, Hungary; **4** Institute for Translational Medicine, Medical School, University of Pécs, Pécs, Hungary

DOI 10.1055/s-0046-1822308

Aims Endoscopic ultrasound (EUS)-guided cystogastrostomy is a key minimally invasive approach for treating pancreatic fluid collections (PFCs), offering high success rates with lower morbidity than surgery. While lumen-apposing metal stents (LAMS) have become widely used—particularly for walled-off necrosis—double pigtail plastic stents (DPPS) remain a safe, cost-effective option, especially for uncomplicated pseudocysts requiring simple drainage. Despite their broad use, real-world outcome data on DPPS remain variable, and evidence from Central and Eastern Europe is limited.

This study aimed to assess the real-world performance of EUS-guided cystogastrostomy using DPPS over a nearly three-year period at a high-volume tertiary pancreatic center.

Methods We conducted a retrospective review of all EUS-guided cystogastrostomy procedures performed with DPPS at our institution between November 2022 and July 2025. Data were collected from electronic medical records and endoscopy reports, including patient demographics, indications, cyst characteristics, procedural steps, stent size and number, and peri-procedural details. Technical success, clinical outcomes, and procedure-related adverse events were assessed according to standard definitions. All variables were analyzed using descriptive statistics.

Results A total of 50 EUS-guided cystogastrostomy procedures were performed during the study period. Most interventions (48/50) targeted pancreatic fluid collections, while 2 were performed for duodenal collections. The cohort included 58 % male patients with a mean age of 56 years. The mean procedure time was 33 minutes. Cyst puncture was performed using a 19G fine-needle aspiration needle, followed by tract dilation with either an 8.5 Fr or 10 Fr cystotome. DPPS (8.5–10 Fr, 2–10 cm) were placed in all cases; two stents were inserted in 6 procedures. Cyst size data were available for 32 patients, the majority of whom had collections measuring > 6 cm.

Technical success was achieved in 48 of 50 cases (96 %). Clinical improvement was observed in most successfully treated patients during follow-up. Four procedure-related adverse events occurred: one perforation requiring urgent surgical management and three bleeding events, all of which were managed endoscopically without further intervention.

Conclusions EUS-guided cystogastrostomy with DPPS proved to be feasible and effective, with high technical success and an acceptable safety profile. While LAMS may be beneficial in more complex cases, our results support DPPS as a cost-effective and reliable option for uncomplicated PFCs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP957 Endoscopic Cystgastrostomy with Lumen Apposing Metal Stents and Necrosectomy for Large Pancreatic Walled off Necrosis – A UK District General Hospital Experience

Authors Kumar M[1], Dissanayake G[1]
Institute 1 King's College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1822309

Aims Endoscopic Cystogastrostomy and Necrosectomy with Lumen Apposing Metal Stents (LAMS) for Large Pancreatic Walled Off Necrosis: A UK District General Hospital Experience

Methods This retrospective study was conducted at a district general hospital in South London between October 2024 and October 2025. Patients with large WON (≥ 10 cm) were identified and reviewed. Management consisted of endoscopic cystogastrostomy using LAMS, followed by endoscopic necrosectomy when required. Data collected included demographics, aetiology of pancreatitis, indications for drainage, procedural outcomes, complications, and recurrence. Continuous variables were summarised using mean, median, and range; categorical variables were expressed as frequencies and percentages. Ethical approval was obtained from the local institutional review board, and all data were anonymised [1, 2].

Results 10 patients were included (mean age 51.8 years; range 22–66 years; 7 males, 3 females). The predominant causes of pancreatitis were alcohol related (50 %) and gallstone pancreatitis (30 %), with autoimmune and post ERCP pancreatitis each accounting for 10 %. Pseudocyst/WON size on initial CT ranged from 10 to 20 cm (median 15 cm; mean 15.4 cm).

Drainage was indicated primarily for sepsis (90 %) and less commonly for abdominal pain (10 %). Clinical success was achieved in all cases (100 %), with a technical success rate of 90 %. Complications occurred in 20 % of patients, mainly stent migration; no bleeding or severe infections were observed. One patient experienced recurrence of fluid collection 8 weeks after stent removal (5 cm in diameter).

Three patients (30 %) required endoscopic necrosectomy, with a mean of 2.7 sessions and a median of 2 sessions among those treated. While most patients did not require necrosectomy, those who did typically needed 2–3 sessions. WON resolution ranged from 8 to 32 weeks (median 14 weeks; mean 16.2 weeks). LAMS sizes used were 15 × 10 mm in 70 % of cases and 20 × 10 mm in 30 %. Double pigtail stents were used in 30 % of patients.

Conclusions Endoscopic cystogastrostomy with LAMS, supplemented by endoscopic necrosectomy when required, is a safe and effective treatment for large pancreatic walled off necrosis and pseudocysts (≥ 10 cm), even in a district general hospital setting. This approach demonstrated high clinical and technical success rates with positive patient outcomes. Careful patient selection standardised follow up with imaging and outpatient review, and timely targeted endoscopic therapy are essential to optimise outcomes and sustain long term resolution.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP958 Romanian Colorectal Cancer Screening Insights: Quality Metrics from 1038 Colonoscopies in the South Muntenia Region Pilot Program

Authors Cristian G[1, 2], Bunduc S[1, 2], Cotruta B[2], Iacob R[2, 1], Saizu AI[2], Dimitriu AM[2, 1], Pitigoi D[2], Ciora CA[3, 1], Bancila I[2], Diculescu MM[2], Becheanu G[2], Dumbrava M[2], Sanduleanu S[4], Manuc M[2, 1]
Institutes 1 Carol Davila University of Medicine and Pharmacy, București, Romania; 2 Fundeni Clinical Institute, București, Romania; 3 Fundeni Clinical Institute, Bucharest, Romania; 4 Maastricht University Medical Center, Maastricht, Netherlands
DOI 10.1055/s-0046-1822310

Aims Population-based Colorectal cancer (CRC) screening using faecal immunochemical testing (FIT) followed by colonoscopy is recommended across the EU. Romania initiated the ROCCAS program in 2019, with pilot implementation in four administrative regions. Our aim was to evaluate the quality metrics and key performance indicators (KPIs) of the ROCCAS pilot program in the South Muntenia region.

Methods A cohort of 50,000 average-risk individuals aged 50–74 years was invited between January 2021–December 2023. Screening was based on biennial FIT (positivity ≥ 20 µg/g). FIT-positive participants were invited for colonoscopy at the regional screening centre. Prospectively collected registry data were analysed. Multivariable logistic regression was used to identify predictors of adenoma, advanced adenoma (AA), sessile serrated lesion (SSL), and CRC detection.

Results : FIT completion rate was 89 %, with 6 % positivity (n = 2576). Colonoscopy uptake was 40 % (n = 1038). Caecal intubation (96 %) and adenoma detection (55 %) exceeded international benchmarks. Advanced adenomas and CRC together represented 38 % of detected lesions. Multivariable analysis showed male sex predicted adenoma (OR 2.72, 95 %CI 2.11–3.51) and AA detection (OR 1.85, 95 %CI 1.41–2.44), while female sex was associated with right-sided SSLs (OR 0.34, 95 %CI 0.14–0.81). FIT values correlated with lesion severity and independently predicted CRC (aOR 1.53 per 100 µg/g, p < .001). CRC was diagnosed in 11 % (n = 114) of scoped individuals. Colonoscopy waiting time was above recommended limits, and uptake was lower than expected.

Conclusions The ROCCAS pilot demonstrated high-quality colonoscopy performance and clinically relevant detection rates. However, colonoscopy participation requires significant improvement before national roll-out. Awareness campaigns, and tailored communication strategies could optimize program effectiveness.

eP959 From Incidental Finding to Diagnosis: EUS-FNB Identifies a Rare CoGNET

Authors Palumbo G[1], Tripodi G[1], Termite F[1], Boskoski I[1], Tringali A[1], Gualtieri L[1], De Lucia SS[1], Nista EC[1], Cammarota G[1], Gasbarrini A[1], Spada C[1], Rizzatti G[1]
Institute 1 Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy
DOI 10.1055/s-0046-1822311

Background: Composite gangliocytoma/neuroma and neuroendocrine tumor (CoGNET) is a rare neoplasm typically arising in the second portion of the duodenum. [1, 2] Its occurrence in young adults and its association with pancreatic anatomical variants are poorly documented. We report the case of a young woman with Neurofibromatosis type I (NF1), pancreas divisum, and recurrent pancreatitis who was incidentally found to have a duodenal CoGNET.

Case Presentation:A 22-year-old woman with NF1 had been followed for recurrent acute pancreatitis. Secretin-enhanced MRCP demonstrated pancreas divisum, and she underwent multiple ERCPs.

Serial imaging years later showed a mildly dilated but stable dorsal duct with features of chronic pancreatitis and no focal lesions. Follow-up contrast-enhanced MRI revealed the new onset of a well-circumscribed, hypervascular solid nodule (23 × 25 mm) between the pancreatic uncinate process and the third duodenal portion.

Endoscopic ultrasound confirmed a 25-mm oval, hypoechoic, hypervascular lesion on eFlow, showing a distinct compressive effect on the uncinate process on endosonographic evaluation and mild endoluminal deformity on endoscopic inspections. EUS-guided fine-needle biopsy was performed using a 22-gauge needle with three passes. Histopathologic analysis demonstrated a well-differ-

entiated neuroendocrine neoplasm with mixed spindle–epithelioid morphology and strong SST2A expression, consistent with a CoGNET.

Discussion: CoGNET is an uncommon entity with very few cases reported, and nearly all published diagnoses have historically been made on surgical specimens. Its coexistence with pancreas divisum and NF1 has not previously been described. Importantly, the role of EUS-guided tissue acquisition in diagnosing CoGNET is virtually absent from current literature, with no dedicated studies or standardized criteria. This case highlights that EUS-FNB may represent a valuable, under-recognized tool for early diagnosis of CoGNET.

Conclusion: This case illustrates a rare duodenal CoGNET identified incidentally during long-term follow-up for chronic pancreatitis in a young woman with NF1 and pancreas divisum. The effective use of EUS-guided FNB to obtain a definitive histologic diagnosis underscores a diagnostic pathway largely absent from the current literature. Increasing awareness of this entity and recognition of its key EUS and FNB characteristics can significantly influence clinical decision-making, surgical planning, and long-term outcomes.

eP960 Endoluminal vacuum-assisted therapy for colorectal anastomotic leaks: early intervention drives success

Authors Gambaccini D[1], Natali V[1], Bolognesi V[1], Stefani Donati D[1], Tapete G[1], Pancetti A[1], Venturini A[1], Visaggi P[1], Marciano E[1]

Institute 1 Digestive Endoscopy Unit, Azienda Ospedaliera Universitaria Pisana, Ospedale Nuovo Santa Chiara, Pisa, Italy

DOI 10.1055/s-0046-1822312

Aims Anastomotic leak represents an important complication following colorectal resection (3-19 % frequency) with a mortality rate varying from to 1.7 % to 16.4 %. The endoluminalvacuum-assisted therapy (EVT) was introduced to treat presacral anastomotic abscesses.The principle is based on the application of negative pressure to drain, to clean, to inducegranulation tissue and to prevent the development of chronic sinus [1–3].

Methods Between January 2023 and November 2025, 11 patients with anastomotic leakagefollowing low anterior resection were treated with EVT. We investigatedpotential factors related to the development of clean leading to cavity closure.

Results Colorectal anastomoses were located at a variable distance from the anal verge, ranging from 3 to 5 cm. All patients had a diverting ileostomy. The diagnosis of leakage was performed after a median interval of 2 weeks, the median size of the cavity was 8 cm.

The median duration of therapy was 35 days with a mean number of 10 EVT replacements.

No complications were recorded.

Interval between the diagnosis of the complication and the start of EVT is the main determinant of outcome, with a strong negative correlation with complete orifice closure (r −0.886, p < 0,001). Age, BMI, distance from the anal verge, cavity length, and number of sponge replacements exhibited weak correlations. A slight positive correlation was observed between initial orifice diameter (r = + 0.266, p < 0,05).

Conclusions EVT seems an effective, minimally invasive procedure to treat anastomotic leakage. The treatment timeliness is crucial for achieving complete closure, underscoring the importance of an early approach of leaks.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822313

Abstract Text

A 49-year-old woman with a family history of colorectal cancer underwent screening colonoscopy, which revealed a 35 mm non-granular laterally spreading tumor (LST-NG) in the cecal fundus. Owing to her previous appendectomy, underwater-EMR was scheduled. After resection, another lesion emerged through the appendiceal stump, prompting us to opt for full-thickness resection (FTR). Post-resection histology unexpectedly identified a high-grade neuroendocrine neoplasm (NEN) with characteristics of large-cell neuroendocrine carcinoma (LCNEN), Ki67 > 60 %, and pT1 in the appendiceal stump. The cecal lesion was a sessile serrated lesion with intramucosal low-grade adenocarcinoma foci. Endoscopic resection achieved R0. Right hemicolectomy was performed, and no evidence of nodal metastases was observed. After radical surgical treatment, patient started adjuvant therapy with somatostatin analogs.

eP962V Treatment of Colonic Varices by Multimodal Therapy on Colonoscopy

Author Achanta SCR[1]

Institute 1 KIMS Hospital, Visakhapatnam, India

DOI 10.1055/s-0046-1822314

Abstract Text

65 year old female with steatosis associated cirrhosis of liver on beta blockers for primary prophylaxis for non bleeding small esophageal varices. She presented with painless hematochezia. After initial fluid resuscitation, intravenous terlipressin and antibiotics and blood transfusion, upper esndoscopy revealed small esophgeal varices with normal stomach. Colonoscopy done after bowel preparation showed a large colonic varix in the transverse colon with signs of recent hemorrhage. Glue was injected in 2 aliquots (1.5 ml each time) using

sclerotherapy needle. Immediately after withdrawal of needle, bleeding started from the varix. 2 Hemoclips were applied on the bleeding colonic varix to acheive hemostasis. Post procedure, she recovered gradually with medical management with no recurrence. Followup colonoscopy done after 3 months showed resolution of varix (Video 1)

eP963 Complete Remission of Neoplasia After Endoscopic Therapy for Barrett's-Related Dysplasia and Early Esophageal Adenocarcinoma : A Retrospective Analysis

Authors Tomba F[1], Massella A[1], Gasparini I[1], Togliani T[1], Granato A[1], Mastromauro M[1], Tebaldi M[1], Mandello M[1], Giacopuzzi S[1], Bencivenga M[1], Frulloni L[2], De Manzoni G[1], Mirante VG[3]

Institutes **1** Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy; **2** University of Verona, Verona, Italy; **3** Azienda Ospedaliera Universitaria Integrata Verona – Gastroenterology Unit, Verona, Italy

DOI 10.1055/s-0046-1822315

Aims The current standard Endoscopic Therapy (ET) for Visible Dysplastic Lesions (VDL) and Early Adenocarcinoma (EAC) in Barrett's Esophagus (BE) is Submucosal Dissection (ESD) or Mucosal Resection (EMR) followed by Radiofrequency Ablation (RFA). However, data on long-term Complete Remission of Neoplasia (CRN) after radical endoscopic resection (R0 – defined as free deep margin) are limited [1–3].

CRN is defined as the complete absence of endoscopic and histological evidence of dysplasia/EAC after ET during the follow up.

Recent studies indicate a substantial long-term risk of neoplastic recurrence, necessitating indefinite surveillance for patients previously treated for High-Grade Dysplasia (HGD) or EAC.

The study aim was to assess the long-term dysplasia/EAC recurrence rate after achieving CRN with ET.

Methods From 2019 to November 2025 (median follow-up 24 months, range 9-74 months), 29 consecutive patients (25 M, 4 F) underwent ET for VDL or EAC in BE. Data on the baseline characteristics of BE and arising lesions, the endoscopic techniques employed and the post-resection histopathological findings were analyzed, along with the number of recurrences during the follow-up according to endoscopic european BE's guidelines.

Results Among the 29 patients, 16 had EAC, 13 had VDL (8 Low-Grade Dysplasia – LGD; 5 High-Grade-Displasia – HGD). ESD was performed in 12 cases and EMR in 17 cases. En-bloc R0 resection was achieved in 28/29 of procedures (96.5 %). The endoscopic resection wasn't curative in 2 patients: one for a positive deep resection margin and the other for lymphovascular invasion and poorly differentiated EAC. The first patient underwent surgery with histopathological evidence of EAC, the second oncological treatment for age and comorbidities. 27 patients with R0 endoscopic resection underwent to follow up.

At first endoscopic follow-up before RFA, one EAC visible lesion was detected (metachronous EAC?) and 4 invisible dysplastic lesions (3 LGD, 1 HGD) at random biopsies. The patient with metachronous EAC underwent surgery.

Two local recurrences of early cancer developed on previous positive lateral margin at first endoscopic resection were detected. One patient was managed with radical surgery and the second with another EMR.

Excluding the two patients who required surgery after non curative endoscopic resection and other two patients who underwent surgery for disease recurrence unfit for ET, CRN rate was achieved in 25/27 patients (92,6 %).

Conclusions These preliminary data, according to the last European Endoscopic BE's guidelines, confirm ET as an effective treatment option for VDL and EAC on BE with a high mid-term CRN rate either as first line or as a rescue strategy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP964 Advancing Paediatric Care in Gastroenterology:Role of Endoscopic Ultrasound in Paediatrics at a Referral Center in Pakistan

Authors Yaseen A[1], Muhammad A[2], Zakaria N[3], Altaf A[4], Niaz S[5]

Institutes **1** Sindh Institute of Advanced Endoscopy and Gastroenterology,, Karachi, Pakistan; **2** Sindh Institute of Advanced Endoscopy and Gastroenterology, karachi, Pakistan; **3** Sindh Institute of Advanced Endoscopy and Gastroenterology,, Karachi, Pakistan, Karachi, Pakistan; **4** Sindh Institute of Advanced Endoscopy and Gastroenterology, Karachi, Pakistan, Karachi, Pakistan; **5** Sindh Institute of Advance Endoscopy and Gastroenterology, Karachi, Pakistan, Karachi, Pakistan

DOI 10.1055/s-0046-1822316

Aims Endoscopic ultrasound (EUS) emerged as a revolutionary intervention, serving both diagnostic and therapeutic purposes for more than four decades among adult patients, however utility in paediatric patients remained limited due to EUS endoscope design e.g. rigidity, diameter, traumatic distal tip, furthermore complicated by need of Monitored Anesthesia Care(MAC) or General Anesthesia(GA). Fewer studies with smaller data have been conducted for EUS effectiveness and safety among children. This article aims to describe the utility of EUS for diagnostic and therapeutic purposes among children at one of the largest referral endoscopy unitsin Pakistan [1, 2].

Methods Retrospective analysis of EUS for patients ≤ 18 years of age, performed at single referral endoscopy center over 18 years, from 2007 to 2024. Data was collected from the institute's database.

Results All the procedures were performed by endoscopist who bear certified training of endoscopic ultrasound. Linear array Echoendoscope and Radial Echoendoscopes were used. A total of 124 patients ≤ 18 years age had EUS, the youngest was 5 years old with mean age of 14.75 ± 3.21years. 54 % were male gender. Primary indications for EUS examination included: 18 chronic pancreatitis, 38 pancreatic pseudocyst, 12 pancreatic mass, 4 suspected choledochal cyst, 7 patients with abdominal lymph nodes, 2 retroperitoneal lesions and 1 lesser sac lesion, 21 gastrointestinal tract lesions,. 90 EUS were performed for diagnostic purpose, 17 patients underwent FNB and 4 underwent FNA. Among Therapeutic EUS, 23 patients underwent EUS guided pseudocyst drainage, 2 patients underwent celiac plexus block referred for pain management of chronic pancreatitis, one patient underwent EUS guided pancreatic duct cannulation with stent placement and one patient underwent EUS guided anterograde rendezvous' technique- choledocoduodenostomy for choledochal cyst**.** All therapeutic procedures were performed under general anesthesia whereas diagnostic EUS were performed under monitored anesthesia care. No immediate or early complications were seen.

Conclusions In this modern era of advanced diagnostic tools and minimally invasive interventions, EUS related procedures are safe and effective in pediatric group of patients too. However, this procedure should be performed at specialized centers with experienced pediatric anesthesia team.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP965 A retrospective single-centre analysis of investigations and management of checkpoint inhibitor colitis

Authors Khan MU[1], Abduljabbar D[2], Mckay L[3], Rahania K[4], Harvey P[5], Kumar A[2]
Institutes **1** University Hospital Birmingham NHS Foundation Trust DC, Birmingham, United Kingdom; **2** New Cross Hospital, Heath Town, United Kingdom; **3** New cross, Wolverhampton, United Kingdom; **4** New Cross Hospital, Wolverhampton, United Kingdom; **5** The Royal Wolverhampton NHS Trust, Stoke-on-Trent, United Kingdom
DOI 10.1055/s-0046-1822317

Aims Checkpoint inhibitor colitis (CIC) is considered to be the most severe adverse effect for patients on immune checkpoint inhibitor (ICI) medications and is the most common cause for discontinuing immunotherapy. However, there is a scarcity in the literature on its investigations and management [1].

Methods All patients at a large district general hospital receiving ICI medications were screened between 01/01/24 – 31/12/24 for CIC. Baseline demographics, cancer diagnosis, and gastroenterology investigations and treatment variables were collected. A p-value < 0.05 was considered statistically significant.

Results Of 424 patients that received ICI medications, 67 (16 %) patients with CIC were identified. The median time from ICI to CIC was 88 days (IQR 59-214). The most common immunotherapy treatment were phosphodiesterase-1 inhibitors (49.3 %).

Cancer treatment common adverse events (CTCAE) grades 1-3 for colitis was 48.2 %, 16.1 % and 35.7 %, respectively. Thirty-two patients (48 %) required treatment with steroids, whilst the remainder settled with supportive measures only. In patients with grade 3 colitis, 90 % required steroid treatment compared to 11.1 % with grade 1 ($p < 0.001$). Of patients requiring steroids, 19 % required biologic treatment, all of whom were CTCAE grade 3 for colitis ($p = 0.001$). Twenty-three (34 %) patients underwent endoscopic evaluation. Erythema was the most common endoscopic finding in 57 % of patients, with 42 % requiring biologics compared to 0 % without erythema ($p = 0.027$). Histologically, 9 patients had acute inflammation, 6 increased apoptosis and 6 crypt distortion with other features including collagenous colitis seen less commonly. Increased apoptosis was associated with the most significant risk factor for requiring biologics (50 % versus 11.8 % without, $p = 0.051$).

Conclusions Our data demonstrates that patients with CTCAE grade £ 2 settles either spontaneously or with steroid treatment. Endoscopic findings of erythema and histological findings of increased apoptosis were associated with the need for biologic initiation. Further work is needed to explore treatment efficacy and treatment prophylaxis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

58 year old male patient presented with hematemesis. He was suffering from systemic hypertension, dyslipidemia. After initial resuscitation, intravenous fluids, pantoprazole infusion and blood transfusion, he underwent upper endoscopy, which showed an ulcer in the posterior wall of the esophagus with unhealthy margins and fresh blood noted in the lumen. A CT aortogram showed contrast extravasation from descending thoracic aorta into esophageal lumen confirming presence of aorto-esophageal fistula. He underwent cathetar aortogram which showed contrast leak in the descending thoracic esophagus into oesophagus. A fully covered aortic stent was placed in the descending thoracic aorta to control leak. He recovered with medical management and repeat endoscopy after 3 days showed signs of healing. There were no features of malignancy upon narrow band imaging and biopsy on followup.

Aims Besides malignant, gastric outlet obstruction (GOO) may develop for differentbenign diseases, including post-inflammatory stenosis of distal stomach/duodenum or duodenalinvolvement in groove pancreatitis. A novel Ultrasound-guided gastroenteroanastomosis (EUS-GE)was introduced to allow creating a direct anastomosis between the stomach and a jejunal loopthrough the placement of a metal stent (LAMS). This procedure is currently suggested to solveGOO in patients unfit for surgery. Consistent data are available on EUS-GE in neoplastic GOO,whilst data are still limited for patients with benign GOO. We aim to assess technical and clinicaloutcomes of EUS-GE in benign GOO.

Methods This was a retrospective study including patients with benign GOO treated with EUS-GEprocedure in 11 tertiary Endoscopy centers. Data about patients, procedure and outcomes wererecovered and collected in a single,

anonymized database for analysis. Technical success wasdefined as the successful placement of a stent across the site of obstruction, and clinical success asat least 1 point increase in the gastric outlet obstruction score (GOOS) system.

Results A total of 31 (67.7 % male; Median age: 69 yrs) patients were included. The mainindications for the EUS-GE procedure were: 13 (41.9 %) post peptic/caustic inflammatory stenosis,9 (29 %) groove/chronic pancreatitis, and 4 (12.9 %) post-surgical stenosis, and 5 (16 %) post morerare causes. In 19 (61.3 %) patients, previous pneumatic dilations (N = 10) or stent placement (N = 9) were unsuccessfully attempted. EUS-GE was the first-line treatment of GOO 12 cases, more thanhalf (58.4 %) of which were pancreatitis. Technical success of EUS-GE was achieved in 30 of 31(96.7 %) patients in a median procedural time of 45 minutes (30-90). The only case of technicalfailure with stent misplacing has been solved with endoscopy. In 5 (16.6 %) cases (3 bleeding and 2stent obstruction) endoscopy reintervention was needed within 30 days. In 2 cases clinicalresolution of GOO was not obtained requiring surgical intervention whereas in 93 % of patients astable benefit was maintained after median follow-up of 4 months (1-18).

Conclusions This report seems to suggest that the EUS-GE, when performed form skill operator, itis very effective procedure with an acceptable rate of complication manageable without surgery. Toextend the application of EUS-GEalso in benign chronic GOO, larger and prospective studies are need especially for what concern thelong-term management of LAMS.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP968 Advanced endoscopic multidisciplinary team meeting: a tertiary centre experience in the management of complex endoscopic cases

Authors Cossa L[1, 2], Dell'Unto E[3, 2], Maristany Bosch E[2], Kalopitas G[2], Rimondi A[4], Lazaridis N[2], Despott E[2], Murino A[5, 2]

Institutes **1** Department of Medicine, Surgery and Pharmacy, University of Sassari, Sassari, Italy; **2** The Royal Free Hospital and University College London Institute for Liver and Digestive Health, London, United Kingdom; **3** The Royal Free Hospital, University College London , London, United Kingdom; **4** Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; **5** Cleveland Clinic London Hospital, London, United Kingdom

DOI 10.1055/s-0046-1822320

Aims Multidisciplinary team (MDT) meetings are established as the standard of care in clinical pathways, ensuring that each patient receives the best management through a coordinated and evidence-based multidisciplinary assessment. This study aimed to assess the influence of MDT discussions on care pathways and their effect on patient outcomes.

Methods The Advanced-Endoscopy MDT was introduced in our Institution in 2021 to review complex luminal endoscopic cases. Weekly meetings are attended by a core consultant body including 2 interventional endoscopists, 1 GI radiologist, 1 colorectal surgeon, 1 histopathologist and 1 MDT coordinator. Endoscopic and radiological images, as well as histopathological specimens, are reviewed to recommend the best management plan. Patients are reviewed in the outpatient clinic after MDT review to discuss the benefit and risk of MDT recommendation and again after the intervention to discuss the results and further management. All cases discussed between 16th of September 2024 – 16th of September 2025 were reviewed. Demographic, clinical, endoscopic findings, and outcome data were analysed.

Results 300 cases (136 patients) were discussed over 45 meeting; 86,7 % of these were discussed at least twice. Patients were referred for colonic lesions (84 patients, 61.8 %), small bowel disease (29 patients, 21,6 %), gastric lesions (9 patients, 6,6 %) or second opinion for GI assessments (14 patients, 10 %). Most referrals (88.9 %) originated internally from the Royal Free Hospital, while 11.1 % referred from other hospitals.

Colonic lesions discussed in the MDT were treated in 93,9%, mostly with endoscopic submucosal dissection (ESD, 82,9%), achieving an R0 resection of 92,6%. 6.1 % of the patients that were not treated (one seeks a second opinion in another centre, one had a synchronous metastatic bowel cancer, and conservative management due to advanced age and complex previous medical history was adopted in other 2 cases).

Nine patients referred with gastric lesions were discussed and referred for endoscopic resection, either by ESD (5) or EFTR (2) or en-bloc EMR (2); R0 resection was achieved in all cases. Twenty-nine complex small bowel cases were discussed at the MDT and 72,4 % were referred for double balloon enteroscopy (DBE): 71,4 % for suspected small bowel lesions, 14,3 % for small bowel bleeding, 9,5 % for anaemia, and 4,8 % for a capsule retention. 24 % required additional evaluation with SBCE or further radiological imaging.

After endoscopy MDT discussion, eleven patients were referred from the endoscopy MDT to other MDTs: six cases were referred to the NET MDT, one to the Anal MDT, one to the Respiratory Team, one to the Upper GI Cancer MDT (UCLH), and two to genetic assessment. In addition, two further patients were referred straight for surgery: one with a gastric neuroendocrine tumour not amenable to endoscopic resection and one patient with sigmoid cancer and liver metastases.

No major complications were recorded. No complaints related to any of these patients were reported.

Conclusions These results suggest that the Advanced-Endoscopy-MDT improves patient care and safety through a stronger hospital governance. In addition, dedicated luminal therapeutical endoscopic pathway, promotes an efficient flow of patients both internally with other MDTs and externally with other Institutions. The MDT structure ensured appropriate referrals and coordinated care, offering a safe and satisfactory experience for patients.

DOI 10.1055/s-0046-1822321

Abstract Text

Background: type II and eosinophilic pancreatitis are two rare etiologies of pancreatitis, with an uncertain pathophysiology. The diagnosis may be challenging, especially because no clear cut-off of eosinophilic infiltration has been identify for the differential diagnosis, and it is still debated if they can be considered two separate diseases [1–5].

Case report: This is a case of a 19-year-old male who was admitted to our hospital for acute pancreatitis (acute abdominal pain, serum lipase up to 6857 mg/dl, and an enlarged edematous pancreatic gland at transabdominal ultrasound). The patient had a history of pollen allergy, recurrent episodes of diarrhea, a perforated duodenal ulcer with a need for a surgical raffia two months earlier, and a recent diagnosis of eosinophilic esophagitis with an ongoing treatment of proton pump inhibitors (PPI) twice a day.

The patient underwent a CT-scan 72 hours later, which showed a diffuse edema of the pancreatic gland without signs of necrosis. Therefore an MRI and CP-MRI were performed, confirming an enlargement of the body-tail of the pancreas, with an inhomogeneous contrast captain and an area of hypo-perfusion at the tail. The was no dilation of the biliary tree, no gallbladder stones. Serum eosinophils, triglycerides, Ig-G4, and anti-nucleus antibody (ANA) were negative, while elevated values of fecal calprotectin (790 g/g) were found.

Therefore, we decided to perform an endoscopic ultrasound (EUS) showing a diffuse enlargement of the pancreatic parenchyma, with a diffusely hypoechoic echostructure, with hyperechoic strands and dilation of secondary ducts,

without evidence of cystic or solid lesions. A heterogeneous enhancement was observed at contrast agent evaluation. A fine needle biopsy (FNB) was performed by using a 19 G needle. The histological examination was suggestive of type 2 autoimmune pancreatitis (perilobular fibrosis and parenchymal and periductal and perivascular lymphomonocytic and plasmacell inflammation, rare granulocytic epithelial lesion), although a significant eosinophilic infiltration was also observed.

The diagnostic work-up was completed with an esophagogastroduodenoscopy (EGDS), which showed signs of esophagitis and a diffuse gastritis, and a colonoscopy that demonstrated the presence of right-sided colitis. At histological examinations an eosinophilic infiltration extending to the esophagus, duodenum, and colon was found, providing a diagnosis of eosinophilic enteritis.

A multidisciplinary evaluation, including Immunologists, in a referral Center was done, concluding that this may represent a case of association of type II autoimmune pancreatitis and eosinophilic gastroenteritis, rather than a eosinophilic pancreatitis. A systemic therapy with steroids was started with a rapid clinical and biochemical amelioration.

Conclusions: this is a rare case of association of type II pancreatitis and eosinophilic gastro-enteritis. However, more defined criteria are needed for a better establishment of eosinophilic pancreatitis and type II pancreatitis.

Aims Malignant esophageal strictures are frequently managed using self-expanding metal stents (SEMS). Stent-related adverse events, especially stent dysfunction, pose a significant challenge and often require reintervention. The aim of this study was to determine predictors of stent dysfunction in malignant esophageal strictures (▶ **Table 1**).

▶ **Table 1**

Factors	Univariable Analysis		Multivariable Analysis	
	OR (95 % CI)	p-value	OR (95 % CI)	p-value
Age ≥ 65 Years	2,2 (1,2–4,4)	0,016	2,4 (1,1–5,2)	0,023
Female Sex	0,7 (0,3-1,5)	0,397		
Cardiac Comorbidity	2,3 (1,2–4,4)	0,008		
Pulmonary Comorbidity	0,8 (0,4-1,8)	0,637		
Hepatic Comorbidity	2,3 (0,6-8,3)	0,208		
Renal Comorbidity	1,4 (0,5-3,6)	0,495		
Dysphagia Score > 1	0,7 (0,3-1,3)	0,180		
Adenocarcinoma	1,8 (1,0-3,5)	0,057		
Upper Esophagus	0,9 (0,3-2,5)	0,875		
Middle Esophagus	0,6 (0,3-1,3)	0,196		
Lower Esophagus	1,6 (0,9-3,2)	0,129		
GE Junction	2,1 (1,1-4,0)	0,019		
Esophagogastrostomy	0,5 (0,1-2,5)	0,426		
Esophagojejunostomy	5,8 (1,1-31,0)	0,039	9,5 (1,6–57,9)	0,014
Stricture Length ≤ 20mm	0,8 (0,3-2,4)	0,682		
Stricture Diameter ≥ 9mm	2,2 (1,2-4,2)	0,012	2,2 (1,1–4,5)	0,024
Fully Covered SEMS	2,4 (1,3-4,5)	0,008	2,5 (1,2–4,9)	0,011
Stent Length ≤ 110 mm	1,6 (0,8-3,0)	0,181		
Stent Diameter ≤ 22mm	2,3 (1,1–4,8)	0,033		

Methods This multicenter, retrospective study included patients with malignant esophageal strictures who were treated with SEMS at three university hospitals between January 2014 and December 2023. The clinical endpoint was the occurrence of stent dysfunction, defined as impairment of lumen patency due to ingrowth, overgrowth, bolus, or dislocation. Patient characteristics, stricture features, and procedural factors were analyzed.

Results In total, 187 patients were included in the study. The mean age was 67 ± 11 years, and 78 % of the patients were male. The overall complication rate was 43 %, stent dysfunction occurred in 32 % of patients.

Univariable logistic regression analysis showed that patients over 65 years (OR 2,2; 95 % CI 1,2–4,4; p = 0,016) or with cardiac comorbidity (OR 2,3; 95 % CI 1,2–4,4; p = 0,008) experienced stent dysfunction significantly more often.

Stents placed at the gastroesophageal (GE) junction (OR 2,1; 95 % CI 1,1–4,0; p = 0,019) or an esophagojejunal anastomosis (OR 5,8; 95 % CI 1,1–31,0; p = 0,039) were more prone to dysfunction.

The risk of stent dysfunction was higher with a stricture diameter ≥ 9 mm (OR 2,2; 95 % CI 1,2–4,2; p = 0,012), and also when fully covered (OR 2,4; 95 % CI 1,3–4,5; p = 0,008) or small-diameter SEMS ≤ 22mm (OR 2,3; 95 % CI 1,1–4,8; p = 0,033) were used.

In multivariable analysis, age ≥ 65 years (OR 2,4; 95 % CI 1,1–5,2; p = 0,023), the presence of an esophagojejunostomy (OR 9,5; 95 % CI 1,6–57,9; p = 0,014), a stricture diameter ≥ 9 mm (OR 2,2; 95 % CI 1,1–4,5; p = 0,024), and the use of a fully covered SEMS (OR 2,5; 95 % CI 1,2–4,9; p = 0,011) were significantly associated with an increased risk of stent dysfunction.

Conclusions A stricture diameter ≥ 9 mm, the use of fully covered SEMS, the presence of an esophagojejunostomy, and older age were identified as independent predictors of stent dysfunction in malignant esophageal strictures. These factors should guide stent choice and individualized therapy.

DOI 10.1055/s-0046-1822323

Aims Post-ERCP pancreatitis (PEP) remains the most frequent and potentially severe adverse event of ERCP. Identifying patient and procedure related risk factors is essential to improve practice and reduce morbidity. We aimed to describe our institutional experience and assess potential predictors of PEP [1–7].

Methods We conducted a retrospective single-center study over 12 months (January–December 2024). All hospitalized patients undergoing ERCP were included. PEP was diagnosed according to clinical and biochemical criteria. Collected variables comprised patient-related data (age, sex, prior pancreatitis, bilirubin level, suspected sphincter of Oddi dysfunction) and procedure-related factors (papillary anatomy, difficulty of cannulation, inadvertent pancreatic duct opacification, prophylactic measures). Severity was assessed using SIRS criteria and CT (Balthazar classification)

Results Among 209 ERCPs, 13 PEP cases were identified (incidence 6.22 %). Mean age was 38 years (23–53), with a predominance of females (sex ratio 3.3). A history of acute pancreatitis was absent in 89.7 %. Bilirubin levels were normal in 50 %. Peri-diverticular papilla was present in 23.07 %. Difficult biliary cannulation occurred in 46.15 %, and pancreatic duct opacification in 38.46 %. Prophylactic pancreatic stenting was used in 30.76 %. All patients received rectal NSAIDs. SIRS was observed in 30.76 % of cases (Balthazar grade E). Clinical outcome was favorable in all patients, with 82.9 % hospitalized for 4–10 days.

Conclusions PEP remains unpredictable but potentially preventable. Optimized patient selection, improved technical proficiency, and systematic use of evidence-based prophylaxis including rectal NSAIDs and pancreatic stents may significantly reduce its incidence.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP972 Patients' experiences and attitudes toward the use of real-time artificial intelligence-assisted colonoscopy

Authors Lagström RMB[1], Krogsgaard M[1, 2], Kindt A[1], Besmalahi B[1], Bulut M[1, 3, 4]

Institutes **1** Zealand University Hospital, Køge, Denmark; **2** Department of People and Technology, Roskilde University, Roskilde, Denmark; **3** University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; **4** Copenhagen Academy for Medical Education and Simulation (CAMES), Copenhagen, Denmark

DOI 10.1055/s-0046-1822324

Aims There is limited knowledge about how patients experience artificial intelligence (AI) in healthcare. Concerns regarding safety and quality could be a barrier between patients and the healthcare system when implementing AI. It is crucial to understand patients´ attitudes, and how they may react to AI being implemented when aiming to preserve their trust. We investigated patients' attitudes toward AI-assisted colonoscopy to gain insights that can be used when introducing this new technology to future patients.

Methods This is a qualitative study based on semi-structured focus group interviews. Habile, Danish-speaking adults who had received an AI-assisted colonoscopy were invited. We conducted six focus group interviews, with 20 participants in total. All interviews were recorded and transcribed. Data was analysed using thematic analysis.

Results Patients described a sense of vulnerability in relation to undergoing a colonoscopy. Within this context four main themes were identified. The first theme is "Machine over man – concerns about the potential consequences of AI use during colonoscopy". The second theme is "Empathy and professionalism – Trust in AI assistance depends on human factors", and the third and fourth are "Information about AI should be proportional to the consequences" and "Trying to make sense of AI during colonoscopy – balancing curiosity, irrelevance, and vulnerability".

Conclusions Trust in AI-assistance is dependent of the healthcare providers. While AI has many strengths, it cannot provide empathy, which patients need in distressing moments, such as during a colonoscopy. If written information about AI is provided, it should be informative but concise, avoiding details that generate more confusion than clarity.

eP973 EUS-guided gallbladder drainage (EUS-GD) in elderly patients with acute cholecystitis (AC): a retrospective cohort study matched comparison with surgical cholecystectomy (SC)

Authors Andreo-Vidal BE[1], Martinez-Ortega A[1], Jimenez-Hernandez B[1], Caballero-Hernandez M[1], Bazaga S[2], Dura Gil M[3], Aranda-Olaizola G[1], Escribano de la Torre V[4], Garcia-Redero M[1], Geijo-Martinez F[1], Velasco-Guardado AJ[5], Alvarez-Delgado A[1]

Institutes 1 Complejo Asistencial Universitario de Salamanca, Salamanca, Spain; 2 Hospital General de Granollers, Granollers, Spain; 3 University Hospital of Cruces, Bilbao, Spain; 4 Salamanca University Hospital, Salamanca, Spain; 5 Digestive Diseases Unit, Salamanca University Hospital., Salamanca, Spain

DOI 10.1055/s-0046-1822325

Aims In elder patients with AC, SC is associated with a higher rate of adverse events (AEs), even in patients with low comorbidity. EUS-GD has emerged as a minimally invasive alternative for non-surgical candidates. The primary aim of this study was to compare clinical success between EUS-GD and SC in patients over 80 years old with AC. The Secondary aims included comparison of overall AEs rate, procedure-related AEs and biliary readmission (BR) between DVUSE and SC.

▶ **Table 1**

Variable	SC (n = 85)	DVUSE (n = 94)	p-value
Age	84.8 (82.8–87.1)	89.3 (87.1–92.7)	**<0,001**
Charlson comorbidity index (without age)	2 (1–4)	3.5 (2–5)	**<0.001**
Heart failure (CHF)	34.1 %	52.1 %	**0,015**
Stroke / TIA	9.4 %	26.6 %	**0,003**
Hemiplegia	0 %	5.3 %	**0,031**
Anticoagulation / antiplatelet therapy (ACO/AAS)	22.3 %	41.5 %	**0,023**
Tokyo grade (I–III)	2.19	2.11	0,423

▶ **Table 2**

	SC (n = 18)	DVUSE (n = 94)	p
Clinical success (%)	94.4 %	92.6 %	0,775
Overall adverse events (%)	44.4 %	22.6 %	0,053
Procedure-related adverse events (%)	75.0 %	24.0 %	**0,004**
Severe complications (AGREE IV–V)	20.0	13.0	0,144
Most frequent adverse events	Bleeding (27.7 %) Bile duct injury (16.6 %)	Stent obstruction (31.5 %) Migration (15.7 %)	0,038

Methods We design a multicenter retrospective cohort study including patients over 80 years old with AC who underwent either EUS-GD or SC between January 2020 and December 2024. To reduce bias due to differences in baseline characteristics (age, Charlson index) between groups, propensity score matching (PSM) was performed. The clinical success was defined as improvement in clinical symptoms and laboratory test. BR was defined as any hospital readmission due to biliary colic, recurrent cholecystitis, cholangitis, choledocholithiasis, or acute pancreatitis. AEs were classified according to AGREE classification.

Results A total of 179 patients were included (94 DVUSE vs. 85 SC). Initially, there were significant differences in baseline characteristics between groups in age (89.5 years DVUSE vs. 85.3 years SC), comorbidity (Charlson 3.6 vs. 2.4; $p < 0.001$), and associated conditions such as heart failure, cerebrovascular accident, dementia, and hemiplegia ($p < 0.05$) (▶ **Table 1**). To adjust for these differences, PSM was applied, yielding 112 comparable patients (94 DVUSE vs. 18 SC). After matching (▶ **Table 2**), clinical success was similar between groups (94.4 % SC vs 92.6 % DVUSE). The rate of adverse events was not statistically different between the two groups, although the SC group showed a higher tendency (44.4 % vs 22.6 %). However, the rate of procedure-related AEs was significantly higher in the SC group (75 % vs 44 %). There were no differences in severe or fatal AEs (AGREE IV-V) between groups. The cumulative BR after 12 moths was 6 % in SC and 16 % in EUS-GD ($p = 0.27$).

Conclusions EUS-GD provides similar clinical success compared to SC but is associated with fewer procedure-related adverse events. EUS-DGD should be considered a valid, safe, and effective alternative in patients over 80 years old with significant comorbidity (Charlson without age ≥ 3, according to our study results).

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP974 Endoscopic Submucosal Dissection of Appendiceal Lesions: Retrospective Study Comparing Adaptive Versus Conventional Traction Techniques

Authors Masgnaux LJ[1], Grimaldi J[2], Wallenhorst T[3], Romain L[4], Rivory J[5], Jacques J[6], Pioche M[5]

Institutes 1 Hospital Edouard Herriot – Hcl, Lyon, France; 2 Hospital Edouard Heriot, Lyon, France; 3 Pontchaillou University Hospital Center, Rennes, France; 4 CHU Dupuytren 1 , Limoges, France; 5 Hospices Civils de Lyon – HCL, Lyon, France; 6 CHU Dupuytren 1, Limoges, France

DOI 10.1055/s-0046-1822326

Aims Endoscopic submucosal dissection (ESD) of lesions involving the appendix remains challenging due to the complex anatomy and high risk of complications, and many patients are still referred for surgery. This study aimed to compare the efficacy and safety of ESD performed with conventional traction techniques versus the adaptive traction strategy with the ATRACT device for appendiceal lesions.

Methods We conducted a retrospective analysis of consecutive patients who underwent ESD for appendiceal lesions between November 2019 and November 2024. Patients were divided into two groups: those treated with conventional traction techniques (T-ESD) and those treated with the ATRACT device according to an adaptive traction strategy (A-ESD). The primary endpoint was lateral R0 resection at the appendiceal margin, the most critical and technically demanding component of R0 achievement because it requires dissecting as deeply as possible into the appendiceal orifice. A multivariate analysis was performed on the primary outcome, adjusting for lesion surface area, operators' mean dissection speed, lesion location, and degree of fibrosis. Secondary endpoints included overall R0 resection rate, perforation rate, and need for additional surgery.

Results A total of 137 patients were included (59 in the A-ESD group, 78 in the T-ESD group). The proportion of lesions in patients with prior appendectomy (Toyonaga 3A) was 22 % in the A-ESD group (13/59) and 32.5 % in the T-ESD group (25/77). Lateral appendiceal R0 resection was achieved more frequently in the A-ESD group (93 % vs 84 %, $p = 0.26$), although the difference did not

reach statistical significance. In the multivariate analysis, the A-ESD group showed a marked increase in lateral appendiceal R0 resection (OR 2.168 [0.702–7.760], p = 0.183), although the study lacked sufficient power for this effect to reach statistical significance. Overall R0 resection was also slightly higher with A-ESD (82.5 % vs 80.5 %, p = 1.00). The rate of secondary surgery was 5.3 % in the A-ESD group (3/57: 2 for perforation, 1 for invaded appendiceal margin) compared with 7.8 % in the T-ESD group (6/76: 1 for perforation, 5 for invaded appendiceal margin). Perforation rates were similar (12 % vs 10 %, p = 0.95). These findings suggest that adaptive traction may improve exposure of the appendiceal margin, thereby reducing the need for rescue surgery, without increasing perforation risk.

Conclusions The findings suggest that the ATRACT device may increase lateral appendiceal R0 resection rates and reduce the need for additional surgery for involved appendiceal margins, without increasing perforation risk. However, the study lacks statistical power due to its limited sample size. Adaptive traction may therefore be particularly advantageous for ESD in this technically challenging location.

eP975 A Rare Cause of Diarrhea in a Patient with Severe Scoliosis

Authors Tadic V[1], Scheppach MW[1], Messmann H[1], Nagl S[1]
Institute 1 University Hospital Augsburg, Augsburg, Germany
DOI 10.1055/s-0046-1822327

Case Presentation A 34-year-old male with severe scoliosis, neurodisability, immobility, and significant weight loss was admitted to our hospital with six weeks of profuse diarrhea and subsequent hypokalemia. Prior stool cultures were negative for common infectious pathogens. The patient had been receiving enteral nutrition via a PEG tube placed three years earlier without complications, and confirmed intragastric position of the PEG plate. Enteral feeding had been well tolerated since that time.

Index esophagogastroduodenoscopy (EGD) and colonoscopy demonstrated complete intraluminal migration of the PEG into the colon. Computed tomography (CT) confirmed colonic migration of the PEG, showing contrast filling the descending colon. The PEG tube was removed, and the colonic fistulous opening was closed using multiple through-the-scope clips (TTSCs). Owing to an unfavorable anatomic configuration resulting from severe scoliosis (specifically, a retrohepatic/retrocardiac stomach with interposed colon), replacement of the PEG was deemed unsafe by both endoscopic and radiologic assessment. A nasogastric tube was inserted for temporary enteral access. Subsequently, a surgical fine-needle catheter jejunostomy (FKJ) was placed for permanent enteral access. Due to persistent intolerance of enteral nutrition, long-term parenteral nutrition via an implanted port was initiated.

During follow-up, recurrent feculent drainage from the stomach prompted repeat endoscopic evaluation. Combined EGD and colonoscopy revealed a reopened gastrocolic fistula with migration of the nasogastric tube into the colon. The fistula was successfully closed using TTSCs on the colonic side and an over-the-scope clip (OTSC) on the gastric side. Post-intervention imaging confirmed complete closure of the fistula without contrast leakage. Retrospectively, it must be assumed that at initial PEG placement an interposed colon was punctured and traversed by the PEG tube, despite correct intragastric positioning of the PEG plate.

Conclusion In patients with severe scoliosis, PEG placement should prompt consideration of adjunctive imaging to verify appropriate anatomical positioning and prevent unrecognized transcolonic placement.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP976 Screening colonoscopy in the elderly – when to stop?

Authors Waldmann E[1], Zessner-Spitzenberg J[1], Klinger A[1], Kammerlander A[2], Demschick A[3], Penz D[4], Rockenbauer LM[5], Asaturi A[1], Trauner M[5], Ferlitsch M[5]
Institutes 1 Medical University of Vienna, Wien, Austria; 2 Medical, Vienna, Austria; 3 Medical U, Vienna, Austria; 4 Klinik Floridsdorf, Vienna, Austria; 5 Medical University of Vienna, Vienna, Austria
DOI 10.1055/s-0046-1822328

Aims To analyze the association between detected lesions at colonoscopy, cancer related death and all-cause mortality in individuals < 75 and ≥ 75 years of age.

Methods We analyzed colonoscopies performed within a national colorectal cancer screening program in Austria.

Results 448,606 colonoscopies were analyzed, 394,917 in individuals < 75, and 43,689 in individuals ≥ 75 years. Sex distribution in both groups were almost equal. The distribution of negative colonoscopies, colonoscopies with low-risk and high-risk lesions, according to the ESGE post-polypectomy surveillance guidelines, were distributed as follows: 62.1 %, 32.5 %, and 5.4 % overall, 62.3 %, 32.5 %, and 5.2 % in individuals < 75, and 59.6 %, 32.9 %, and 7.5 % in individuals ≥ 75 years of age. Colorectal cancer related mortality was significantly increased in individuals ≥ 75 years with high-risk lesions while overall mortality was similar in all risk groups.

Conclusions Colorectal cancer screening in the elderly should focus on individuals with high-risk lesions in prior colonoscopies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP977 Is the double-wire cannulation technique superior to precut or transpancreatic sphincterotomy for difficult biliary access? A real-life multicenter registry study

Authors Papatzelou I[1], Nakou E[2], Voudoukis E[3], Trimponias G[3], Theocharis G[4], Giannis A[5], Gkolfakis P[5], Triantafyllou K[5], Kalochristiannakis M[6], Augoustaki A[7], Valatas V[8], Moutzoukis M[9], Papadopoulos V[10], Christodoulou D, Kalaitzakis E[8]

DOI 10.1055/s-0046-1822329

Aims Common bile duct cannulation can be achieved with various techniques, depending on factors such as ampulla anatomy, technical difficulties, and endoscopist preference. Advanced cannulation techniques (eg transpancreatic sphincterotomy/precut sphincterotomy and the double-wire technique) are mostly used in cases of difficult cannulation. Our aim was to compare advanced cannulation techniques in terms of cannulation success and adverse event rates using real-life data from the Greek ERCP registry.

Methods We conducted a multicenter observational study with prospectively collected data from the Greek national ERCP database. The registry was searched for ERCP cases performed January 2023 – September 2025, in patients with naïve ampulla of Vater. We performed univariate and multivariate analyses.

Results A total of 1693 ERCP procedures in patients with naïve ampulla of Vater were included (mean age 73 yo (SD 15.7), 69.4 % with bile duct stones, 36.4 % jaundice, 15.7 % cholangitis/sepsis, 11.5 % biliary stricture). The most frequent-

ly used cannulation technique was conventional guide-wire guided cannulation (n = 1283, 80.4 %), followed by transpancreatic sphincterotomy (n = 140, 8.8 %), double-wire (n = 97, 6.1 %), precut sphincterotomy (n = 72, 4.5 %) and "rendezvous" (n = 4, 0.3 %). Overall, 51.3 % of the cases were performed electively, most patients had an ASA score of 2 (42.5 %, 27.9 % score 1, 25.7 % score 3, 3.8 % score 4 and 0.2 % score 5) and the most common type of sedation was conscious sedation (82.9 % followed be 16.4 % deep sedation and 0.7 % general anesthesia). The overall deep bile duct cannulation success rate was 94.1 %. The cannulation success rate was higher in the double wire technique (100 %) compared to transpancreatic/precut sphincterotomy (89.6 %, p < 0.01). The overall adverse event rate was 9.8 % (post ERCP pancreatitis 6.5 % and post ERCP cholangitis 5.8 %). The overall adverse event rate did not differ significantly between the double-wire (6.2 %) and the transpancreatic/precut sphincterotomy group (11.3 %, p = 0.1), and the same was true for post ERCP cholangitis, perforation, bleeding, respiratory or cardiovascular adverse events (p > 0.05 for all). However, the post ERCP pancreatitis rate was higher with the double-wire technique (17.5 %) compared to the transpancreatic/precut sphincterotomy group (8.5 %, p = 0.02). In multivariate analysis the use of transpancreatic or precut sphincterotomy vs double wire technique was not an independent predictive factor of cannulation failure (p = 0.9).

Conclusions In a real-life multicenter registry study, there do not appear to be major differences in cannulation success among different advanced cannulation techniques. Further randomized trials are warranted.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP978 Endoscopic Therapy for Post-Cholecystectomy Biliary Strictures: Multiple Plastic Stents Versus Fully Covered Self-Expandable Metal Stents – A Scoping Review

Authors Dakka A[1], Shvarts B[1], Barkay O[1, 2]
Institutes **1** Barzilai Medical Center, Ashkelon, Israel; **2** Ben-Gurion University of the Negev, Beer-Sheva, Israel
DOI 10.1055/s-0046-1822330

Aims Post-cholecystectomy benign biliary strictures (PCBS) represent a significant clinical challenge, occurring in 0.3–0.7 % of laparoscopic cholecystectomies. Despite their clinical impact, the optimal endoscopic management strategy remains ill-defined, particularly regarding the choice between multiple plastic stents (MPS) and fully covered self-expanding metal stents (FCSEMS). This scoping review therefore aimed to synthesize the current evidence on PCBS management and identify areas requiring further research.

Methods We conducted a systematic search of PubMed, Embase, Scopus, and ClinicalTrials.gov for all publications through 14 October 2025, following Joanna Briggs Institute (JBI) and PRISMA-ScR guidance. The search strategy combined database-specific subject headings (e.g., MeSH, Emtree) and free-text keywords related to PCBS and their endoscopic management with MPS and FCSEMS. Two authors independently screened all titles, abstracts, and full-text articles for eligibility, with discrepancies resolved by consensus.

Results Following deduplication, 3,231 records were screened, with 3,063 excluded at the title and abstract stage. The remaining 168 articles underwent full-text review, of which 64 met the inclusion criteria and were incorporated into the synthesis. Conference abstracts meeting criteria were also included but are presented separately.

Among studies reporting outcomes for PCBS patients treated with MPS, most cohorts comprised predominantly homogeneous PCBS populations, with restenosis rates ranging from 0 % to 33.3 % (median 10.2 %, IQR 5.3 %–18.5 %). In contrast, substantially fewer studies reported sufficient numbers of PCBS patients treated with FCSEMS, with reported restenosis rates ranging from 10.7 % to 15.4 % (median 13.1 %).

Only one randomized comparative trial (Coté et al., JAMA 2016) directly compared FCSEMS with MPS; however, outcomes were not stratified by stricture etiology, precluding extraction of PCBS-specific data. Several additional studies evaluated heterogeneous postoperative benign biliary stricture cohorts without separately reporting outcomes for the PCBS subgroup.

Conclusions Available evidence suggests that MPS therapy provides favorable long-term outcomes for PCBS. Although FCSEMS may demonstrate comparable long-term results, the evidence is less well established owing to the scarcity of PCBS-specific data. Heterogeneous definitions of restenosis, inconsistent follow-up, and the absence of rigorous comparative trials further limit evidence-based stent selection. These gaps highlight the need for prospective, etiology-specific studies using standardized outcome definitions to guide optimal endoscopic management of PCBS.

eP979 Predictive Factors of Inadequate Bowel Preparation

Authors Aissat Y[1], Ziane I[2], Saichi S[3], Meriem HR[3], Hamidouche D[4], Benrabia A[3], Mitiche A[5], Aissaoui M[3], Boutaleb FA[3], Mahiou H[6], Osmane R[4]
Institutes **1** CHU BAB ELOUED, Algiers, Algeria; **2** CHU Bab El Oued, Bab El Oued, Algeria; **3** CHU Lamine Debaghine, Bab El Oued, Algeria; **4** Hopital mayo, Bab El Oued, Algeria; **5** Chu lamine debaghine, bab el oued, algeria, algier, Algeria; **6** Chu lamine debaghine, bab el oued, algiers, Algeria
DOI 10.1055/s-0046-1822331

Aims Despite significant technological progress in endoscopic imaging and device performance, the usefulness of these advances remains highly dependent on bowel preparation quality. The aim of this study was to identify **predictive factors of inadequate bowel preparation**

Methods This was a prospective study conducted as part of a professional practice evaluation in the digestive endoscopy unit of the Hepato-Gastroenterology Department at **Bab El Oued University Hospital**, during the period from january to july 2024.Polyethylene glycol (PEG) was used as the bowel preparation agent.Preparation quality was assessed using the **Boston Bowel Preparation Scale (BBPS)**, with inadequate preparation defined as a total score **strictly below 7**.Data were analyzed using SPSS v20, including univariate analyses (Chi-square test, ROC curve) and multivariate logistic regression [1–3].

Results A total of **227 patients** were included. The mean age was **52.39 ± 18.85 years** and the sex ratio was **0.91**. The complete colonoscopy rate was **74.9 %**. A split-dose regimen was used in **77.5 %** of cases, and good tolerance to preparation was reported in **63 %** of patients.Inadequate bowel preparation was observed in **47.6 %** of cases.

Multivariate analysis identified three independent predictors of inadequate preparation: **Constipation** (OR = 0.4; p = 0.008),**History of abdominal or uterine surgery** (OR = 0.46; p = 0.027),**Interval > 5 hours** between the last PEG intake and the colonoscopy (OR = 0.4; p = 0.005)

Conclusions This prospective study identified three independent predictors of inadequate bowel preparation, mainly related to patient factors: **constipation**, **previous abdominal/uterine surgery**, and a **delay exceeding 5 hours** between the last PEG dose and the colonoscopy. Optimizing these factors could improve preparation quality and enhance colonoscopy outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A 65-year-old woman with right hepatectomy for hydatidosis and history of ERCPs in other center for biliary stricture was referred to our hospital. Cholangiography revealed a stricture at the hepatic hilum with a 30 mm-dilatation of intrahepatic duct. An attempt to cannulate the intrahepatic ducts with a guidewire and sphincterotome was unsuccessful. Cholangioscopy identified the stricture with an impacted stone. Electrohydraulic lithotripsy was carried out, after which a bundle of suture material was visualized. Using SpyBite, part of the suture was grasped and removed. Subsequently, guidewire passage across the stricture was achieved. The stricture was dilated with a 6-mm Hurricane balloon, and a 10 Fr × 15 cm straight plastic stent was placed. Post-surgical biliary strictures represent a diagnostic and therapeutic challenge. Cholangioscopy is very useful for the diagnosis and management of complex biliary strictures.

eP981 Perceived Stress and Its Influence on Procedural Performance Among Interventional GI Endoscopists

Authors Zouaki I[1], Ait Errami A[2], Krati K[2], Nacir O[3], Fatima Ezzahra L[2]

Institutes 1 UHC MED VI, Marrakesh, Morocco; 2 CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco; 3 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco

DOI 10.1055/s-0046-1822333

Aims nterventional gastrointestinal endoscopy requires advanced technical expertise, rapid problem-solving, and sustained cognitive focus. These demands expose operators to significant acute stress, yet its prevalence, determinants, and impact on clinical performance remain insufficiently characterized. Understanding stress within this high-stakes specialty is essential for optimizing patient safety, supporting practitioner well-being, and guiding institutional training policies.

Methods We conducted a cross-sectional, anonymous global survey of practicing interventional gastrointestinal endoscopists (IGE). The questionnaire comprised five domains: demographics and workload, perceived stress (including an adapted work-related Perceived Stress Scale), impact on procedural performance, coping strategies, and professional views on training. Descriptive and inferential statistics were applied to assess stress prevalence and explore associations between stress scores and practitioner characteristics.

Results A total of 100 IGE participated. Most respondents were male (84 %), aged 30–50 years (82 %), and had more than 5 years' interventional endoscopy experience (53 %). Despite this seniority, 56 % reported experiencing stress "sometimes," 19 % "often," and 2 % "always." The mean work-related PSS score was 20.75 (SD 3.36), indicating moderate procedural stress, with similar levels for general perceived stress. Stress was perceived to impair concentration mildly (61 %) or moderately (24 %), and 11 % reported substantial performance impairment. Nearly half (48 %) attributed at least some procedural failures to stress, and 39 % reported stress-related delays within the previous month. Only 15 % had received formal stress-management training, yet 74 % believed such strategies could enhance performance, and 78 % supported simulation-based training under controlled stressful conditions. No significant associations were observed between stress scores and demographic variables.

Conclusions Acute stress is prevalent among interventional gastrointestinal endoscopists and is widely perceived to detrimentally affect concentration and procedural performance. The paucity of structured stress-management training and the strong practitioner support for simulation-based approaches highlight an important opportunity to implement targeted interventions aimed at improving both operator well-being and procedural safety.

eP982 Incidence and Risk Factors of Post-Colonoscopy Infections in Liver Transplant Candidates: A Retrospective Cohort Study

Authors Vandebroek V[1], Laleman W[2, 1], Van der Merwe S[1], Demedts I[3], Verbeek J[1], van Malenstein H[1]

Institutes 1 University Hospital Leuven, Leuven, Belgium; 2 Department of Internal Medicine B, University of Münster, Münster, Germany; 3 Department of Translational Research in Gastrointestinal Diseases (TARGID), KU Leuven, Leuven, Belgium

DOI 10.1055/s-0046-1822334

Aims Liver transplant candidates, especially those with cirrhosis are more prone to infections, which may be precipitated by semi-invasive procedures like colonoscopy. Limited data exist on infection rates post-colonoscopy and risk factors in this population. This study aimed to determine the incidence of post-colonoscopy infections and identify associated risk factors in patients awaiting liver transplantation.

Methods A retrospective single-centre cohort study included 141 adult liver transplant candidates who underwent screening colonoscopy at a Belgian tertiary hospital (2019-2023). Inclusion required ≥ 24h post-procedural observation. Infection was defined as fever ≥ 38 °C, leucocytosis (> 12,000/µL), need for antibiotics or bacteraemia within 72 hours. Data on demographics, liver disease severity (MELD/Child-Pugh), comorbidities and procedural characteristics such as bowel preparation adequacy, sedation type, polypectomy were analysed. Both univariate, as well as multivariate backward logistic regression analysis was performed to identify risk factors for infections.

Results The overall infection rate was 6.4 % (9/141), rising to 8.9 % (9/101) in cirrhotic patients. Documented infections included bacteraemia, spontaneous bacterial peritonitis, and pneumonia. In univariate analysis significant risk factors were higher Child-Pugh score ≥ 9 (p = 0.04), ascites grade ≥ 2 (77.8 % vs. 36.4 %; p = 0.028), and diverticulosis (55.6 % vs. 18.2 %; p = 0.018). In multivariate analysis MELD score (p = 0.032), Child Pugh ≥ 9 (p = 0.01), INR (p = 0.024), ascites grade ≥ 2 (p = 0.068) and diverticulosis (p = 0.027) were independent risk factors for infections. Inadequate bowel preparation occurred in 29.1 % but was not associated with infection. No significant associations were found for antibiotic/immunosuppressive use, polypectomy, or sedation type and risk for infection.

Conclusions Liver transplant candidates, particularly those with advanced cirrhosis (higher MELD score and Child-Pugh ≥ 9), increased INR, ascites grade ≥ 2 or diverticulosis, face substantial infection risk (6.4-8.9 %) after screening colonoscopy. Heightened clinical vigilance and optimized preventive strategies are warranted in this high-risk population.

DOI 10.1055/s-0046-1822335

Aims Gastric cancer (GC) presents with variable incidence across the globe, which is translated to different screening approaches. Various guidelines attempt to present the optimal strategies for GC and premalignant conditions management; however, it is not recorded whether endoscopists comply with these recommendations. This study aimed to illustrate the current screening practices, adherence to guidelines, and variability in GC management among different countries.

Methods A web-based cross-sectional survey of 28 items was distributed to various countries by individuals who were members of either World Endoscopy Organization (WEO) Emerging Stars or European Society of Gastrointestinal Endoscopy Young Endoscopists (EYE) Committee through September 2025. Questions about endoscopists' status, screening and sampling for GC and premalignant lesions during esophagogastroduodenoscopy (EGD), post-diagnosis surveillance, counseling and treatment policies were included. Data were analyzed using descriptive statistics, and potential associations were investigated using chi-square test and multi-nominal regression analysis. Statistical significance was set at a p-value £ 0.005.

Results Eight hundred and twenty physicians from 20 countries participated in this questionnaire-based survey. The majority of them were Europeans (62.8 %), but endoscopists from every continent were included. Age-standardized rate (ASR) of GC was < 10 per 100,000 person-years in all of the included countries, except for Japan, according to the GLOBOCAN 2022 records. In South America, a variety of answers about the existence of formal GC screening programs was recorded, ranging from 20 % to 35 %. EGD is performed at a high rate (18.2-50 %) regardless of a clear indication in several countries (Italy, Kenya, Brazil). Considering the quality of service, although high-definition equipment with virtual chromoendoscopy is available in every country, in some of them (Kenya, Serbia, Greece, Brazil and other Latin American countries) a high percentage of endoscopists (20-75 %) only has access to conventional white light endoscopes. Likewise, expert upper GI pathologist is readily available for less than 50 % of endoscopists in 11 out of 20 countries. Chi-square test indicated that the regional ASR, level of training, professional status and working place were associated with the different practices of physicians in GC surveillance. In the multi-nominal analyses, the country of practicing and the dedicated training in EGD and chromoendoscopy were more commonly associated with the differences in screening strategies, adherence to guidelines, endoscopy process and quality indicators. Contrariwise, endoscopists' age, current status (supervised or independent trainee or fully competent endoscopist) and institution of practicing (public, academic or private sector) were not significantly associated with the investigated parameters.

Conclusions Despite the existence of established guidance on GC screening and premalignant lesions management, there is a broad heterogeneity in the applied practices across the globe mainly associated with the country of practicing and the specialized training in upper GI endoscopy. These findings might be affected by the design of the study and the different number of physicians per country who answered the questionnaire. Therefore, national endoscopy societies are encouraged to record their internal variances to achieve uniform policies and compliance to the guidelines for GC and premalignant conditions management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP984 Virtual Chromoendoscopy with Linked Color Imaging versus Dye Chromoendoscopy in the surveillance of Patients with Long-standing Colonic Inflammatory Bowel Disease

Authors Gabbiadini R[1], franchellucci G[2, 1], Minini F[3], Dal Buono A[1], Privitera G[1], Spadaccini M[4, 2], Migliorisi G[1], Petronio L[5], Bezzio C[4], Hassan C[4, 2], Repici A[4, 2], Alessandro A[1]

Institutes **1** IBD Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; **2** Endoscopy Unit, IRCCS, Humanitas Research Hospital, Rozzano, Italy; **3** Endoscopy Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; **4** Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy; **5** Endoscopy Unit, IRCCS Humanitas Research Hospital, Milan, Italy

DOI 10.1055/s-0046-1822336

Aims The iam of the study is compare the performance of virtual chromoendoscopy (VCE) using Linked Color Imaging(LCI) and dye-chromoendoscopy (DCE) with methylene blue for the detection of colonic neoplasticlesions during surveillance colonoscopy in patients with inflammatory bowel disease (IBD), since curently data on LCI performances ford etecting dysplasia specifically among IBD patients undergoing surveillance remain scarce compare to other virtual chromoendoscopy technology including Narrow Band Imaging (NBI, Olympus, Japan) or i-SCAN (Pentax, Japan).

Methods This is a single-centre retrospective cohort study included patients with colonic IBD undergoingcolorectal cancer (CRC) surveillance colonoscopy between June 2018 and December 2024. The primary outcome was the detection of total neoplastic lesions, defined as the mean number ofneoplastic lesions detected per colonoscopy, including colitis-associated dysplasia,adenocarcinoma, sporadic adenoma, serrated lesions, by targeted biopsies or polypectomy witheither DCE or LCI in subjects with long-standing colonic IBD. The secondary outcome was theneoplastic lesions detection rate, defined as the proportion of colonoscopies with at least oneneoplastic lesion over the total number of colonoscopies

Propensity-score matchingand multivariable Poisson and logistic regression were used to adjust for baseline differences andidentify independent predictors.

Results A total of 404 patients underwent surveillance colonoscopy during the study period, 135 with DCEand 269 with LCI. After exclusion of 93 patients because of inadequate bowel preparation orendoscopically active disease (23

in the DCE group, 70 in the LCI group, Figure 3), 311 wereincluded in the final analysis (112 DCE, 199 LCI). Due to the retrospective design, baseline characteristicswere not fully balanced between the two groups. Compared with the LCI group, patients in the DCE group had a longer disease duration (19.58 vs 17.12 years, p = 0.021), a higher prevalence ofextensive (E3) UC, a higher frequency of concomitant primary sclerosing cholangitis, and a greaterproportion with a personal history of colonic lesions. A first-degree family history of colorectalcancer (CRC) was also more common in the DCE arm. After the 1:1 propensity-score matching, 208 procedures (104 DCE and 104 LCI) were available foranalysis.

Neoplasia detection did not differ significantly between DCE and LCI. The mean number ofneoplastic lesions identified per colonoscopy was 0.116 with DCE and 0.085 with LCI (p = 0.472).Similarly, the neoplasia detection rate was comparable between techniques (8.03 % for DCE vs7.53 % for LCI; OR 1.07, 95 % CI 0.45-2.54, p = 0.874). After 1:1 propensity score matching, thechromoendoscopy modality (LCI vs DCE) was not associated with the total number of neoplasticlesions (IRR 0.77; 95 % CI 0.34–1.78; p = 0.543) and with the neoplastic lesions detection rate (OR0.58; 95 % CI 0.21–1.65; p = 0.310).

Conclusions LCI-based VCE provides a neoplastic yield comparable to traditional DCE in patients with long-standing colonic IBD undergoing surveillance colonoscopy. As with other VCE modalities, LCImay be adopted as an acceptable alternative to DCE for dysplasia surveillance in IBD.

DOI 10.1055/s-0046-1822337

Aims To describe the **epidemiological, clinical, and therapeutic characteristics** of foreign bodies in the upper GI tract

Methods This is a **retrospective, single-center descriptive study** including patients admitted for management of upper GI tract foreign bodies between january 2018 and August 2025 at **Bab El Oued University Hospital**. Patients managed in the emergency department were excluded. Data analysis was performed using **SPSS v24**

Results A total of **80 patients** were included, with a sex ratio of 0.9. The mean age was **44 years** (range: 15–60). In **72.5 %** of cases, the context of ingestion was known, of which **70 % were accidental** and **2.5 % intentional**. The main presenting symptoms were **dysphagia** and **hypersalivation**[1–3].

Standard radiological exams were performed in **100 %** of cases, whereas **only one patient** underwent a CT scan,which did not reveal complications.Upper endoscopy (esophagogastroduodenoscopy) was performed in **70 %** of cases. The foreign body was located in the **esophagus** in **50 %** of cases, and **pre-existing esophageal lesions** were found in **22.5 %** of these patients. Endoscopic removal was successful in **75 %** of cases. **Only 3.3 %** of patients required surgical intervention.

Conclusions In our experience, Foreign body ingestion was predominantly **accidental**. Diagnosis relies primarily on **endoscopy**, which allows visualization and removal in most cases. However, **surgical intervention** may be required in selected situations

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822338

Aims Quality assessment is a priority in the field of gastroenterology. However, limited data are available from Greece regarding adherence to quality standards in gastrointestinal endoscopy. This study aims at assessing the knowledge and compliance of Greek gastroenterologists with established quality standards for upper and lower digestive endoscopy, while exploring factors that may influence compliance [1].

Methods This prospective study recorded data on the quality of upper and lower digestive endoscopy performed in Greece from October 2024 to January 2025. All members of the Hellenic Society of Gastroenterology (n = 668) were invited to participate via an electronic survey. The survey included a questionnaire designed specifically for this study, covering demographic and professional characteristics, as well as quality indicators for gastroscopy and colonoscopy.

Results A total of 164 gastroenterologists participated (response rate 24.55 %), of whom 107(65.24 %) were male, and 102(62.2 %) working in public or academic hospitals. The duration of gastroscopy was not recorded by 116(70.73 %) participants, while 102(62.2 %) systematically used photodocumentation. Most participants utilized the Prague and Los Angeles classifications (156, 95.12 % and 159, 96.95 %, respectively). Additionally, 140(85.37 %) followed the Seattle protocol, and 158 (96.34 %) conducted biopsies according to ESGE guidelines for precancerous gastric lesions. However, 83(50.61 %) don’t use a registry for patients with Barrett’s esophagus. Complications were systematically recorded after gastroscopy by 103(62.8 %) and after colonoscopy by 90(54.88 %).In colonoscopy, 149(90.85 %) use the BBPS scale, and 158(96.34 %) reported successful cecal intubation. Withdrawal times exceeded six minutes for 151(92.07 %) participants. An adenoma detection rate of over 25 % was achieved by 117(71.78 %), while 103(62.8 %) consistently used the Paris classification. Proper polypectomy techniques were employed by 111(67.68 %), but 100(60.98 %) recommended follow-up intervals shorter than guidelines suggest. Patient experience following gastroscopy and colonoscopy was not

recorded by 126(76.83 %) and 116(70.73 %) participants, respectively. Overall, compliance with quality indicators for upper and lower digestive endoscopy was observed in 87(53.05 %) and 75(45.73 %) participants, respectively. Multivariate analysis revealed that greater experience (p = 0,05), the use of video recording (p = 0,01), and use of high-resolution endoscopes (p < 0,01) were associated with improved compliance.

Conclusions In this study, discrepancies were observed in the compliance of Greek endoscopists with endoscopic quality indicators, highlighting the need for further improvement. The systematic recording of these quality indicators is essential, highlighting the important role of scientific societies in this process.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP987 Cap-assisted colonoscopy increases polyp detection rate but does not affect the adenoma detection rate

Authors Ioannou A[1], Pardalis P[1], Delidis T[1], Dimitriadis K[1], Bakogiannis K[1], Koumentakis C[1], Vassilieva L[1], Leonidakis G[1], Zampeli E[1], Michopoulos S[1]

Institute **1** Gastroenterology Department, "Alexandra" General Hospital of Athens, Athens, Greece

DOI 10.1055/s-0046-1822339

Aims Evaluation of the use of CAP in lower digestive tract endoscopies in terms of polyp detection rate (PDR) and adenoma detection rate (ADR).

Methods Prospective registration of consecutive patients with lower GI endoscopy with or without the use of CAP. Demographic, clinical and endoscopic data (cleanliness, cecal catheterization, polyp detection) as well as the pathological result were recorded. Bowel cleanliness was assessed with the BBPS scale (Optimal: 9, Suboptimal: 6-8). All endoscopies were performed under conscious sedation by residents with supervision and/or assistance from specialists using high-resolution endoscopes (Olympus CF-H185L, CF-HQ190L) and CO_2 insufflation [1, 2].

Results 440 endoscopies were analyzed [(260F/180M, median age 63 years [(IQR 55-70)]. 87 (19.8 %) without the use of CAP and 353 (80.2 %) with the use of CAP. The mean BBPS value was 8.32 ± 1.01 and there was no difference between optimal and suboptimal preparation between the 2 groups (with or without CAP). In total, polyps were found in 350 endoscopies with PDR 79.5 % while in 228 endoscopies adenomas were found with ADR 51.8 %. In the 353 endoscopies with the use of CAP, polyps were found in 289 (PDR:81.8 %) and adenomas in 185 (ADR 52.4 %) while in the 87 without the use of CAP, polyps were found in 61 (PDR 70.1 %) and adenomas in 44 (ADR 50.6 %). Statistical analysis (χ2 test) revealed that the use of CAP helped in the detection of polyps by significantly improving the PDR (OR = 1.92, 95 %CI: 1.13-3.28; p = 0.015) but did not contribute to the detection of adenomas and therefore did not improve the ADR to statistically significant levels (OR 1.12, 95 %CI: 0.7-1.8; p = 0.61). In the univariate analysis, age was also significantly associated with PDR (p = 0.001), whereas sex, bowel preparation quality, and endoscopist experience (senior vs fellow) showed no significant associations. In the multivariable model adjusting for age, sex, bowel preparation quality, endoscopist experience, and bisacodyl use, cap-assisted colonoscopy remained an independent predictor of improved PDR (OR = 0.56, 95 % CI: 0.34–0.95; p = 0.030). Bisacodyl use was also associated with higher PDR (p = 0.034), while sex, preparation quality, and endoscopist level showed no significant associations (▶ **Table 1**).

▶ **Table 1**

	Use of CAP (353 colonoscopies)	No CAP (87 colonoscopies)	p
Polyps	289	61	0.015
Adenomas	185	44	0.61

Conclusions The use of CAP significantly improves polyp detection and remains an independent predictor of higher PDR after adjustment for key confounders, whereas it does not improve the ADR

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822340

Aims Endoscopic recurrence after ileocecal or ileocolic resection in Crohn's disease occurs in up to 70 % of patients within one year without prophylactic therapy. Identifying risk and protective factors is crucial for patient management. This study aimed to assess recurrence rates and associated factors in a single-center cohort [1, 2].

Methods Retrospective study including Crohn's disease patients undergoing ileocecal or ileocolic resection between 2000 and 2023, with endoscopic follow-up. Primary endpoint: endoscopic recurrence (Rutgeerts score). Statistical analysis was performed using SPSS 23.

Results Among 181 patients (113 women, 68 men; mean age 31 years), 56.9 % had ileal disease and 43.1 % had ileocolic disease; 43.1 % had penetrating phenotype. Indications for surgery included stenosis (40 %), penetrating disease (35 %), obstruction (23 %), and perforation (2 %). Anastomosis was mainly end-to-side (84 %), side-to-side in 4 %. Preventive therapy was given to 78.5 % (thiopurines 59.9 %, anti-TNF 24.6 %). Endoscopic recurrence occurred in 60.8 % (i2 17.1 %, i3 19.3 %, i4 25.4 %). Clinical recurrence was observed in 37 %, and surgical recurrence in 18 % after a median of 6 years.

Penetrating phenotype was identified as a risk factor, while side-to-side anastomosis (P = 0.009) and early prophylactic therapy with thiopurines (P = 0.027) or anti-TNF (P = 0.011) were protective.

Conclusions Endoscopic recurrence after ileocolic resection is frequent. Penetrating phenotype increases recurrence risk, whereas side-to-side anastomosis and early preventive therapy reduce it. Early endoscopic monitoring and tailored prophylaxis are essential to improve outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP989 When ERCP alone is not enough: Rendezvous repair of complete bile duct transection

Authors Caballero-Hernandez M[1], Escribano de la Torre V[2], Aranda-Olaizola G[1], Andreo-Vidal BE[1], Jimenez-Hernandez B[1], Garcia-Redero M[1], García Martín A[2], Vicente López S[2], Gomez-Hidalgo R[1], Tejerizo-García L[1], Segarra Ortega JX[2], Geijo-Martinez F[1], Martinez-Ortega A[1], Velasco-Guardado AJ[3], Alvarez-Delgado A[1]

DOI 10.1055/s-0046-1822341

Background A 45-year-old woman with a history of cholelithiasis, choledocholithiasis and benign biliary stricture developed necrotizing pancreatitis with extensive intra-abdominal collections. After laparotomy for perforated cholecystitis with purulent peritonitis, she presented a vascular injury leading to hepatic ischemia and bile duct perforation secondary to a complicated cholecystectomy.

Case report The patient underwent ERCP revealing a normal intrapancreatic bile duct with complete transection at the level of the common hepatic duct (Figure 1, Figure 2), with contrast filling of a heterogeneous subhepatic collection and spontaneous biliary drainage through the papilla (Figure 3).

Endoscopic recanalization of the intrahepatic duct or common hepatic duct was not technically achievable. Interventional radiology performed a percutaneous transhepatic cholangiography with placement of an internal–external biliary drain.

During a second ERCP, a guidewire was advanced through the percutaneous drain and retrieved endoscopically in the duodenum ("rendezvous"). A guidewire was then passed into the right hepatic duct and subsequently into the left hepatic duct. Plastic stents (9 cm × 8.5 Fr) were placed in each hepatic duct (Figure 4), and the external drain was removed.

Subsequently, both plastic stents were replaced with a fully covered self-expandable metal stent with anchoring flaps (80 × 10 mm), which was removed two months later. Follow-up cholangiography and cholangioscopy confirmed resolution of the leak and absence of biliary stricture (Figure 5).

Conclusions Therapeutic ERCP is a fundamental tool in the management of post-surgical bile leaks.In complex scenarios such as complete bile duct transections, the combined percutaneous–endoscopic "rendezvous" technique allows restoration of biliary continuity, avoidance of major surgery, and reduction of morbidity, with technical success rates exceeding 94 %. Even after failed ERCP or radiological attempts we must continue to pursue minimally invasive management options whenever possible, as demonstrated in this case.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP990 Cholangioscopy-guided electrohydraulic lithotripsy versus laser lithotripsy for the treatment of choledocholithiasis: single center experience

Authors Scaramuzza G[1], Bronzini F[2], Blois M[2], Sterpi C[2], Sostilio A[2], Leonardi G[2], Adamo G[2], Manta R[2]
Institutes **1** N.O.A. – Nuovo Ospedale Apuane, Marina di Massa, Italy; **2** United Hospitals of Livorno, Livorno, Italy
DOI 10.1055/s-0046-1822342

Aims Endoscopic retrograde cholangiopancreatography (ERCP) is the first-line therapy for choledocholithiasis; standard techniques—extraction baskets/balloons and mechanical lithotripsy—clear most stones. Difficult stones can be successfully approached with cholangioscopy-guided intraductal lithotripsy using electrohydraulic (EHL) or laser (LL) energy. The choice between EHL and LL remains debated. Our aim is to compare efficacy and safety between EHL and LL in the management of large difficult biliary stones

Methods We have included all intraductal lithotripsy procedures carried out from November 2021 to October 2025.

Results 32 adult patients (M/F: 12/20) with a mean age of 80 years were included. 18 patients underwent EHL lithotripsy and 14 LL. All procedures were performed in general anesthesia. Patients and stones characteristics were reported in the ▶ **Table 1**. Complete ductal clearance was achieved in 16/18 (89 %) EHL patients and 13/14 (93 %) LL patients. First-session clearance occurred in 13/16 (81 %) with EHL and 12/13 (92 %) with LL (p = 0.39). The mean procedure time was 101.1 vs 105.8 minutes (p = 0.35). Biliary stent use was similar (39 % EHL vs 28 % LL; p = 0.45) and not associated with clearance success (p = 0.13). Adverse events were rare: mild cholangitis in 1/22 (4.5 %) EHL procedures and 1/18 (5.5 %) LL procedures (p = 0.85). Performance data were reported in ▶ **Table 2**.

▶ **Table 1**

	EHL	LL	p
Patients	18	14	
Mean age media	82.61 ± 7.40	76.78 ± 7.95	**0.04**
M/F (n. / %)	4 (22 %) / 14 (78 %)	8 (57 %) / 6 (43 %)	**0.04**
ASA I-II / ASA III-IV	4 (22 %) / 14 (78 %)	6 (43 %) / 8 (57 %)	0.21
Previous ERCP	11/18 (61 %)	11/14 (78 %)	0.29
Multiple stones	14/18 (78 %)	13/14 (93 %)	0.24
Mean n. of stones	2.0 ± 0.76	2.5 ± 1.16	0.76
Stone size (cm)	2.77 ± 0.57	2.71 ± 0.51	0.45
Strictures	1/18 (5 %)	1/14 (7 %)	0.85

▶ **Table 2**

	EHL	LL	p
N. patients	18	14	-
N. procedures	22	18	0.38
Procedures per patient	1.22 ± 0.55	1.28 ± 0.72	0.38
Procedure time (min.)	101.13 ± 28.19	105.83 ± 47.13	0.35
Stent placement	7/18 (39 %)	4/14 (28 %)	0.45
Complete clearance	16/18 (89 %)	13/14 (93 %)	0.70
Clearance at I session	13/16 (81 %)	12/13 (92 %)	0.39
Advers events (cholangitis)	1/22 (4.5 %)	1/18 (5.5 %)	0.85

Conclusions Cholangioscopy-guided intraductal lithotripsy has markedly improved the management of difficult biliary stones. In our single-center study, both EHL and LL achieved high success rates with a favorable safety profile and low adverse-event rates; no statistically significant differences in efficacy or safety were detected between techniques. Future work should include larger prospective and randomized studies comparing the two techniques.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Endoscopy 2026; 58: S1–S1041

eP991 Elevated Lipase with a Normal Pancreas: The Key Role of Endoscopic Ultrasound

Authors Caballero-Hernandez M[1], Escribano de la Torre V[2], Aranda-Olaizola G[1], Andreo-Vidal BE[1], Garcia-Redero M[1], Jimenez-Hernandez B[1], García Martín A[2], Vicente López S[2], Martinez-Ortega A[1], Tejerizo-García L[1], Segarra Ortega JX[2], Concepción PP[1], Velasco-Guardado AJ[3], Geijo-Martinez F[1], Alvarez-Delgado A[1]

Institutes **1** Complejo Asistencial Universitario de Salamanca, Salamanca, Spain; **2** Salamanca University Hospital, Salamanca, Spain; **3** Digestive Diseases Unit, Salamanca University Hospital., Salamanca, Spain

DOI 10.1055/s-0046-1822343

Background Ectopic pancreas is a rare congenital anomaly characterized by pancreatic tissue located outside its normal anatomic position and not connected to the main gland. Although frequently an incidental finding, it may lead to clinical symptoms such as abdominal pain, gastrointestinal bleeding, or, less commonly, acute or chronic pancreatitis. The diagnosis can be challenging, and endoscopic ultrasound (EUS) plays a decisive role in characterizing gastric subepithelial lesions and guiding their management.

Case Description A 22-year-old woman with no significant medical history presented with five days of epigastric pain, heartburn and nausea. Laboratory tests revealed a five-fold elevation in serum lipase. Upper endoscopy identified two submucosal lesions, 2–3 cm in diameter, at the gastric antrum–body junction (Figure 1).

Radial and linear EUS demonstrated two heterogeneous, lobulated subepithelial masses along the greater curvature: one arising from the submucosa (20 × 12 mm) and another extending into the muscularis propria (22 × 14 mm), while preserving wall layer anatomy (Figure 2). Fine-needle aspiration (25G) confirmed ectopic pancreatic tissue without atypia.

Abdominal CT revealed solid, contrast-enhancing gastric-wall lesions with surrounding inflammatory changes, without involvement of the orthotopic pancreas (Figures 3 and 4). Given the patient's clinical stability and the absence of complications, conservative management with outpatient follow-up was chosen, reserving endoscopic resection for possible recurrence.

Conclusion This case illustrates acute idiopathic-like pancreatitis originating from gastric ectopic pancreatic tissue, confirmed by EUS-guided FNA. EUS was decisive in establishing the diagnosis and avoiding unnecessary investigations, delays, or inappropriate treatments in this uncommon entity. Careful follow-up is appropriate in clinically stable patients, while endoscopic resection remains a therapeutic option if symptoms recur.

Institutes **1** Research Center of Gastroenterology and Hepatology of Craiova, Romania, Craiova, Romania; **2** Pathology Department, University of Medicine and Pharmacy of Craiova, Craiova, Romania; **3** Department of Histology, University of Medicine and Pharmacy of Craiova, Craiova, Romania; **4** Oncology Department, University of Medicine and Pharmacy of Craiova, Craiova, Romania; **5** 3 Department of Pharmacoeconomics, University of Medicine and Pharmacy of Craiova, Craiova, Romania

DOI 10.1055/s-0046-1822344

Aims To evaluate a combined approach using EUS-guided real-time elastography (RTE) and mesenchymal immunohistochemical markers to predict prognosis in pancreatic cancer.

Methods Twenty-three consecutive patients diagnosed with PC by EUS-FNB at the Research Center for Gastroenterology and Hepatology, University of Medicine and Pharmacy of Craiova, between January and April 2025, were enrolled. All patients underwent RTE-EUS using the ARIETTA 850 system. Histopathology confirmed the diagnosis, and immunohistochemistry for α-SMA and vimentin was performed to assess mesenchymal activation. Quantitative morphologic and textural classifiers were automatically generated using Image ProPlus AMS analysis software, including: hole area, roundness, heterogeneity, integrated optical density (IOD), Feret max, Feret mean, fractal dimension, and clumpiness [1].

Results High expression of α-SMA and vimentin was significantly associated with the presence of metastases and decreased survival ($p < 0.05$). Morphologic classifiers applied to both elastography and IHC images demonstrated increased stiffness and dense fibrosis in advanced disease stages. Significant associations were found for heterogeneity, IOD, Feret max, Feret mean, fractal dimension, and clumpiness ($p < 0.001$), and for hole area and roundness ($p < 0.05$).

Conclusions This study highlights the potential of EUS-RTE as a real-time imaging tool for improving prognostic assessment in PDAC by integrating mesenchymal marker–based quantitative denominators. Combined elastography–IHC analysis may contribute to more refined risk stratification and personalized management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822346

Aims Multidrug-resistant (MDR) pathogens may compromise empiric therapy in acute cholangitis, particularly after repeated biliary interventions. We aimed to describe MDR prevalence and identify patient- and procedure-related risk factors.

Methods We prospectively analysed 1960 Tokyo Guideline–defined acute cholangitis episodes in a multicenter cohort. Bile and blood isolates were classified as MDR if non-susceptible to ≥ 1 agent in ≥ 3 antimicrobial classes; episodes were labelled MDR when ≥ 1 MDR isolate was recovered. Analyses were restricted to culture-positive episodes.

Results Among 979 culture-positive episodes, 350 (35.8 %) were MDR, corresponding to 17.9 % of all cholangitis episodes. Patients with MDR organisms were older (mean 70.2 vs 68.0 years). MDR clustered in those with prior healthcare and biliary manipulation: previous hospitalisation increased MDR from 30.8 % to 40.7 %, prior ERCP from 30.1 % to 46.0 %, and any previous biliary stent from 30.7 % to 47.5 %. Stenting at the index ERCP was also associated with higher MDR rates (39.7 % vs 29.5 % without stent). MDR isolates accounted for 35.4 % of bile and 23.3 % of blood cultures. In multivariable analysis, older age (30 % higher odds per decade), previous ERCP (adjusted odds ratio [aOR] 2.4) and antibiotic administration before ERCP (aOR 1.5) remained independently associated with MDR.

Conclusions In this large acute cholangitis cohort, over one-third of culture-positive episodes involved MDR organisms, with substantially higher rates

in older patients and those with recent hospitalisation, prior ERCP, and biliary stents. These findings support escalation of empiric therapy for patients with significant prior biliary manipulation or healthcare exposure, while antimicrobial-sparing regimens may remain appropriate for truly community-acquired cases without such risk factors.

eP995 Quality in Focus: Performance Measures in Upper Gastrointestinal Endoscopy in a Single-centre Cohort

Authors Regatia R[1], Saraiva S[1], Areia M[1], Viegas MI[1], Sarmento Costa M[1], Elvas L[1], Alves S[1], Brito D[1], Cadime AT[1]
Institute 1 Gastroenterology Department, Portuguese Oncology Institute of Coimbra, Portugal, Coimbra, Portugal
DOI 10.1055/s-0046-1822347

Aims Improving the quality of upper gastrointestinal endoscopy (UGE) relies increasingly on structured performance measures (PMs) defined by the European Society of Gastrointestinal Endoscopy (ESGE). The 2025 update introduced revised key and minor PMs to strengthen standardization and enhance diagnostic performance. The aim of this study was to evaluate compliance with the updated 2025 ESGE UGE performance measures in a cohort of 100 consecutive UGE procedures, to calculate local quality metrics, and to compare these results with those obtained in the same centre in 2023, when examinations were assessed according to the 2016 ESGE framework.

Methods Retrospective cohort study including 100 consecutive UGE performed in 2025 and 309 consecutive procedures performed in 2023 in a single centre. Standard exclusion criteria aligned with ESGE recommendations were applied to both cohorts. Each examination was evaluated against the corresponding ESGE performance measures: the 2025 PMs for the 2025 cohort and the 2016 PMs for the 2023 cohort. Extracted variables included key and minor performance measures, and a comparative analysis between 2023 and 2025 was performed using chi-square, with significance set at $p < 0.05$.

Results In 2025, regarding key PMs, appropriate indication for the procedure was documented in 98 % of examinations, fasting instructions in 100 %, accurate photodocumentation in 99 %, and standardized terminology in 91 %. The management of epithelial precancerous conditions and early neoplasia of the stomach (MAPS) protocol was followed in 100 % of applicable procedures (n = 40), and recommended surveillance intervals in patients with gastric precancerous conditions were respected in 100 % of applicable cases (n = 21). Two key performance measures remained below ESGE minimum thresholds: the use of a validated mucosal visibility score (39 %) and documentation of an inspection time ≥ 7 minutes (39 %). Among minor PMs, a minimum 20-minute allocated time slot was assured in 100 % of procedures and patients' experience was not evaluated. Some PMs were not applicable due to the absence of eligible cases among the 100 consecutive UGE evaluated: Barrett's oesophagus-related measures, chromoendoscopy in squamous neoplasia risk groups and post-therapeutic complications. Comparative analysis of PMs available in both 2023 and 2025 revealed no relevant differences in fasting documentation (100 % vs. 100 %, $p = 1.00$), photodocumentation adequacy (99 % vs. 99 %, $p = 0.85$), or use of standardized terminology (94 % vs. 91 %, $p = 0.54$). There was a statistically significant improvement in the proportion of procedures in which the MAPS protocol was applied, when relevant (89 % vs. 100 %, $p = 0.03$). Comparing the 2016 ESGE measures requiring documentation of time vs. the 2025 update additionally mandating an inspection time ≥ 7 minutes, the proportion of examinations meeting the PM improved significantly (22 % vs. 39 %, $p < 0.01$), indicating a meaningful enhancement in compliance with time-related key PM. Overall, in 2025, 7 of the 10 available PM to evaluate were performed according to the ESGE minimum standard ≥ 90 %.

Conclusions This two-cohort analysis demonstrates measurable progress in adherence to ESGE performance measures following the 2025 update, with several key PMs meeting or approaching target standards. Improvements were particularly evident in time-related documentation and use of MAPS protocol for gastric precancerous assessment. Some PMs remain below ESGE minimum thresholds, giving room for continuous improvement, but the overall trend supports the positive impact of systematic quality monitoring and highlights ongoing opportunities to optimize UGE performance in accordance with evolving European standards.

eP996 Evaluation of the Efficacy and Safety of Botulinum Toxin Injection in the Treatment of Chronic Anal Fissures

Authors Carvalho I[1], Gago T[2], Relvas L[2], Portugal M[2], Aguieiras C[2], Peixe B[2]
Institutes 1 University Hospital Center of Algarve, Faro, Faro, Portugal; 2 ULS Algarve – Hospital de Faro, Faro, Portugal
DOI 10.1055/s-0046-1822348

Aims To assess the real-world efficacy and safety of botulinum toxin type A (BTX-A) injection as a minimally invasive therapeutic alternative for chronic anal fissures and to identify factors associated with early treatment success.

Methods We conducted a retrospective observational study including all patients aged ≥ 18 years with chronic anal fissure treated with BTX-A in a proctology outpatient clinic between January 2021 and September 2024, with a minimum follow-up of 12 months. Patients with inflammatory bowel disease were excluded. A standardized dose of 20 IU of BTX-A divided into two injections was administered in all cases. Primary outcomes were healing rate, number of treatment sessions required, recurrence, and procedure-related complications. The impact of optimized peri-procedural medical therapy (topical treatment and constipation control) on treatment response was also evaluated.

Results Twenty-two patients were included (54.5 % male). Complete fissure healing was achieved in 64 % after a single BTX-A session and in the remaining 36 % after a second session, resulting in a 100 % overall healing rate with no recurrences at 1-year follow-up. Patients with optimized peri-procedural medical therapy (n = 16, 73 %) showed a significantly higher early success rate, as all healed after one session ($p < 0.001$). Only one case of transient mild fecal incontinence (4.5 %) was observed, with no permanent sequelae. Complex fissure patterns (combined anterior and posterior fissures and fissure with anal ulcer) were exclusively identified among patients requiring two sessions.

Conclusions In this real-world cohort, BTX-A injection demonstrated excellent efficacy and an outstanding safety profile for the treatment of chronic anal fissures, achieving universal healing with minimal morbidity. Optimized peri-procedural medical therapy emerged as a key modifiable factor for early success, significantly reducing the need for repeated interventions. These data strongly support BTX-A as a first-line, sphincter-preserving, minimally invasive alternative to lateral internal sphincterotomy, with the potential to change current therapeutic paradigms.

eP997 Use of topical hemostatic agents in upper gastrointestinal bleeding: experience in a reference center in the province of girona

Authors Barreto LP[1], Albert M[1], Hombrados M[1], Busquets D[1], Pardo Grau L[1], Torrealba L[2], Oliveras B[1], Huertas C[3]
Institutes 1 Hospital Universitari de Girona Doctor Josep Trueta, Girona, Spain; 2 Hospital Universitari de Girona Doctor Josep Trueta, Giro, Spain; 3 Endoscopy Unit, Digestive Diseases Department, Doctor Josep Trueta University Hospital of Girona, Girona, Spain
DOI 10.1055/s-0046-1822349

Aims To evaluate the effectiveness and safety of topical hemostatic agents in the treatment of UGIB in a tertiary hospital.

Methods A retrospective study conducted at Hospital Universitari Dr. Josep Trueta in Girona. Patients with UGIB treated between January 2016 and June 2025 were included. Data were obtained from the Endobase database. Demo-

graphic variables, indication for gastroscopy, etiology of bleeding, use of topical hemostatic agent as first-line treatment, technical success, rebleeding, and 30-day survival were collected [1, 2].

Results A total of 47 patients were analyzed, with a mean age of 66.08 years and a male predominance (76.6 %). The main indication for gastroscopy was hematemesis (53.2 %), followed by melena (34.0 %) and rectal bleeding (4.3 %). The most frequent etiology was esophagogastroduodenal neoplasm (25.5 %), followed by duodenal ulcer (21.3 %), esophagitis (14.9 %), gastric ulcer (6.4 %), and variceal bleeding (6.4 %). The topical hemostatic agent was used as first-line treatment in 27.7 % of cases. Immediate hemostasis was achieved in 91.5 %, with technical success in 89.4 %. Rebleeding at 7 days was 19.1 % and at 30 days 23.4 %. The 30-day survival rate was 78.7 %.

Conclusions The use of topical hemostatic agents in UGIB showed a high rate of technical success and immediate hemostasis. These results support their use as an effective tool in the endoscopic management of UGIB, especially in selected cases (neoplasms or refractory bleeding) and even as a first-line option.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP998 Endoscopic removal of an unusual foreign body from the stomach

Authors Saichi S[1], Saoula H[2]

Institutes **1** CHU Lamine Debaghine Bab El Oued, Algiers, Algeria; **2** CHU Lamine Debaghine Bab El Oued, Algeria, Algiers, Algeria

DOI 10.1055/s-0046-1822350

Abstract Text

Foreign body (FB) ingestion is common and usually benign. At-risk populations include children, elderly patients, psychiatric patients, prisoners, and those with esophageal disease. While most FBs pass spontaneously, 10–20 % require endoscopic removal, and only ~1 % need surgery. We report a case of toothbrush ingestion successfully removed endoscopically after multiple failed attempts [1, 2].

Case: A 40-year-old obese woman with allergic rhinitis accidentally ingested a toothbrush during a coughing episode. She presented with nausea and gastric fullness. Physical examination and plain thoraco-abdominal radiographs were unremarkable (radiolucent object). Urgent esophagogastroduodenoscopy without sedation revealed the toothbrush lodged horizontally in the gastric fundus. After repositioning maneuvers and use of a diathermic snare, the object was turned vertically, grasped by the head, and removed successfully without complications. The patient was discharged the same day.

Conclusion: Long objects (>6 cm), such as toothbrushes, can become impacted in the stomach or duodenum and often require endoscopic removal. Use of a snare, basket, and appropriately sized overtube facilitates safe extraction. Management should be multidisciplinary, and preventive measures including patient and caregiver education are essential to reduce such incidents.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822351

Problem to solve Training in gastrointestinal (GI) endoscopy has mainly relied on plastic simulators, virtual reality platforms, mechanical, and animal tissue models. While widely used, the above modalities lack key features of the human GI tract, including anatomical accuracy, mucosal appearance, and tissue responsiveness. Human cadaver models provide a lifelike experience in surgical training. However, despite various efforts to develop GI endoscopy training on human cadavers, limitations in preservation methods, tissue quality, and reproducibility have prevented widespread adoption so far.

Innovation We developed a novel soft-embalming technique specifically optimised to preserve the human GI tract. Preservation quality was initially validated on three cadavers via standard upper and lower GI endoscopy. We established an international one-day hands-on GI endoscopy training program using our novel, next-generation human cadaver models designed explicitly for the realistic practice of diagnostic and basic therapeutic endoscopic techniques. Participants practiced diagnostic upper and lower GI endoscopy and basic therapeutic procedures, including endoscopic band ligation (EBL) and submucosal injection using Fujifilm devices.

Results The preserved GI tracts closely resembled living tissue, with realistic mucosal appearance, tissue pliability, and luminal distension. Notably, the reduced adherence of the upper GI mucosa to the submucosa proved beneficial for practising submucosal injection and EBL techniques. Preservation chemicals caused no damage to endoscopic equipment, and the cadavers remained suitable for reuse. 70 participants from 14 countries have completed the training across three courses since 2024, and reported significant improvements in both endoscopic technical proficiency and confidence. A total of 51 trainees completed a standardized evaluation (Likert scale 1–5), the results of which are summarized in ▶ **Table 1**.

▶ **Table 1** Summary of Trainee Evaluations (1 = poor, 5 = excellent)

Parameter	Mean Score, (n = 51)
Odour intensity of preservation method (low = better)	**1.4**
Mucosal realism	**3.6**
Tissue consistency	**3.6**
GI tract cleanliness	**4.3**
Endoscope handling realism	**4.1**
Overall examination realism	**4.1**
Comfort working on cadavers	**3.8**
Usefulness for diagnostic endoscopy training	**4.3**

Conclusions This new-generation human cadaver model provides a realistic, safe, and reusable platform for GI endoscopy training. Quantitative evaluations from 51 trainees demonstrate high realism and educational value, supporting its integration into international endoscopy curricula. Its ability to enable both

diagnostic and therapeutic training – especially submucosal injection, rarely feasible in cadaver models – positions this innovation as a promising bridge between simulation tools and real-world clinical practice.

eP1025 Navigating ERCP Through Duodenal Stenosis and Pre-existing Enteral Stents: A Single-Center Experience

Authors Conti Bellocchi MC[1], Del Fauro V[1], Agnolon C[1], De Pretis N[1], Crinò SF[1]

Institute 1 University of Verona, Verona, Italy

DOI 10.1055/s-0046-1822352

Aims Malignant biliary obstruction (MBO) in the setting of duodenal narrowing is a frequent and challenging scenario in advanced gastrointestinal cancers. Although EUS-guided biliary drainage has emerged as a promising alternative, its use is still limited to specialized centers with dedicated expertise. In daily practice, endoscopists often face two situations: patients with pre-existing enteral stents placed for gastric outlet obstruction (GOO), which complicate biliary access, and patients with duodenal substenoses that appear clinically insignificant but prove non-transitable during ERCP. In both cases, positioning or navigating through duodenal stents can represent a pragmatic solution to enable ERCP.

Methods We conducted a single-center observational study including consecutive patients with MBO in the setting of duodenal narrowing. Patients were stratified into two groups according to stent indication: those who underwent ERCP-directed stent placement to enable biliary access, and those with pre-existing enteral stents previously positioned for palliation of GOO. The primary aim was the technical success, defined as successful cannulation of the biliary tract followed by correct placement of a stent. Secondary endpoints included the clinical success, the safety of the procedure, and the need for reintervention. Reinterventions were categorized according to indication: biliary reintervention, performed for stent dysfunction or recurrent biliary obstruction, and GOO-related reintervention, performed for recurrence or progression of duodenal obstruction.

Results Thirty-five patients were included, with a mean age of 68 years and a slight male predominance. The majority had pancreatic cancer and advanced disease stages. Most underwent ERCP-directed stent placement (29, 80.5 %) , while a smaller subgroup carried pre-existing enteral stents for GOO (7, 19.5 %). Clinical indications were mainly jaundice, with a minority presenting with cholangitis. Papilla status was balanced between naïve and previously treated, and sphincterotomy was rarely performed. Metal stents were the preferred choice, either fully covered (82.7 %) or uncovered (13.8 %), with only one case requiring plastic stents due to hilar cholangiocarcinoma. ERCP was feasible in 30 out of 35 patients (82.9 %), confirming a high rate of technical success. Clinical success was achieved in 26 out of 35 patients (74.3 %). Procedural adverse events occurred in 2 patients (5.7 %), both classified as grade IIIb, consisting of periprocedural collections requiring drainage. Reintervention was necessary in four cases (11.4 %): three for cholangitis due to stent dysfunction, and one for stent occlusion, with subsequent ERCP and EUS-guided gastroenterostomy.

Conclusions ERCP in malignant biliary obstruction with duodenal stenosis is feasible (83.3 % technical success), with a good clinical efficacy. Severe procedural adverse events were rare (5.6 %) , while stent dysfunction required reintervention in 11.1 % of cases. Overall survival remained limited, reflecting advanced disease stage.

eP1026 Acute bleeding from a downhill esophageal varix treated by endoscopic band ligation

Authors Birzle L[1], Roser DA[1], Braun G[1], Karpynec S[1], Krapp N[1], Römmele C[2], Nagl S[1], Scheurig-Münkler C[1], Messmann H[3]

Institutes 1 University Hospital Augsburg, Augsburg, Germany; 2 Internal Medicine III – Gastroenterology, University Hospital Augsburg, Augsburg, Germany; 3 Internal Medicine III – Gastroenterology, University Hospital Augsburg, Augsburg, Germany

DOI 10.1055/s-0046-1822353

Case description: A 87-year-old patient presented to our emergency department with hematemesis and melena. With an initial hemoglobin level of 5 g/dL, two units of packed red blood cells were transfused before the hemodynamically stable patient was transferred to our endoscopy unit.

Emergency upper endoscopy revealed a column of downhill varices with stigmata of recent bleeding, characterized by a white nipple sign. During inspection, active bleeding from the downhill varix recurred. The remaining esophagus and stomach showed no signs of portal hypertensive gastropathy or additional varices.

Due to acitve hemorrhage, endoscopic band ligation was performed using a multiband ligator, resulting in immediate hemostasis. No additional endoscopic therapy was required.

To clarify the etiology of the downhill varices, contrast-enhanced CT of the chest was obtained. It demonstrated a 3.7×9 mm thrombus in the superior vena cava with collateralization through the azygos system. The patient had a previously implanted a CRT-D device for complete atrioventricular block, and the transvenous leads were regarded as the causative factor for the SVC thrombosis.

The patient was started on anticoagulation. Given the elevated risk of damaging the CRT-D system, an initial attempt was made to embolize the azygos vein. However, the procedure proved technically unfeasible, and the patient is now being evaluated for stenting of the superior vena cava.

Conclusion Acute bleeding from downhill esophageal varices is rare but can be effectively treated with endoscopic band ligation. Identification and management of the underlying SVC obstruction is crucial for preventing recurrence.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1027 Endocytoscopy in the evaluation of histological remission in ulcerative colitis

Authors Suarez-Ferrer C[1, 2], Martin Arranz E[1, 2], Rueda Garcia JL[1, 2], Sanchez-Azofra M, Poza Cordon J[1, 2], Mendez Diaz MC[3], Amiama Roig C[1], García Ramirez L[4], Martin-Arranz MD[2, 1, 5]

Institutes 1 La Paz University Hospital, Madrid, Spain; 2 IdiPAZ, Madrid, Spain; 3 La Paz University Hospital, Pathology department, Madrid, Spain; 4 Fundacion para la investigación biomedica del Hospital Universitario La Paz FIBHULP, Madrid, Spain; 5 Autonomous University of Madrid, Madrid, Spain

DOI 10.1055/s-0046-1822354

Aims Endoscopic and histologic remission are therapeutic targets in ulcerative colitis (UC). Endocytoscopy (EC), provides optical magnification up to 520x, this real-time imaging modality offers the potential to assess histologic healing without tissue sampling. The objective of this study was to evaluate the diagnostic performance of EC to assess endoscopic and histologic healing in UC [1–3].

Methods We conducted a prospective observational study including consecutive patients with UC in clinical remission undergoing colonoscopy. EC and biopsies were performed and in the segment with the highest previously documented inflammatory activity. Endoscopic activity was evaluated using the Mayo endoscopic subscore and UCEIS. Clinical activity (PRO2) and biochemical markers (fecal calprotectin and C-reactive protein) were recorded. Endocytoscopy (ECI-H290ECI, Olympus) was evaluated using three different scores (ELECT, ICC and ESS) using NBI and 1 % methylene blue staining. Three independent endoscopist reviewed EC videos for interobserver correlation. Histologic activity using Nancy index served as the gold standard.

Results Thirty-seven patients were included. Mean age was 52,3 (SD16,6) and 56,8 % were female. Baseline characteristics are shown in ▶ **Table 1**. Only three

patients (8,6 %) had demonstrated mucosal healing on the prior endoscopy. Clinically, patients were in remission, with normal bowel movements number (73 % reporting 1 bowel movement/day) and no rectal bleeding in 100 %. Median fecal calprotectin was 39.5 µg/g (IQR 19.1-91.3), CRP 1.2mg/L (IQR 0.5-5.4), hemoglobin 14.8 g/dL (IQR 13.6-15.4), and albumin 4.5 g/dL (IQR 4.4-4.7).

▶ **Table 1** Baseline characteristics

Age mean (SD)	52,3 (16.6)
Sex	16(43,2 %) male, 21 (56,8 %) female
Smoking status	27 (73 %) No, 5(13,5) Yes, 5(13,5 %)Ex
UC extension	Proctitis 8,6 %, Left-sided 54,3 %, extensive 37,1 %

Most patients were in endoscopic remission, with 90 % with Mayo 0 and UCEIS 0. Histologic remission (Nancy 0-1) was present in 78,4 % of patients.
EC assessment showed 81 % patients scored as ELECT 0 or 1, 83 % as ICC 0 or 1 and 57 % as ESS 3.
Concordance between Nancy and EC indexes was good. 93,1 % of patients in histologic remission were correctly classified as ELECT 0 or 1, ICC 0 or 1 while 62 % as ESS 3.
Among 6 patients with significant histologic activity (Nancy 2-3), 3 were classified as ELECT 2-3, 2 as ICC 2 and 4 as ESS 4.
Interobserver agreement was good for ELECT score (kappa 0.67), and moderate for ICC and ESS (kappa 0.4). Concordance was 83.3 % for ELECT and 66,7 % for ICC and ESS scores. Of individual variables vascular architecture, distance between crypts, and abscence of crypt abscesses had good agreement, while capilar morphology and presence of inflammatory infiltrate only had 33,3 % concordance.

Conclusions Endocytoscopy allows accurate in vivo assessment of histologic remission in patients with ulcerative colitis, with an excellent negative predictive value and could be a feasible alternative to biopsies in patients in endoscopic remission.

Conflicts of Interest Equipment support provided by Olympus

Aims Proper prioritization is essential for optimizing waiting lists and ensuring that endoscopic procedures provide meaningful diagnostic value. This study aimed to evaluate whether a gastroenterologist's review of General Pratictioners (GP)-issued referrals could improve appropriateness and enhance the detection of clinically significant findings.

Methods A single-center retrospective observational study was conducted, including all patients who underwent upper or lower gastrointestinal endoscopy between January 2022 and December 2024. All referrals were issued by GP with a 60 day-priority. Patients were divided into two cohorts: the "GP" group, in which booking occurred directly through the regional scheduling system without specialist input, and the "Specialist" group, in which a gastroenterologist reviewed and, if necessary, modified the assigned priority before scheduling. Appropriateness was assessed using italian (Raggruppamenti di Attesa Omogenea, RAO) [1] and American Society for Gastrointestinal Endoscopy (ASGE) [2] criteria, and endoscopic outcomes were evaluated for significant organic pathology.

Results A total of 602 patients (302 in the "Specialist" group and 300 in the "GP" group) were included in the study. The "Specialist" cohort demonstrated markedly improved appropriateness of referrals according to RAO (77.5 % vs 59.0 %, p < 0.001) and ASGE (94.0 % vs 83.0 %, p < 0.001) criteria and increased rates of significant organic pathology (23.2 % vs. 15.0 %, p = 0.014), both neoplastic (2.6 % vs 2 %) and non-neoplastic (20.5 % vs 13 %), compared with CUP. Across both cohorts, appropriate referrals were associated with a higher diagnostic yield and no neoplastic lesions were found in examinations classified as inappropriate.
The general features of the two cohorts and the more significant results are summarized in ▶ **Table 1**.

▶ **Table 1**

	Specialist (n = 302)	GP (n = 300)	p-value
Female sex	145 (48,0 %)	176 (58,7 %)	
Age (yrs; mean, SD)	63,71 (15,36)	62,81 (14,34)	
Esophagogastroduodenoscopy	191 (63,2 %)	132 (44,0 %)	
Colonoscopy	111 (36,8 %)	168 (56,0 %)	
RAO criteria	234 (77,5 %)	177 (59,0 %)	<0,001
ASGE criteria	284 (94 %)	249 (83 %)	<0,001
Significant pathology *	70 (23,2 %)	45 (15,0 %)	0,014
Neoplastic disease (GC/CRC)	8 (2,6 %)	6 (2,0 %)	0,078
Non-neoplastic disease	62 (20,5 %)	39 (13,0 %)	0,016

*Esophageal varices, Barrett's esophagus, erosive esophagitis grade C/D, eosinophilic/infectious esophagitis, gastric cancer (GC), gastric/duodenal ulcers, gastric antral vascular ectasia, gastric varices, endoscopic findings suspicious for coeliac disease, colorectal cancer (CRC), active inflammatory bowel disease, acute diverticulitis,recurrence of previously endoscopically resected lesion, high-risk colorectal polyp, anastomotic stenosis, rectal fistula, radiation proctitis

Conclusions Specialist review enhances prioritization accuracy and overall diagnostic yield, suggesting that implementing specialist triage may help manage the increasing demand for endoscopic procedures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822356

Aims Oesophageal endoscopic submucosal dissection (ESD) is increasingly used for the treatment of early oesophageal neoplasia. Post-ESD stricture remains a frequent adverse event, often requiring repeated therapeutic endoscopy. Although several factors have been proposed to influence stricture risk, reported associations vary and the relative importance of individual factors remains uncertain. We aimed to identify predictors of stricture requiring therapeutic endoscopic intervention (SRT) following oesophageal ESD in a real-world cohort.

Methods We performed a retrospective analysis of all oesophageal ESDs with accessible follow-up undertaken at our centre between July 2023 and September 2025. Collected variables included demographic, lesion-related (location, length, circumferential extent, histologic subtype, depth of invasion, histology-based risk category); and procedural characteristics (knife type, endoscopist, procedural complication).

The primary outcome was SRT. Secondary outcomes included the number of endoscopic dilatations at predefined intervals (2 months, 4 months, 6 months, last follow-up) and change in dysphagia grade from pre-procedure to peak post-procedure and last follow-up. Clinically important events including oesophageal stenting, non-oral feeding, and stricture-related perforation were also recorded. All variables underwent univariate testing, and the strongest univariate predictors were entered into an exploratory multivariable model.

Results 70 oesophageal ESDs were included in the analysis (median age 71.5 years [IQR 62–77], 71 % male). Lesions were located in the upper (6 %), mid (26 %), lower (47 %) oesophagus or at the gastro-oesophageal junction (19 %). Median lesion length was 40 mm (IQR 30–60). Median circumferential extent was 50 % (IQR 26.3–78.8), with 22/70 (31.4 %) involving ≥ 75 % of the circumference. Histology comprised glandular neoplasia in 61.4 %, squamous neoplasia in 32.9 % and other subtypes. Depth of invasion included no invasion (24.3 %), T1a (50.0 %) and T1b (22.9 %).

28 patients (40 %) developed SRT. On univariate analysis, circumferential extent showed a strong association with SRT (median 87.5 % [IQR 46.5–100 %] vs 31.5 % [IQR 25–50 %]; p < 0.0001), while all other variables were non-significant. In the multivariable model containing the strongest univariate predictors, circumferential extent remained the only independent predictor of SRT (OR 1.04 per 1 %, 95 % CI 1.014–1.061; p = 0.0016). Histologic subtype (OR 2.92, 95 % CI 0.91–9.41; p = 0.073), lesion length (OR 0.996, 95 % CI 0.98–1.02; p = 0.70) and age (OR 1.009, 95 % CI 0.95–1.07; p = 0.78) were not significant.

Circumferential extent also demonstrated moderate to strong associations with dilatation burden across all intervals (Spearman ρ = 0.55–0.59, p < 0.0001), was strongly associated with peak dysphagia worsening (ρ = 0.60, p < 0.0001), and moderately associated with dysphagia at last follow-up (ρ = 0.40, p = 0.001). Lesion length showed weak associations with dilatation number and peak dysphagia (ρ ≈ 0.25, p < 0.04), and histologic subtype showed borderline associations with dilatation burden (p ≈ 0.05–0.09) but no association with dysphagia. Neither variable remained significant after adjusting for circumferential extent. All other variables showed no meaningful association with any secondary outcome.

All clinically important events were confined to 100 % circumferential ESDs, including oesophageal stenting (n = 5), need for non-oral feeding (n = 2), and dilatation-related perforation (n = 3).

Conclusions Circumferential extent was the sole independent predictor of SRT following oesophageal ESD and the only factor consistently associated with stricture severity across dysphagia and dilatation outcomes. These findings highlight circumferential involvement as the dominant determinant of clinically significant post-ESD stricture and support its use as the primary basis for risk stratification and preventive strategies.

eP1030 New-Onset Eosinophilic Esophagitis Following Radiofrequency Ablation for Barrett's Esophagus: A Case Report

Authors Soldaini C[1], Verrusio G[1], Falcone B[1], Diretto A[1], Perullo G[1], Pellegrini L[1], Palma R[1], Santonicola A[1], Iovino P[1]

Institute **1** Gastrointestinal Unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Salerno, Italy

DOI 10.1055/s-0046-1822357

Introduction Eosinophilic esophagitis (EoE) is a chronic, immune-mediated esophageal disorder characterized by eosinophil-predominant inflammation [1]. Esophageal eosinophilia may also be seen in gastroesophageal reflux disease (GERD) and Barrett's esophagus (BE) [2, 3]. However, the onset of EoE after endoscopic eradication therapy—particularly radiofrequency ablation (RFA)—is rare, with only a single case described in the literature [4]. We report a case of de novo EoE developing after successful RFA for BE.

Methods A 43-year-old woman with a 10-year history of GERD and BE underwent RFA in 2021 and remained on single-dose proton pump inhibitor (PPI) therapy thereafter. Surveillance esophagogastroduodenoscopy (EGD) in 2022 showed normal-appearing mucosa, while biopsies revealed > 15 eosinophils per high-power field (HPF) without dysplasia. After a four-week PPI washout, repeat EGD demonstrated mucosal edema and longitudinal furrows (EREFS score: 2). Biopsies from distal, medium and proximal esophagus showed up to 35 eosinophils/HPF, confirming EoE.

Results High-dose PPI therapy was initiated, resulting in both symptomatic and histologic improvement. Three-month EGD revealed partial mucosal healing (EREFS score: 1) and reduced eosinophilic count (9 eosinophils/HPF). As of today, the patient maintained sustained clinical, endoscopic, and histologic remission of EoE, with no recurrence of BE or dysplasia.

Conclusions This case illustrates the rare occurrence of EoE arising after RFA for BE. Clinicians should consider EoE in patients with previously treated esophageal conditions who develop persistent or unexplained symptoms, even after successful eradication therapy. Early recognition and appropriate management can prevent chronic inflammation and disease-related complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1031 Incidental Endoscopic Diagnosis of a Hepatoduodenal Fistula Secondary to a Pyogenic Liver Abscess

Authors Scopelliti N[1], Soldaini C[1], Verrusio G[1], De Filippo FR[1], Diasco A[1], Iovino P[1], Santonicola A[1]
Institute 1 Gastrointestinal Unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Salerno, Italy
DOI 10.1055/s-0046-1822358

Introduction Enterohepatic fistulas are rare complications of pyogenic liver abscesses, typically involving the stomach, colon, or duodenum [1, 2]. Prompt identification may be challenging, as symptoms are often nonspecific. Esophagogastroduodenoscopy (EGD) may reveal unexpected fistulous tracts, while contrast-enhanced CT remains the gold standard for detailed characterization [3, 4]. No standardized management guidelines exist; conservative drainage may allow spontaneous closure, though surgery is often required [3].

Methods A 76-year-old woman presented to the emergency department with abdominal pain, epigastric pain, fever, and coffee-ground vomiting. Given the suspicion of upper gastrointestinal bleeding, an urgent EGD was performed. The examination revealed an orifice with inflamed margins in the duodenal bulb, exuding purulent material—highly suggestive of a fistulous tract. Based on these findings, a contrast-enhanced CT scan was promptly obtained, demonstrating a 42 × 30 mm abscess in segment V of the liver, containing air–fluid levels and extending toward the gallbladder bed and duodenum, confirming a hepato-duodenal fistula.

Results Ultrasound-guided percutaneous drainage was performed and intravenous piperacillin/tazobactam was initiated. Despite a significative clinical improvement, persistence of the fistulous tract on follow-up imaging required surgical intervention. Postoperatively, the patient showed rapid clinical and biochemical improvement, and a CT scan confirmed complete resolution.

Conclusions This case describes the endoscopic detection of a rare hepato-duodenal fistula secondary to a pyogenic liver abscess. The initial EGD—performed for suspected upper GI bleeding—proved crucial in early detection of the fistulous tract and guided subsequent imaging and therapy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1032 The Association of Extremely Elevated Pancreatic Cyst Fluid CEA with Underlying Malignancy Risk: A Single-Center Cohort Study

Authors Thanos C[1], Tsitsigiannis K[1], Georgakopoulou N[1], Piskopou D[1], Kalakos N[1], Ntailianas D[1], Triantafyllou M[1], Georgiou E[1], Varmpompitis I[2], Argyropoulos T[1], Michalopoulos G[1], Karoumpalis I[1]
Institutes 1 General Hospital of Athens "G. Gennimatas", Athens, Greece; 2 General Hospital of Athens "G. Gennimatas", Athina, Greece
DOI 10.1055/s-0046-1822359

Aims Pancreatic cystic neoplasms present a diagnostic challenge in determining which lesions are malignant or carry a high malignant potential. Cyst fluid carcinoembryonic antigen (CEA) is traditionally used to distinguish mucinous from non-mucinous pancreatic cysts, with limited value in identifying malignancy. However, in clinical practice, markedly elevated CEA levels are occasionally observed in patients with invasive cystic neoplasms. This study investigates the association between extremely high cyst fluid CEA concentrations and the presence of underlying malignancy in pancreatic cysts [1–3].

Methods We retrospectively analyzed pancreatic cyst fluid CEA concentrations in patients with known cyst outcomes. A total of 177 patients who underwent EUS-FNA between 2022 and 2024 for the evaluation of pancreatic cysts were included.Malignancy was established by expert cytopathology. Non-malignant lesions included low-grade intraductal papillary mucinous neoplasms, pseudocysts, serous cystadenomas, and lymphoepithelial cysts. We compared CEA levels between non-malignant and malignant groups and constructed a receiver operating characteristic (ROC) curve using malignant cytology (Yes/No) as the reference standard. The area under the curve (AUC) was calculated (accounting for tied values in CEA measurements), and we examined sensitivity and specificity at a high CEA cutoff. Finally, a univariable logistic regression was performed with log-transformed CEA (ln[CEA]) as the predictor of malignancy, reporting the odds ratio (OR) and model performance metrics.

Results A total of 177 pancreatic cysts were included (122 non-malignant, 55 malignant by cytology). Cyst fluid CEA levels ranged widely in both groups. The median CEA was 18 ng/mL in non-malignant cysts versus 800 ng/mL in malignant cysts, although there was notable variance and overlap between groups (some malignant cysts exhibited only modest CEA elevations, and occasional benign lesions had moderately increased CEA). ROC analysis yielded an AUC of 0.873 for CEA in predicting malignant cytology. Using an exemplary high cutoff (CEA > 1500 ng/mL), sensitivity was 78.8 % and specificity 94.3 % for identifying malignancy (based on cross-tabulation of the dichotomized CEA). In a logistic regression model, ln(CEA) was a significant independent predictor of malignancy (OR ≈ 1.97 per unit increase, $p < 0.001$). This single-predictor model achieved an overall diagnostic accuracy of 82.4 %, with a Nagelkerke R^2 of 0.504, indicating that approximately half of the variance in cyst malignancy status was explained by fluid CEA alone.

Conclusions Extremely elevated pancreatic cyst fluid CEA levels are associated with malignancy, yet the overlap with benign lesions limits CEA's role as a standalone diagnostic marker. These findings support CEA as a valuable, though imperfect, tool in malignancy risk stratification. Clinicians may tailor interpretation of CEA thresholds based on the desired balance between sensitivity and specificity in the context of surgical decision-making. Our retrospective analysis suggests that markedly elevated CEA levels (in the thousands of ng/mL) are indicative of an invasive mucinous cyst and may aid in identifying high-risk cysts that warrant more aggressive management. Therefore, cyst fluid CEA results should be interpreted in conjunction with cytology, imaging, and clinical findings rather than in isolation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1033 Dual Remission of Eosinophilic Esophagitis and Ulcerative Colitis With Dupilumab: A Case Report

Authors Soldaini C[1], Verrusio G[1], Falcone B[1], Giaquinto A[1], Baratta T[1], Fricano I[1], Camera S[1], Iovino P[1], Santonicola A[1]
Institute 1 Gastrointestinal Unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Salerno, Italy
DOI 10.1055/s-0046-1822360

Introduction Eosinophilic esophagitis (EoE) is a chronic, immune-mediated disease characterized by a T-helper 2 (Th2)–driven inflammatory response [1]. Ulcerative colitis (UC), although distinct, also involves dysregulated Th2-related pathways [2]. Dupilumab, a monoclonal antibody targeting IL-4Rα and modulating Th2 inflammation, has demonstrated efficacy in allergic disorders, including EoE [3]. Although theoretical concerns exist regarding IL-17 downregulation and potential inflammatory bowel disease (IBD) activation, current evidence does not indicate an increased risk of UC exacerbation [4]. We report a case of coexisting EoE and UC successfully managed with dupilumab and mesalazine.

Methods A 43-year-old man with chronic atopic asthma treated with inhaled corticosteroids (ICS) and antihistamines was evaluated for recurrent bloody diarrhea. Colonoscopy and biopsies confirmed UC and combined oral and rectal mesalazine induced clinical remission. 2 years later, he developed reflux symptoms and dysphagia. Esophagogastroduodenoscopy (EGD) revealed distal esophagitis and a fixed ring, with 15 eosinophils/high-power field (HPF). After discontinuing ICS, a repeat EGD demonstrated edema, rings, and furrows (EREFS: E1R1Ex0F1S0) with > 70 eosinophils/HPF, confirming EoE. High-dose proton pump inhibitor therapy failed to improve symptoms. Given persistent EoE and worsening asthma control, dupilumab was initiated.

Results After three months of dupilumab, dysphagia resolved, and follow-up EGD showed near-complete mucosal healing (EREFS: E0R1Ex0F0S0) with 5 eosinophils/HPF. A same-visit colonoscopy demonstrated endoscopic and histologic remission of UC. At the follow-up 4 years later, the patient maintained sustained clinical, endoscopic, and histologic remission of both EoE and UC under dupilumab and mesalazine.

Conclusions This case highlights the efficacy and safety of dupilumab in a patient with concurrent EoE and UC, without IBD exacerbation. The findings support the potential role of Th2-targeted biologics in managing overlapping allergic and immune-mediated gastrointestinal diseases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1034 Endoscopic Musosal Resection of rare rectal composite neuroendocrine tumor and intramucosal adenocarcinoma

Authors Scopelliti N[1], Soldaini C[1], Diasco A[1], Rocco C[1], Fricano I[1], Iovino P[1], Santonicola A[1]
Institute 1 Gastrointestinal Unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Salerno, Italy
DOI 10.1055/s-0046-1822361

Introduction Composite colorectal tumors combining neuroendocrine and glandular neoplastic components are exceptionally uncommon and may present diagnostic and therapeutic challenges [1, 2]. Advances in high-definition endoscopy and resection techniques allow effective, minimally invasive treatment when lesions are accurately staged [3].

Methods A 70-year-old man underwent colonoscopy for evaluation of non-specific abdominal discomfort. Endoscopic examination revealed a 40-mm sessile lesion in the proximal rectum. High-definition white-light and narrow-band imaging demonstrated a mixed pit pattern with glandular and slightly depressed areas, suggestive of early neoplasia limited to the mucosa. An en bloc endoscopic mucosal resection (EMR) was performed after submucosal injection with saline, epinephrine, and indigo carmine. The resection was macroscopically complete, and the procedure was uneventful.

Results Histopathologic analysis confirmed a composite tumor composed of a well-differentiated NET G1 (trabeculo-microacinar pattern; CKpan + , chromogranin + , synaptophysin + , Ki-67 < 3 %) and a coexisting intramucosal adenocarcinoma. Both components were strictly confined to the mucosa, with negative lateral and deep margins and no lymphovascular invasion. A contrast-enhanced CT performed after EMR showed no residual disease, regional lymphadenopathy, or complications. The final diagnosis was composite NET G1 and intramucosal adenocarcinoma with R0 resection. Considering the complete removal and low metastatic risk, conservative management was chosen, with follow-up colonoscopy scheduled at 12 months.

Conclusions This case illustrates that en bloc EMR can be a definitive, minimally invasive treatment for selected composite colorectal tumors when both endoscopic staging and histology confirm mucosal confinement. High-quality imaging, meticulous resection technique, and comprehensive pathology review remain essential to guide optimal management and surveillance in these rare lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1035 Therapeutic ERCP is safe in patients over the age of 80 years when Imaging, biochemical and symptomatic profile fulfils the criteria

Authors Rameshshanker R[1, 2], Jani V[3], Postgate A[4]
Institutes 1 Hillingdon Hospital, London, United Kingdom; 2 The Brunel Medical School, London, United Kingdom; 3 The Hillingdon Hospitals NHS FoundationTrust, London, United Kingdom; 4 The Hillingdon Hospital NHS Foundation Trust, London, United Kingdom
DOI 10.1055/s-0046-1822362

Aims Endoscopic retrograde cholangiopancreatography (ERCP) is utilised as a therapeutic tool to treat pancreatobiliary diseases. Inherently, it carries a risk of complications ranging from mild to fatal. With an ageing population, a significant proportion of patients requiring an ERCP are > 80 years. Complications in this age group are significantly higher. The aim of this study was to evaluate the safety of ERCPs in individuals > 80 years by calculating the incidence of complications and associated mortality rate at our centre.

Methods A retrospective review of individuals > 80 years old who underwent an ERCP at our centre. Data was collected across 2 years and 10 months between January 2023 and October 2025. Endoscopic database was scrutinised to obtain data regarding details of the procedure, including medications administered and immediate complications. Electronic records were analysed to determine the indications, the presence of any intermediate/medium term

complications as well as mortality. Pathology database was reviewed to assess blood results at the time of the procedure.

Results A total of 398 ERCPs were performed during the 34-month time frame. Of which, 110 (27.6 %) procedures had been performed on individuals of at least 80 years of age. Median age was 86 (IQ range 83-89). 56.4 % of them were male. Median dose of midazolam and fentanyl administered were 1.25mg (IQ range 1-1.25), 25mcg (IQ range 25-37.5), respectively. 43.1 % of patients received hyoscine butylbromide.

91.8 % of patients received PR diclofenac. All patients received intravenous fluids pre and post procedure. Mean ALT, ALP and bilirubin prior to ERCP was 125 (IQ range 36.5-169), 592 (IQ range 174-705) and 115 (IQ range 14.5-155), respectively.

The decision to perform an initial ERCP was determined by at least 2 of the 3 parameters: imaging, biochemistry or symptoms. 90.6 % of patients fulfilled minimum 2 criteria. Most common indication for ERCP was choledocholithiasis + /- cholangitis (68 %). Other indications were abnormal imaging indicative of hepato pancreato biliary cancer.

Complications were found in 10 % of the cohort. Most common complication was post-ERCP pancreatitis and post ERCP cholangitis, occurring in 4.5 % and 3.6 % of procedures respectively. Delayed bleeding occurred in 0.1 % of patients. There were no patients in this study who sustained a perforation. One patient in the cohort of 110 patients died from cardiorespiratory arrest and 1 patient died from post-ERCP pancreatitis resulting in a total mortality rate of 1.8 % (multiple co-morbidities and frailty). In 5 of the 110 procedures, a repeat ERCP was required due to inability to cannulate. An alternative procedure, such as an EUS or PTC was organised.

Conclusions Outcomes of this study indicate that ERCP is safe in this age group for sepsis and decompressing of the biliary system, when two out of three pre-requisition criteria are met and safe sedation practices are followed. When compared to national metrics there is no difference in complication rates in those over the age of 80.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1036 Real world outcomes from endoscopic ultrasound guided gastrojejunostomy for malignant gastric outlet obstruction

Authors Keating E[1], Hakeem K[1], Bashir K[1], Ahmed W[2], Simon D[2], Nayar M[1], Leeds J[1]

Institutes **1** Freeman Hospital, Newcastle upon Tyne, United Kingdom; **2** Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom

DOI 10.1055/s-0046-1822363

Aims Endoscopic ultrasound guided gastrojejunostomy (EUS-GJ) has recently been shown to be superior to enteral stenting and surgery for management of gastric outlet obstruction (GOO). Outcomes outside of randomised trials is limited. We aimed to assess the outcomes from EUS-GJ for management of malignant gastric outlet obstruction in 2 UK centres.

Methods Retrospective analysis of patients undergoing EUS-GJ was conducted in 2 tertiary centres. Information was collected including demographics, indication, sedation, pre- and post- GOOS score, stent size, technique used, number of days to commencing diet, adverse events, reintervention rate, other interventions required, receipt of oncological treatment and survival. Univariate analysis was performed to assess pre- and post-procedure GOOS scores. Survival was assessed using Kaplan-Meier curves and assessment of factors associated with survival using Cox regression analysis.

Results 46 patients were included with mean age 68.8 year and 22 females. The majority were for obstruction due to pancreaticobiliary cancer (n = 38) and 23 were performed under anaesthesia and 23 sedation. Median pre-procedure GOOS score was 0.5 (IQR 0 – 1). Technical success was achieved in 44/46 (95.6 %) with 2 stents having a type 1 maldeployment (1 managed endoscopically with subsequent success). Median GOOS score rose to 3 (IQR 3 – 3, p < 0.0001) post-procedure with a median of 1 day to full diet. Overall 7-day adverse event rate was 4/46 (8.7 %) which were maldeployment (2), acute kidney injury (1) and failure to improve (1). 21/46 (45.7 %) also required biliary intervention. Overall survival was 113 days which was shorter in those needing biliary intervention (97 days biliary vs. 150 days non-biliary, p = 0.3). Improved survival was associated with subsequently receiving chemotherapy (HR 1.2, 95 % confidence interval 1.07 – 1.6, p = 0.0004).

Conclusions EUS-GJ is an effective intervention for malignant gastric outlet obstruction showing significant improvement in GOOS scores and early return to full diet. Adverse event rates are low and allows receipt of chemotherapy which improves survival. Larger studies are needed to determine factors affecting survival.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1037 EUS-guided Double Drainage outcomes in real world practice

Authors Keating E[1], Hakeem K[1], Bashir K[1], Ahmed W[2], Simon D[2], Nayar M[1], Leeds J[1]

Institutes **1** Freeman Hospital, Newcastle upon Tyne, United Kingdom; **2** Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom

DOI 10.1055/s-0046-1822364

Aims Malignant pancreaticobiliary pathology can result in simultaneous gastric outlet obstruction (GOO) and biliary obstruction. Previously, surgical and/or radiological intervention was required to alleviate this combination of symptoms. Endoscopic ultrasound guided gastrojejunostomy (EUS-GJ) and EUS-biliary drainage (EUS-BD) now affords patients endoscopic options for double drainage, relieving both GOO and obstructive jaundice. Real world data on double drainage feasibility is emerging.

Methods A retrospective analysis of patients undergoing both EUS-GJ and EUS-BD was conducted across 2 UK centres over 17 months. Data collected included demographics, indication, sedation approach, drainage approach, technical success rate, clinical success rate, adverse events, re-intervention rate and survival. Univariate analysis was performed to compare outcomes and Cox regression used to determine factors influencing survival.

Results 18 patients underwent double drainage intervention. Mean patient age was 69.7 with 55 % male predominance (n = 10/18). 78 % of procedures were completed under conscious sedation (n = 14/18). Pancreatic adenocarcinoma was the most common pathology (44 %, n = 8/18), followed by duodenal adenocarcinoma (22 %, n = 4/18). EUS-GB was the most common biliary drainage approach (33 %, n = 6/18), followed by EUS-CDD (27 %, n = 5/18). Technical success was achieved in 100 % of patients. Clinical success rate was 88.9 % (n = 16/18) with a significant drop in bilirubin (median pre-bilirubin 158 vs median post-bilirubin 36, p = 0.0007). Adverse events were recorded in 16.7 % (3/18; acute renal failure, lower respiratory tract infection, CDD stent occlusion). Re-intervention was required in 11 % (2/18). Median survival post intervention was 97 days (range 40-171). Palliative chemotherapy post intervention conferred a significant survival benefit, OR 1.2 (95 % CI 1.07-1.6).

Conclusions Real world date demonstrates that EUS double-drainage provides a single session alternative to surgical or radiological drainage options. Clinical success and complication rates were comparable with international standards. Although conscious sedation supported double-drainage is feasible, general anaesthetic remains the preferred sedation approach to facilitate prolonged interventional procedures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1038 The Index of Severity for Eosinophilic Esophagitis is associated with baseline clinical and endoscopic characteristics but not predict the response to BOT in adult patients

Authors Pellegatta G[1,2], Giugliano F[1,2], Nicita G[1,2], Marcozzi G[1,2], Poletti V[2,1], Petronio L[1,2], Drago A[2], Hassan C[1,2], Repici A[1,2]
Institutes **1** Humanitas Research Hospital, Rozzano, Italy; **2** Humanitas University, Pieve Emanuele, Italy
DOI 10.1055/s-0046-1822365

Aims The Index of Severity for Eosinophilic Esophagitis (I-SEE, EoE) is a longitudinal, clinically applicable scoring system designed to evaluate the complete extent of EoE symptoms, endoscopic and histologic activity, fibrostenotic progression, and the risk of complications. We aimed to define the relationship between the I-SEE score and EoE features and disease severity at diagnosis, and to assess whether the I-SEE score could predict the loss of response to budesonide orodispersible tablets (BOT).

Methods Patients with EoE undergoing at least one year of BOT maintenance therapy at the dosage of 1 mg/day were enrolled. The I-SEE score was calculated at the time of EoE diagnosis. According to the score, patients were classified as mild (1–6 points), moderate (7–14 points) or severe (≥15 points). Patients characteristics and disease features, including symptoms, endoscopy and histology, were collected at baseline and after one year of BOT therapy. Pearson correlation, chi-square test and logistic regression analysis were used where appropriate. A p value < 0.05 was considered statistically significant.

Results A total of 114 adult EoE patients (81.6 % male) with a mean age of 38.7 (SD ± 12.8) were retrospectively enrolled in the study. At baseline, 27.2 %, 54.4 % and 18.4 % of patients had mild, moderate and severe I-SEE scores, respectively.
At diagnosis, the total I-SEE score positively correlated with diagnostic delay ($r^2 = 0.18$, $p = 0.043$) and with the EREFS score ($r^2 = 0.40$, $p < 0.001$). Moderate/severe I-SEE was significantly associated with food impaction ($\chi^2 = 13.6$, $p = 0.001$) the presence of stenosis ($\chi^2 = 28.4$, $p < 0.001$) and the need for endoscopic dilation ($\chi^2 = 20.9$, $p < 0.001$) at diagnosis. Presence of atopic comorbidities at baseline did not correlate with I-SEE severity score.
In the logistic regression model, increasing I-SEE severity was a strong independent predictor of endoscopic dilation ($p < 0.01$), corresponding to almost ten-fold increase in risk for each severity category (OR = 9.97, 95 % CI:2.8-34.4).
In our cohort, 4.9 % has not responded to induction treatment and 24.7 % lost histological response after 1 year of BOT. The I-SEE score at diagnosis did not correlate with BOT failure and it could not predict loss of response after one year of follow-up.

Conclusions In our study, the I-SEE score could not predict loss of response to BOT treatment. However, our results suggest that the I-SEE is a valuable tool for classifying EoE patients according to the severity of their symptoms, endoscopic activity and fibrostenotic features, and for predicting the need for endoscopic dilation at diagnosis.

DOI 10.1055/s-0046-1822366

Aims Endoscopic ultrasound-guided liver biopsy (EUGLB) has become an alternative to percutaneous biopsy. The most commonly used techniques require several punctures in both hepatic lobes. The technique with dynamic aspiration with heparin (DAH) allows the procedure to be performed with a single puncture without affecting quality indicators. Our aim is to describe our center's experience with the implementation of EUGLB with DAH.

Methods Retrospective study of patients undergoing EUGLB with DAH from September 2024 to June 2025 at our center. Clinical, anatomicopathological, and procedural data were collected. The procedure was performed using the DAH technique with a single transduodenal puncture with a 19F biopsy needle (Boston Adquire) on the right hepatic lobe. An adequate sample was defined as ≥ 20 mm in size and including ≥ 11 complete portal spaces (CPS).

Results A total of 30 EUGLB procedures were performed with DAH. The main indication was hypertransaminasemia (81.7 %). Other indications were suspected rejection (4.5 %) and acute hepatitis (13.7 %). The mean total sample size was 58.7 ± 26.6 mm, the mean size of the largest fragment was 20.6 ± 9.22 mm, and the mean number of CPS was 12 ± 6.79. An adequate sample was obtained in 68.7 % of cases, and a histological diagnosis was possible in 100 % of cases. No serious adverse effects were observed, and all patients were discharged in less than 12 hours. In 2 cases (6.6 %), abdominal pain was reported, which was controlled with first-line analgesia.

Conclusions EUGLB with DAH has proven to be a safe and effective technique for obtaining liver parenchyma samples with a single puncture.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1040 Clinical benefits of prucalopride in colon capsule endoscopy: A Real-World comparative analysis

Authors Németh B[1,2], Finta A[1], Bélafi D[1], Novák P[3,1], Göbl J[1], Szombath R[1], Tupcsia F[1], Maróti Z[1], Sziklási T[1], Tőgl K[1], Szalai M[1], Katona M[1], Madácsy L[1]
Institutes **1** Endo – Kapszula Magánorvosi Centrum, Székesfehérvár, Hungary; **2** Petz Aladár County Teaching Hospital, Győr, Hungary; **3** Kiskun County Hospital, Kecskemét, Hungary
DOI 10.1055/s-0046-1822367

Aims Colon capsule endoscopy (CCE) is a noninvasive alternative for colorectal evaluation; however, its widespread adoption has been limited by historically suboptimal completion rates and inadequate colonic cleanliness compared with conventional colonoscopy. Prucalopride, a selective 5-HT4 agonist, may improve gastrointestinal motility and enhance CCE performance, but real-world data are limited.

Methods A prospective, cohort analysis was performed on 500 CCE examinations. Asymptomatic, FIT negative patients (aged between 40 and 60 years) were enrolled and divided into two groups: those who did not receive prucalopride and/or fleet enema (n = 250) and those who received 2 mg prucalopride immediately after gastric imaging (n = 250). In this group if colonic transit was already prolonged, patients (who consented) received an on-demand rectal sodium phosphate enema as a rescue booster. Gastric, small bowel, colonic and total transit times were compared using Welch's t-test. Completion rates (defined as excretion or visualization of the hemorrhoidal plexus before battery depletion) were compared using chi-square and Fisher's exact tests. Polyp detection rates and CC-CLEAR colonic cleanliness scores were also analyzed.

Results Prucalopride and enema booster administration significantly reduced small bowel transit time (mean 99.7 vs. 54.6 min, $p < 0.001$) and total examination time (392.9 vs. 315.9 min, $p = 0.0056$), while gastric and colonic transit times showed no significant differences.
The technical incomplete examination rate was markedly lower in the new protocol group (15/493) compared with the control group (16/100) ($p < 0.00001$; OR 6.07), indicating a more than six-fold reduction in failure risk. Polyp detection rates did not differ significantly between the groups (21 % vs. 29 %; $p = 0.11$).

In the CC-CLEAR subset, colonic cleanliness was significantly better with prucalopride (mean score 3.8 vs. 8.4; p < 0.001).

Conclusions Our new protocol improves the efficiency and technical success of colon capsule endoscopy by significantly accelerating transit and enhancing colonic cleanliness, while maintaining comparable polyp detection rates. These findings suggest that optimized CCE protocols may help overcome longstanding limitations of the modality and hold promise for future application as a non-invasive colorectal cancer screening alternative, particularly in FIT-negative screening populations who require reliable yet patient-friendly diagnostic pathways.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1041 Comparison of AI-based CADx systems for optical diagnosis of colorectal polyps

Authors Finta A[1], Németh B[1, 2], Bélafi D[1], Novák P[3, 1], Göbl J[1], Szombath R[1], Sziklási T[1], Tupcsia F[1], Maróti Z[1], Tőgl K[1], Szalai M[1], Katona M[1], Madácsy L[1]
Institutes 1 Endo – Kapszula Magánorvosi Centrum, Székesfehérvár, Hungary; 2 Petz Aladár County Teaching Hospital, Győr, Hungary; 3 Kiskun County Hospital, Kecskemét, Hungary
DOI 10.1055/s-0046-1822368

Aims Artificial intelligence (AI)–assisted polyp characterization during colonoscopy may support real-time decisions on resection strategy and surveillance intervals. Several systems are now available, but head-to-head comparative data remain limited.

Our aim was to compare the diagnostic performance of two CADx systems (MagentiQ and PolypBrain) for differentiating neoplastic from non-neoplastic colorectal polyps during colonoscopy, using histology as the gold standard.

Methods We performed a retrospective single-centre analysis of 62 colorectal polyps with available histology and AI-based predictions from both systems. Histopathology was classified as neoplastic (adenomas, sessile serrated adenomas/lesions, adenocarcinoma, high-grade neoplasia) or non-neoplastic (hyperplastic and juvenile polyps, inflammatory/IBD-related changes, normal mucosa). For MagentiQ, outputs labelled "Neo" / "Neo–Neo" were considered neoplastic; "Non-Neo", "Inconclusive" or "not found" were considered non-neoplastic. For PolypBrain, any output containing "adenoma" was classified as neoplastic; all other outputs (including "too small / too bloody / not classified") were considered non-neoplastic. We calculated sensitivity, specificity, positive and negative predictive values (PPV, NPV) and overall accuracy, and compared paired classifier performance using McNemar's test.

Results Histology identified 46/62 (74.2 %) lesions as neoplastic. For MagentiQ, sensitivity was 67.4 % (31/46), specificity 68.8 % (11/16), PPV 86.1 % (31/36), NPV 42.3 % (11/26), and accuracy 67.7 % (42/62). For PolypBrain, sensitivity was 73.9 % (34/46), specificity 62.5 % (10/16), PPV 85.0 % (34/40), NPV 45.5 % (10/22), and accuracy 71.0 % (44/62). PolypBrain correctly classified 14 lesions that MagentiQ misclassified, whereas MagentiQ correctly classified 12 lesions misclassified by PolypBrain (McNemar p = 0.85).

Conclusions Both AI systems achieved high PPV but only moderate sensitivity for identifying neoplastic colorectal polyps. PolypBrain showed slightly higher sensitivity and overall accuracy at the expense of somewhat lower specificity, while overall performance differences were not statistically significant. These findings support the potential of AI-assisted polyp characterization but highlight the need for the opinion of experts as AI systems remain suboptimal.

eP1042 Comparison of EUS-Guided and Percutaneous Liver Biopsy Needles for Diagnostic Yield and Tissue Adequacy in Explanted Cirrhotic Livers: A Prospective Comparative Study

Authors Puri R[1], Ashwin K[2], Mehta S[2], Jain HP[2], Panchal H[2], Rawal P[2]
Institutes 1 Institute of Digestive and Hepatobiliary Sciences, Medanta, the Medicity, Gurugram, India; 2 Institute of digestive and Hepatobiliary sciences, Medanta the Medicity, Gurugram, India
DOI 10.1055/s-0046-1822369

Aims Endoscopic ultrasound–guided liver biopsy (EUS-LB) isincreasingly used as an alternative to percutaneous liver biopsy (PC-LB), butcomparative evidence on optimal needle selection remains limited. This studycompared diagnostic yield and tissue adequacy of EUS and percutaneous biopsy needles using explanted cirrhotic livers [1].

Methods In this prospective, comparative ex-vivo study, 30 adult explanted cirrhotic livers underwent biopsies using four needles: PC-16G, PC-18G, EUS-19G FNB, and EUS-22G FNB from both lobes (total 240 biopsies). Tissueadequacy was defined as specimen length >15 mm and ≥ 11 complete portaltracts (CPT). Histopathology was assessed by a blinded pathologist. Repeated-measures ANOVA, Cochran's Q, and McNemar tests were used (▶ **Table 1**).

▶ **Table 1** DIAGNOSTIC ACCURACY OF EUS AND PC NEEDLES

Sl no.	Needles	Stage 2 n (%)	Stage 3 n (%)	Stage 4 n (%)
1	PC 16 G	1 (3.3 %)	1 (3.3 %)	58 (96.6 %)
2	PC 18 G	0	8 (13.3 %)	52 (86.6 %)
3	EUS 19 G	0	21 (35 %)	39 (65 %)
4	EUS 22 G	16 (26.6 %)	43 (71.6 %)	1 (3.3 %)

Results Mean total specimen length was highest with EUS-19G (26.8 ± 14.9mm), followed by PC-16G (18.8 ± 5.5 mm), PC-18G (17.9 ± 6.2 mm), and EUS-22G (12.9 ± 8.2 mm) (p<0.001). Mean CPT was comparable between EUS-19G(13.5 ± 3.8) and PC-16G (13.4 ± 2.8), but significantly lower with EUS-22G (8.9 ± 3.2, p<0.001). Tissue adequacy was achieved in 98 % with PC-16G, 93 % with PC-18G, 92 % with EUS-19G, and 50 % with EUS-22G (p<0.001). Cirrhosis was most accurately identified with PC-16G and EUS-19G, while EUS-22G had higher non-diagnostic rates and lower fibrosis staging accuracy.

Conclusions EUS-19G provides tissue adequacy and portal tract yieldcomparable to standard percutaneous biopsy needles and yields significantlylonger core specimens. EUS-22G is inferior for diagnostic liver biopsy. EUS-19Grepresents a reliable alternative to PC-LB in appropriately selected patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1043 Utility of EUS chronic pancreatitis criteria in prediction of pancreatic texture and pancreatic fistula post pancreaticoduodenectomy

Authors Puri R[1], Wasi S[2], Mehta S[3], Jain HP[3], Panchal H[3], Rawal P[3]
Institutes 1 Institute of Digestive and Hepatobiliary Sciences, Medanta, the Medicity, Gurugram, India; 2 Institute of Digestive and Hepatobiliary Sciences, Medanta the Medicity, Gurugram, Gurugram, India; 3 Institute of Digestive and Hepatobiliary Sciences, Medanta the Medicity, Gurugram, India
DOI 10.1055/s-0046-1822370

Aims Postoperative pancreatic fistula (POPF) remains the most significant complication following pancreaticoduodenectomy (PD), and pancreatic parenchymal texture is a key determinant of POPF risk. While intraoperative palpation and histopathological fibrosis assessment are traditional methods to evaluate pancreatic texture, a reliable preoperative tool is lacking. Endoscopic ultrasound (EUS) provides high-resolution evaluation of pancreatic parenchyma. EUS conventional criteria of chronic pancreatitis (EUS CP criteria) has been found to corelate well with pancreatic fibrosis but whether the criteria can predict POPF has not been established. The aim of the study was to evaluate the accuracy of the preoperative EUS CP criteria in predicting POPF and to assess its association with intraoperative pancreatic texture by palpation and histopathological fibrosis [1].

Methods A prospective observational study was conducted on patients with benign and malignant periampullary disease undergoing PD. Preoperatively, all patients underwent EUS and CP scoring (0–9). Intraoperative pancreatic texture by palpation and histopathological fibrosis (Klöppel score) were recorded. Comparative analysis was performed between patients with and without POPF (▶ **Table 1**).

▶ **Table 1**

Statistic	Value	95 % Confidence Interval
Sensitivity	95.24 %	76.18 % to 99.88 %
Specificity	27.78 %	9.69 % to 53.48 %
Positive Predictive Value	60.61 %	53.21 % to 67.54 %
Negative Predictive Value	83.33 %	39.10 % to 97.50 %
Accuracy	64.10 %	47.18 % to 78.80 %

Results POPF occurred in 53.8 % (21/39), with clinically relevant POPF in 19 %. Soft pancreas and non-dilated pancreatic duct were significantly associated with POPF (p = 0.003 and p = 0.002). EUS CP criteria ≥ 3 was significantly associated with firm/hard pancreas and lower POPF incidence (16.7 %) whereas those with criteria < 3 was associated with soft pancreas and higher POPF incidence (60.6 %). EUS CP criteria correlated significantly with intraoperative pancreatic texture (p = 0.001) and histopathological fibrosis (p = 0.005). EUS CP criteria predicted POPF (p = 0.047), demonstrating high sensitivity (95 %) and NPV (83 %) but lower specificity (28 %) and PPV (63 %), with an overall diagnostic accuracy of 64 %.

Conclusions Preoperative EUS using the CP criteria reliably predicts pancreatic texture and can serve as a valuable screening tool to identify patients at high risk for POPF prior to PD. Incorporating EUS-based assessment into preoperative planning may enhance risk stratification and guide perioperative management

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1044 Diagnostic Utility of Pancreatic and Bile Duct Brushing for Pancreatic Cancer During ERCP: A Systematic Review and Meta-Analysis

Authors Kollanyi G[1], Hegyi PJ[2], Váncsa S[3], Obeidat M[2], Hegyi P[4], Erőss B[1]
Institutes **1** Semmelweis University, Budapest, Hungary; **2** Centre for Translational Medicine, Semmelweis University, Budapest, Hungary; **3** Centre for Translational Medicine, Semmelweis University, Budapest, Hungary, Budapest, Hungary; **4** Division of Pancreatic Diseases, Heart and Vascular Center, Semmelweis University, Budapest, Hungary
DOI 10.1055/s-0046-1822371

Aims Pancreatic cancer is a highly lethal disease, often diagnosed at an advanced stage when onlypalliative care is available. Endoscopic retrograde cholangiopancreatography (ERCP) withbrush cytology or forceps biopsy is commonly used to obtain samples from the bile duct (BD)and pancreatic duct (PD) in patients presenting with distal biliary strictures; however, itsdiagnostic accuracy remains debated. This study aimed to assess the pooled sensitivity of BDand PD brushing, as well as BD forceps biopsy, in detecting pancreatic cancer compared tohistology.

Methods A systematic search was conducted in three major medical databases on November 05, 2024.We included studies reporting the performance measures of BD and/or PD brushing or forcepsbiopsy, primarily based on histology, but also considering radiological follow-up, laparotomy,or other accepted diagnostic methods. A random-effects meta-analysis was performed tocalculate the pooled sensitivity of each technique for various cytopathological interpretations,with results presented as percentages and 95 % confidence intervals (CI).

Results Our systematic search identified 11340 articles, of which 83 met the inclusion criteria for thefinal analysis. These included 6,638 BD brushing procedures, 1,089 PD brushing procedures,and 3,416 BD forceps biopsies. The pooled sensitivity for PD brushing was 53 % (95 % CI:28 % – 76 %; I 2 = 70.3 %), for BD brushing 28 % (95 % CI: 23 % – 34 %; I 2 = 58.8 %), for BDforceps biopsy 36 % (95 % CI: 29 % – 45 %; I 2 = 0 %) when only clearly malignant sampleswere considered positive. Additional analyses were performed to explore differences ofdifferent cytopathological interpretations. The post-ERCP pancreatitis rate did not differbetween index tests, and it remained under 5 % for each. However, data on the safety andadverse events associated with ERCP were limited among the included studies.

Conclusions PD brushing may increase the sensitivity compared to BD brushing during ERCP and providea valuable ancillary diagnostic technique in detecting pancreatic cancer in patients with distalbiliary strictures. Moreover, PD brushing may not elevate the risk for post-ERCP pancreatitisin this population. These findings support the integration of brush cytology in ERCPprocedures to enhance early detection of pancreatic cancer, ultimately facilitating moreinformed clinical decision-making.

eP1045 Evaluation of the Safety and Diagnostic Yield of Transvascular and Thrombus Fine-Needle Aspiration in Suspected Malignancy

Authors Sanjosé Crespo A[1], Cobreros del Caz M[1], Martinez C[1], Sánchez-Ocaña R[1], Fernández Prada SJ[1], Perez-Miranda M[2], De La Serna Higuera C[1]
Institutes **1** Rio Hortega University Hospital, Valladolid, Spain; **2** Hospital Universitario Rio Hortega, Valladolid, Spain
DOI 10.1055/s-0046-1822372

Aims Endoscopic ultrasound-guided fine-needle aspiration has become an indispensable tool for the diagnostic workup and biological characterization of lesions arising within or adjacent to the gastrointestinal tract. However, in certain clinical scenarios, the presence of interposed vascular structures may impede direct access to the target lesion, limiting the feasibility of conventional approaches. In recent years, transvascular EUS-guided puncture has emerged as a technically feasible and potentially safe diagnostic alternative.

The aim of this study was to evaluate the feasibility, safety profile, and diagnostic performance of EUS-guided transvascular fine-needle aspiration, including portal thrombus puncture, in patients undergoing workup for suspected malignant disease in a tertiary referral centre.

Methods A retrospective case series was conducted including consecutive patients who underwent EUS-guided transvascular aspiration of suspicious lesions between 2014 and 2025. Demographic characteristics, comorbidities, procedural variables (including needle gauge, type of access, target anatomy, and number of needle passes), and peri-procedural management were record-

ed. Diagnostic performance (sensitivity, specificity, and accuracy) was assessed based on cytopathological results, including immunohistochemical profiling when available. Procedural safety was evaluated by documenting adverse events and classifying them according to severity.

Results Sixteen patients were included, with a median age of 69.5 years; 75 % were male. Most patients were classified as ASA II, and the mean Charlson Comorbidity Index was 4.75. Anticoagulant or antiplatelet therapy had been prescribed in 25 % of cases and was temporarily discontinued before the procedure. Targets included suspected malignant portal thromb (50 %), pancreatic cystic lesions (25 %), lymphadenopathy (12.5 %), and solid masses (12.5 %). Access routes comprised transportal puncture (31.25 %), non-portal transvascular routes (18.75 %), and direct puncture of portal thrombi (50 %). A 22G needle was used in 62.5 % of procedures, employing a slow-pull technique with two to three passes. A diagnostic specimen was successfully obtained in 81 % of cases, sensitivity of 81.8 % (95 % CI 52.3–94.9), specificity of 100 % (95 % CI 56.6–100), and overall accuracy of 87.5 % (95 % CI 63.0–96.8). Malignancy was confirmed in 56.25 % of patients, and immunohistochemistry was feasible in all cytologically malignant specimens.

A total of 43.75 % of procedures were performed in hospitalized patients and 56.25 % on an outpatient basis. Only one patient required admission due to acute pancreatitis, which resolved with conservative management. The composite adverse event rate was 12.5 %, and no statistically significant association was found between adverse events and age, sex, ASA score, Charlson Index, or anticoagulant use ($p > 0.15$).

Conclusions EUS-guided transvascular puncture appears to be a feasible and safe technique with high diagnostic performance in selected clinical scenarios involving difficult-to-access lesions or malignant thrombi. The favourable outcomes and low complication rate observed in this cohort support the incorporation of transvascular access as a complementary diagnostic strategy in advanced endoscopic practice. Furthermore, these findings raise the possibility that transvascular access may eventually extend beyond diagnostic applications and into therapeutic endoscopic interventions.

eP1046 The Introduction of Safety Checklist in Endoscopy: A Nationwide Prospective Multicentric Study

Authors Tari E[1], Hegyi PJ[1], Hegyi P[2], Patai AV[3], Fürst E[4], Tari K[5], Barkai LJ[6], Erőss B[5]

Institutes **1** Centre for Translational Medicine, Semmelweis University, Budapest, Hungary; **2** Division of Pancreatic Diseases, Heart and Vascular Center, Semmelweis University, Budapest, Hungary; **3** Department of Surgery, Transplantation and Gastroenterology, Semmelweis University, Budapest, Hungary; **4** Semmelweis University Centre for Translational Medicine, Centre for Pancreatic Diseases, Budapest, Hungary; **5** Semmelweis University, Budapest, Hungary; **6** Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary

DOI 10.1055/s-0046-1822373

Aims The European Society of Gastrointestinal Endoscopy (ESGE) recommends the use of a standardized safety checklist. The concept is gaining attention, but real-world data on its implementation and impact remain limited. This study aimed to assess the feasibility, adherence, and user perception of implementing the ESGE Safety Checklist in gastrointestinal endoscopic practice across Hungary.

Methods A nationwide, prospective, multicenter observational study was conducted between 20 January and 14 February 2025 in 14 public and seven private endoscopy units. The ESGE Safety Checklist was translated into Hungarian and locally adapted before implementation. Data were collected on the checklist application, procedure type, preventable errors, and user feedback. Quantitative data were analyzed descriptively, and qualitative comments were thematically summarized.

Results Altogether, 5124 procedures were performed, of which 4160 (81.2 %) were completed with the checklist. Adherence was higher in private (94.7 %) than in public centers (80.0 %). The checklist identified at least one preventable error in 335 procedures (8.0 %) and multiple deficiencies in 117 (2.8 %). The most frequent omissions were team introductions (5.7 %), post-procedure instructions (2.7 %), resumption of anticoagulation (1.9 %), and rectal administration of nonsteroidal anti-inflammatory drugs during endoscopic retrograde cholangiopancreatography (2 %). Preventable errors occurred most often during colonoscopy (4.5 %) and gastroscopy (2.6 %). Most centers reported improved communication, organization, and attention to patient safety.

Conclusions In a considerable proportion of endoscopic procedures, the ESGE Safety Checklist helped identify preventable errors, confirming its practical value in improving procedural safety. Its implementation enhanced procedural structure and supports broader adoption, strengthening patient safety and quality.

eP1047 Dual Endoscopic Approach for Radiation-induced Complete Esophageal Obstruction in the Upper Esophagus: Insights from Two Challenging cases

Authors Siyal M[1], Siddiqui A[1], Kadir S[1], Niaz S[1], Altaf A[1]

Institute **1** Sindh Institute of Advanced Endoscopy and Gastroenterology, Karachi, Pakistan

DOI 10.1055/s-0046-1822374

Abstract Text

Complete esophageal obstruction (CEO) is an uncommon but debilitating late complication of chemoradiotherapy for head and neck cancers, with reported incidence ranging from 0.8 % to 5 %. Affected patients experience profound dysphagia, often losing the ability to swallow even saliva, resulting in dependence on enteral feeding and markedly impaired quality of life. While traditional management relied on complex surgical reconstruction, the combined antegrade and retrograde endoscopic dilation (CARD) technique has emerged as a less invasive and increasingly preferred option. CARD facilitates safe recanalization of obstructed esophageal segments, but its use in upper esophageal strictures, particularly those near the upper esophageal sphincter, remains technically challenging and underreported. We present two cases of radiation-induced CEO involving the upper esophagus, emphasizing procedural strategies, outcomes, and practical considerations [1–8].

The first case involved a 54-year-old man treated previously with chemotherapy and radiotherapy for buccal squamous cell carcinoma. He presented with complete dysphagia (FOIS 1) and dependence on a pre-existing PEG tube. Endoscopic evaluation revealed total obstruction just below the pyriform fossa. CARD was performed using dual ultrathin gastroscopes introduced antegrade and retrograde, with transillumination enabling precise scope alignment in this anatomically difficult region. A needle-knife puncture was made through the fibrotic segment, followed by guidewire passage and sequential Savary dilation up to 15 mm. The procedure was technically successful and complication-free. After subsequent dilations, the patient achieved sustained recanalization and full PEG removal, ultimately tolerating a soft diet (FOIS 6) at one year.

The second case involved a 15-year-old boy with hypopharyngeal squamous cell carcinoma who also presented with absolute dysphagia and PEG dependence. CARD was performed with transillumination guidance, needle puncture, cystotome-assisted tract creation, and sequential balloon and mechanical dilatation. A nasogastric tube was left across the recanalized lumen to maintain patency. Although initial improvement allowed limited oral intake, early recurrence was noted. Repeat CARD and serial dilations resulted in improvement to FOIS 3 (liquids only), though PEG dependence persisted. Mild bleeding occurred but resolved spontaneously, consistent with the low complication rates reported in the literature.

These cases demonstrate that CARD is a safe and effective modality for managing radiation-induced CEO, even in anatomically constrained upper esophageal locations. Successful recanalization can significantly improve swallowing function and quality of life. However, recurrence remains a major limitation, particularly in pediatric patients and in severe post-radiation fibrosis, necessitating repeated interventions and long-term multidisciplinary follow-up. Overall, CARD offers a minimally invasive alternative to surgery, with meaningful functional benefits despite its inherent challenges.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1048 The road to papilla- ERCP in patients with altered anatomy Following Billroth II Gastrectomy: A 20-year, retrospective, single-center study

Authors Kontonikola A[1], Manganari E[1], Mouallimoglou F[1], Tolis C[1], Brouvalis M[1], Karakousi K[1], Konstantaras V[1], Tzitzi E[1], Tsaktsira V[1], Vasiliou K[1], Avgerinos A[1], Dimoulios F[1], Kapetanos D[1]

Institute 1 General Hospital of Thessaloniki "Georgios Papanikolaou", Thessaloniki, Greece

DOI 10.1055/s-0046-1822375

Aims Endoscopic Retrograde Cholangiopancreatography (ERCP) in patients with altered anatomy due to Billroth II (BII) gastrectomy remains challenging. Difficulties arise from the need to traverse the afferent loop, reach the major duodenal papilla, and achieve selective cannulation due to reversed anatomy. These challenges often demand the use of specialized techniques and both side-viewing and forward-viewing endoscopes. This study aims to evaluate the efficacy and safety of ERCP in this patient population [1, 2].

Methods We conducted a 20-year retrospective study in our hospital between February 2005 and October 2025. Non-naive ERCP patients with BII anatomy were excluded. Data on demographics, indications, endoscope type used (duodenoscope, gastroscope) and procedural outcomes were systematically collected. Initial endoscopic evaluation with gastroscope was performed in all patients to determine the optimal approach. The study outcomes included successful afferent loop intubation, papilla cannulation, completion of procedure, and rate of procedure-related complications. Standard ERCP devices and pharmacological sedation were used in all patients.

Results A total of 54 patients (42 males, 12 females) were studied. The median age of the group was 78.5 years. The most common indication was choledocholithiasis (n = 42, 77.8 %). Other indications included cholangitis (n = 3, 5.6 %), obstructive jaundice (n = 3, 5.6 %), biliary colic (n = 2, 3.7 %), cholangiocarcinoma (n = 2, 3.7 %), and pancreatic cancer (n = 2, 3.7 %).

The majority of procedures, 44 (81.5 %), were performed using a duodenoscope, while 10 procedures (18.5 %) utilized a gastroscope. The overall technical success rate for the entire cohort was 85.2 % (46/54). A detailed analysis revealed a success rate of 84.1 % (37/44) in the duodenoscope group compared to 90.0 % (9/10) in the gastroscope group (p = 0.46). The rates of successful afferent loop intubation (95.5 % vs 90 %) and selective cannulation (86.4 % vs 90 %) did not differ significantly between the two endoscope type groups.

Among the cohort, 6 patients (11.1 %) had a concurrent Braun anastomosis, a configuration usually excluded from prior studies. Success was significantly lower in patients of this subgroup compared to standard BII anatomy (50.0 % vs 89.6 %,p = 0.036, < 0.05).

Regarding safety, major complications occured in 5 patients (9.3 %). This included three perforations(5.5 %) requiring surgery, one post-ERCP bleeding managed endoscopically, and one case of pancreatitis. All complications except one perforation occurred in the duodenoscope group. No case of cholangitis were recorded in either group.

Conclusions In this study, ERCP in patients with Billroth II anatomy demonstrated efficacy and safety comparable to existing literature. No statistically significant differences were found between endoscope types. However, patients with a concurrent Braun anastomosis had a statistically significant lower sucess rate (p = 0,036), highlighting the technical challenge of this complex anatomy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Autoimmune pancreatitis (AIP) is a rare form of chronic pancreatitis and is classified into two subtypes: type 1 (associated with systemic IgG4-related disease) and type 2 (not associated with IgG4). Diagnosis is based on a combination of clinical, imaging, serological, and histological findings [1–4].

We present the case of a 52-year-old woman who was referred to our department for endoscopic ultrasound (EUS) evaluation due to an enlargement of the pancreatic head. The reported lesion has been identified in recent imaging studies (CT, MRI) performed due to painless obstructive jaundice. Serologically, a markedly elevated serum IgG4 level was recorded, while tumor markers CEA and CA19-9 were within normal limits. Medical history revealed a possibly underdiagnosed IgG4-related ocular disease; the patient had undergone sur-

gical excision of the lacrimal gland three years earlier, due to severe inflammation and vision impairment. The histological exams revealed dense lymphoplasmacytic infiltrate, storiform fibrosis and IgG4-positive lymphoplasmacytic infiltration with IgG4 + /IgG plasma cell ratio < 20 %.

EUS revealed diffuse, homogeneous and hypoechoic enlargement of the head, uncinate, isthmus, and part of the body of the pancreas, without clear features of an infiltrative neoplasm. The pancreatic duct appeared thin yet visible, whereas the intrapancreatic portion of the common bile duct was narrow with upstream dilatation. Endoscopic ultrasound-guided biopsy showed extensive fibrosis with scattered lymphocytic aggregates, numerous small tubular formations, and scattered plasma cells without IgG4 expression.

A presumptive diagnosis of type 1 AIP was made based on the medical history, imaging features and elevated serum IgG4, despite certain atypical findings. Corticosteroid therapy was initiated, leading to rapid clinical and biochemical improvement and marked regression of the imaging findings.

Nonetheless, symptoms relapsed during corticosteroid tapering. The patient, subsequently, appeared with jaundice, blared vision and arthralgia. Following consultation with a rheumatologist, a shared decision was made to initiate rituximab and a substantial improvement was observed. The patient remains under close surveillance with blood tests and frequent clinical assessment.

This case demonstrates the diagnostic problems associated with autoimmune pancreatitis in the absence of histological IgG4 confirmation, underlining the need for a multifactorial approach, particularly when a relevant medical history is present. In uncertain cases, where the diagnosis is unclear, particularly when the traditional diagnostic criteria are not entirely satisfied, the therapeutic response can support the diagnosis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1050 Comparison of Biliary Decompression Methods in Malignant Distal Biliary Obstruction when Failed ERCP: A Single Referral Centre Experience

Authors Provi D[1], Papastergiou V[1], Rallatou M[1], Paparizou N[1], Patsi M[1], Vergenaki E[1], Sofianopoulos D[1], Georgilis E[1], Kalogiros G[1], Themeli S[1], Kozompoli D[1], Fiagkousakis K[1], Archavlis E[1], Varytimiadis K[1], Vienna E[1], Viazis N[1]

Institute 1 Evangelismos General Hospital, Athina, Greece

DOI 10.1055/s-0046-1822377

Aims ERCP is the established method for biliary drainage in patients with malignant distal biliary obstruction (MDBO); however, in approximately 5-15 % of cases ERCP may fail.Various salvage techniques are used to effectively drain the biliary tract in patients with MDBO, including percutaneous transhepatic cholangiography (PTC), EUS-guided choledochoduodenostomy (EUS-CDS) and EUS-guided rendezvous technique (EUS-RV). The aim of this study is to compare the clinical efficacy and safety of PTC, EUS-CD and EUS-RV in patients with MDBO and failed ERCP drainage.

Methods Data from patients with MDBO who underwent PTC, EUS-CDS or EUS-RV (1/2022-8/2024) after failed ERCP were retrospectively studied. MDBO was defined as malignant obstruction between the papilla and the cystic duct. All patients had previously failed ERCP drainage, either because it was not technically feasible or because it did not reduce bilirubin levels. The primary endpoint was the clinical success of the method (reduction in total bilirubin of at least 50 % at 2 weeks). The secondary endpoint was the occurrence of complications.

Results A total of 66 patients (45,9 % males) were included, categorized by underlying pathology: distal cholangiocarcinoma (24 patients, 36,4 %), periampullary carcinoma (23 patients, 34,8 %), and pancreatic carcinoma (19 patients, 28,8 %). Intervention types included EUS-CDS drainage (30 patients, 45,5 %), PTC (13 patients, 34,8 %), and EUS-rendezvous technique (23 patients, 34,8 %). Mean initial total bilirubin was 10.6 ± 4.7 mg/dL, decreasing to 3.1 ± 3.4 mg/dL post-intervention, representing a mean reduction of 69.6 %. The clinical success rate of EUS-CDS (90 %) was significantly higher as compared , with the most common complications being bleeding (6.7 %) and peritonitis (3.3 %). Regarding clinical success, EUS-CDS showed a statistical trend toward higher clinical success compared to PTBD (90 % vs 69.2 %, p = 0,09), although no significant difference was detected in comparison with EUS-RV (90 % vs 78.3 %, p = 0.237). PTC showed a success rate of 69.2 % with the most common complications being abscess formation (15.4 %), biloma (7.7 %) and cholangitis (7.7 %). The EUS-RV technique was clinically successful in 78.3 %, with the most frequent complication being bleeding (17.4 %) followed by cholangitis (4.3 %). Pairwise comparisons of complication distributions showed a borderline significant difference between EUS-CDS and EUS-RV technique (p ≈ 0.04–0.05), with higher bleeding in the rendezvous group. Comparisons between EUS-CDS vs PTC and PTC vs EUS-RV did not reach statistical significance (p > 0.05), although PTC tended to have more infectious complications and abscess, while EUS-RV technique had more bleeding.

All complications were treated conservatively and no patient died due to complications.

Conclusions EUS-guided biliary drainage demonstrates superior clinical success rates and lower complication rates compared to PTC and EUS-RV technique in patients with failed ERCP for MDBO. These findings support EUS-guided intervention as the preferred alternative drainage method when ERCP is unsuccessful.

eP1051 Evaluating the Diagnostic Accuracy of EUS-FNB Compared to On-site Evaluations for Diagnosing Pancreatic Neoplasias: A Systematic Review and Meta-analysis

Authors Banfalvi ZI[1, 2], Roman Z[1, 2], Khan A[1], Turquier C[1, 2], Toth R[1], Fehervari P[1], Lee J[1], Obeidat M[1], Bálint E[1, 2], Hegyi JP[1, 2]

Institutes 1 Semmelweis University, Centre for Translational Medicine, Budapest, Hungary; 2 Semmelweis University, Institute of Pancreatic Diseases, Budapest, Hungary

DOI 10.1055/s-0046-1822378

Aims Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) is the primary diagnostic tool for assessing pancreatic masses. The time taken to obtain an accurate diagnosis is critical; therefore, it is essential to acquire a high-quality histological sample. Techniques such as Rapid On-Site Evaluation (ROSE) and Macroscopic On-Site Evaluation (MOSE) may enhance the diagnostic accuracy of EUS-FNB and increase the proportion of histologically adequate samples. However, the necessity of these on-site evaluation techniques remains a topic of debate. This study aims to determine whether these techniques should be incorporated into routine practice.

Methods Five medical databases (PubMed, EMBASE, CENTRAL, Scopus, WebOfScience) were searched comprehensively for studies comparing the diagnostic accuracy of EUS-FNB ± ROSE and/or MOSE in solid pancreatic lesions. In the meta-analysis, pooled proportion rates with 95 % confidence intervals (CIs) were calculated, and then a multivariate meta-analysis model was constructed to calculate the differences.

PROSPERO registration number: CRD42024613021.

Results Altogether, we included 4562 patients' data from 31 articles in our quantitative and qualitative synthesis.
The sensitivity of ROSE (95 % [92 %; 97 %]; p = 0.0087) and MOSE (93 % [92 %; 95 %]; p = 0.0349) is significantly higher than stand-alone EUS-FNB (88 % [83 %; 92 %]).
The specificity of both ROSE (94 % [89 %; 97 %]; p = 0.2368) and MOSE (90 % [81 %; 95 %]; p = 0.5854) does not differ significantly from stand-alone EUS-FNB (92 % [85 %; 96 %]; p = 0.0087).
Both the sensitivity (p = 0.2535) and specificity (p = 0.2535) of ROSE and MOSE are not significantly different.
Conclusions MOSE is equally effective compared to ROSE, suggesting that routine incorporation of MOSE is sufficient in the diagnosis of pancreatic lesions.

eP1052 Vac stent therapy for esophageal perforations after interventional endoscopy: a preliminary case series

Authors Altieri G[1], Dell'Anna G[1], Bernardi F[1], Barchi A[1], Vespa E[1], Viale E[1], Danese S[1], Azzolini F[1], Mandarino FV[1]
Institute 1 Gastroenterology and Gastrointestinal Endoscopy, IRCCS San Raffaele Scientific Institute, Milan, Italy
DOI 10.1055/s-0046-1822379
Aims The Vac Stent system, combining the mechanical properties of self-expandable metal stents with endoluminal negative pressure therapy, has emerged as a promising option for the treatment of post-esophagectomy leaks. However, its role in the management of esophageal perforations following interventional endoscopy has not yet been clearly defined [1].
Methods All consecutive patients with esophageal perforation after interventional endoscopic procedures treated with a Vac Stent at San Raffaele Hospital, Milan, between May 2024 and September 2025 were prospectively included. Placement was performed under fluoroscopic guidance and managed according to the manufacturer's recommendations, including continuous negative pressure settings and predefined timing and modality of removal.
The primary outcome was clinical success, defined as complete closure of the perforation, confirmed by endoscopy, fluoroscopy, and/or CT imaging, along with clinical resolution of symptoms. Secondary outcomes included technical success (successful placement and removal of the Vac Stent), adverse events, total treatment duration, and length of hospital stay.
Results Five patients (4/5 male; median age 66 years, range 55–78) with esophageal perforation were included: four following endoscopic submucosal dissection (ESD) and one following 30-mm balloon dilation for type II achalasia. Histological analysis of the ESD specimens revealed adenocarcinoma in all cases. The mean maximum perforation size was 13 mm (range 5–30).
In three cases, post-procedural CT imaging demonstrated a leak-associated cavity, with a mean cavity size of 17 mm (range 12–24).
Clinical and technical success were achieved in 100 % of cases. The mean total Vac Stent treatment duration was 11 days (range 6–14), with a mean of 1.6 devices per patient (range 1–2). The mean length of hospital stay was 19.4 days (range 7–33). No Vac Stent–related adverse events occurred, and no patient required surgical rescue therapy. Notably, the patient treated after a fully circumferential esophageal ESD did not develop post-procedural esophageal stricture.
Conclusions In this prospective case series, Vac Stent therapy proved to be a safe and effective treatment for esophageal perforations following interventional endoscopy. In addition, it may contribute to the prevention of post-resection esophageal stricture after extensive mucosal resections. Larger, controlled studies are warranted to confirm these preliminary findings.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1053 Compliance with the 2025 ESGE Performance Measures in Endoscopic Ultrasound: a Single-centre Cohort Study

Authors Regatia R[1], Brito D[1], Elvas L[1], Saraiva S[1], Areia M[1], Viegas MI[1], Sarmento Costa M[1], Alves S[1], Cadime AT[1]
Institute 1 Gastroenterology Department, Portuguese Oncology Institute of Coimbra, Portugal, Coimbra, Portugal
DOI 10.1055/s-0046-1822380
Aims Quality improvement in endoscopic ultrasound (EUS) is essential to ensure diagnostic accuracy, procedural safety, and consistency in clinical practice. Given the expanding use of EUS, the European Society of Gastrointestinal Endoscopy (ESGE) released in 2025 an updated set of key performance measures (KPMs) to standardize and enhance quality assessment. The aim of this study was to evaluate compliance with the 2025 ESGE EUS KPMs in a cohort of 124 consecutive EUS procedures and to evaluate our centre's performance across applicable KPMs.
Methods Retrospective cohort study including 124 consecutive EUS procedures performed from September 2024 to October 2025 at a single centre, of which 50 involved EUS-guided fine-needle aspiration/biopsy (EUS-FNA/FNB) of solid lesions. Exclusion criteria were applied according to the 2025 ESGE recommendations. Each procedure was assessed individually for adherence to the relevant KPMs, encompassing both diagnostic EUS and EUS-FNA/FNB indicators. An overall compliance analysis was carried out for each applicable KPM to determine our centre's adherence to the updated 2025 minimum standards (MS) proposed.
Results Among the six KPMs assessed, four met the established minimum standards. Informed patient consent was documented in 100 % of all procedures (MS = 100 %). Adequate documentation of EUS anatomical landmarks was achieved in 96 % of examinations (MS ≥ 90 %). Regarding tissue acquisition from solid lesions, the overall success rate, defined as obtaining a tissue sample that allows an accurate diagnosis, was 86 % (MS ≥ 85 %). No adverse events related to EUS-FNA/FNB were recorded (MS < 5 % in cystic, < 3 % in solid lesions). The remaining indicators performed below the recommended thresholds. For cases involving pancreatic cystic lesions, standardized lesion description was recorded in 70 % (7/10) (MS ≥ 85 %). Finally, formal competence assessment of trainees performing EUS was not documented in any of the 11 eligible procedures (MS ≥ 20 %).
Conclusions This assessment of the 2025 ESGE EUS key performance measures demonstrated strong compliance across several essential domains, including informed consent, adequate documentation, successful and safe tissue acquisition from solid lesions. While some indicators did not fully meet the recommended thresholds, the findings primarily highlight opportunities for continued improvement of practice. Ongoing systematic monitoring of these indicators is crucial to optimize procedural quality, enhance training, and ensure consistent, high-standard EUS practice within our centre.

eP1054 Peroral pancreatoscopy for the assessment of intraductal papillary mucinous neoplasm of the pancreas

Authors Bruckmayer L[1], Benson A[1], Wengrover D[1], Odeh Q[1], Mahamid M[1]
Institute 1 Shaare Zedek Medical Center, Jerusalem, Israel
DOI 10.1055/s-0046-1822381
Aims Peroral pancreatoscopy (POPS) is an endoscopic procedure that allows for direct visualization of the main pancreatic duct (MPD) along with to sample tissue and perform directed local therapy. This study evaluates POPS assess-

ment of intraductal papillary mucinous neoplasm (IPMN) of the pancreas with MPD involvement.

Methods A retrospective, cross-sectional study was conducted on individuals with IPMN who underwent POPS using the Boston Scientific Spyglass system at a tertiary medical center between 2020-2023. Multivariate logistic regression evaluated the association between both quality of visualization, as well as pathological results, and IPMN with MPD involvement. In addition, a univariate logistic regression model was applied to determine whether POPS independently influenced management of these individuals.

Results Eleven patients who underwent POPS were evaluated. Among them, 7 (63.6 %) were males and the mean age was 57 + 13. Eight (72.7 %) had main duct IPMN, two (18.2 %) had mixed-type IPMN, and one (9.1 %) had branch-duct IPMN. Quality of visualization was good in all individuals. No suspicious lesions were found and no targeted biopsies were taken. Random biopsies were successfully taken in 10 (90.9 %) patients. Biopsy specimens did not show malignant or premalignant lesions (including dysplasia of any grade). Benign neoplastic epithelium was found in 3 individuals (27.2 %), all with main duct IPMN. In one case (9.1 %) biopsies showed mild atypia with reactive and regenerative changes. Post-POPS prophylactic pancreatic stent was inserted in 4 (36.3 %) patients. Post-POPS complications were observed in one patient (9.1 %) who developed asymptomatic mild hyperamylasemia and one patient (9.1 %) who developed mild post-POPS pancreatitis. POPS results did not change the pre-POPS multidisciplinary decision or the management in any of the patients.

Conclusions POPS appears to be feasible and safe, but did not impact clinical management among patients with IPMN of the pancreas with suspected MPD involvement.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1055 Endoscopic management of post-orthotopic liver transplantation of anastomotic biliary stenosis with multiple plastic stents: preliminary prospective study

Authors Gambaccini D[1], Grosso A[1], Stefani Donati D[2], Natali V[1], Tapete G[1], Bolognesi V[1], Visaggi P[1], Pancetti A[1], Venturini A[1], Marciano E[1]

Institutes **1** Digestive Endoscopy Unit, Azienda Ospedaliera Universitaria Pisana, Ospedale Nuovo Santa Chiara, Pisa, Italy; **2** Pisan University Hospital Cisanello, Pisa, Italy

DOI 10.1055/s-0046-1822382

Aims Post–orthotopic liver transplantation (OLT) anastomotic biliary strictures (ABS) are commonly treated with multiple plastic stents (MPS), but data on protocol performance and the role of endoscopic ultrasound (EUS) remain limited. We evaluated efficacy, safety and technical characteristics of an MPS protocol in ABS, focusing on patients with associated ischemic-type biliary lesions (ITBL).

Methods This single-centre retrospective study included 28-OLT recipients with ABS treated with ERCP-guided MPS. Of the 31-screened patients, 3 were excluded as they didn't fulfill the cholangiographic criteria for ABS. In a subset, linear EUS or transpapillary miniprobe EUS was performed before/after MPS.

Results Ten patients had completed the MPS protocol and 18 are still on treatment. Among completed, 2 had isolated ABS and 8 ABS + ITBL: overall, 35 ERCPs were performed (3.5 per patient; 38 minutes per session). A mean of 3.3 stents were placed, achieving a cumulative diameter of 29.6 Fr. Biliary clearance with stent removal was required in 40 % of procedures (50 % in ABS + ITBL, 0 % in isolated ABS), and mechanical dilation in 40 %. Adverse events included two mild–moderate postERCP pancreatitis and one moderate cholangitis. Resolution of ABS at the end of MPS, according to predefined cholangiographic criteria, was achieved in 90 %. In five ABS + ITBL patients with follow-up (5.25 months), three maintained stricture resolution and two developed recurrence requiring retransplantation.

Conclusions ERCP-guided MPS is an effective and safe strategy for post-OLT ABS, whereas concomitant ITBL identifies a more complex subgroup in which adjunctive EUS may help to identify anatomical alterations and to customize treatment.

eP1056V Removal of an intragallbladder migrated lumen apposing metal stent through a secondary endoscopic ultrasound-guided gallbladder drainage

Author Altieri G[1]

Institute **1** San Raffaele Hospital, Milan, Italy

DOI 10.1055/s-0046-1822383

Abstract Text

Aims: Endoscopic ultrasonography-guided gallbladder drainage (EUS-GBD) with lumen-apposing metal stents (LAMS) is a minimally invasive option for managing high-risk, non-surgical patients with acute calculous cholecystitis. LAMS migration represents a potential adverse event. Methods: We report a case of complete intragallbladder LAMS migration following EUS-GBD. Results: A 74-year-old woman with significant comorbidities and grade 2 acute cholecystitis underwent initial PTGBD, but was referred for persistent symptoms and bile leakage. After conversion to EUS-GBD, she returned one month later for planned stent removal. Endoscopy, EUS, and fluoroscopy revealed full intragallbladder migration. A repeat EUS-GBD with a LAMS enabled trans-LAMS extraction of the migrated stent and gallstone removal. Conclusion: EUS-guided LAMS retrieval may serve as an effective rescue strategy.

eP1057 Diagnostic Yield of Capsule Endoscopy in Patients with Suspected Small Bowel Bleeding: A Single-Centre retrospective Study

Authors Crepaldi M[1, 2], Caranfil C[1, 3], Galeazzi F[1], Bertin L[1, 3], D' Odorico A[1], Rigato M[1], Barberio B[1], Zingone F[1, 3]

Institutes **1** Padova University Hospital, Padova, Italy; **2** Gastroenterology and Endoscopy Unit, Vicenza, Italy; **3** University of Padua, Padova, Italy

DOI 10.1055/s-0046-1822384

Aims The primary aim of this study was to evaluate the diagnostic yield of CE in patients with obscure small bowel bleeding. A secondary objective was to identify predictive factors for angiodysplasia in the two patient groups under investigation: those with occult bleeding and those with overt bleeding.

Methods We conducted a single-center, retrospective observational study including all CE procedures performed at the Gastroenterology Unit of Azienda Ospedaliera–University of Padua between January 2018 and September 2025 for overt or occult gastrointestinal bleeding. Demographic, clinical, biochemical, and endoscopic data were prospectively recorded in a dedicated database. CE findings were classified according to the presence of angiodysplasias, ulcers, erosions, red spots, polyps, and evidence of bleeding. Furthermore, the Saurin classification was employed to evaluate the bleeding risk, according to each lesion's potential for clinically significant hemorrhage. Patients were categorized into overt bleeding (melena or hematochezia) and occult bleeding (anemia or positive fecal occult blood test) groups. Univariate and multivariate analyses were performed to identify factors associated with angiodysplasia, ulcers, and red spots. Statistical analyses were conducted using STATA 18.

Results A total of 1,049 CE procedures were performed for suspected gastrointestinal bleeding, including 323 for overt and 726 for occult bleeding. The mean age of the patients was 71 ± 14 years, with a predominance over 60 years, and 54 % were male, without significant differences between groups (p = 0.084). At least one comorbidity was present in 66 % of the case. The overall diagnostic yield was 71 % (75 % for overt and 74 % for occult bleeding). Angiodysplasia was the most common finding, with similar prevalence in both groups (53.2 % vs. 56.0 %, p = 0.398). In multivariate analysis, a hemoglobin drop of at least 2 g/

dL and iron supplementation therapy were the only independent risk factors for angiodysplasia among patients undergoing CE for overt bleeding. In patients who underwent CE for anemia or occult blood, the probability of detecting angiodysplasia increased with age in multivariate analysis: 45–60 vs. < 45 years OR 5.03 (95 % CI: 1.37–18.46); 61–80 vs. < 45 years, OR 7.22 (95 % CI: 2.08–25.01); and > 80 vs. < 45 years, OR 10.59 (95 % CI: 2.98–37.56).

Conclusions Our study confirms the high diagnostic yield of capsule endoscopy in patients with both overt and occult gastrointestinal bleeding. Angiodysplasia emerged as the most frequently detected lesion and we identified advanced age, iron supplementation therapy, and a hemoglobin drop of at least 2 g/dL from baseline as independent risk factors for detecting these lesions. These findings underscore the importance of considering patient age and the degree of anemia when evaluating patients with obscure gastrointestinal bleeding and may help guide the prioritization of CE in clinical practice.

eP1058 A rare cause of an upper gastrointestinal obstruction – Bouveret's syndrome in 73-old man

Authors Misztal Z[1], Swiech M[1], Kujawski K[1], Nowicki M[1]
Institute 1 Uniwersytecki Szpital Kliniczny nr 2 Uniwersytetu Medycznego w Łodzi, Łódź, Poland
DOI 10.1055/s-0046-1822385

Abstract Text

Bouveret's syndrome is a gastric outlet obstruction caused by gallstone blockage. We report a case of a 73-years old man who was admitted to the hospital with a symptoms of upper gastrointestinal (GI) obstruction. In CT scan Ringler's triad was observed, including intestinal obstruction, pneumobilia, and an aberrant gallstone in the bowel. At admission we decided to perform endoscopic removal of the gallstone from the duodenum, which after many attempts with a loop and an extraction basket was unsuccessful. Subsequently, the surgical treatment with omega loop gastric bypass was accomplished. In the postoperative period patient developed upper GI obstruction. Due to persistent symptoms and increase in inflammatory parameters relaparotomy was conducted upon which the right hepatic lobe abscess was revealed and removed. In the following days patient presented intolerance of oral alimentation therefore gastroscopy with insertion of nasointestinal feeding tube was performed. To supplement the calorie deficit and adjust the diet to the metabolic demand the patient was referred to a nutritional treatment center.

eP1059 Comparative Accuracy of Endoscopic Ultrasound and Pelvic MRI for Locoregional Staging of Rectal Cancer

Authors Constantin AL[1], Podină N[1], Bejinariu N[2], Copaescu C[1], Saftoiu A[3, 4]
Institutes 1 Ponderas Academic Hospital, Bucharest, Romania; 2 Department of Pathology, Regina Maria Network, Cluj-Napoca, Romania; 3 Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 4 Department of Gastroenterology and Hepatology, Elias University Emergency Hospital, Bucharest, Romania
DOI 10.1055/s-0046-1822386

Aims Accurate locoregional staging is essential for optimal management of rectal cancer. Both endoscopic ultrasound (EUS) and pelvic magnetic resonance imaging (MRI) are widely used, but their comparative performance in routine clinical practice remains debated. This study aimed to evaluate and compare the accuracy of EUS and MRI for T and N staging in a consecutive cohort of rectal cancer patients.

Methods Thirty consecutive patients with histologically confirmed rectal cancer underwent both EUS and pelvic MRI prior to definitive treatment. Staging results were compared to surgical pathology as the reference standard. The primary endpoints were the accuracy of T and N staging for each modality.

Results The accuracy of EUS for T staging was 73 %, while the accuracy for N staging was 66 %. These findings are consistent with published data, where EUS and MRI demonstrate similar accuracy for T staging (typically 70–89 %) and N staging (65–90 %), with some studies reporting a slight advantage for EUS in overall T staging and for MRI in N staging. [1, 4, 5] The American College of Radiology and the World Society of Emergency Surgery recommend both modalities as complementary, with EUS favored for early-stage tumors and MRI for advanced disease and assessment of mesorectal fascia involvement. [2–3]

Conclusions In this single-center cohort, EUS and MRI demonstrated comparable accuracy for T and N staging of rectal cancer, supporting their complementary use in clinical practice. These results reinforce current guideline recommendations for a multimodal approach to locoregional staging.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1060 Enhanced natural retraction with trans-anal platform combined with speedboat assisted endoscopic submucosal disection for distal colon polyps- Single center prospective observational study

Authors Alexopoulos T[1], Zeidan S[2], Sebatian J[3], Albéniz E[4], Adolfo PB[5], Oikonomakis A[6], Fukami N[7], Tsiamoulos Z[8]
Institutes 1 East Kent Hospitals University NHS Foundation Trust, Margate, United Kingdom; 2 William Harvey Hospital , Ashford United Kingdom; 3 Queen Elizabeth The Queen Mother Hospital, Margate, United Kingdom; 4 Navarra Hospital Complex – Navarra Hospital, Pamplona, Spain; 5 Nottingham City Hospital, Nottingham, United Kingdom; 6 251 Air Force General Hospital, Athina, Greece; 7 Mayo Clinic Hospital PHX-1, Phoenix, United States of America; 8 East Kent Hospitals University Foundation NHS Trust, Margate, United Kingdom
DOI 10.1055/s-0046-1822387

Aims Speedboat is a novel multimodal endosurgical device. It utilizes the use of advanced bipolar energy for cutting/dissection and super-high frequency microwave energy for coagulation. The trans-anal platform comprises the Gelpoint as an access port and the Airseal as a CO2 exchange apparatus. It creates an "invisible pneumo- dissection" effect due to intraluminal CO2 pressure gradient. This study aims to evaluate the efficacy of Speedboat assisted Endoscopic Submucosal Dissection (S-ESD) with and without the trans-anal platform (TAP) in the management of complex distal colorectal polyps as well as the speed of dissection.

Methods Data, from a prospectively collected clinical audit (2018-2025) was analyzed. Cases were divided into two groups, the pre-TAP group (2018-2020 TAP not introduced) and the post-TAP group (2021-2025) which was further analyzed in two subgroups, the non-TAP and the TAP group when the platform was indicated. Lesion characteristics, long and short axis length, and time dissection were collected. Lesion surface (cm^2), Speed (cm2/hr) and Clinical outcomes were compared between the three groups.

Results Over the study period, a total of 291 consecutive patients [55.7 % male, age 72 (IQR: 64-77)] had a distal colorectal lesion completely excised using S-ESD with median surface of 13.73cm^2 (IQR:6.86-25.12), long axis 5,0 cm (IQR: 3.5-7.0) and speed 10.23cm2/hr (IQR:6.97-16.75).

Pre-TAP group included 58 patients [58.6 % male, age 72 (IQR 65-77)] with median surface of 9.81cm^2 (IQR:6.72-15.89), long axis 4.5cm (IQR: 3.5-6.1) and speed 7.15 (IQR: 6.86-9.31). Post-TAP group included 233 patients with distal polyps had S-ESD [54.9 %male, age 72 (IQR: 64-77)] with median surface of 15.11 cm^2 (IQR:6.96-28.26), long axis 5.0cm (IQR: 3.5-7.25) and speed 12.19 (IQR: 7.18-18.84)].

Within the post-TAP group, the TAP subgroup included 145 patients who underwent S-ESD [60.0 % male, age 71(IQR: 63-76) with median surface 15.70 (IQR: 8.83-34.34) and speed 12.18 (IQR: 7.06-18.59). In the non-TAP subgroup 88 patients were subject to S-ESD [46.6 % male, age 72 (IQR: 64-79), median surface 11.77 (IQR: 4.90-20.16)] and speed 11.99 (IQR: 7.39-21.81).

Overall, the speed and surface were significantly increased in the post-TAP group when compared with the pre-TAP group ($p < 0.001$ and $p = 0.006$ respectively. There was not a statistical significant difference in dissection speed within the the post-TAP subgroups ($p = 0.563$). The median surface of the polyps removed were significantly larger in the TAP subgroup ($p = 0.002$). No statistically significant difference in regards with age and gender was found among any of the groups.

Conclusions The use of TAP modality combined with S-ESD appears to facilitate excision of distal lesions with larger surface with reasonable speed over time. A randomized trial and/or an international registry to investigate the role of pneumo-dissection is warranted.

eP1061 Tailored-made vacuum-sponge for treating large cavities

Author Ahola R[1]
Institute 1 TAYS, Tampere, Finland
DOI 10.1055/s-0046-1822388

Problem to solve Endoscopic vacuum therapy has been used in treating leakages and perforations in gastrointestinal tract. For patients having a larger leakage cavity, the standard-sized sponge for upper gastrointestinal leakages can be too small, being only 5cm long. Even though it is possible to place two sponges, it would also mean two nasal tubes resulting in increased discomfort for the patient and may challenge the swallowing process. Taking this into consideration, novel techniques to cover larger cavities is needed.

Innovation A tailored-made sponge solution was created for larger cavities. A second sponge was fastened above the original sponge with non-absorbable sutures. The original nasal tube was pierced to allow the air to flow into the vacuum system. The original overtube was cut to accommodate the new length of the combined sponge enabling a feasible the placement of the lengthened sponge. The innovation was tested with a patient having a complex, large fistula cavity at the resection line of the stomach which did not respond to standard therapeutic options.

Results The sponge was prepared for the patient before the visit at the outpatient clinic.

Insertation of the combined sponge solution was feasible when the overtube was cut accordingly.

During the therapy, the vacuum-sponge was changed once a week. The double sponge needed was tightly attached to the cavity walls showing good contact.

During the changes a longer moisturizing time was used to safely remove or change the system.

Minimal bowel content was detected in the cavity during the sponge changes demonstrating a sufficient occlusion of the mouth of the fistula.

The sutures and sponges stayed intact during the therapy and the vacuum through the sponge shrank the cavity.

Conclusions The developed sponge solution was found to offer an alternative techinique for vacuum therapy of complex cavities.

eP1062 Comparative analysis of EUS and US guided biopsy methods in pancreatic solid tumors

Authors Sapundzhiev K[1], Katzarov K[1], Dunkov Z[1], Katzarov A[1], Popadiin I[1], Chingov M[1]
Institute 1 Military Medical Academy, Sofia, Bulgaria
DOI 10.1055/s-0046-1822389

Aims 1. To compare diagnostic accuracy between EUS-guided and US-guided biopsy approaches in pancreatis solid tumors. 2. To evaluate procedural safety, including complication rates such as bleeding and pancreatitis. 3. To assess sample adequacy, number of passes required, technical success rates and cost-effectiveness of the two methods.

Methods A retrospective analysis was conducted at Military Medical Academy – Sofia, including 170 consecutive patients with suspected pancreatic solid tumors who underwent pancreatic biopsy between January 2024 and December 2024. Patients were divided into two groups – the first with patients who underwent endoscopic ultrasound guided (EUS-guided) pancreatic biopsy and the second with patients who underwent ultrasound guided (US-guided) pancreatic biopsy. For the patients in the EUS group 22G needle was used and for the patients in the US group 18G needle was used.

Results After the final analysis, we found that the male-to-female ratio in the two groups was equivalent: 50.5 % to 49.5 %. The mean age in the US-guided core biopsy group was 66.5 years, and the mean age in the EUS-guided biopsy group was 70 years. The mean size of the pancreatic solid tumor in the US group was 38.75 mm, and the mean size of the solid pancreatic lesions in the EUS group was 34.65 mm. The mean number of needle passes in both groups was two. ERCP was performed in 50.5 % of the patients in the US group and in 44.1 % of those in the EUS group. The mean hospital stay was 4 days in the US group and 4.6 days in the EUS group. The most common complications were pancreatitis and bleeding. We found that ERCP was an independent risk factor for complications. The rate of pancreatitis in the US group was 1.17 % without ERCP and 8.23 % with ERCP in addition to the biopsy. The rate of bleeding in the US group was 1.17 % without ERCP and 10.58 % with ERCP. In the EUS group, the rate of pancreatitis was 2.35 % without ERCP and 11.62 % with ERCP. Bleeding occurred in 3.52 % of the patients undergoing EUS-guided biopsy without ERCP and in 8.23 % of those with ERCP. Histology results in the US group showed 86 % pancreatic adenocarcinoma, 11 % chronic pancreatitis, and 3 % other solid pancreatic lesions. In the EUS group, pancreatic adenocarcinoma was diagnosed in 77 % of the patients, chronic pancreatitis in 10 %, and other solid lesions in 13 %.The positive predictive value in the US group was 100 %, the negative predictive value was 90.12 %, sensitivity was 100 %, specificity was 99 %, and overall accuracy was 98.70 %. In the EUS group, the positive predictive value was 98.48 %, the negative predictive value was 47.48 %, sensitivity was 91 %, specificity was 86.70 %, and overall accuracy was 87.20 %.

Conclusions US-guided core biopsy demonstrated higher diagnostic accuracy (98.70 %) compared to EUS-guided biopsy (87.20 %) in this cohort of 170 patients. Although both techniques required a similar number of passes and had comparable safety profiles, ERCP significantly increased the risk of pancreatitis and bleeding in both groups. EUS was more frequently associated with pancreatitis, while US-guided biopsy showed higher bleeding rates when combined with ERCP.

eP1063V Modified Mickey PEG tube placement(push method)

Author Yarlagadda R[1]
Institute 1 American Oncology Institute (Cancer Treatment Hospital) – Hyderabad, Hyderabad, India
DOI 10.1055/s-0046-1822390

Problem to solve For enteral nutrition especially in adults, in cases of Mickey PEG(button type) placement only upto 20Fr introducer kits are available making it possible only to place 20Fr tubes initially(push technique) and asking the patient to come back for placement of 24 Fr tube once the tract matures. More visits, more interventions, more costs, more time lost.

Innovation This problem can be overcome by simply modifying the technique of placement by push technique with available accessories in endoscopy room. All the steps till introduction of 20Fr sheath of dilatation system are the same. Once the 20 Fr sheath goes in, the inner dilators are removed by rotation. Normally a 20 Fr tube is placed by peeling of the sheath. To place 24 Fr tube, few steps are to be followed more. Once the 20 Fr sheath is in and inner dilators are removed, the 20 Fr sheath is peeled a little (approximately equal to the distance/abdominal wall thickness measured by the measuring ballon of introducer kit) above the skin surface. Then 9mm Savary Gilliard (SG) dilator(8mm not available) is introduced over the guidewire until it fits completely inside the sheath. Peeled sheath is held close to the dilator preparing it to dilate the tract. Then 20 fr sheath along with the SG dilator is pushed inside till the upper margin of the sheath is abutting the skin surface thus dilating the tract. Then sheath and dilator are pulled back till peeled part of sheath is above skin surface and the dilator is removed. Now the 24 Fr tube loaded over the removed dilators is placed inside the partially peeled sheath. 24 Fr tube is pushed inside while peeling the 20 Fr sheath. Once inside the lumen ballon inflated with 5ml NS and tube placement secured [1, 2].

Results Until now 18 Mickey PEG tube (button type) placements have been done in last two years using the modified technique. No events of pneumoperitoneum noted. Hematoma or bleeding or infection of PEG site are not seen. No peri PEG tube leakage seen. Mild pain at PEG site seen in few patients which resolved in a day or two. No major adverse events noted. All were discharged on the same day.

Conclusions 24 Fr Mickey PEG tube can be be safely placedd in the first go with simple modification of the technique. Simple modification of the procedure needing no extra skill set.

Done with the available accessories.

Reduces the number of visits, number of interventions thereby reducing costs and time(for patients as well as heath personnel)

No adverse events related to modification of the procedure.

Future implications –

Such modifications obviates the need for 24 Fr introducer kit.

8mm dilator is better if available(American dilator)

eP1064 Rate and Predictors of Conversion from Small Bowel Capsule Endoscopy to Double Balloon Enteroscopy

Authors Sheehan T[1], Sihag S[1, 2], Leung E[2], McNamara D[1, 2]
Institutes 1 Tallaght University Hospital, Dublin, Ireland; 2 Trinity Academic Gastroenterology Group, Trinity College, Dublin, Ireland
DOI 10.1055/s-0046-1822391

Aims Small bowel capsule endoscopy (SBCE) is an established, minimally invasive technique for evaluating small bowel pathology, offering high diagnostic yield across a range of clinical indications. The European Society of Gastrointestinal Endoscopy (ESGE) recommends that at least 75 % of patients who require further assessment with Double Balloon Enteroscopy (DBE) should successfully progress as a key performance indicator (KPI). However, little is known about the expected SBCE to DBE conversion rate. This knowledge will help in monitoring performance as well as aiding service provision. Understanding conversion rates may also help clarify which clinical indications are most likely to proceed to DBE, supporting more efficient triage and referral pathways. Our aim is to evaluate the SBCE-to-DBE conversion rate. Secondly, we will assess our DBE compliance against ESGE standards. We also seek to examine how clinical indications influence the likelihood of requiring DBE and to assess whether these patterns have changed over time. By analysing these factors, we aim to provide insight into procedural demand, referral optimisation, and alignment with recognised performance standards.

Methods All SBCE procedures performed between 2018 and 2023 were retrospectively analysed using data extracted from the local PillCam database. Each SBCE report was individually reviewed, and no inclusion or exclusion criteria were applied to ensure complete case capture. Indications were broadly grouped into 5 categories; Iron Deficiency Anaemia (IDA) and suspected bleeding, suspected small bowel Crohn's (CD), coeliac or enteropathy, polyps or lesions and finally radiology correlation. Recommendations for DBE were cross-checked against the endoscopy reporting software to confirm procedure completion. Overall and indication-specific SBCE-to-DBE conversion rates were calculated. Odds ratios with 95 % confidence intervals were derived using Fisher's exact test, and year-to-year DBE conversion rates were summarised descriptively and benchmarked against the ESGE 75 % performance standard

Results A total of 3,105 SBCE procedures were performed during the study period. DBE was recommended in 311 (10 %). Of these, 176 DBEs were completed, corresponding to an actual SBCE-to-DBE completion rate of 5.7 %. This gives a total DBE completion rate of 56.6 %, below the ESGE standard of 75 %. Yearly analysis demonstrated marked variability in DBE completion performance. KPI compliance ranged from a low of 41.8 % in 2020 to a high of 77.4 % in 2023, with only 2023 meeting the ESGE KPI threshold. Indication-specific analysis showed significant differences in the likelihood of progressing from SBCE to DBE. Compared with all other indications combined, patients with IDA demonstrated a significantly increased probability of undergoing DBE (OR 3.70, $p < 0.001$), while those with polyps also showed an elevated likelihood (OR 2.08, $p = 0.045$). In contrast, suspected Crohn's disease was associated with a markedly decreased likelihood of DBE (OR 0.16, $p < 0.001$). Coeliac disease (OR 0.69, $p = 0.47$) and radiology-driven indications (OR 1.34, $p = 0.55$) did not significantly influence DBE utilisation. These patterns confirm a strong dependence of DBE conversion on underlying clinical indication.

Conclusions Overall, our centre did not meet the ESGE 75 % KPI for progression from SBCE to DBE, with the most pronounced decline occurring during the COVID-19 period, when elective services were significantly disrupted. As a national referral pathway, the geographical separation from the DBE centre may have played a role in reduced completion rates, potentially amplified by historically limited recognition within smaller referring units of the procedural importance and clinical benefits of DBE. Indication-specific analysis showed a high odds ratio for DBE in iron-deficiency anaemia, consistent with the high diagnostic yield of SBCE in this group, while polyp detection appropriately prompted DBE for therapeutic polypectomy. In contrast, low conversion in suspected

Crohn's disease may reflect reliance on complementary evidence such as biomarkers, faecal calprotectin, and cross-sectional imaging before committing to enteroscopy. Understanding these conversion patterns is valuable for informing service planning, optimising triage pathways, and strengthening referral practices to ensure timely access to DBE.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1065 Impact of Heparin-Bridging Therapy on Delayed Bleeding Risk in Colorectal Endoscopic Submucosal Dissection (ESD) Among Patients on Vitamin K Antagonists

Authors El Hajra Martínez I[1], Santiago Garcia J[2], de Frutos D[1], Valentin Gomez F[2], Blázquez E[3], Cabrero AI[1], Molinero B[1], Herreros De Tejada A[1]

Institutes **1** Puerta de Hierro Majadahonda University Hospital, Majadahonda, Spain; **2** Department of Gastroenterology, Endoscopy Unit. Puerta de Hierro University Hospital, Majadahonda, Spain; **3** Puerta de hierro, Madrid, Spain

DOI 10.1055/s-0046-1822392

Aims One of the main challenges after colorectal endoscopic submucosal dissection (ESD) is the management of oral anticoagulation. Heparin-bridging therapy (HBT) has been associated with an increased risk of delayed bleeding in gastric ESD, but its impact in the colorectal setting remains controversial. The aim of the study was to evaluate the impact of HBT on the rate of delayed bleeding after colorectal ESD in patients treated with vitamin K antagonists.

Methods We performed a multicenter retrospective cohort study based on a consecutive prospective registry (11/2012–04/2025). We included patients ≥ 18 years undergoing colorectal ESD. Delayed bleeding was defined as any bleeding event within 30 days requiring urgent evaluation, hospitalization, or endoscopic reintervention. Procedures aborted or referred to surgery for non-bleeding reasons were excluded [1–5].

Results A total of 855 ESDs were included; 49 patients were on vitamin K antagonists, of whom 38 (77.6 %) received HBT. Mean age was 73.8 years (SD 8), and 79.2 % were male. The timing of anticoagulation resumption was similar between groups (day 1 in 78.9 % with HBT vs 72.7 % without HBT; p = 0.98). Among vitamin K antagonist users, no significant differences were observed between HBT and non-HBT groups in baseline characteristics, concomitant antiplatelet therapy, lesion morphology, or lesion location.

The overall delayed bleeding rate was 4.5 % (95 % CI 3.3–6.1 %), and 33.3 % (95 % CI 21.7–47.5 %) among patients on vitamin K antagonists (p < 0.001). Median DEBE score was 6 (IQR 4–8) and 17 (IQR 13–19), respectively (p < 0.001).

No significant differences were found between HBT and non-HBT groups in delayed bleeding rates (34.3 % vs 30 %; p = 1) or in time to bleeding (median 4 vs 3 days; p = 0.57). Two patients (12.5 %) required transfusion, and no thromboembolic events occurred.

Conclusions Reinitiation of anticoagulation using heparin-bridging therapy was not associated with a higher risk of delayed bleeding compared with direct reinitiation. However, the limited sample size affects the robustness of the conclusions and supports the need for prospective studies with a larger sample size.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims EUS-guided fine-needle biopsy (EUS-FNB) is a key modality for diagnosing pancreatic lesions, but its real-world accuracy may be influenced by sampling adequacy, tumor heterogeneity, and inconclusive histology. This study aimed to evaluate the diagnostic performance of EUS-FNB for (1) all pancreatic tumors and (2) specifically pancreatic adenocarcinoma, using final histopathology as the reference standard.

Methods We retrospectively analyzed patients undergoing EUS-FNB for pancreatic lesions in a tertiary center. Based on procedural assessment, FNB results were categorized as tumoral or non-tumoral. Final histopathology classified lesions as pancreatic tumors (adenocarcinoma, pancreatic neuroendocrine tumors, ampullary/periampullary carcinoma, insulinoma), non-tumoral pancreatic disease, or indeterminate. Diagnostic accuracy was calculated for cases with conclusive histology; indeterminate outcomes were recorded to reflect sampling limitations.

Results Eighty-three patients had paired FNB and final histology results. Conclusive histopathology was available in 70/83 cases (60 pancreatic tumors, 10 non-tumoral lesions). For all pancreatic tumors, EUS-FNB demonstrated a sensitivity of 96.7 %, specificity of 80.0 %, and an overall accuracy of 94.3 % (95 % CI: 86.2 %–97.8 %), consistent with recent large-scale studies reporting comparable accuracy for pancreatic EUS-FNB [1, 2].When restricting the target condition to pancreatic adenocarcinoma, FNB showed a sensitivity of 100 %, specificity of 50 %, and an overall accuracy of 72.3 %. Histopathology was indeterminate in 13/83 patients (15.7 %), reflecting insufficient or non-diagnostic tissue acquisition.

Conclusions EUS-FNB demonstrated high diagnostic accuracy for pancreatic tumors, with results aligning with the upper range of contemporary evidence, in which accuracies of 85–95 % are typically reported for solid pancreatic lesions [1–3]. The lower accuracy observed for pancreatic adenocarcinoma alone, despite excellent sensitivity, highlights the challenge of differentiating adenocarcinoma from other neoplastic entities when tissue sampling is limited. These findings reinforce the strong diagnostic utility of EUS-FNB while underscoring the importance of optimal sampling techniques and careful interpretation, particularly when precise tumor subtyping is clinically relevant.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1067 Transnasal Endoscopy as a Patient-Centered Solution to Strengthen Diagnostic Services

Authors Medas R[1], Craveiro F[1], Soares C[2], Antunes P[1], Leitão C[1], Baldaque-Silva F[3], Pereira JP[1]
Institutes **1** Gastroenterology Department and Advanced Endoscopy Center Carlos Moreira da Silva, ULSMatosinhos, Matosinhos, Portugal; **2** Centro Hospitalar Tondela – Viseu, EPE, Viseu, Portugal; **3** Karolinska University Hospital, Stockholm, Sweden
DOI 10.1055/s-0046-1822394

Aims Conventional esophagogastroduodenoscopy (cEGD) is increasingly performed under sedation, adding costs and logistical complexity, while delaying patients' return to normal daily activities. Transnasal esophagogastroduodenoscopy (tnEGD) emerged as a less invasive, better-tolerated alternative to cEGD. Several UK centres have reported high patient acceptance and superior comfort compared to cEGD, with fewer instances of gag reflex, reduced cardiovascular stress and no need for sedation enabling immediate return to usual daily activities. Recent data show that new generation tnEGD offers comparable diagnostic accuracy for oesophageal and gastric pathology, including early gastric cancer and premalignant conditions, while improving throughput, reducing use of resources, and facilitating outpatient-based endoscopic services. Despite its benefits, there is no widespread use in continental Europe.Conventional esophagogastroduodenoscopy (cEGD) is increasingly performed under sedation, adding costs and logistical complexity, while delaying patients' return to normal daily activities. Transnasal esophagogastroduodenoscopy (tnEGD) emerged as a less invasive, better-tolerated alternative to cEGD. Several UK centres have reported high patient acceptance and superior comfort compared to cEGD, with fewer instances of gag reflex, reduced cardiovascular stress and no need for sedation enabling immediate return to usual daily activities. Recent data show that new generation tnEGD offers comparable diagnostic accuracy for oesophageal and gastric pathology, including early gastric cancer and premalignant conditions, while improving throughput, reducing use of resources, and facilitating outpatient-based endoscopic services. Despite its benefits, there is no widespread use in continental Europe. We aim to test the feasibility and efficacy of tnEGD in the first transnasal unit in Iberia.

Methods This study included all tnEGD performed between April and November 2025. Before starting, the team of doctors, nurses and assistants, went through a dedicated learning program. Prospective data collection was performed, including patient demographics, procedural success, tolerance, adverse events, and patient-reported satisfaction through standardized Likert-scale questionnaires. All patients had a telephone interview one week after the procedure.

Results During this period, 291 procedures (in 290 patients) were performed for diagnostic purposes. Most frequent indications were pre-surgical assessment (28 %), dyspepsia/GERD (16 %), post-surgical evaluation (10 %) and premalignant gastric conditions surveillance (10 %). Complete tnEGD was possible in 265 procedures (91 %). Incomplete cases were related to nasal cavity anatomical limitations in 22 patients (nasal conchae hypertrophy/congestion), while only 2 cases were due to patient intolerance. There were 7 immediate adverse events (AE): 5 nasal discomfort/pain and 2 mild epistaxis – all self-limited. Concerning the following days after the procedure, 13 patients reported late AE: 6 mild epistaxis, 5 rhinosinusitis, 1 migraine and 1 throat irritation. Overall, 226 patients (77.9 %) reported being satisfied with the examination and 228 (78.6 %) patients would repeat the examination. Among 135 individuals who had previously undergone cEGD, 121 (89.6 %) reported the tnEGD to be more comfortable. Regarding the costs related to sedation (previous analysis, anesthesiologist and nurse fee), a saving of approximately €63.60 per procedure is estimated.

Conclusions This early experience in a large cohort confirms that tnEGD is a well-accepted, highly tolerable, and safe alternative to cEGD, maintaining procedural efficacy while enhancing patient satisfaction. These results were consistent since the beginning of operations and support wider implementation of tnEGD across Europe.

eP1068 Prevalence and Histopathological Patterns of Inflammatory Bowel Changes Among Patients Undergoing Colonoscopy in sub-saharan Africa – Nigeria

Authors Onabanjo T[1], Awosola A[1]
Institute **1** OUTPATIENT SURGERY AND ENDOSCOPY CLINIC (OSEC), Lagos, Nigeria, Federal Republic of
DOI 10.1055/s-0046-1822395

Aims Inflammatory bowel changes which include inflammatory bowel disease (ulcerative colitis) and others like Proctitis, chronic colitis, is characterized by immune-mediated inflammation of the intestines, chronic gastrointestinal inflammation, often induce by underlying predisposing factors such as genetics, environmental factors, and the gut microbiota.[1]Formerly, Inflammatory bowel changes which include inflammatory bowel disease (ulcerative colitis) and others like Proctitis, chronic colitis is not considered as a common diagnosis within the sub-saharan African population Asia and South America population, but lately the incidence of the disease is now on the rise.[2,3]Endoscopy preceding histopathological evaluation remains a cornerstone in understanding disease mechanisms and early detections of these changes [1–3].

Methods A retrospective review of this inflammatory bowel changes was conducted using a total of 238 histological reports of patients gotten during an endoscopy examination to ascertain the incidence and distribution of this inflammatory bowel changes. Their clinical presentation, endoscopic findings, and the risk factors which predisposed them to these symptoms were evaluated.

Results Out of the 238 patients included in the study, 66 cases (27.7 %) were identified as being related to inflammatory bowel disease (IBD), comprising colitis & IBD (61 cases, 25.6 %) and proctitis (5 cases, 2.1 %). Ulcerative Colitis represented the predominant inflammatory bowel change diagnosis, reflecting the higher prevalence of ulcerative colitis in the sampled population, while proctitis likely represents localized or early-stage IBD manifestations. This indicates that approximately one in four patients in the study population exhibited IBD-related gastrointestinal inflammation. These findings underscore the clinical importance of accurate histopathological evaluation to distinguish inflammatory bowel changes from other gastrointestinal disorders and to guide appropriate management.

Conclusions Inflammatory bowel changes are increasingly detected among patients in our setting, indicating a shifting disease pattern once considered uncommon in sub-Saharan Africa. Early endoscopic and histological diagnosis is crucial for proper management. Ongoing surveillance is needed to better understand its evolving burden and risk factors in the region.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1069 Performance of a New Bipolar Knife in Third-Space Endoscopy: A Single-Center Experience

Authors Craveiro F[1], Antunes P[1], Pereira JP[1], Medas R[1], Albéniz E[2], Baldaque-Silva F[3]
Institutes **1** Gastroenterology Department and Advanced Endoscopy Center Carlos Moreira da Silva, ULSMatosinhos, Matosinhos, Portugal; **2** Navarra Hospital Complex – Navarra Hospital, Pamplona, Spain; **3** Karolinska University Hospital, Stockholm, Sweden
DOI 10.1055/s-0046-1822396

Aims There has been growing interest in the development of bipolar knives in therapeutic endoscopy due to their safety profile. These devices incorporate a negative electrode at the tip, ensuring closed-circuit current transmission. Thus, they have the potential to reduce transmural thermal injury, lowering the risk of perforation or stricture, as well as decreasing interference with implanted cardiac devices. However, reports describe lower cutting efficiency, with longer procedure times. We want to test the efficacy and safety of a new bipolar knife in a clinical setting.

Methods Patients were prospective enrolled. In all, a newly certified bipolar knife wa used, with a 1.4-mm ball-type device and cap. A dedicated electrosurgical unit was utilized (Hangzhou AGS MedTech Co, China).

Results Twenty-six patients were included, with a median age of 69,5 (IQR 61,0-77,5) years, inwhom 28 procedures were performed: 16 gastric endoscopic submucosal dissections(ESD), 4 colonic ESD, 3 rectal ESD, 3 esophageal ESD and 2 peroral endoscopic myotomies. The median procedure time was 70 minutes (IQR 40-121). Regarding the 26 endoscopic resections, 24 were en bloc, of which 20 were curative. The median size of lesions was 25,0 mm (range 10–104mm). Two ESDs were converted to a hybridtechnique, one due to device malfunction. Only one major adverse event occurred (post-ESD rectal bleeding in a patient on dual antiplatelet therapy), which was endoscopically treated. No post-ESD strictures were observed, including in lesions on the cardia and rectum with significant luminal circumference involvement.

Conclusions This new bipolar knife seems to be safe and effective in advanced endoscopic therapies, with potential to reduce the risk of perforation or stricture. Bipolar knives may play an important role in the future of third-space endoscopy, particularly in high-risk patients,although further comparative studies are needed to confirm our findings.

eP1070 Quality Improvement Project in Cavan Monaghan Hospital to Change Prescribing Practices For The Eradication of Helicobacter Pylori using a pro-forma prescription

Authors Whitmarsh R[1], Hunter S[1], Ismail MS[1]
Institute **1** Cavan General Hospital, Cavan, Ireland
DOI 10.1055/s-0046-1822397

Aims Helicobacter Pylori (HP) is a class-1 carcinogen and Bismuth Quadruple Therapy (BQT) has recently been recommended as first line eradication therapy in Ireland. Previous local audits have shown that there is a variety of prescribed therapy for HP eradication; causes include unfamiliarity with BQT and cumbersome prescription. When BQT was used, eradication rates in our local service was 90 %.

Since January 2025, we introduced a simple pro-forma prescription in Cavan Monaghan Hospital for BQT that only requires prescribers' identifiers. The aim of this audit was to assess prescribing rates of BQT since introduction.Since January 2025, we introduced a simple pro-forma prescription in Cavan Monaghan Hospital for BQT that only requires prescribers' identifiers. The aim of this audit was to assess prescribing rates of BQT since introduction.

Methods We reviewed both physical and electronic records of patients who had a positive Rapid Urease Test (RUT) over a 1 year period (July 2024-July 2025). We then compared prescribing practices of HP eradication once the pro-forma was introduced. We also checked return rates of HP stool antigen post eradication therapy, which is the only non-invasive HP test available to us.

Results Over the 1 year period, we had a total of 202 positive RUT tests. Incomplete data sets were removed and only 201 cases was included in the analysis. 108 (54 %) had positive RUT prior to proforma introduction and 93 (46 %) after.

In total prior to introduction of pro forma – 69 (64 %) patients were prescribed Triple Therapy (TT); 39 (36 %) was given BQT.

After the pro forma introduction TT was prescribed in only 10 (11 %) patients and BQT was prescribed in 83 (89 %) patients.

Overall stool return rate for HP serology was only 53 % (106 patient), eradication was achieved in 92 % (98).

Conclusions The introduction of the pro-forma BQT prescription has shown that there has been a marked increase (53 % increase) in the use of the most effective nationally recommended HP eradication regimen. In line with previous studies, stool sample returns were low; limiting data on post treatment eradication. This supports the development of other services including Urea Breath Testing for diagnosis and to assess post treatment eradication.

Orsola-Malpighi Hospital, Bologna, Italy; **5** Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy; **6** Endoscopy Unit, Gastroenterology Department, Humanitas Research Hospital IRCCS, Milano, Italy; **7** Gastroenterology and Digestive Endoscopy Unit, AUSL Romagna, Rimini, Italy; **8** Gastroenterology and Endoscopy Unit, Ospedale "Infermi" di Rimini, Rimini, Italy; **9** Galliera Hospital, Genova, Italy; **10** Agostino Gemelli University Policlinic, Roma, Italy
DOI 10.1055/s-0046-1822398

Aims Endoscopic Retrograde Cholangio-Pancreatography (ERCP) is among the most complex procedures in digestive endoscopy, associated with high technical demands and risk of complications. While proficiency is essential for safe and effective clinical practice, training programs remain highly variable across Europe. To address these inconsistencies, the European Society of Gastrointestinal Endoscopy (ESGE) has published a structured core curriculum that outlines minimum standards for ERCP training. However, it is unclear to what extent these recommendations are being implemented in Italy. This study aims at exploring the current ERCP training practices among young Italian endoscopists [1–6].

Methods An anonymous e-survey was developed and distributed via Google Forms to all members of the Italian Association of Young Gastroenterologists and Endoscopists (AGGEI) since October 2024. The questionnaire was designed to assess demographics, ERCP training characteristics, procedural exposure, perceived competence, feedback and assessment methods, and overall satisfaction. Responses were collected up to January 2025. Inclusion criteria were age under 40 and less than 5 years of ERCP training experience. Descriptive statistics were calculated, and a multivariable linear regression analysis was

performed to identify factors independently associated with perceived training quality.

Results A total of 39 out of 904 young Italian endoscopists completed the survey (response rate: 4.3 %). Most were male (69 %) and aged 30–34 years (56 %). The majority (87 %) began ERCP training during residency, typically in the last year, and 67 % worked in high-volume centres (≥ 200 ERCPs/year). Training practices varied considerably. While 67 % had access to a dedicated ERCP mentor and 74 % received integrated EUS training, only 3 % reported using simulation-based tools. Regular feedback from mentors (daily or weekly) was reported by 62 %, yet only 4 (10.3 %) had completed a structured core curriculum. Participants expressed higher confidence in cognitive skills (mean 3.5/5, 79.5 % ≥ 3) than in motor skills (mean 2.9/5, 61.5 % ≥ 3). Most trainees required supervision for core therapeutic manoeuvres, with only 43.6 % performing ERCPs at least partially independently; the majority (53.8 %) required constant supervision or served only as assistants. Perceived training quality was rated as "Excellent" by 13 %, "Very Good" by 18 %, "Good" by 33 %, "Fair" by 28 %, and "Poor" by 8 %. In multivariable regression, two factors were significantly associated with higher perceived quality: motor skill confidence ($\beta = 0.46$, $p = 0.004$) and inclusion of EUS training ($\beta = 0.81$, $p = 0.044$). Mentor availability, simulator use, and feedback frequency were not significantly associated with perceived quality.

Conclusions These early findings indicate substantial variability in ERCP training practices among young Italian endoscopists, with limited adherence to the ESGE curriculum recommendations. The inconsistent presence of mentors, minimal use of simulation tools, and unstructured assessment frameworks may hinder the development of essential competencies. As ESGE emphasises a structured, competency-based approach, including simulation and summative assessment, efforts should be made to align national training programs with these standards. Greater adoption of the ESGE core curriculum could help standardise ERCP education, promote procedural safety, and ensure a more equitable learning experience across training centres in Italy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1072 Single Pass Dynamic Suction Technique for EUS-Guided Liver Biopsy

Authors Dang F[1], Le B[1], Masroor M[1], Tavangar A[1], Sidhu S[1], Herekar A[1], Chen K[1], Garabet R[1], Vazirnia P[1], Gandhi S[1], Nguyen H[1], Hu KQ[1], Shah S[1], Chandan V[1], Samarasena J[1]

Institute 1 University of California, Irvine, Irvine, United States of America

DOI 10.1055/s-0046-1822399

Aims Liver biopsy is important for diagnosing liver disease. Adequacy of biopsy specimen is essential for accurate pathology evaluation. The American Association for the Study of Liver Disease (AASLD) defines an adequate sample containing more than eleven complete portal tracts (CPT) and measuring at least 1.5 cm in length. EUS-guided liver biopsy (EUS-LB) has emerged as a promising alternative to traditional percutaneous or transjugular liver biopsy. Prior studies have shown that variation in liver biopsy technique impacts tissue yield, and studies evaluating various techniques have been performed. The dynamic suction technique is a simple modification of the wet heparin suction technique that obtains exceedingly adequate liver biopsy specimens for diagnosis. The aim of this study is to evaluate the safety, efficacy, and tissue adequacy of EUS-LB with the dynamic suction technique.

Methods This is a retrospective study including all patients that underwent EUS-LB with the dynamic suction technique at our institution in 2025. Clinical, laboratory, and procedural data were collected. All biopsies were performed with 1 pass, 3 actuations using a 19 G EUS-FNB needle primed with 3 mL of heparinized saline. The primary endpoint was technical success rate and diagnostic adequacy as per pathologist. Secondary endpoints include total specimen length, number of complete portal tracts, stage of fibrosis, and rate of adverse events.

Results A total of 23 patients were identified to have undergone EUS-LB with dynamic suction technique from January to November 2025. The average age was 61, with 48 % female. The mean INR was 1.08 (0.9-1.2) and the mean platelet count was 164.5 (x10^3/mm3) (56-334). Unilobar biopsy was performed in all cases (87 % in right lobe and 13 % left lobe). Indications for liver biopsy included chronic liver disease (57 %), evaluation of abnormal LFTs (43 %), and stratification of portal hypertension (17 %). The technical success rate of EUS-LB was 100 % with diagnostic adequacy by pathology achieved in all cases. The average fixed liver specimen length per pathology was 6 cm (SD 1.5) and average CPT 14 (SD 6.2). 22 % of specimens were staged as fibrosis stages F1-F2, while 39 % were staged as F3-F4. There were no adverse events or procedure complications reported.

Conclusions The dynamic suction method is an effective adaptation of the wet suction method during EUS-LB. We achieved consistently adequate tissue acquisition with 1 pass, 3 actuations with no adverse events. Our findings support the dynamic suction method as a safe, reliable, and practical approach for obtaining diagnostic liver tissue.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1073 Overcoming challenging biliary diseases with percutaneous Digital Cholangioscopy: A Pilot Study

Authors Binda C[1], Coluccio C[2], Renzulli M[3], Vizzuso A[4], Cristofaro L[5], Di Giorgio V[5], Fabbri S[6], Giuffrida P[2], Giampalma E[7], Fabbri C[8]

DOI 10.1055/s-0046-1822400

Aims Endoscopic retrograde cholangiopancreatography (ERCP) can fail in some challenging situations, such as surgically altered anatomy, complex/intrahepatic biliary strictures, or difficult lithiasis. Percutaneous approach using digital single-use cholangioscopy (DSOC), eventually in combination with an endoscopic procedure ("rendezvous") may provide a prompt and effective rescue option. The aim of this pilot study was to evaluate feasibility, safety, and effectiveness of percutaneous cholangioscope in the management of complex biliary diseases.

Methods This single-center retrospective analysis included all consecutive patients who underwent percutaneous biliary access with the simultaneous

collaboration between interventional radiologist and endoscopist (2021–24). Data were extracted from a prospectively maintained database. All procedures were performed under general anesthesia. DSOC with SpyGlass Discover (Boston Scientific) system was employed (always handled by the endoscopist) for direct visualization of biliary mucosa, selective biopsies (SpyBite forceps) or stone treatment through electrohydraulic lithotripsy (EHL with Autolith). All patients received antibiotic prophylaxis, rectal indomethacin in case of a rendezvous procedure. Descriptive analysis was performed regarding baseline characteristics, clinical indication, therapeutic details, and adverse events.

Results Twelve patients were included (mean age 71.5 years; 7 females, 5 males). For 3 patients a rendez-vous procedure was performed (with contemporary endoscopic access from the papilla and a percutaneous one); the remaining 9 procedures were carried out through percutaneous access with the endoscopist managing the cholangioscope. Indications were predominantly choledocholithiasis and complex stone disease (n = 8), followed by biliary strictures (n = 4), including 2 cases of hilar cholangiocarcinoma. ERCP failure was previously reported in 50 % of cases (6 pts), mainly due to duodenal diverticula (n = 2), luminal strictures (n = 2), altered anatomy such as Roux-en-Y or bilio-digestive anastomosis (n = 1), or impossibility of oral intubation (n = 1); 3 more patients had surgically altered anatomy directly approached in a percutaneous fashion. The largest biliary stone diameter ranged from **5 mm to 50 mm**. EHL was required in **10 patients**: 6 needed one session, 3 required two sessions, and 1 required three sessions to achieve complete clearance. Technical success of the combined procedure was obtained in all patients, allowing biliary drainage, stone removal, or targeted biopsies when indicated. Among the 4 cases of biliary strictures, 3 were subjected to biopsy sampling obtaining diagnostic confirmation of malignancy (n = 2) or inflammation (n = 1). Safety evaluation showed a low complication rate: **8 patients experienced no adverse events**. Four complications occurred overall: 2 cases of post-procedural fever managed conservatively (antibiotc therapy), 1 mild bleeding/anemia not requiring blood transfusion, 1 severe hemoperitoneum resulting in death. No perforations or sepsis were reported. Overall, **minor complications represented 75 %** of all adverse events. No patient required urgent re-intervention due to treatment failure, and in selected cases repeat procedures were performed solely to complete EHL-guided lithotripsy or planned re-evaluation of biliary bening stenosis.

Conclusions This pilot study demonstrates that percutaneous cholangioscopy, with or without a "rendezvous" approach, with the simultaneous presence of high professional figures like interventional radiologist and endoscopist, is **feasible, effective, and generally safe** for managing complex biliary conditions. DSOC enables a precise diagnosis in hard-to-reach areas both for diagnositc purposes or for targeted therapy, achieving successful stone clearance or stricture evaluation in challenging anatomies. The safety profile was acceptable considering the high-risk population (fragile/oncological patients), but the occurrence of 1 fatal adverse event should enfasize the need of performing this procedure in expert centers, where all facilities are available in a multidisciplinary setting, and by skilled operators able to interpret in real-time the intraductal findings to optimize the treatment strategy.

eP1074 EUS-guided management of combined esophageal and gastric varices using coil-and-glue technique in a young high-risk patient ineligible for standard treatment

Authors Tenorio Gonzalez E[1], Soualy A[2], Becq A[2]
Institutes **1** Henri-Mondor University Hospital, PARIS, France; **2** Henri-Mondor University Hospital, Créteil, France
DOI 10.1055/s-0046-1822401

Abstract Text

A 37-year-old patient with cirrhosis secondary to hepatitis B, complicated by hepatocellular carcinoma previously treated with right hepatectomy, presented with recurrence in the remnant liver requiring chemoembolization and treatment with Atezolizumab–Bevacizumab. He had a history of multiple episodes of gastrointestinal bleeding refractory to repeated endoscopic band ligation, with no other complications related to portal hypertension. CT imaging demonstrated multiple portosystemic collaterals and partial splenic vein thrombosis, managed with anticoagulation without resolution after 6 months [1, 2].

Following discussion at the multidisciplinary tumor board, and given the contraindication to beta-blockers due to dilated cardiomyopathy, endoscopic ultrasound (EUS)-guided treatment of the varices was recommended prior to initiating systemic therapy. EUS re-evaluation revealed esophageal varices and residual gastric varices. The decision was made to perform glue injection of the esophageal varices first, followed by treatment of the gastric varices.

During the initial procedure, EUS identified a perforating vein (5 mm diameter) feeding the esophageal collateral system, confirmed by lipiodol injection. Using a 19G FNA needle, 2 cc of glue were injected, resulting in immediate cessation of flow within the esophageal varices. One month later, resolution of the esophageal varices was confirmed, with persistence of collateral gastric flow; therefore, treatment was completed with placement of one coil (14 cm × 10 mm) plus 1 cc of glue—also delivered through a 19G FNA needle—leading to significant flow reduction.

No complications or new bleeding episodes have occurred to date, with no evidence of intraluminal collateral flow on follow-up EUS at 3 months.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1075 The Gallbladder: An Endoscopic Access Route for Choledocholithiasis in Roux-en-Y Gastric Bypass (RYGB) After Failed Enteroscopy-ERCP and EUS-Guided Biliary Drainage (EUS-BD)

Authors Sanjosé Crespo A[1], Sánchez-Ocaña R[1], Cobreros del Caz M[1], De La Serna Higuera C[1], Perez-Miranda M[1]
Institute **1** Rio Hortega University Hospital, Valladolid, Spain
DOI 10.1055/s-0046-1822402

Abstract Text

Choledocholithiasis after Roux-en-Y gastric bypass poses major endoscopic challenges. When enteroscopy fails, EUS-guided options are often unfeasible: EDGE is not possible, EDEE is unpredictable, and EUS-BD lacks intrahepatic dilation. We report a single-session rendezvous using the gallbladder as an access port. After failed ERCP, EDEE, and EUS-BD, a Spaxus cholecysto-jejunostomy enabled cholecystoscopy and transcystic guidewire passage to the duodenum. Saline instillation allowed creation of a 20 × 10-mm Axios jejuno-duodenostomy, granting gastroscopic access to the papilla. Sphincterotomy, stone extraction, and temporary covered stent placement restored biliary drainage, resolving symptoms. The gallbladder offers a feasible endoscopic route to perform ERCP in altered anatomy when standard strategies fail.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1076 Association between the duration of stent indwell and the adverse events in patients with EUS-guided drainage of peripancreatic fluid collections using LAMS

Authors López-Arce Angeles G[1], Marquina V[2], Ruiz Romero D[3], Borjas-Almaguer OD[4], Bartnicki-Navarrete I[3], Blake L[5], Murcio-Pérez E[6], Perez-Miranda M[7], Tellez Avila FI[8]

DOI 10.1055/s-0046-1822403

Aims Early reports on the application of Lumen-Apposing Metal Stents (LAMS) guided by EUS for the drainage of peripancreatic fluid collections (PFCs) reported a high number of adverse events (AEs) mainly related to the indwelling time of the stent. The recommendation is to remove LAMS within 3-4 weeks of placement. [1] The aim was to evaluate the AEs rate in patients undergoing PFC drainage with LAMS, focusing on the timing of these events with the date of stent placement.

Methods A total of 1,242 studies were identified in the initial search. After the selection process, 15 studies were included, comprising 674 patients. The databases consulted were: Scopus (n = 250), Web of Science (n = 286), PubMed (n = 243), Embase (n = 226), and Cochrane Library (n = 83).

Results 1,242 references were identified, of which 15 studies encompassing 674 patients were included. 129 (19.1 %; CI 95 % 0.17-0.23) AEs were reported, with the timing ascertainable for 123 (95.3 %) cases. The most frequently reported AEs were stent obstruction (n = 39, 31.7 %; CI95 %: 0.22-0.37) and bleeding (n = 31, 24 %; CI95 %: 0.15-0.29). 12 (8.8 %; CI 95 %: 0.06-0.18) AEs occurred during the stent removal. 41 (6 %; CI95 %:0.04-0.08) AEs were classified as severe. Mortality associated with LAMS was reported in 5 (0.73 %; CI95 % = 0-0.02) cases. Of the total AEs for which the timing of occurrence was documented (n = 123), 65 AEs (52.8 %; CI 95 % = 0.41-0.58) occurred within the first 4 weeks following stent placement. The remaining AEs (n = 58, 47.2 %; CI95 % = 0.42-0.59) occurred in patients who retained the stent > 4 weeks. No significant differences were observed concerning the type of collection (pseudocyst vs. necrosis).

Conclusions The observed AEs rate is noteworthy; however, most reported AEs (94 %) were mild. This study did not find a correlation between the duration of stent indwelling and the development or severity of complications.

DOI 10.1055/s-0046-1822404

Aims Effective sedation is critical for endoscopic retrograde cholangiopancreatography (ERCP). While pethidine (meperidine) has traditionally been used for procedural analgesia, many centers are shifting toward fentanyl due to its favorable pharmacokinetic profile. We aimed to compare ERCP success rates and sedation characteristics between patients receiving fentanyl versus pethidine in a real-world endoscopy unit setting [1–3].

Methods We retrospectively analyzed 2,871 ERCP procedures performed between 2004 and 2025 at our tertiary endoscopy center. Patients were grouped based on analgesic received (pethidine or fentanyl). Primary outcome was procedural success. Secondary outcomes included the total intravenous midazolam dose administered during the procedure, as well as procedural complexity indicators such as the need for needle-knife precut sphincterotomy and the presence of difficult biliary cannulation, as defined by ESGE criteria. Multivariable logistic regression and inverse probability of treatment weighting (IPTW) using propensity scores were applied to adjust for confounding (covariates: age, gender, year, procedure difficulty, precut use, midazolam dose).

Results Fentanyl was used in 348 cases (12.1 %), primarily in 2024–2025, while pethidine was used in 2,523 (87.9 %). Despite higher rates of difficult cannulation (37.1 % vs 23.5 %, $p < 0.001$), fentanyl cases had significantly higher unadjusted success rates (95.4 % vs 89.6 %, $p = 0.0008$). In adjusted logistic regression, fentanyl was independently associated with increased ERCP success (OR 7.08, 95 % CI 3.58–14.03, $p < 0.001$). IPTW analysis confirmed this association. Median midazolam dose was higher in fentanyl cases (3 mg vs 2 mg, $p < 0.001$), likely reflecting the greater procedural complexity and evolving sedation practices during the study period.

Conclusions Fentanyl use during ERCP was independently associated with significantly higher procedural success, even in cases with increased technical difficulty. While fentanyl is typically associated with reduced midazolam requirements in procedural sedation, our finding of higher midazolam dosing in the fentanyl group likely reflects the significantly higher procedural complexity and case difficulty. Fentanyl was introduced in the most recent period, coinciding with more advanced therapeutic ERCPs, often requiring precut sphincterotomy and prolonged cannulation attempts, necessitating deeper sedation. Furthermore, evolving practice patterns may have permitted more aggressive midazolam titration when using fentanyl, due to its rapid onset and shorter duration of action. These findings suggest that fentanyl may offer clinical advantages over pethidine in achieving successful outcomes, particularly in challenging ERCPs, and support its adoption as the preferred analgesic in modern endoscopy sedation protocols.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822405

Aims Pan-intestinal Capsule Endoscopy (PIC) offers a potential to assess the entire small bowel and colon in a single test. PIC may be advantageous in a variety of clinical scenarios, including the established indication of Crohn's disease assessment and the more recently proposed indication of suspected mid-lower GI bleeding and for selected patients with polyposis syndromes. Its uptake and efficacy in routine clinical practice remain to be assessed.

Methods PIC procedural data uploaded to the Irish Capsule Endoscopy Registry (ICaRe) from 2024 to date were included for analysis. Patient demographics, clinical indication, and procedural variables – including bowel preparation and booster regimen, capsule type, complete transit rate (capsule reaching the dentate line), adequate image quality, complete study rate (transit and image quality) and significant small bowel or colonic findings – were documented.

Results In all, 307 PIC procedures were included in the registry. The median age was 57 years (IQR 40–71), and 134 (44 %) were male. A dedicated PIC capsule was used in only 32 (10 %) of cases, with the remainder employing colon capsules. The indication given for PIC was obscure GI bleeding in 48 % (n = 146), Crohn's disease assessment in 16 % (n = 49), new GI symptoms in 10 % (n = 32), screening in 6 % (n = 19), polyp surveillance in 4 % (n = 12), incomplete colonoscopy in 4 % (n = 13), and other indications in 8 % (n = 36). The complete transit rate was 78 % (n = 240) and adequate image quality in both the small bowel and colon was reported in 76 % (n = 234). The combined complete study rate (transit and adequate image quality) was 65 % (n = 198). While the overall diagnostic yield was 47 % (n = 145), significant colonic findings (CRC, significant polyps, or colitis) were found in 25 % (n = 76), including two with colorectal cancer. While significant small bowel disease was found in 26 % (n = 81), indication did not affect diagnostic yield. Of interest, PIC performance varied by preparation and booster regimen. Higher complete transit rates were seen in subjects who received low-dose PEG-based bowel preparation with Plenvu, 100 % vs 75.6 % (OR 23.7; 95 % CI 1.4–392.1; p < 0.001). Patients who received higher-volume PEG (2 litres of Moviprep), compared with other bowel preparation regimens, were more likely to have inadequate image quality (OR 0.37; 95 % CI 0.17–0.82; p = 0.014). Of note, prucalopride as a booster had no impact on either transit or complete study rate, while the use of castor oil as a booster was significantly associated with a higher complete study rate, 55 % vs 75 % (OR 2.4; 95 % CI 1.5–3.9; p < 0.001). Although transit rates were similar (28/32 [88 %] vs 212/275 [77 %]), both adequate image quality and resultant complete study rates were higher with dedicated PIC Crohn's capsules compared with colon capsules. Adequate image quality was achieved in 29/32 (91 %) vs 205/275 (75 %) (OR 0.30; 95 % CI 0.09–1.03; p = 0.05), and complete studies were achieved in 28/32 (88 %) vs 172/275 (63 %) (OR 0.24; 95 % CI 0.08–0.67; p = 0.009). However, patients in the Crohn's capsule cohort were significantly younger, which may have affected outcomes (p = 0.03).

Conclusions Our clinical data suggests PIC is being employed in a variety of clinical scenarios, with variable procedural success. Despite this, the overall diagnostic yield for both colonic and small bowel disease was high, irrespective of indication. PIC procedures should be considered as a distinct capsule entity, with specific procedural recommendations, as variations in bowel preparation, boosters and capsule type all impact performance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1079 Colonoscopy in patients with infections of unknown origin has a high diagnostic yield for detecting colonic lesions

Authors Poggi F[1], Burti C[1], Dimaggio A[1], Franchina M[1], Laffusa A[1], Orlando S[1], Tomba C[1], Greco S[1], Occhipinti V[1]
Institute 1 Endoscopy Unit, Internal Medicine Department, ASST Papa Giovanni XXIII, Bergamo, Italy
DOI 10.1055/s-0046-1822406

Aims Infective endocarditis and infections of unknown origin have been associated with an increased risk of either benign or malignant colonic lesions. Aim of our study is to determine the diagnostic yield of colonoscopy in this setting.

Methods We retrospectively evaluated all colonoscopies performed at our center from 2013 to the present for endocarditis or systemic infections of unknown origin. Clinical, microbiological and endoscopic data, including polyp detection rate (PDR), adenoma and advanced adenoma detection rate (ADR and AADR) and cancer detection rate were analyzed. The correlation between different infective agents or sites of infection and endoscopic findings was examinated.

Results 107 patients (mean age 68 years, 77.6 % males) were enrolled; main cause of admission was endocarditis (66 patients, 61.7 %), followed by sepsis (21, 19.6 %) and hepatic abscesses (14, 13.1 %). 25 (23.4 %) patients carried biological cardiac valve prostheses and 11 (10.3 %) had mechanical prostheses. 18 (16.8 %) had diabetes, 12 (11.2 %) had chronic kidney disease, 6 (5.6 %) had cirrhosis, 7 (6.6 %) were immunocompromised, and 5 (4.7 %) had an active malignancy. The most frequently isolated etiological agents were *E. faecalis* (38, 35.5 %) and *S. gallolyticus* (36, 33.6 %). Adequate bowel preparation rate was 82.2 %. Overall, PDR and ADR were 44.8 % (48/107) and 36.4 % (39/107). Advanced adenomas were found in 22 patients (AADR 20.6 %), and adenocarcinoma in 6 (5.6 %). S. *gallolyticus* isolation was associated with higher PDR (58.3 %, OR 2.28, 95 CI 1.00-5.16, p = 0.048), ADR (50 %, OR 2.38, 95 CI 1.03-5.45, p = 0.04) and AADR (33.3 %, OR 3.93, 95 CI 1.43-10.81, p = 0.007) compared to other etiological agents. Among patients diagnosed with cancer, no statistically significant differences were observed across the various infectious agents. No differences were observed between endocarditis and other infections.

Conclusions Performing colonoscopy in patients with endocarditis or infections of unknown origin is justified by a high diagnostic yield. Identification of colonic lesions is particularly frequent when the isolated etiological agent is S. *gallolyticus*.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1080 Automated Grading of Capsule Endoscopy Cleanliness by Analysis of the Capsule Reader's Colour Progress Bar: An AI Success Story

Authors Leung E[1, 2], Sihag S[1, 2], Sheehan T[1], Bailey Y[1], Eagle N[1], McNamara D[1, 2]
Institutes 1 Tallaght University Hospital, Dublin, Ireland; 2 Trinity Academic Gastroenterology Group, Trinity College, Dublin, Ireland
DOI 10.1055/s-0046-1822407

Aims Small bowel capsule endoscopy preparation quality is typically graded qualitatively and is largely subjective and subject to inter-observer variability. Quantitative scoring systems, such as the Brotz scale, exist but are cumbersome to implement. Deep learning models are being developed to grade quality from capsule video frames. However, these tools will be limited to commercial software and may not be readily accessible. We aimed to develop a novel, open access, reliable clinical tool to objectively grade capsule endoscopy cleanliness by analysing the colour progress bar displayed by the capsule reader's software.

Methods We developed an AI algorithm deployed via ChatGPT that processes screenshots of the colour progress bar that is automatically generated by capsule reader software. This bar represents the dominant colour of each video frame throughout the small bowel transit and we hypothesised that analysis of

these colours could provide an objective surrogate for preparation quality. To train the algorithm, a human reader labelled multiple individual frames from real studies as having either good or poor mucosal visibility. For each labelled frame, the dominant mucosal colour was sampled, creating a library of colours associated with good or poor views. Using this library, the algorithm defined rules describing which colours typically represent good and poor visibility. When a screenshot of a colour bar is uploaded, the algorithm applies these rules to classify each small portion of the bar as good or poor. While several metrics can be generated from this, we evaluated the performance of the overall fraction of poor-classified portions (the PoorFrac score, range 0–1). We selected a cohort of small bowel capsule studies with both human adequacy grading and Brotz-score adequacy grading (inadequate was defined as a Brotz score < 10). Each colour bar was processed by the algorithm and their PoorFrac scores were generated. The relationship between the PoorFrac score and both human grade and Brotz-score were assessed using Pearson's r, point-biserial Correlation, and ROC analysis.

Results A total of 54 studies were analysed, with a human grading of adequate in 32 (59 %) and inadequate in 22 (41 %). Median Brotz score for this cohort was 12 (range 2–18). There was a strong correlation between human adequacy grading and Brotz score ($r = 0.68$, 95 % CI 0.45–0.83; $p < 0.001$). The AI-automated PoorFrac score was strongly negatively correlated with the Brotz score ($r = -0.69$; 95 % CI −0.83 to −0.46; $p < 0.001$) and strongly positively correlated with the human adequacy grade ($r = 0.59$; 95 % CI 0.38 to 0.74; $p < 0.001$). A PoorFrac cutoff of 0.28 yielded an AUC of 0.836, with 70 % sensitivity and 88 % specificity for identifying inadequate studies (Brotz score < 10) on ROC analysis.

Conclusions Our AI algorithm offers a simple method to objectively assess capsule endoscopy preparation quality from the colour progress bar. The score from this approach correlated well with the established Brotz scale. Pending further refinement and validation of the algorithm, this could be a highly useful and widely accessible clinical tool.

DOI 10.1055/s-0046-1822408

Abstract Text

DESCRIPTION OF PROCEDURE AND KEY FINDINGS

En block resection using Bipolar-Microwave assisted Endoscopic Submucosal Dissection modality of the rectal malignant lesion (T1 sm3) was achieved with targeted separation of the layers of the bowel wall. Gradual increase CO2 pressure every 2mm Hg by CO2 exchange apparatus allowed ease separation of the circular layer in 2 stages: first peeling off the superficial surface of the circular followed by a deeper dissection to the intermuscular space. With aid of the bipolar/microwave device and a smoke free CO2 exchange apparatus, the intermuscular dissection was achieved by pulsed injections prior to the bipolar cutting modality.Follow up endocyroscopy check confirmed granulation tissue.

eP1082 Optimization of Indication and Prioritization of Digestive Endoscopy Requests Submitted from Primary Care

Authors Sanjosé Crespo A[1], Martinez-Cuevas C[1], Velasco E[1], Saracibar E[1], Nuñez Rodriguez H[1], Diez Redondo P[1]

Institute **1** Rio Hortega University Hospital, Valladolid, Spain

DOI 10.1055/s-0046-1822409

Aims Effective coordination between Primary Care (PC) and hospital-based endoscopy units plays a crucial role in improving early diagnosis and timely detection of relevant gastrointestinal pathology. The increasing demand for endoscopic procedures requires the implementation of standardized referral pathways to ensure adequate patient selection, avoid inappropriate indications, and prioritize individuals at higher risk. Structured collaboration, supported by evidence-based protocols and continuous feedback to referring clinicians, can improve efficiency, reduce unnecessary procedures, and enhance diagnostic performance across the healthcare system.

To evaluate the indications, appropriateness, acceptance, and reasons for rejection of endoscopies requested from PC during 2024, while assessing the influence of clinical referral protocols and the colorectal cancer (CRC) screening program on decision-making and final scheduling outcome

Methods A retrospective descriptive analysis was performed of all digestive endoscopy requests submitted from PC throughout 2024. Data collected included reason for referral, compliance with predefined clinical criteria and CRC Screening Program requirements, type of endoscopy requested, and whether the procedure was accepted, temporarily deferred, or definitively rejected. Reasons for non-acceptance were categorized according to predefined clinical and organizational criteria.

Results A total of 3,281 endoscopy requests from PC were evaluated: 1,289 gastroscopies (95.3 % accepted), 1,830 colonoscopies (86 % accepted), and 162 combined procedures (95 % accepted). The overall rejection rate was 9 %. For gastroscopies, the leading causes of rejection were uncomplicated dyspepsia without alarm features and without prior Helicobacter pylori testing (37.7 %), followed by inadequate or prematurely requested surveillance of previously detected lesions (34.4 %). For colonoscopies, the most frequent reasons for rejection were post-polypectomy surveillance intervals not aligned with clinical guideline recommendations (39 %) and inappropriate requests related to family-history–based CRC screening (32 %). Among colonoscopies requested within the CRC Screening Program (n = 1,124), 16 % were rejected for failing to meet program criteria. The most common causes were a previous colonoscopy performed within the last 10 years (50.55 %) and the presence of gastrointestinal symptoms (17.58 %); most symptomatic patients were subsequently reassigned as diagnostic colonoscopies. A comparative evaluation with previous years showed a progressive reduction in inappropriate referrals (▶ **Table 1**)

▶ **Table 1** Anual proportion of Endoscopic procedures rejection

YEAR	Upper Endoscopy	Colonoscopy	CRC screening
2021	10 %	19 %	19 %
2023	4 %	20 %	13 %
2024	4,7 %	14 %	16 %

Endoscopy 2026; 58: S1–S1041

Conclusions The structured implementation of shared referral protocols between PC and the Endoscopy Unit, together with systematic assessment of indication appropriateness, has led to a measurable improvement in the quality of endoscopy requests. This has contributed to reducing unnecessary procedures, optimizing resource allocation, and enhancing diagnostic yield. Sustained communication with PC, ongoing updates on referral criteria, and feedback on screening indications remain essential to consolidate and further strengthen this positive trend.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1083 Bringing Light into the Tunnel: Laser-Assisted Per Oral Endoscopic Myotomy (LA-POEM)

Authors Craveiro F[1], Soares C[2], Medas R[1], Pereira JP[1], Antunes P[1], Baldaque-Silva F[3]

Institutes **1** Gastroenterology Department and Advanced Endoscopy Center Carlos Moreira da Silva, ULSMatosinhos, Matosinhos, Portugal; **2** Centro Hospitalar Tondela – Viseu, EPE, Viseu, Portugal; **3** Karolinska University Hospital, Stockholm, Sweden

DOI 10.1055/s-0046-1822410

Aims Per oral endoscopic myotomy (POEM) is a minimally invasive treatment that has become the first-line treatment for achalasia, and it is emerging as a therapeutic option for other esophageal spastic disorders. Although the main procedural steps are well established, myotomy technique varies according to the centre's expertise, ranging from conventional to underwater, or from selective to full thickness. POEM is considered a safe procedure but may be associated with adverse events in up to 7.5 % of cases, with some reports of capno-pericardium and cardiac arrest. Fiber laser have been used in different applications on interventional endoscopy, and more recently on POEM. This technology enables precise and direct cut without the use of conventional monopolar current.

Methods We report the use of holmium fiber laser technology (Quanta System, Samarate, Italy) as primary treatment on four patients with different esophageal motility disorders: type 1 and type 2 achalasia, esophagogastric junction outlet obstruction and hypercontractile esophagus.

Results Patients' age ranged between 47 and 77 years. The procedures were performed under general anesthesia at the endoscopy unit after multidisciplinary conference and patient informed consent. Conventional esophageal incision and submucosa tunnelling extending to the gastric cavity was performed using an ESD knife. Subsequently, under saline immersion and through an endoscopic catheter, a 365 µm holmium laser fiber was used for the myotomy (1.5-1.8 J; 10 Hz). Myotomy length varied according to the clinical indication and manometric results, from 6 to 10 cm. Selective myotomy was performed without bleeding or any other intraprocedural adverse event. All patients were admitted for 24 hours and resumed liquid diet on day 1, without adverse events. At 3-month follow-up, all patients achieved clinical remission, one continued PPI therapy for persistent reflux symptoms.

Conclusions Holmium fiber laser technology appears to be an effective and safe therapeutic tool for POEM, especially due to its ease of use, precise cutting and ability to avoid bleeding during the procedure. Robust comparative studies are needed to demonstrate the advantages of using fibre laser over standard techniques in third-space endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1084 The Importance Of P53 As A Biomarker Of Dysplasia In Ibd – Reconfirmed By The Application Of Artificial Intelligence

Author Juniku Shkololli A[1]

Institute **1** University of Prishtina "Hasan Prishtina", Pristina, Kosovo

DOI 10.1055/s-0046-1822411

Aims The aim of our study is to determine the most valuable marker for early detection of dysplasia in colorectal tissues of patients with IBD. These results will contribute for patient classification into different risk groups regarding closer follow-up. Artificial intelligence is being useful during colonoscopy examination (for diagnosis of IBD, detection and chracterisation of dysplasia, quantifying disease severity and integration with digital pathology), as well as in IBD histologic assessment (in p53 evaluation in particular).

Methods For investigation of IHC expression of several markers (beta-catenin, VDR, NF-kappaB) in IBD patients, colorectal tissue samples from 30 patients who underwent colonoscopy examination were selected. IHC examinations in the tissue slides of patients with IBD were performed at the "Laboratory for Tumor Pathology" – Medical University of Vienna [1–9].

Results Of all IHC markers we have analyzed, staining intensity of p53 best correlated with disease activity and intensity of inflammation. Positive nuclear p53 expression was found in 52 % of patients with IBD, of which 32 % showed low expression, 15 % – medium expression, and 6 % – high expression).

Conclusions Our results are in line with the majority of publications in this field, which consider the protein expression of p53 in dysplastic crypts as a good biomarker and a very valuable diagnostic tool in IBD-associated colon cancers. Traditional diagnostic methods, such as IHC for p53 combined with H&E staining, are widely used to identify colitis-associated dysplasia precisely, but remain subject to inter-observer variability – at this point artificial intelligence offers a promising alternative.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1085 Investigating the Characteristics of Bile Culture Organisms in Patients with Cholangitis Undergoing ERCP: A Systematic Review and Meta-analysis

Authors Beck YK[1], Obeidat M[2], Futó F[3], Mariyappan D[3], Marchis A[1], Hegyi PJ[2], Erőss B[1]
Institutes 1 Semmelweis University, Budapest, Hungary; 2 Centre for Translational Medicine, Semmelweis University, Budapest, Hungary; 3 Institute of Pancreatic Diseases, Semmelweis University, Budapest, Hungary
DOI 10.1055/s-0046-1822412

Aims Tokyo Guidelines 2018 (TG18) recommend providing empiric therapy to patients with moderate to severe (Grades III – IV) cholangitis before bile duct decompression through Endoscopic Retrograde cholagiopancreatography (ERCP). Current literature indicates an increase in antibiotic resistance, highlighting the importance of enhanced antibiotic management. If empiric antibiotic therapy is not sufficient, complications of cholangitis can result in bacteremia and subsequent organ failure. TG18 suggests taking bile culture to convert to targeted antibiotic therapy, while European Society for Gastrointestinal Endoscopy (ESGE) and American Society for Gastrointestinal Endoscopy (ASGE) guidelines do not yet specify taking bile culture during ERCP. This systematic review and meta-analysis aims to synthesize evidence that may guide conversion to earlier targeted antibiotic therapy in patients with cholangitis undergoing ERCP.

Methods This review follows the recommendations of the PRISMA 2020 guideline and has a registered protocol on PROSPERO (CRD420251164558). We systematically searched five major databases: MEDLINE (via PubMed), Embase, CENTRAL, SCOPUS, and Web of Science. Eligible studies include patients with cholangitis who undergo ERCP and receive empiric antibiotic therapy. We include comparative and single-arm studies reporting extractable or calculable prevalence data. Two reviewers independently performed title-abstract and full-text screening, data extraction, and risk of bias assessment using the Joanna Briggs Institute Critical Appraisal Checklist for Prevalence Studies. Planned analysis includes pooled proportions with 95 % confidence intervals (CI), and heterogeneity will be assessed by Higgins and Thompson's I2 statistics and variance measure (tau-square, t2).

Results Preliminary results from 11 studies showed a 27 % prevalence of *E. coli* **(Figure 1), 17 % for** *Klebsiella* **(Figure 2), 6 % for** *Pseudomonas* **(Figure 3), and 4 % for** *Staphylococcus* **(Figure 4) in patients with cholangitis undergoing ERCP.**

Conclusions Our preliminary data suggests *Escherichia coli (E.coli)* **is the most common organism diagnosed from bile cultures in patients with cholangitis undergoing ERCP. Our meta-analysis will include an estimated 70 studies in the final analysis, and we will include results for more subgroups of bacteria, fungi, as well as an analysis of multidrug-resistant organisms (MDROs).**

eP1086 Endoscopic management of post–gastric sleeve leaks using vacuum assisted closure stents (VacStents) and adjunct therapies: A retrospective review of 11 cases

Authors Bashir MF[1], Siofra B[1], Mcdermott E[2]
Institutes 1 St. Vincent's University Hospital, Dublin, Ireland; 2 Department of Gastroenterology, St. Vincent's University Hospital, Dublin, Ireland
DOI 10.1055/s-0046-1822413

Aims We aimed to assess the outcomes of patients treated endoscopically for post-gastric sleeve leaks in a single tertiary referral centre in Ireland, with a particular assessment of the use of VacStents. These patients had primary surgeries done various helath centres.

Methods Retrospectively data was collected from EndoRaad (endoscopy reporting system) in the hospital was conducted to assess for all patient reports that contained 'VacsSent' or 'Post-sleeve leak' or similar variations for the years 2021-2025 and we collected the data from radiology system for same patients to assess the procedural burden until the leak was healed.

Results 11 patients had endoscopic treatment of post-bariatric leak, 9 of which were female. The median age was 48 (range 28-66). Surgeries were performed in Turkey (6), Ireland (3), Spain (1) and Poland (1).

Overall the median time from surgery to first stent was 17 days for patients for whom the date of operation is available.

7 patients (64 %) have achieved healing with endoscopic therapy. A further 3 patients have had surgery, and the final patient is undergoing active surveillance to assess for healing. VacStent was used in 7 patients (64 %) Three of these patients (43 % of Vacstent cohort) achieved healing. The median number of OGDs was 6 (range 3-12). Median number of stents per patinet was 3 (range 1-7) and these included SEMS,OTSC and EndoVac.

Patients were also noted to have significant overall use of healthcare resources. 10 patients had radiological drainage of collections. Median number of CXR was 14(3-25) and median CT Abdomen & Pelvis was 4 (2-15). The median length of stay was 78 days (35-240).

Conclusions VacStents were used in 64 % of patients, with a 43 % healing rate within that subgroup and 64 % overall healing across the cohort. There were 3 surgical failures (27 %) and 1 non-surgical failure with persistent leak (9 %). VacStents contributed meaningfully to closure in complex leaks but were rarely sufficient alone. Optimal outcomes depended on multimodal management integrating SEMS, OTSC, NJ feeding, and radiologic drainage. Despite the procedural burden, most patients achieved healing, underscoring the value of coordinated, stepwise care.

eP1087 Surgical Emergency after EUS-guided gastroenterostomy for Malignant Gastric Outlet Obstruction: When the Mesentery Twists – A case of Petersen-type internal herniation

Authors Bousson J[1], De Somer T[1], Vansteenkiste C[1], Bouderez V[1], Rasquin K[1], Demarest A[1], De Decker I[1], Bronswijk M[2], Van Der Fraenen D[1], Van Langendonck S[1]
Institutes 1 Maria Middelares, Gent, Belgium; 2 Imeldaziekenhuis, Bonheiden, Belgium
DOI 10.1055/s-0046-1822414

Abstract Text

Case: A 59-year-old man, without prior medical history, presented with high-grade obstructive symptoms, including coffee-ground vomiting. CT revealed a pancreatic mass causing gastric outlet obstruction due to duodenal invasion. With partial encasement of the superior mesenteric vein and side branch of the superior mesenteric artery, the disease was deemed locally advanced, requiring neoadjuvant treatment. To facilitate oncological therapy, a bypass was indicated for which creation of an EUS-GE was elected.

The procedure was performed using a 20 × 10 mm electrocautery-enhanced Lumen Apposed Metal Stent (LAMS; Hot AXIOS) and the Wireless Endoscopic Simplified Technique (WEST). Utilizing an oro-enteric catheter for enteric distention, the LAMS was correctly deployed without immediate adverse events. The patient resumed intake and was discharged after achieving clinical success. Four days after, he was re-admitted with obstructive symptoms and a distended non-peritonitic abdomen. Laboratory findings were unremarkable. A CT scan confirmed LAMS patency but revealed a mesenteric "whirl sign" and caliber transition, diagnostic of acute mesenteric volvulus with closed-loop small bowel obstruction.

Endoscopy 2026; 58: S1–S1041

Emergency laparoscopy confirmed an intact EUS-GE with LAMS positioned 10-15 cm beyond the ligament of Treitz. However, a complete Petersen-type internal herniation of the small bowel through the mesenteric defect created by the gastrojejunostomy was found. After reduction, torsion of the efferent jejunal segment became apparent, but tissue appeared non-ischemic. To prevent recurrence, the Petersen space was closed and a distal side-to-side gastrojejunostomy in omega configuration was created. The postoperative course was favorable.

EUS-GE theoretically confers the same anatomical risk as surgical bypass procedures (e.g., Roux-en-Y gastric bypass): formation of a Petersen space, a mesenteric defect with a gateway for internal herniation and volvulus. The rarity of this complication suggests an unusual contributing mechanism in this patient. We hypothesize that herniation in this patient resulted from the combined effects of tumor-related distortion and the slightly more distal placement of the EUS-GE (~10-15 cm distal to Treitz), allowing for a larger Petersen space and more torsion.

Immediate detorsion, reduction and defect stabilization (closure of the Petersen space and creation of gastrojejunostomy performed here) yields favorable results. Whereas delayed diagnosis leads to bowel necrosis, perforation, and sepsis, carrying a mortality rate up to 30 %.

Conclusion: Our case is a reminder that despite minimal invasiveness of EUS-GE, the resulting anatomical reconstruction might result in internal herniation with secondary mesenteric volvulus. Recurrent obstructive symptoms following EUS-GE should prompt early imaging to identify mesenteric abnormalities (the "whirl sign"). Early recognition and intervention are essential to prevent ischemic injury, morbidity and mortality risk associated with delayed management.

eP1088 Clinical Factors Associated With Prolonged Caecal Intubation Time

Authors Vanis N[1], Husić A[1], Vanis N[2], Meša F[3], Selimović E[3], Horozić D[4], Mesihović R[5]

Institutes **1** General hospital "Prim. dr. Abdulah Nakaš", Sarajevo, Bosnia and Herzegovina; **2** ASA Bolnica, Sarajevo, Bosnia and Herzegovina; **3** Sarajevo School of Science and Technology, Ilidža, Bosnia and Herzegovina; **4** Clinic for diseases of the heart, blood vessels and rheumatism, Sarajevo, Bosnia and Herzegovina; **5** MC Merus, Ljubljana, Slovenia

DOI 10.1055/s-0046-1822415

Aims To identify factors associated with prolonged cecal intubation time (CIT); to assess the impact of patients' anthropometric parameters on CIT; and to determine the influence of previous intra-abdominal surgical procedures on CIT.

Methods This retrospective, cross-sectional, single-center study included 201 patients who underwent total colonoscopy under procedural sedation/analgesia between January 2025 and August 2025. Data collected included age, sex, height, weight, body mass index (BMI), CIT, presence of diverticulosis and hemorrhoids, and history of intra-abdominal surgery. Exclusion criteria were failure to achieve cecal intubation, inadequate bowel cleansing, defined as Boston Bowel Preparation Scale (BBPS) score 0 and a history of colorectal resection. The association between CIT and demographic/anthropometric parameters, as well as prior surgical history, was evaluated [1–3].

Results A total of 100 male and 101 female patients participated in the study. Male patients had significantly lower CIT values (5.0 (4.0–7.0) min) compared with female patients (8.0 (5.5–10.0) min; $p < 0.001$). Patients who had undergone previous abdominal surgery had significantly higher CIT (7.0 (5.0–11.0) min) than those without prior surgery (6.0 (4.0–8.0) min; $p = 0.012$). BMI correlated significantly with CIT (rho = –0.308; $p < 0.001$). In a linear regression model, lower BMI ($\beta = -0.375$, $p < 0.001$), female gender ($\beta = 0.267$, $p < 0.001$), and previous abdominal surgery ($\beta = 0.353$, $p < 0.001$) were independent predictors of prolonged CIT, explaining 26.4 % of the variance ($R^2 = 0.264$).

Conclusions Female sex, low BMI, and a history of prior intra-abdominal surgical procedures emerged as independent predictors of prolonged CIT in a linear regression model.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1089V Laser on: a case of laser assisted peroral endoscopic miotomy (POEM)

Authors Craveiro F[1], Pereira JP[1], Soares C[2], Medas R[1], Antunes P[1], Baldaque-Silva F[3, 1]

Institutes **1** Gastroenterology Department and Advanced Endoscopy Center Carlos Moreira da Silva, ULSMatosinhos, Matosinhos, Portugal; **2** Centro Hospitalar Tondela – Viseu, EPE, Viseu, Portugal; **3** Karolinska University Hospital, Stockholm, Sweden

DOI 10.1055/s-0046-1822416

Abstract Text

Per oral endoscopic myotomy (POEM) is currently the first-line treatment for achalasia. Myotomy is the step most prone to complications, namely bleeding or electrocoagulation organ injury, and its technique is still variable around expert centers. We report a case of type 1 achalasia with a 10-point Eckardt score, treated with laser-assisted POEM. After standard esophageal mucosal incision and submucosal tunnel creation with a TriangleTipKnife J (Olympus, Tokyo, Japan) a 9-cm selective myotomy was performed using a 365 µm holmium laser fiber (Quanta System, Samarate, Italy). Patient resumed oral liquid diet on day 1 and was discharged after 24 hours. At 3-month follow-up patient achieved clinical remission and weight regain. Holmium laser fiber technology offers an easy, safe and precise myotomy method during POEM.

eP1090 Modified conservative hydration regimen combined with indomethacin as a prophylaxis in patients at high risk of post-ERCP pancreatitis

Author Vasquez Sanchez L[1]

Institute **1** General Hospital Tláhuac, Ciudad de México, Mexico

DOI 10.1055/s-0046-1822417

Aims The overall documented PEP rate is 3.5 % to 9.7 %, while the rate of high-risk patients is 14.7 %. The guidelines recommend a minimum standard of < 10 % of PEP, with a target of 5.1 %.

There are well-recognized risk factors, including suspected SOD, previous pancreatitis, previous PEP, female sex, difficult cannulation, pancreatic guidewire passages > 1 and pancreatic injection. There are likely risk factors as younger age, nondilated extrahepatic bile duct, normal serum bilirubin, end-stage renal disease, biliary balloon sphincter dilation, failure to clear bile duct stones.

ESGE suggests that patients should be considered to be at high risk for PEP when at least one definite or two likely patient-related or procedure-related risk factors are present.

ESGE recommends PEP prophylaxis using rectal administration of 100mg of diclofenac or indomethacin immediately before ERCP in all patients in whom a contraindication does not exist. Current ESGE and ASGE do not recommend routine combination prophylaxis in all patients. Current studies demonstrated potential benefits in combining rectal NSAIDs with other strategies.

Methods Objective: There are studies that compares aggressive hydration with Ringer lactate versus moderate hydration with saline solution during and after procedures. We describe the first results of a combination of a conservative hydration regimen with Hartmann´s solution and NSAIDs, since we already

using indomethacin. Among patients with high risk for PEP, compare indomethacin with moderate IV hydration versus indomethacin with modified aggressive IV hydration.

Material and methods: Prospective study, including adult patients > 18yo, with high risk of post-ERCP pancreatitis, from 2022 to 2024 at Hospital General de Tláhuac, a 2nd level hospital in México City.

The patients were randomly assigned to a combination of rectal indomethacin combined with a modified aggressive hydration (maximum 1.5ml/kg/hr during procedure, 20mg/kg bolus of Hartmann solution at the end of procedure, followed by 3ml/kg/hr for 8 hours) or indomethacin combined with moderate hydration (maximum 1.5ml/kg/hr during and after the procedure for 8 hours).

Inclusion criteria: Adult patients > 18yo with at least one definite or two likely patient-related or procedure-related risk factors are present before undergoing to ERCP, with a documented indication. Patients with additional pancreatic stent were excluded.

Descriptive analysis with measures of central tendency for quantitative variables and frequency distribution for qualitative variables.

Results Between January 2021 and December 2024, 71 patients met the criteria for high-risk patients to develop PEP, with a total of 87 procedures. There was a total of 37 patients in the group of indomethacin with modified moderate hydration and 50 patients in the modified aggressive hydration group.

A total of 11 (12.7 %) patients developed PEP, consistent with literature of 14.7 % high-risk PEP patients. It is worth mentioning that if we break down the rate by year, the percentage of PEP fell to 5.7 % during 2024, possibly due to the learning curve of the newly graduated endoscopist. Among high-risk patients receiving rectal indomethacin, the incidence of post-ERCP pancreatitis was 13.5 % (5/37) in the indomethacin with modified moderate hydration group and 12.0 % (6/50) in the indomethacin plus modified aggressive hydration regimen group. There was no statistically significant difference between groups (RR 1.13, 95 % CI 0.37–3.41; OR 1.15, 95 % CI 0.32–4.09; Fisher's exact test p = 1.00).

Conclusions At least in these early results, the modified hydration regimen shows that it is not inferior than the established one. There was **no significant difference** in the incidence of post-ERCP pancreatitis between both groups

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1091 Sedation practices in Gastrointestinal Endoscopy: Italian Society of Digestive Endoscopy (SIED) survey

Authors Bombaci F[1], Conigliaro R[2], Pasquale L[3], Parodi MC[4], Galloro G[5], Zagari RM[6, 7]

Institutes **1** Alma Mater Studiorum – Università di Bologna, Bologna, Italy; **2** Gastroenterology and Digestive Endoscopy Unit, University Hospital Modena, Italy; **3** Gastroenterology Unit, Monaldi Hospital, Naples, Italy; **4** Hospital Policlinico San Martino – Hall Monobloc, Genova, Italy; **5** University of Naples Federico II, Napoli, Italy; **6** Department of Medical and Surgical Sciences, S. Orsola Hospital, University of Bologna, Bologna, Italy; **7** Upper GI Unit, S. Orsola Hospital, Bologna, Italy

DOI 10.1055/s-0046-1822418

Aims Appropriate sedation is essential for safe and effective gastrointestinal endoscopy. The Italian Society of Digestive Endoscopy (SIED) conducted a survey to assess current sedation practices ingastrointestinal endoscopy among its members.

Methods The survey was carried out from 1 November 2024 to 30 January 2025 through an online self administered questionnaire.

Results Of the 1,337 SIED members, 592 (44.3 %) completed the questionnaire. Most endoscopists (84.7 %) reported routinely performing sedation following the SIED–SIAARTI good clinical practice recommendations (67.8 %). However, almost all participants (93.4 %) indicated the need for a national guideline on sedation in gastrointestinal endoscopy. Mild (benzodiazepine alone) to moderate (benzodiazepines + opioids) sedation was preferred for gastroscopy, colonoscopy, and endoscopicultrasound (EUS), whereas deep sedation (propofol) was mainly used for endoscopic retrograde cholangiopancreatography (ERCP) and enteroscopy. Anesthesiologist assistance was available at least once a week for 77.5 % of participants, but only 20.5 % reported availability on almost all workingdays. Notably, 22.5 % of endoscopists reported no availability of anesthesiologist assistance for gastrointestinal endoscopy. Although almost all participants considered a training course on sedation in gastrointestinal endoscopy essential, only 36 % had actually attended one. All endoscopists reported monitoring peripheral oxygen saturation and heart rate during mild-to-moderate sedation, while blood pressure, ECG, and capnography were frequently monitored during deep sedation [1–6].

Conclusions This nationwide survey provides essential information to improve and standardize sedation practicesin gastrointestinal endoscopy in Italy. These findings may support the development of a nationalguideline on sedation in gastrointestinal endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1092 Improving histological assessment of intraductal extension in papillary adenomas by guidewire cannulation of the ex vivo specimen

Authors Kerrison C[1], De Haan B[2], Van Crevel J[2], Sakiris A[3], Lam B[1], Fritzsche JA[4], Gupta S[5], Lee EYT[1], Burgess N[1], Michael J B[1]

Institutes **1** Westmead Hospital, Westmead, Australia; **2** Amsterdam UMC, locatie AMC, Amsterdam, Netherlands; **3** Gold Coast University Hospital, Southport, Australia; **4** Amsterdam UMC, location University of Amsterdam, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands; **5** St. Michael's Hospital, Toronto, Canada

DOI 10.1055/s-0046-1822419

Aims Endoscopic papillectomy (EP) is an effective treatment for papillary adenomas, but intraductal extension (IDE) is a known risk factor for incomplete resection and recurrence. Accurate histological assessment of IDE is often challenging due to specimen orientation. We evaluated whether ex-vivo guidewire cannulation of specimens improved histological assessment.

Methods Consecutive Patients undergoing EP with ex-vivo guidewire cannulation of major papilla at a tertiary centre over 30 months, to Oct 2025 were included. Specimens with non-adenomatous histopathology were excluded. Propensity score matching (1:1) was performed for size, en-bloc resection, and laterally spreading component (LSL) against a prior cohort. Outcomes included histological identification of the biliary duct orifice and intraductal extension.

Results 60 patients were included, 30 with ex-vivo guidewire cannulation (wired) and 30 propensity-matched controls without guidewire (non-wired). The groups were balanced for age (mean 64 years), sex (16 males per group), median lesion size (25 mm), en-bloc resection (21 per group), and lateral spreading component > 10 mm (12 per group). Histopathology comprised

tubular adenomas with low-grade dysplasia (LGD) in 38 patients (20 wired, 18 non-wired), tubulovillous adenomas with LGD in 15 (10 wired, 5 non-wired), high-grade tubulovillous adenomas in 2 (1 wired, 1 non-wired), and carcinoma in 9 (5 wired, 4 non-wired). The common bile duct orifice was identified in 23/30 (77 %) wired versus 13/30 (43 %) non-wired specimens (p = 0.017), and histologic intraductal extension was detected in 17/30 (57 %) wired versus 10/30 (33 %) non-wired specimens (p = 0.119).

Conclusions Ex-vivo guidewire cannulation of papillary specimens improved identification of the CBD orifice by 33 % and nearly doubled the detection of intraductal adenoma. This technique allows identification of a subgroup at risk of intraductal recurrence, the primary means by which papillary adenomas reoccur. These findings have important implications for subsequent surveillance and therapy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1093 Attitudes towards green endoscopy and sustainable conferences in Ireland, a nationwide survey

Authors O'Grady Walshe A[1], McNamara D[2], O'Morain N[3]
Institutes **1** Tallaght University Hospital, Dublin, Ireland; **2** Trinity College Dublin and Tallaght University Hospital, Dublin 24, Ireland; **3** St. Vincent's University Hospital, Dublin, Ireland
DOI 10.1055/s-0046-1822420

Aims Environmental impacts of clinical practice are increasingly an area of focus internationally. In this study, we surveyed members of the I Irish Society of Gastroenterology to get a better understanding of current attitudes towards Green Endoscopy practices and the environmental impact of conference attendance in Ireland. We hope that the results of this study can guide policy development in Green Endoscopy nationally, and contribute to strategies for reducing the carbon footprint of Conferences globally.

Methods An anonymous 21 question survey using Microsoft Forms was distributed via email to members of the Irish Society of Gastroenterology. The age profile and position of responders was recorded, as was their region of practice. We assessed the prevalence of Green Endoscopy initiatives in Endoscopy Units by region, awareness of Green Endoscopy policies , and what barriers exist to introducing such policies locally. Data regarding the number of conferences attended annually, both nationally and internationally, was recorded, as were the methods of transport used to attend these conferences. We collected data regarding responders attitudes towards virtual conference attendance and the environmental impact of conferences.

Results A total of 65 responses were received from Consultants(n = 25) , GI trainees (n = 14), Endoscopy Nurses (n = 21), Nurse Endoscopists (n = 4). The majority (52 %) were aged 30-39 (n = 34) and worked in urban areas (72 %). 40 % of those surveyed said that their unit had a Green endoscopy programme (n = 26), and 69 % of those who responded stated that their endoscopy unit recycled green waste (n = 45). 55 % of respondents confirmed that their endoscopy unit did adhere to guideline recommended biopsy protocols (n = 36).

18 % of those who responded were aware of barriers to implementing a green endoscopy initiative (n = 14), reporting issues with waste segregation or a lack of leadership for policy rollout. 60 % of respondents said that their unit had a digital system for endoscopy appointments (n = 39). 58 % of respondents attended 1-2 conferences annually (n = 38), 38 % attended 3-5 conferences annually (n = 25) and 3 % attended more than 5 conferences annually (n = 2), with in-person attendance favoured by 91 % (n = 59). The reasons for attending included CPD (46 %, n = 30), abstract presentation(20 %, n = 13),and networking purposes (22 %, n = 14). Conference attendance increased for some (20 %, n = 13), decreased for others (29 %, n = 19) or had not changed (51 %, n = 33). 94 % of respondents attended 1-2 conferences in Ireland annually. 94 % of those who responded stated that they attended 1-2 conferences outside of Ireland annually. For conferences within Ireland, the preferred method of transport was by car (single occupancy) (57 %, n = 37), car pool (34 %, n = 22), or train (9 %, n = 6). Most reported gaining more knowledge from in-person attendance (85 %, n = 55). The environmental impact of attending a conference was a factor for 26 % (n = 17) but not for 38 % (n = 25) . If available in advance, the predicted environmental impact of a conference would be a factor in attending for 66 % (n = 43).

Conclusions This survey captured attitudes of various Endoscopy practitioners in Ireland. Responses showed there is scope for improved rollout of green endoscopy initiatives in Irish hospitals, particularly for recycling of green waste part. Our survey also showed that most individuals prefer in-person conference attendance for networking and learning opportunities. Surprisingly, only a third take the environmental impact of conferences into account when deciding to attend. This survey may suggest that advanced awareness of predicted environmental impact, along with choosing conference location with good public transport options, may help to reduce the environmental impact of conferences in the future. We hope that this study contributes to policy development for the reduction of the environmental impact of our practice nationally going forward.

eP1094 EUS-guided biopsies of an abdominal paraganglioma: A case report

Authors Gutierrez-Lozano I[1], Kohansal A[1]
Institute **1** University Health Network, Toronto, Canada
DOI 10.1055/s-0046-1822421

Abstract Text

A 40-year-old Iranian female patient with no relevant past medical history underwent an abdominal ultrasound (US) during evaluation of mildly elevated liver enzymes, revealing an incidental mass in the caudate lobe. Magnetic resonance imaging (MRI) demonstrated a 3.5 × 2.8 cm caudate lesion with a central scar and high T2 signal, raising strong suspicion for fibrolamellar hepatocellular carcinoma (FL-HCC). Given the lesion's deep location, percutaneous biopsy was deemed challenging, and an endoscopic ultrasound (EUS)-guided approach was recommended. EUS revealed a hypoechoic, hypervascular, oval mass measuring 32 × 27 mm with well-defined, smooth borders, located near the liver but with unclear site of origin. Fine-needle biopsies (FNB) were performed using a 22-gauge Acquire needle (Boston Scientific). Histopathology demonstrated a succinate dehydrogenase (SDH)-deficient paraganglioma (Ki-67 3.8 %). A DOTATATE PET/CT showed moderate uptake confined to the lesion with no evidence of metastases. Biochemical evaluation revealed elevated plasma normetanephrine at 3 nmol/L (normal < 0.9 nmol/L), with normal chromogranin A. The patient reported only occasional night sweats without classical symptoms of catecholamine excess. Blood pressure remained stable throughout the evaluation, including after and during EUS-FNB. Given the functional nature of the tumor, surgical resection was advised. The patient is currently undergoing preoperative preparation with doxazosin [1–3].

Paragangliomas are rare neuroendocrine tumors that may present at any age and can cause secretory hypertension due to excessive catecholamine release. Most abdominal sympathetic paragangliomas arise from chromaffin tissue near the inferior mesenteric artery and the aortic bifurcation. Intra-abdominal paragangliomas are particularly uncommon, with an estimated incidence of 1 in 500,000. Diagnosis is typically established through plasma or urinary metanephrines and functional imaging, while tissue sampling is rarely performed due to bleeding and hypertensive risks.

This case highlights the diagnostic utility and safety of EUS-guided tissue acquisition for a functional abdominal paraganglioma. Despite the tumor's biochemical activity, the patient tolerated EUS-FNB without hemodynamic instability, underscoring that EUS-guided biopsy may be considered in select cases where the diagnosis is unclear and histology is essential. To our knowledge, EUS-guided biopsy of an abdominal paraganglioma is exceedingly rare. This case emphasizes the importance of maintaining a broad differential for liver masses and demonstrates the expanding role of EUS-guided tissue sampling.

eP1095 Evaluation of Low-Cost Non-Pharmacological Interventions for Reducing Patient Anxiety During Colonoscopy: A Cross-Sectional Study

Authors Kambhotla A[1], Rayamajhi S[2], Paterson R[2]
Institutes 1 Royal Gwent Hospital, Newport, United Kingdom; 2 Edinburgh Napier University Merchiston Campus, Edinburgh, United Kingdom
DOI 10.1055/s-0046-1822422

Aims Colonoscopy is a routinely performed procedure for diagnosing and managing large bowel pathology. Despite its clinical value, pre-procedural anxiety remains common and can adversely affect patient experience, cooperation, and compliance with future screening. Non-pharmacological interventions offer promising, low-cost strategies for minimising procedural anxiety without introducing clinical risks. This study aimed to evaluate the effectiveness of selected non-pharmacological interventions in reducing patient anxiety during colonoscopy and to explore patients' preferences and satisfaction with these interventions.

Methods A quantitative cross-sectional study was conducted at the Royal Gwent Hospital between April and July 2025. From 1,324 colonoscopy patients, those receiving pharmacological sedation and non-consenting individuals were excluded. The final sample comprised 130 participants who completed the State-Trait Anxiety Inventory (STAI) before their procedure and a post-procedure satisfaction questionnaire. Participants voluntarily selected one of four anxiety-reducing interventions: conversation, breathing exercises, guided relaxation, or music therapy. Data were analysed using SPSS version 23. Descriptive statistics, reliability analyses, assumption tests, and both parametric (ANOVA) and non-parametric (Kruskal–Wallis) group comparisons were performed. Associations between demographic variables and high anxiety (top quartile, STAI ≥ 44) were assessed using chi-square tests.

Results Intervention preferences were as follows: 35 % selected breathing exercises, 32 % conversation, 20 % guided relaxation, and 12 % music therapy. The overall mean anxiety score was 37.04 (SD = 9.94, range = 17–65). Conversation was associated with the lowest mean anxiety (M = 34.19, SD = 8.87), followed by music (M = 36.63, SD = 10.31), breathing exercises (M = 38.62, SD = 9.56), and guided relaxation (M = 39.23, SD = 10.03). Internal consistency of the anxiety scale was good (Cronbach's α = 0.82). Both Shapiro–Wilk and Levene's tests indicated partial violations of normality and homogeneity assumptions; thus, results from both ANOVA and Kruskal–Wallis tests were considered. No statistically significant differences were found in total anxiety scores across the four intervention groups ($p > .05$), and post hoc Mann–Whitney U tests confirmed no significant pairwise differences.

In terms of satisfaction (0–10 scale), guided relaxation (M = 8.92, SD = 0.97) and breathing exercises (M = 8.78, SD = 0.86) received the highest ratings, followed by conversation (M = 8.17, SD = 1.14) and music therapy (M = 5.63, SD = 1.52). Perceived helpfulness ratings (1–4 scale) were generally high (~3/4) across interventions. Chi-square analyses revealed no significant association between gender and high anxiety ($p > .05$), although participants with school-level education showed a higher proportion of high anxiety scores compared with those with university-level education.

Conclusions Breathing exercises and guided relaxation techniques demonstrated favourable patient satisfaction and potential in reducing anxiety during colonoscopy. Although mean anxiety scores did not differ significantly between intervention groups, the overall positive response and low cost highlight the feasibility of integrating such interventions into routine endoscopy practice. Implementing simple, non-invasive, patient-selected anxiety management strategies could enhance the overall patient experience, reduce reliance on sedative medication, and support more patient-centred care delivery in endoscopy units. Future studies with larger samples and controlled designs are warranted to verify these findings and further optimize tailored anxiety reduction interventions in gastroenterological settings.

eP1096 Improving Mucosal Visibility in EGD: A Comparative Study of Premedication Protocols

Authors Kashin S[1], Kuvaev R[2]
Institutes 1 Yaroslavl Regional Cancer Hospital, Department of Endoscopy, Yaroslavl, Russia; 2 Endoscopy Department, Yaroslavl Regional Cancer Hospital, Yaroslavl, Russia
DOI 10.1055/s-0046-1822423

Aims Foam and bubbles can interfere with the detection of small or early lesions during esophagogastroduodenoscopy (EGD), prolong procedures, and increase complication risks. Pre-procedural preparation may reduce the need for mucus removal. This study evaluated the efficacy and safety of various pre-EGD preparation methods. Simethicone is known to reduce foam and improve visibility, though it may be less effective in patients with dense mucus, such as those with autoimmune or atrophic gastritis.

Methods From July 2024 to July 2025, 192 patients aged 20–94 participated in a prospective, single-center, randomized, blinded study (Table 1). **Exclusion criteria:** prior gastrointestinal surgery, upper GI tract strictures, dysphagia, or allergy to premedications.

Premedication protocols:
Group A: no premedication
Group B: simethicone 40 ml
Group C: simethicone 20 ml + 5 % sodium bicarbonate 20 ml
Group D: 5 % sodium bicarbonate 20 ml
All solutions were administered 20 minutes before EGD.

Outcomes measured: mucosal visibility (GRACE scale), procedure duration, mucus removal time, and need for additional cleansing agents.

Results Group C (preparation with simethicone 20 ml + 5 % sodium bicarbonate 20 ml) showed the shortest mucus removal time (20.8 seconds), highest GRACE score (6.7 in Group A vs. 8.4 in Group C), and the best subjective mucosal cleanliness, rated "excellent" in 88.9 % of cases. The use of a combined preparation solution of simethicone and sodium bicarbonate demonstrated the highest efficiency in detecting pathological lesions – 51.1 %, while the proportion of lesions less than 1 cm in size was 65.2 %.

Conclusions The combination of sodium bicarbonate and simethicone is a safe, effective method to improve mucosal visibility during EGD and shorten procedure time, particularly in patients with dense mucus

eP1097 Prospective Evaluation of the CAD EYE System for Computer-Aided Detection and Characterization of Colorectal Polyps: A Comparative Study

Authors Kashin S[1], Kuvaev R[2]
Institutes 1 Yaroslavl Regional Cancer Hospital, Department of Endoscopy, Yaroslavl, Russia; 2 Endoscopy Department, Yaroslavl Regional Cancer Hospital, Yaroslavl, Russia
DOI 10.1055/s-0046-1822424

Aims Computer-aided detection (CADe) and diagnosis (CADx) systems aim to improve colonoscopy quality. This study evaluated the real-time performance of the CAD EYE system (Fujifilm, Japan) for both polyp detection and

the optical characterization of colorectal lesions into hyperplastic vs. neoplastic categories.

Methods A prospective, comparative study was conducted. Consecutive patients undergoing colonoscopy were allocated to procedures either with (study group, n = 56) or without (control group, n = 54) CAD EYE assistance. The system was used in CADe mode with white light imaging (WLI) and linked color imaging (LCI). For characterization (CADx), blue light imaging (BLI) mode was used to predict histology (neoplastic vs. hyperplastic). Primary outcomes were the sensitivity and specificity of CADe for polyp detection and of CADx for optical diagnosis. Secondary endpoints included procedural metrics. Statistical analysis included calculation of performance metrics with 95 % confidence intervals and AUC.

Results A total of 241 lesions (mean size 7.9 mm) were analyzed from 110 patients: 135 (56 %) neoplastic and 106 (44 %) hyperplastic. Patient groups were well-matched for bowel preparation (Boston Bowel Prep Score > 7: 87.5 % vs 87 %) and cecal intubation (100 % each). The CADe system demonstrated a sensitivity of 97 %, specificity of 84 %, accuracy of 93 %, and an AUC of 0.95 for polyp detection. For optical characterization, the CADx mode achieved a sensitivity of 96 %, specificity of 99 %, accuracy of 98 %, and an AUC of 0.96 for differentiating neoplastic from hyperplastic lesions.

Conclusions The CAD EYE system shows high accuracy for both real-time polyp detection and optical characterization of colorectal lesions, performing at expert-level benchmarks. Its integration into clinical practice has the potential to enhance the quality of screening colonoscopy, increase adenoma detection rates (ADR), and support real-time endoscopic decision-making. Prospective multicenter studies are warranted to confirm its impact on long-term patient outcomes.

eP1098 "Occult" metachronous gastric cancer diagnosed by narrow-band imaging endocytoscopy in patient after endoscopic submucosal dissection for early neoplasia: clinical case presentation

Authors Kashin S[1], Kuvaev R[2]
Institutes 1 Yaroslavl Regional Cancer Hospital, Department of Endoscopy, Yaroslavl, Russia; 2 Endoscopy Department, Yaroslavl Regional Cancer Hospital, Yaroslavl, Russia
DOI 10.1055/s-0046-1822425

Abstract Text

A 80-year-old Caucasian male patient was referred to Yaroslavl Regional Cancer Hospital for follow up upper gastrointestinal (GI) endoscopy after endoscopic submucosal dissection (ESD) for early gastric cancer. In 2012 and 2015 patient underwent curative ESD for early neoplastic lesion of gastric body. Two postESD scars on the greater curvature of gastric body without any signs of cancer recurrence were detected during white light imaging upper GI endoscopy (Olympus EVIS X1, GIF H290EC). Advanced atrophic changes in gastric body and gastric antrum were confirmed at the background gastric mucosa, Helicobacter pylori infection was not detected, no suspicious lesion was identified. Narrow-band imaging (NBI) with magnification and NBI endocytoscopy (520 × magnification) was performed for all local mucosal changes. A 2-mm flat area with microvascular irregularity and irregular cellular architecture and marginal crypt epithelium border was detected on ultra-magnifying NBI observation. Target forceps biopsy was taken for histological assessment of the lesion. Histology showed well-differentiated adenocarcinoma.

eP1099 First experience of using a new generation thulium laser for lithotripsy during cholangioscopy: case report

Authors Gusev D[1], Kashin S[2]
Institutes 1 Cancer Hospital №57, Moskva, Russia; 2 Yaroslavl Regional Cancer Hospital, Department of Endoscopy, Yaroslavl, Russia
DOI 10.1055/s-0046-1822426

Abstract Text

Therapeutic Thulium laser usually use in urology [1]. But now the indications for applying a new generation thulium laser in endoscopy are expanding [2]. In this case, we report one of the first experience of successful management of choledocholithiasis using cholangioscopy-assisted thulium laser lithotripsy.

A 68-year-old female showed typical symptoms of progressive jaundice. Chronic calculous cholecystitis was known from the medical history. Laboratory tests were consistent with obstructive jaundice: elevated hepatic enzymes (total bilirubin-207 mg/dL, direct bilirubin 138 mg/dL, ALT – 254 IU/L, AST – 353 IU/L). Transabdominal ultrasound (TUS) showed dilated intrahepatic and extrahepatic bile ducts with a 20 mm stuck stone in the common bile duct (CBD). MRI showed chronic calculous cholecystitis and signs of moderate biliary hypertension with obstruction at the middle and lower thirds of the CBD (fig.1.) We also performed EUS which showed the biliary hypertension and the bile stone (> 15 mm) at the level of the confluence of the cystic duct (fig.2.) Standard ERCP-lithoextraction with balloon sweep and basket retrieval was failed. Then our treatment plan included performing a repeat ERCP to visualize the biliary tree and facilitate cholangiscopy-assisted thulium laser lithotripsy to break down the stone and remove the fragments.

We performed cholangioscopy-assisted lithotripsy for a fixed CBD stone using a superpulse thulium laser (power: 30 W, pulse energy: 30 J, frequency: 1 Hz, fiber diameter: 365 µm, Urolase + Premium). (fig.3,4.) The design of thulium laser minimizes retropulsion compared to other lithotripsy lasers. The selected pulse frequency effectively fragments stones into small pieces, including sand-sized particles (fig.5.) The thulium laser features an innovative tissue sensor function that enhances the safety and efficacy of laser treatments by distinguishing between hard and soft tissues. During lithotripsy, this technology automatically halts laser emission when aimed at the mucosa, thereby reducing the risk of tissue damage. Following the lithotripsy procedure, all fragments were successfully removed from the CBD (fig.6.) The procedure was completed without any adverse events or complications, and the patient was subsequently discharged.

This case report aimed to explore the efficacy and safety of new generation thulium laser (fig.7.) Thulium laser lithotripsy can be applied in endoscopic management of biliary stones during ERCP to fragment large stones that cannot be removed by standard ERCP-techniques. There are no any published cases of in vivo experience using the thulium laser for bile stone fragmentation. Further research and clinical trials will help to refine thulium laser use and establish best practices for optimal patient outcomes in the management of bile duct stones.

eP1100 Fluoroscopy-Free Endoscopic Biliary Stenting using SpyGlass-cholangioscopy and Transabdominal Ultrasound Guidance for Malignant Obstruction : A Case Series

Authors Gusev D[1], Kashin S[2]
Institutes 1 Cancer Hospital №57, Moskva, Russia; 2 Yaroslavl Regional Cancer Hospital, Department of Endoscopy, Yaroslavl, Russia
DOI 10.1055/s-0046-1822427

Aims Standard ERCP with biliary stenting requires fluoroscopy, exposing patients and staff to radiation. We describe a novel technique using SpyGlass-cholangioscopy and transabdominal ultrasound (TUS) guidance to eliminate radi-

ation exposure entirely. Aim is to evaluate feasibility, safety and efficacy of fluoroscopy-free endoscopic biliary stenting using SpyGlass and TUS guidance.
Methods Twelve patients (8F/4M; mean age 72) with malignant distal biliary obstruction from pancreatic head cancer underwent standard duodenoscopy with selective bile duct cannulation. The length and localization of tumor stenosis were accessed by SpyGlass cholangioscopy. It's allow to choose right stent design, take biopsy. Guidewire advanced to upper part of biliary tree by direct visualization Stent deployment (8 plastic, 4 SEMS) were monitored in real-time using TUS instead of fluoroscopy. Adequate placement was confirmed by bile flow and resolution of biliary dilation on ultrasound. In case with SEMS placement, position control may be access with SpyGlass.
Results Technical success was achieved in all 12 cases (100 %). Clinical success with jaundice resolution was 100 %. Mean procedure time was shorter than conventional fluoroscopic ERCP. No complications occurred. The key advantage was zero radiation exposure for patients and staff.
Conclusions SpyGlass-cholangioscopy/TUS-guided endoscopic biliary stenting is feasible and safe, completely eliminating radiation exposure while maintaining high success rates. The technique is applicable for both: plastic and metal stents, offering a promising radiation-free alternative for palliative biliary drainage.

eP1101 Long-Term Risk of Major Gastrointestinal Bleeding After Antithrombotic Therapy in Atrial Fibrillation: Role of Hemoglobin and Albumin

Authors Kim HS[1], Seo GS[2], Park SY[1], Kim D[1]
Institutes **1** Chonnam National University Hospital, GwangJu, Republic of Korea; **2** Wonkwang University Medical Center, Iksan, Republic of Korea
DOI 10.1055/s-0046-1822428
Aims Gastrointestinal bleeding (GIB) is a critical complication in patients receiving antithrombotic agents (ATs). We aimed to (1) investigate the incidence and timing of major GIB, (2) classify the etiologies of upper GIB (UGIB) and lower GIB (LGIB), and (3) identify the risk factors for GIB following AT initiation during long-term follow-up.
Methods A retrospective cohort study of 8,699 patients with atrial fibrillation (AFib) initiating ATs was conducted using electronic health records from a tertiary hospital. Major GIB was defined as bleeding requiring therapeutic intervention and classified anatomically as UGIB or LGIB. Incidence rates were calculated, and risk factors were examined via multivariable Cox regression and 1-year landmark analysis.
Results : During a mean follow-up of 6.5 years, 2.4 % of patients experienced major GIB (1.7 % UGIB; 0.8 % LGIB), and incidence was the highest in the first year (79.0 per 10,000 person-years). Ulcers and angiodysplasia were the leading etiologies. In addition to well-known comorbidities, low baseline hemoglobin and albumin were independently associated with the increased GIB risk. As hemoglobin decreased, the risk increased progressively, beginning at ≤ 12 g/dL and peaking at ≤ 8 g/dL (adjusted HR 10.95, 95 % CI 6.36–18.85). Landmark analysis confirmed that low hemoglobin predicted GIB in the first year and thereafter.
Conclusions : Major GIB is the most frequent in the first year following AT initiation but remains a long-term concern. Low baseline hemoglobin and albumin levels, as readily available markers, may be valuable in the early identification and risk stratification of high-risk patients with AFib.

DOI 10.1055/s-0046-1822429
Abstract Text
EUS-directed transgastric ERCP (EDGE) is an effective minimally invasive technique for ERCP in patients with Roux-en-Y gastric bypass (RYGB), though adverse events such as lumen-apposing metal stent (LAMS) displacement may occur [1]. We report a 69-year-old patient with RYGB and obstructive jaundice due to choledocholithiasis who underwent EDGE. ERCP achieved complete bile duct clearance, but LAMS displacement occurred during scope withdrawal, resulting in loss of anastomotic continuity. Endoscopic removal of the displaced stent and peritoneal navigation allowed successful deployment of a new LAMS, restoring the anastomosis. No delayed adverse events occurred. This case highlights the role of advanced endoscopic management in resolving complex EDGE-related complications and avoiding surgery.

Abstract Text
Postoperative duodenal fistulas are associated with high morbidity, particularly in patients with surgically altered anatomy. We report successful endoscopic management of a complex duodenal fistula in a 69-year-old man with prior Billroth II gastrectomy, complicated by colon cancer–related duodenal perforation after surgery. Persistent high-output fistula following two surgical revisions prompted a multidisciplinary endoscopic rescue approach. Using a duodenoscope, biliary and pancreatic ducts were selectively cannulated and plastic stents placed with distal ends in the gastric remnant to divert bile and pancreatic secretions away from the fistula. A fully covered enteral metal stent was deployed across the duodenal defect, combined with continuous nasoduodenal suction drainage. Drain output progressively resolved. Four-week follow-up imaging confirmed fistula closure, allowing safe removal of all devices [1].

Abstract Text

Biliary complications after orthotopic liver transplantation (OLT) remain a major cause of morbidity. Complete hepatico-jejunal anastomotic disconnection is rare and often refractory to conventional endoscopic treatment. We report a 60-year-old man who underwent OLT with Roux-en-Y biliodigestive anastomosis for primary sclerosing cholangitis and developed recurrent cholangitis. Percutaneous cholangiography suggested complete anastomotic disconnection, and enteroscopic ERCP attempts failed. EUS-guided duodenojejunostomy was created using a lumen-apposing metal stent (LAMS), followed by transenteric ERCP. Due to incomplete biliary access, EUS-guided hepaticojejunostomy through the LAMS with placement of a fully covered metal stent was performed. At three-month follow-up, cholestasis improved and no further cholangitis occurred [1, 2].

DOI 10.1055/s-0046-1822432

Abstract Text

A 72-year-old female underwent pylorus-preserving pancreaticoduodenectomy due to a non-ampullary HDG LST of the descending duodenum (R0). Post-surgical adverse events included a millimetric jejunal perforation due to the migration of the surgical pancreatic stent against the limb wall. During the endoscopic retrograde treatment attempt of the perforation, a dehiscence of the hepaticojejunostomy was noticed and addressed by placing an enteral fc-SEMS and through-the-meshes biliary fc-SEMS. Subsequent EUS-guided antegrade fc-SEMS was placed through the pancreaticojejunostomy to guarantee an access route to retrieve the migrated pancreatic surgical stent. Challenges with stent migration led to further interventions, highlighting the complexities of postoperative management following pancreatic surgery and the pivotal therapeutic role of a multimodal endoscopic approach.

DOI 10.1055/s-0046-1822433

Abstract Text

A 64-year-old man underwent piecemeal EMR of a 20-mm duodenal adenoma and developed delayed perforation with retroperitoneal free air. Endoscopy revealed a large duodenal wall defect. ERCP with biliary and pancreatic stenting was performed to divert secretions. The defect was treated with enteral self-expandable metal stents and continuous negative-pressure therapy using double-lumen tubes, combined with periduodenal drainage and enteral nutrition. Despite initial improvement, stent migration and infected retroperitoneal collection occurred. A step-up hybrid approach including deployment of a customized chimeric duodenal stent and combined endoscopic–percutaneous drainage achieved complete sealing of the defect and fistula. Follow-up imaging confirmed resolution of the collection. The patient resumed oral feeding and was discharged in good clinical condition [1, 2].

Aims Endoscopic closure is the preferred therapy for iatrogenic gastrointestinal perforations, but real-world data, especially for the loop-and-clip technique, remain limited. This study evaluated technical success, clinical success, and adverse events, and the requirement of surgery across commonly used endoscopic closure methods [1–23].

Methods This retrospective cohort study analyzed all patients with iatrogenic perforations during 229,712 endoscopic procedures (upper endoscopy, colonoscopy, ERCP, EUS, enteroscopy) at Asian Institute of Gastroenterology, Hyderabad, India from November 2022 to November 2024. Endoscopic closure

strategy was determined by defect size, morphology, anatomical site, timing of recognition, and patient stability, with final discretion left to the endoscopist. Closure techniques included loop-and-clip, through-the-scope (TTS) clips and over-the-scope clips (OTSCs). The primary outcome was clinical success, while secondary outcomes included technical success, need of surgical intervention, and adverse events.

Results During the study period, 82 perforations occurred (0.039 % of incidence). The mean age of patients was 58.9 ± 14.9 years; and 54 % were male. The most frequent organs with iatrogenic perforation were the duodenum (32.9 %) and colon (29.2 %). Perforation was identified intraprocedurally in 90 % of cases, with early diagnosis (< 12 hs) in 3.6 % and delayed diagnosis (≥ 12 hs) in 6 %. Endoscopic closure was attempted in 76 (92.6 %) cases. Technical success was high across closure methods: Loop-and-clip achieved 92 % (median size perforation size: 2.3 cm, range: 1-4cm), TTS 100 % (median size 0.5cm, range: 0.5-1 cm), and OTSC 100 % (median size: 1.5 cm, range: 1.0- 2.0 cm). Clinical success was achieved in 88.2 % of attempted closures (loop-and-clip achieved 90 % clinical success, TTS 94.7 %, OTSC 100 %). Perforation size was an independent predictor of closure failure (OR 2.87; 95 %CI: 1.38-6.07). Adverse events occurred in 28 % of the cohort (AGREE II), and overall mortality was 2.4 %. Eight patients (9.7 %) required surgery, including six after failed endoscopic closure attempts. Among the six patients in whom endoscopic closure was not attempted, conservative management was successful in 66.7 % (4/6).

Conclusions Endoscopic closure showed strong technical and clinical performance across modalities. The loop-and-clip technique demonstrated high effectiveness and broad applicability, supporting its role as a practical closure method with acceptable adverse event rates.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1108 Endoscopic submucosal dissection including papilla (ESDIP) for laterally spreading ampullary tumors in patients with pancreas divisum: A practical postoperative approach without pancreatic duct drainage

Aims Endoscopic papillectomy enables resection of ampullary lesions but has notable limitations, including piecemeal resection and high recurrence rates. To overcome these limitations, we previously reported the feasibility of endoscopic submucosal dissection including the papilla (ESDIP) as an alternative approach. ESDIP extends conventional ESD to the ampullary region, allowing en bloc resection while dividing the sphincter of Oddi. However, this division increases postoperative exposure to bile and pancreatic juice, making biliary and pancreatic duct drainage essential to prevent complications. In patients with pancreas divisum, anatomical variation often renders endoscopic nasopancreatic drainage (ENPD) unfeasible, resulting in more complex postoperative management. This study aimed to evaluate the feasibility and safety of ESDIP for ampullary tumors in patients with pancreas divisum.

Methods Among 70 patients who underwent ESDIP at our institution between August 2011 and October 2025, two patients with pancreas divisum and ampullary neoplasms were retrospectively analyzed.

ESDIP was performed by creating a distal mucosal incision, forming a mucosal flap from the oral side, conducting submucosal dissection with identification

and division of the sphincter of Oddi, and subsequently achieving en bloc resection of the lesion.

According to our standard ESDIP protocol, postoperative management typically involves ERCP-guided biliary and pancreatic drainage to prevent bile and pancreatic juice exposure to the resection defect. However, in the present two cases with pancreas divisum, ENPD was not feasible due to the anatomical configuration of the pancreatic duct.

After resection, endoscopic retrograde biliary drainage (ERBD) was performed. The mucosal defect, excluding the papilla, was partially closed using clips, and continuous duodenal suction was applied using a nasogastric tube placed near the duodenal ESD defect. Octreotide was additionally administered to minimize pancreatic juice exposure.

Primary outcomes included en bloc resection, intraoperative perforation, length of hospital stay, white blood cell count, C-reactive protein, serum amylase level, and post-ERCP pancreatitis.

Results En bloc resection was achieved in both cases. No intraoperative or delayed perforation, postoperative bleeding, or post-ERCP pancreatitis occurred. One patient experienced mild abdominal pain on postoperative day 1, and computed tomography revealed minor retroperitoneal emphysema, which resolved with conservative treatment. The nasogastric tube was removed on postoperative days 4–5, after which oral intake was resumed. Patients were discharged on postoperative days 10 and 12, respectively, with uneventful clinical courses.

Conclusions ESDIP for ampullary tumors in patients with pancreas divisum can be safely performed even when ENPD is not feasible. Continuous duodenal suction using a nasogastric tube, combined with partial ulcer closure and octreotide administration, effectively reduced pancreatic juice exposure and enabled safe postoperative management. This strategy may represent a practical therapeutic option for pancreas divisum cases in which pancreatic duct drainage cannot be achieved.

DOI 10.1055/s-0046-1822436

Aims Colon capsule endoscopy (CCE) offers a minimally invasive alternative to conventional colonoscopy, yet its clinical impact is strictly dependent on achieving adequate colon cleansing rates (ACR) and completion rates (CR). These requirements impose more stringent preparatory demands than traditional colonoscopy, as capsules cannot rinse or flush the lumen. Existing systematic reviews (SRs) and meta-analyses (MAs) on CCE procedure laxatives and boosters' regimens show significant variability in recommendations and methodological rigor, creating a barrier to clinical practice harmonization. The aim of this umbrella review is to synthesize and critically appraise findings from existing SRs/MAs to evaluate the comparative effectiveness of CCE bowel preparation strategies, and identify areas of consensus and uncertainty [1–15].

Methods A literature search to November 2025 identified SRs/MAs evaluating preparation regimens for CCE. Methodological quality was assessed using AMSTAR-2. Primary study overlap was quantified using the Corrected Covered Area (CCA). Primary outcomes were ACR and CR; data were stratified by regimen components (laxatives, boosters, prokinetics, diet) and specific populations. AI assistance (Google Gemini 3 Pro) was used for data organization.

Results Fourteen SRs (comprising 11 MAs) including 102 unique primary studies and over 16,000 patients were included. The CCA was 8.59 %, indicating moderate overlap and confirming that reviews provide complementary evidence. Methodological quality was variable, with only two reviews rated as high quality, while the majority were classified as low or critically low due to reporting limitations. Overall pooled ACR (72.5 %–76.8 %) and CR (79.8 %–83.0 %) remained suboptimal compared to colonoscopy standards. In patients with Inflammatory Bowel Disease (IBD), efficacy varied widely (ACR 49–98.5 %) with no significant difference between regimens. However, component analysis identified superior strategies: low-volume polyethylene glycol (PEG, < 4L) yielded numerically higher ACR (77.5 %) compared to high-volume regimens (72.9 %). Sodium phosphate (NaP) boosters consistently outperformed PEG boosters, with the NaP + Gastrografin combination achieving the highest absolute CR (93.1 %). Castor oil significantly improved excretion rates (92 % vs 73 %), and routine prokinetics were superior to selective use (OR 1.86). Finally, a low-fiber diet was associated with better cleansing than a clear liquid diet (ACR 78.5 % vs 70.0 %).

Conclusions CCE bowel preparation regimens frequently result in suboptimal CR and ACR, highlighting the need for protocol standardization. Meta-analytic evidence consistently demonstrates that the optimization of regimens by combining low-volume PEG, NaP-based or Gastrografin boosters, and routine prokinetics yield superior outcomes, though specific needs may vary in IBD populations. The substantial heterogeneity across reviews, driven by variable definitions and protocols, underscores the need for consensus. The 2025 Nyborg Consensus recommendations, such as the adoption of the CC-CLEAR scale and mandatory reporting fields, are critical next steps. Since ACR and CR are significant inverse predictors of follow-up endoscopy rates, the future adoption of optimized and personalized protocols is crucial for cost-effectiveness.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1111 Comparison of Serrated Lesion Detection Rates Using High-Definition Versus Standard-Definition Endoscopes: A Retrospective Analysis of BowelScreen patients in a Model 4 Irish Hospital

Authors Ulaganathan H[1], Slattery E[1]
Institute 1 University Hospital Galway, Galway, Ireland
DOI 10.1055/s-0046-1822438

Aims Serrated polyps are diverse lesions that encompass hyperplastic polyps (HPs) proximal to the rectum, sessile serrated lesions (SSLs) with or without dysplasia, and traditional serrated adenomas (TSAs) [1]. Although most sporadic colorectal cancers (CRCs) arise from adenomas, it is believed that about 15-30 % of CRCs [2] arise through an alternate serrated neoplasia pathway. This is particularly true for proximal and interval cancers. Serrated lesions can be flat, with a mucous cap, and are easily missed compared to adenomas. Improving detection rates is crucial to reducing CRC incidence and mortality.
We aim to compare the ability to detect sessile serrated lesions with high definition scopes (HD) versus standard definition scopes (SD) in a faecal immunochemical test (FIT) – positive national screening cohort.

▶ **Table 1**

	High Definition	Standard Definition	P Value
Total number of procedures	200	200	
Serrated Polyps (HP, SSL w and w/o dysplasia, TSA)	70	56	0.162
Hyperplastic Polyps	51	37	0.116
SSL	30	25	0.561
SSL w Dysplasia	1	0	>0.999
Traditional Serrated Adenoma	1	1	>0.999
Adenomas	166	170	0.682

Methods A retrospective analysis was conducted of 400 BowelScreen (NCSS) participants in Ireland's national colorectal screening program who underwent colonoscopy after a positive faecal immunochemical test (>45 ug/g) and had polyps removed. All colonoscopies were performed by a BowelScreen endoscopist. They were evenly split between HD and SD. Detection rates were calculated for SSLs and HPs, and statistical analysis was performed with chi-square testing with a two-sided significance level of $\alpha = 0.05$. Adenomas, serrated lesions with dysplasia, traditional serrated adenomas and identifying serrated polyposis syndromes were also assessed in this cohort (▶ **Table 1**).
Results The mean age of the cohort was 66.6 years, with data collected between 2018 and 2025. Among 200 HD scopes performed, 30 SSLs were detected (15 %) compared to 25 in the SD group (12.5 %) (**p = 0.561**). For hyperplastic polyps, 51 HD scopes detected HPs (25.5 %) compared to 37 (18.5 %) in SD (**p = 0.117**). One SSL with dysplasia was detected in the HD arm, and 1 TSA was detected in each arm. It is worth noting that there was one patient in whom serrated polyposis syndrome was diagnosed with a high-definition endoscope. No observed statistical significance achieved.
Conclusions Although this initial retrospective analysis did not show statistical significance, an observed higher absolute detection rate of serrated lesions with HD scopes suggests a potential benefit. Post hoc power considerations indicate that a substantially larger sample size would be required to reflect the actual technology effect. Key limitations include the lack of standardised withdrawal times and unmeasured variation in bowel preparation quality, especially in the proximal colon, which can affect lesion detection rate. Given the established contribution of serrated lesions to proximal and interval CRC, and emerging quality metrics such as SSL detection rate, prospective, adequately powered studies are needed to clarify if HD colonoscopy should be mandated as standard, especially for population-based screening programmes.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822439

Aims Conventional white light imaging (WLI) frequently fails to detect subtle colorectal lesions, which contributes significantly to the incidence of interval colorectal cancer. Texture and Color Enhancement Imaging (TXI™) is a novel endoscopic technology utilizing a proprietary algorithm to enhance image clarity, thus facilitating the detection, particularly of subtle lesions. Preliminary studies have reported conflicting evidence: one trial indicated that TXI improved the adenoma detection rate (ADR), while another demonstrated improvement only in the detection of flat lesions [1, 2]. This systematic review and meta-analysis was therefore conducted to comprehensively assess the efficacy of TXI compared to WLI for colorectal lesion detection.

Methods We performed a systematic literature search in accordance with the PRISMA guidelines up to 3th november 2025 after protocol registration on OSF. Articles were retrieved from PubMed and EMBASE, limited to English, full-text, original research papers on adults comparing the efficacy of TXI vs WLI. Two independent, blinded reviewers will perform the selection process. Primary endpoint was evaluate the performance in ADR of TXI vs. WLI. Secondary endpoints include serrated polyp detection rate (SPDR), right ADR (rADR), and flat polyp detection rate (FDR).

Results Overall, seven studies were included in the analysis [1–7]. For the primary endpoint, five studies involving 6377 participants were included. The pooled random-effects model showed a statistically significant improvement in ADR with TXI (RR 1.19; 95 % CI 1.07–1.32; p = 0.0015) compared to WLI. The right ADR was evaluated across three studies including 2451 patients. The pooled analysis demonstrated a statistically significant improvement with TXI (RR 1.26; 95 % CI 1.13–1.42; p < 0.0001) compared to WLI. The serrated polyp detection rate was evaluate in four studies comprising 5907 patients. The pooled analysis evidenced a significant, but bordeline, benefit for TXI compared to WLI (RR 1.13; 95 % CI 1.00–1.27; p = 0.048). Lastly, for the flat polyp detection rate, two studies involving 4687 patients, showed a pooled RR of 1.19 (95 % CI 0.98–1.46; p = 0.0845), indicating a non-significant trend toward improved detection with TXI. General heterogeneity across outcomes was low to moderate (ADR: I^2 = 70 %; SPDR, rADR; I^2 = 0 %; FDR: I^2 = 26 %)

Conclusions This systematic review and meta-analysis including recent RCTs, evidences that TXI provides a significant improvement compared to WLI in overall ADR, SPDR and especially rADR, suggesting enhanced recognition of clinically relevant lesions, including serrated and right-sided precursors associated with interval colorectal cancer risk. While the benefit for flat lesions was not statistically significant, the direction of effect aligns with the broader pattern favoring TXI. Further studies are needed to evaluate its impact on mortality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822440

Aims Percutaneous endoscopic gastrostomy (PEG), used for long-term enteral nutrition is associated with postprocedural infections. Therefore, the European Society of Gastrointestinal Endoscopy (ESGE) recommends periinterventional intravenous antimicrobial prophylaxis. This study aimed to evaluate guideline adherence, determine the impact of different antibiotic strategies on infection rates and analyze their association with 90-day survival post PEG-Implantation [1, 2].

Methods This retrospective single-center study included all patients who underwent PEG placement between January 2017 and December 2023. Patients were categorized into four groups based on their periinterventional antibiotic status: no antibiotics, ongoing antibiotic treatment, pre-interventional EGSE-compliant prophylaxis and pre-interventional non-compliant prophylaxis. Infections were defined as newly elevated CRP values > 5 mg/dl and/or clinical or microbiological signs of infection within 7 days post-PEG. Group comparisons used Fisher's exact test and Mann-Whitney U tests; pairwise odds ratios (OR) with confidence intervals (CI) were calculated. Ninety-day mortality was analyzed using Kaplan-Meier estimates with log-rank tests. Effect sizes were expressed as rank-biserial correlation coefficients (r). Analyses were performed using RStudio (4.4.3).

Results A total of 689 patients, median age 68 years (IQR 18.2), 39 % female, were included. Indications for PEG were tumors (45.6 %), cerebrovascular events (35.1 %), and neurological diseases (19.3 %). Pre-interventional single-shot prophylaxis was administered in 427 cases (62 %), 148 patients (21.5 %) were already on antibiotic treatment at the time of PEG placement, and 90 (13.1 %) received no antibiotics, 24 patients (3.5 %) were excluded. Cephalosporins (51.1 %) and penicillin combined with β-lactamase inhibitors (29.3 %) were most frequently used, resulting in an overall ESGE-adherence of 91.4 %, with some leniency (i.e., considering broader coverage as ESGE-compliant). The overall postprocedural infection rate was 22.6 % (n = 128), the most common sources were unclear (40.6 %), local infections at the insertion site (19.5 %), peritonitis (10.9 %), and pneumonia (10.2 %). Infection rates did not differ significantly between ESGE-complaint vs. non-complaint prophylaxis (18.5 % vs. 26.7 %; OR 0.62, 95 %CI 0.17-2.77, p = 0.49). The numerically highest postprocedural infection rate was observed in patients receiving no antibiotics (28.4 %; OR 1.74, 95 %CI 0.93-3.20, p = 0.07). Patients on systemic antibiotics at the time of PEG placement had the second highest infection rate (27 %, OR = 1.63, 95 %CI 0.95-2.70, p = 0.053 – vs. ESGE-compliant prophylaxis). Overall, 90-day survival differed statistically significantly between the subgroups (p = 0.019). The highest survival was seen with ESGE-complaint prophylaxis (83.1 %), followed by non-complaint prophylaxis (78.6 %) and no prophylaxis (78.7 %). The lowest survival occurred in patients with ongoing antibiotic therapy (73.4 %), significantly worse than ESGE-complaint prophylaxis (p = 0.0015). Comparative analysis of baseline and inflammatory parameters demonstrated that patients with ongoing antibiotic therapy exhibited a higher systemic inflammatory burden, with elevated CRP (3.05 vs.1.; r = 0.36, p < 0.001) and leukocyte levels (8.8 vs

8.16; r = 0.12; p < 0.01). They also presented with higher comorbidity (CCI 6 vs 5; r = 0.1, p = 0.025) and poorer functional status (ECOG ≥ 3: 45.6 % vs. 26 %; r = 0.22, p < 0.001). Also, PEG indication differed significantly between antibiotic groups (p < 0.001), with tumor-patients being less often on ongoing antibiotic therapy (29.1 % vs. 51.1 %, p < 0.001), and stroke more often (50 % vs. 32.9 %, p < 0.001).

Conclusions Overall adherence to ESGE-recommended prophylaxis was high, when also accepting broader coverage. The lowest rate of infection and highest 90-day survival was observed in patients receiving ESGE-compliant prophylaxis, while some of the analyses were not statistically significant, possibly being underpowered due to high compliance rates. Patients on ongoing systemic antibiotics exhibited the lowest 90-day survival. This finding reflected both their higher comorbidity burden and elevated inflammatory activity, confirming that systemic inflammation, frailty and comorbidities substantially contribute to post-PEG mortality. Future studies could focus on finding subgroups where optimization of patients and delaying PEG placement may improve outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1114 Antiplatelet and anticoagulant therapy in endoscopy: Do we follow the same ESGE hymn sheet in clinical practice?

Authors Wallis S[1], Besherdas K[2]

Institutes 1 Royal Free Hospital, London, United Kingdom; 2 Royal Free Hospital, London, United Kingdom, United Kingdom

DOI 10.1055/s-0046-1822441

Aims An audit to assess the adherence to British Society of Gastroenterology (BSG) and European Society of Gastrointestinal Endoscopy (ESGE) guidelines in patients on antiplatelet or anticoagulant therapy in clinical practice in a UK endoscopy service.

Methods A prospective analysis of patients on anticoagulant and antiplatelet undergoing endoscopy over a period of six weeks from September 2025 at a district general hospital in North London was undertaken. Electronic patient notes along with the endoscopy reports were scrutinized for management of antiplatelet/anticoagulation during the time of their diagnostic or therapeutic endoscopy and compared to the recommendations according to BSG and ESGE guidance.

Results 55 patients were included, median age 72 and 62 % were male. A low-risk diagnostic endoscopy was performed in 69 % of patients, whilst 31 % of patients had a high-risk therapeutic procedure which included either polypectomy (n = 16) or oesophageal stricture dilatation (n = 1).

BSG/EGSE guidelines were followed in 42 % of patients. Lower adherence rates were seen in low-risk diagnostic endoscopy (37 %).

Of those having a low-risk diagnostic procedure, 50 % of patients stopped their antiplatelet medication unnecessarily; this includes clopidogrel (n = 10), aspirin (n = 5) and dual antiplatelet therapy (DAPT, n = 3). For patients taking DOACs (direct oral anticoagulants), guidelines were not followed appropriately in any of the five patients- three patients did not omit their medication on the morning of the procedure, and two patients omitted them for an unnecessarily long period of time.

For high-risk therapeutic procedures, BSG/EGSE guidelines were correctly followed in 53 % of patients. Non-adherence with guidelines included not discussing strategy for temporarily stopping P2Y12 receptor antagonists with an interventional cardiologist for high-risk conditions (coronary artery stents, n = 3), stopping aspirin unnecessarily prior to procedure (n = 3), and stopping apixaban for 24 hours only, instead of the required 72 hours (n = 2).

Conclusions The audit found a significant gap between current practice and best practice guidelines with only 42 % following recommendation guidelines. The largest gap identified was the unnecessary cessation of aspirin for both diagnostic and therapeutic procedures, as well as the unnecessary prolonged cessation of P2Y12 receptor antagonists for diagnostic procedures. Of concern was the lack of communication with cardiologists regarding the cessation of dual antiplatelet therapy in high-risk patients.

Possible reasons for this are that patients are predominantly counselled and booked for procedures by nursing colleagues, who may not be familiar with BSG/EGSE guidance. In addition, patients referred for endoscopic procedures come from multiple referral pathways which may be the reason for variability of practice.

From this study we recommend better implementation and adherence antiplatelet or anticoagulant therapy for endoscopic procedures.

The findings of this audit will be presented at the next endoscopy user group meeting to highlight non-adherence to guidelines, and to remind members of the multidisciplinary team of best practice guidance. Patient information leaflets and counselling protocols will be reviewed to ensure they are in-line with BSG/ESGE guidance. The service will be re-audited following these changes.

eP1115 Classification of gastric mucosal patterns associated with Helicobacter pylori infection using electronic chromoendoscopy: a prospective single-center study

Authors Dilaghi E[1], Esposito G[1], Ligato I[1], Cozza G[1], Annibale B[1]

Institute 1 Department of Medical-Surgical Sciences and Translational Medicine, Sapienza University of Rome, Rome, Italy

DOI 10.1055/s-0046-1822442

Aims*Helicobacter pylori* (Hp) infection remains the leading cause of chronic gastritis and gastric cancer worldwide. Asian studies described specific gastric mucosal patterns observed by electronic chromoendoscopy, the “spotty” and “cracked” patterns, which are associated with active and past Hp infection, respectively [1]. However, no prospective European study evaluated their diagnostic performance. This study aimed to assess the reproducibility and diagnostic accuracy of mucosal pattern recognition by Blue Light Imaging (BLI) for the identification of active or past *Hp* infection.

Methods This was a prospective, single-center study conducted between 2023 and 2025. Adult outpatients (≥ 18 years) undergoing gastroscopy for dyspepsia, gastroesophageal reflux, post-eradication follow-up (≥ 6 months after therapy), or first-degree family history of gastric cancer were enrolled. An expert endoscopist performed endoscopic examinations. For each patient, five non-magnified BLI images (two antrum, one angulus, two corpus) were prospectively selected and anonymized. Three experienced endoscopists independently evaluated all images, classifying each as normal, spotty, or cracked. A fourth expert adjudicated discordant evaluations. For diagnostic performance, the final pattern assigned to each image was defined when all three or at least two endoscopists agreed; in cases of complete disagreement, the final classification was established after discussion with the fourth expert. Histological assessment, following the updated Sydney System, served as the reference standard. Analyses were performed at the image level. Interobserver agreement was quantified by Fleiss’ κ and pairwise Cohen’s κ. Diagnostic performance was calculated for each mucosal pattern, overall, and stratified by gastric region and proton pump inhibitor (PPI) status. Comparisons between diagnostic performance proportions were conducted using two-sided *z*-tests.

Results A total of 120 patients (mean age 54.2 ± 17.0 years; 65.0 % female) were enrolled, yielding 600 BLI images, of which 29 were excluded after con-

sensus for insufficient quality, resulting in 571 images. Overall interobserver agreement among the three endoscopists was substantial (Fleiss' κ = 0.74; p < 0.001), with comparable values in the antrum (κ = 0.73) and corpus (κ = 0.75). Pairwise κ values ranged from 0.72 to 0.77, and the overall proportion agreement was 0.79, confirming high reproducibility across endoscopists. Using histology as the reference, the spotty and cracked patterns showed very high specificities of 98.9 % (95 % CI 97.5–99.6) and 87.9 % (95 % CI 84.3–91.0), diagnostic accuracies of 96.1 % (95 % CI 94.2–97.6) and 86.0 % (95 % CI 82.9–88.8), and sensitivities of 43.5 % (95 % CI 34.3–53.0) and 50.6 % (95 % CI 43.1–58.0), respectively. Conversely, the normal pattern achieved high sensitivity of 95.7 % (95 % CI 92.5–97.9) but a moderate specificity of 58.5 % (95 % CI 52.8–64.0), with a diagnostic accuracy of 75.3 % (95 % CI 71.6–78.8). Regional analyses revealed complementary diagnostic behavior across gastric sites: the normal pattern was more accurately identified in the antrum (72.6 %; 95 % CI 67.5–77.3) than in the corpus (42.4 %; 95 % CI 36.0–49.1; p < 0.0001), while the cracked pattern performed better in the corpus (90.8 %; 95 % CI 86.4–94.1) than in the antrum (83.1 %; 95 % CI 78.7–87.0; p = 0.0089). When stratified by PPI use, diagnostic performance remained stable for the spotty and cracked patterns, but the normal pattern showed lower accuracy in patients receiving PPIs (53.1 %; 95 % CI 46.7–59.5) compared with those not receiving PPIs (64.8 %; 95 % CI 59.3–70.0; p = 0.0048).

Conclusions This first European prospective study showed substantial interobserver agreement and consistent diagnostic accuracy in BLI-based assessment of gastric mucosal patterns associated with active and past *Hp* infection. Electronic chromoendoscopy may contribute to defining the infection status, although awareness of PPI use remains important to avoid potential misinterpretation of mucosal patterns.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1116 Subcecal Appendix is Associated with the Failure of Visual Endoscopic Retrograde Appendicitis Therapy: A Comparative Analysis of Clinical and Laboratory Characteristics

Authors Lai Y[1], Zhang Q[1], Chen X[1], Yang J[1], Sun J[1], Huo G[1], Lin J[1], Xiang L[1]
Institute 1 the Second Affiliated Hospital of The Chinese University of Hong Kong, (Shenzhen), Shenzhen, China
DOI 10.1055/s-0046-1822443

Aims Visual endoscopic retrograde appendicitis therapy (V-ERAT) has emerged as a promising minimally invasive alternative for acute appendicitis. While its safety and efficacy have been extensively validated, comprehensive understanding of risk factors associated with V-ERAT failure remains limited. This study aimed to compare clinical and laboratory characteristics between V-ERAT success and failure groups to identify potential associations [1].

Methods A retrospective analysis was conducted on patients aged 18-65 years who underwent V-ERAT between January 1, 2024, and July 1, 2025. All patients had confirmed or suspected acute appendicitis by computed tomography (CT) and declined surgical intervention. The cohort was stratified into a success group (n = 140) and a failure group (n = 12). Demographic characteristics, clinical features, and laboratory parameters were collected for analysis. Continuous variables were analyzed using the Mann-Whitney U test, while categorical variables were compared using the Chi-square test or Fisher's exact test, as appropriate. P < 0.05 was considered statistically significant.

Results The overall success rate of V-ERAT was 92.1 %, with a failure rate of 7.9 %. Patients in the failure group were significantly older (48 years, 95 % CI: 34.5-58.5 vs. 36 years, 95 % CI: 34-38; P = 0.026). The failure group also demonstrated substantially longer procedure duration (78 min, 95 % CI: 51-100 vs. 29 min, 95 % CI: 26-33; P < 0.001) and extended hospitalization (6 days, 95 % CI: 4.5-7.5 vs. 3 days, 95 % CI: 3-3; P < 0.001). Laboratory findings revealed significantly elevated white blood cell counts in the failure group (11.38 × 10^9/L, 95 % CI: 9.63-12.70) compared to the success group (6.93 × 10^9/L, 95 % CI: 6.43-8.39) (P = 0.0182). Similarly, neutrophil percentage was markedly higher in failure cases (81.30 %, 95 % CI: 75.15-83.40) than in the successful cases (65.90 %, 95 % CI: 62.60-68.32) (P = 0.0034). Furthermore, the presence of complicated acute appendicitis (P < 0.001) and peritonitis (P < 0.001) were significantly associated with the failure of V-ERAT. Notably, subcecal appendix was identified in 91.6 % cases of the failure group, representing a critical anatomical predictor of unsuccessful outcomes.

Conclusions Subcecal appendix shows a strong association with V-ERAT failure, along with advanced age, elevated inflammatory markers, and peritonitis. Pre-procedural identification of appendix position through CT three-dimensional reconstruction combined with clinical and laboratory parameters may help identify patients at higher risk of V-ERAT failure.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1117 Retrospective, single-centre evaluation of endoscopic vacuum therapy for leaks in the upper gastrointestinal tract

Authors Schmidt J[1], Brunner M[1], Baumer S[1], Muehlenberg K[1], Schorr W[1], Salzberger A[1], Pfeifer L[1], Pech O[1]
Institute 1 Department of Gastroenterology and Interventional Endoscopy, St John of God Hospital, Regensburg, Germany
DOI 10.1055/s-0046-1822444

Aims Endoscopic vacuum therapy (EVT) is an established procedure for treating leaks in the gastrointestinal tract (GIT). This study aimed to investigate overarching factors influencing the success of therapy and the effects of EVT in the upper GIT. Patient characteristics associated with prolonged or complicated courses of EVT should be identified.

Methods All patients who underwent EVT treatment at a tertiary care centre between 2019 and 2024 were included in this retrospective analysis (n = 35). EVT was performed by placing an open-cell polyurethane sponge either endoluminally or intracavitarily at the site of the leak, typically using a standard gastroscope with an overtube or piggyback technique. Continuous debridement and enhanced secretion drainage were achieved by applying a constant negative pressure of -125 mmHg. Sponge changes were carried out every 3–4 days under endoscopic guidance. Commercially available systems were used (Eso-/Endo SPONGE, B. Braun Melsungen AG, Melsungen, Germany; Suprasorb CNP wound foam, Lohmann & Rauscher GmbH & Co. KG, Neuwied, Germany; VacStent Medtech AG, Steinhausen, Switzerland).

The defect size was categorised as small (0-9 mm), medium (10-20 mm) or large (> 20 mm) for the leakage and small (≤ 20 mm), medium (21-50 mm) or large (> 50 mm) for the insufficiency cavity.

Therapeutic success was defined as an endoscopically verified complete closure of the leak.

Results EVT achieved an overall success rate of 83.3 % in this cohort, with a mean treatment duration of 33 days and an average of 9 sponge changes per patient.

A higher Charlson Comorbidity Index (CCI) and ASA score were associated with a poorer therapeutic outcome (p = 0.023 and p = 0.031, respectively). The sponge location significantly influenced the total duration of therapy (p = 0.009), with intraluminal placement being associated with a shorter total duration of EVT. BMI, sex, age, number of sponge changes and intervals of change showed no statistically significant effects on therapeutic success. Patients who had received neoadjuvant chemotherapy tended to have significantly smaller fistula cavities (p = 0.031). Larger insufficiency cavities as well as larger leakages were associated with poorer outcomes (p = 0.0015 and p = 0.006). Kruskal–Wallis analyses demonstrated that medium-sized (p = 0.016) and large cavities (p = 0.001) were significantly associated with longer treatment duration. In contrast, no significant effect was found on the total duration of EVT in this cohort. Complications occurred in 22.9 % of cases (n = 12), including therapy-related issues (e.g. suction problems), endoscopic complications and late complications (e.g. stenosis). However, no significant association with treatment duration (p = 0.122) or therapeutic success (p = 0.127) was found.

Conclusions Our results confirm EVT as an established and clinically relevant treatment option for leaks, with high success rates and a low incidence of serious complications. Compared to surgical methods, EVT is significantly less invasive.

This study also identifies initial risk factors for prolonged treatment courses (fistula cavity, cavity size, high CCI and ASA score) and provides further evidence of EVT effectiveness.

eP1118 Spray coagulation reduces bleeding and improves efficiency during endoscopic submucosal dissection compared with swift coagulation mode: the SPRAY study

Authors Sorge A[1], Argenziano ME[2], Ferrando L[3], Montori M[4, 2], Badrulhisham F[2], Tornai T[2, 5], Monod A[2], Poortmans PJ[2], Debels L[6], Desomer L[7, 2], Tate D[2]

DOI 10.1055/s-0046-1822445

Aims Spray coagulation mode provides a powerful non-contact coagulative effect that may facilitate bleeding control and increase the efficiency of endoscopic submucosal dissection (ESD). [1] However, evidence supporting its use is limited. We aimed to compare bleeding control, safety and technical outcomes between spray-coagulation ESD (SP-ESD) and swift-coagulation ESD (SW-ESD).

Methods We conducted a retrospective cohort study of consecutive ESDs performed at a tertiary referral center between December 2021 and December 2024. Two predefined time-based cohorts were analysed using complete procedural video review: SW-ESD and SP-ESD. Procedures with mixed energy modes or incomplete video/data were excluded. ESDs were performed by experts and fellows using various techniques (conventional, pocket-creation method, traction, saline-immersion).

Primary outcomes were: number of intraprocedural bleedings, bleeding time (duration of intraprocedural bleeding), dissection speed (mm^2/min), effective dissection rate (1 – [bleeding time/dissection duration]), ESD completion without coagulation forceps, and intraprocedural perforation.

Secondary outcomes included R0 resection rate and adverse events (delayed bleeding, delayed perforation).

We employed non-parametric tests and evaluated covariate imbalance between groups to ensure comparability.

Results 141 ESDs (SP-ESD: n = 114; SW-ESD: n = 27) were included, performed in the oesophagus (52/141, 36.9 %), stomach (16, 11.3 %), duodenum (2, 1.4 %), colon (39, 27.7 %), and rectum (32, 22.7 %). Baseline patient, lesion, and operator characteristics were similar between groups.

The mean number of intraprocedural bleeding events (2.2 ± 4.1 vs. 4.4 ± 2.6; $P = 0.007$) and median bleeding time (0.6 min, IQR 0–3.7 vs. 5.8 min, IQR 1.4–11.8; $P < 0.001$) were significantly lower in SP-ESD than in SW-ESD.

The median dissection speed (16.8 mm^2/min, IQR 12.2 vs. 11.2 mm^2/min, IQR 9.2; P = 0.003), effective dissection rate (99.3 % vs. 95.5 %; P = 0.001), and rate of ESD completion without coagulation forceps (95 % vs. 26 %; P < 0.001) were significantly higher in SP-ESD compared with SW-ESD.

SP-ESD and SW-ESD did not differ significantly in delayed perforation (0.8 % vs. 0 %; P = 1.00), delayed bleeding (6.7 % vs. 3.7 %; P = 1.00), or R0 resection rates (85 % vs. 81 %; P = 0.77).

Conclusions Spray coagulation during ESD significantly reduces both the frequency and duration of intraprocedural bleeding, resulting in faster dissection, fewer device exchanges, and improved procedural efficiency without compromising safety or the completeness of resection. SP-ESD may also reduce the environmental and financial footprint of ESD by lowering the need for coagulation forceps. Given the possibility of confounding from learning curve effects, prospective multicenter validation is warranted.

Conflicts of Interest D.J. Tate is a consultant for and has received research support from Fujifilm and Olympus.The other authors declare that they have no conflict of interest.

eP1119 Case Selection and Clinical Outcomes of Upper GI Endoscopic Submucosal Dissection: A Four-Year Experience at a Regional UK Centre

Authors Chudasama A[1], Rassam T[1], Direkze N[2], Stevens S[2], Hoare J[3], Hong SP[2]

Institutes **1** Imperial College Healthcare NHS Trust, London, United Kingdom; **2** Imperial College London, London, United Kingdom; **3** Imperial College London, Faculty of Medicine, Department of Surgery & Cancer, London, United Kingdom

DOI 10.1055/s-0046-1822446

Aims Upper gastrointestinal (GI) endoscopic submucosal dissection (ESD) is an increasingly adopted technique in the United Kingdom. This study presents a prospective analysis of clinical outcomes associated with the establishment of an ESD service at a single tertiary referral centre over four years. The findings aim to contribute to the growing national experience in advanced endoscopic resection [1].

Methods A prospective cohort study was conducted of all patients who underwent upper GI ESD at Imperial College Healthcare NHS Trust between 2021 and 2025. The Trust serves as a regional referral centre for complex endoscopic resections in North West London and has provided an ESD service since December 2021. All referrals were discussed with a multidisciplinary team (MDT) involving gastroenterologists, surgeons, oncologists, radiologists, and pathologists. Treatment decisions followed ESGE guidance. ESDs were performed under general anaesthesia, and patients discharged the same day, unless clinically indicated otherwise. Data included procedure count, lesion type (epithelial vs subepithelial), site, histology, size, duration, R0 and curative rates, and complications.

Results A total of 67 ESDs were performed, 86 % epithelial and 14 % subepithelial. Seventy percent were in males, mean age 69.6 years. Most resections were gastric (59.7 %), followed by oesophageal (26.9 %), gastro-oesophageal

Endoscopy 2026; 58: S1–S1041

junction (9.0 %) and duodenal (4.5 %). Histology varied by site: among oesophageal lesions, 44 % contained intramucosal carcinoma (IMC) and 56 % high-grade squamous dysplasia; of gastro-oesophageal junction (GOJ) lesions, 83 % were IMC, with half of IMC cases in the oesophagus or GOJ arising in Barrett's oesophagus. Gastric lesions were heterogeneous—IMC (27 %), low-grade dysplasia (23 %), stromal tumours (12 %)—with occasional lipomas, neuroendocrine tumours (NETs) and inflammatory polyps. Duodenal lesions comprised 66 % NETs and 33 % IMC.

Mean lesion size was 21 mm. Oesophageal lesions were largest (23.5 mm), followed by gastric (21.9 mm) and duodenal (12 mm). Mean resected lesion size increased from 16.6 mm in 2022 to 26.4 mm in 2025. In the oesophagus, squamous HGD measured 27.8 mm on average, IMC with Barrett's 18.5 mm, and IMC without Barrett's 13.1 mm. Mean procedure time was 70.6 ± 38.3 minutes, increasing from 56 minutes in 2022 to 74 minutes in 2025; oesophageal ESDs were longest (77 minutes) and duodenal shortest (52 minutes). Mean resection time was 70 minutes for a 20mm lesion.

Among epithelial lesions, the en bloc resection rate was 95 %, R0 rate 88 %, and curative rate 83 %. Same-day discharge occurred in 78 % of cases. The overall complication rate was 7 % (n = 9): perforations (n = 5, mainly duodenal or gastric) and strictures (n = 2, all oesophageal). There were no ESD-related deaths.

Conclusions ESD is the gold-standard therapy for selected epithelial lesions of the upper GI tract. As per ESGE guidance (1), it is indicated for all T1 oesophageal squamous lesions without deep submucosal invasion (T1a M2), Barrett's-related neoplasia > 2 cm or with submucosal invasion or fibrosis, and all dysplastic gastric lesions (T1a and limited T1b). Its capacity for en bloc resection reduces the need for surgery and enables accurate histological assessment. No definitive guidelines currently exist for subepithelial endoscopic resection.

A dedicated Upper GI Endoscopy MDT was established to optimise case selection and accept regional referrals for endoscopic resection, leading to a marked increase in procedural volume. Challenges in expanding an ESD service include case volume, operator training, endoscopy capacity, anaesthetic support, and multidisciplinary availability. Our results demonstrate a correlation between experience, referral volume, and case complexity, reflected by increasing mean lesion size and procedure time. Between 2023 and 2025, mean procedure time rose 18 minutes and lesion size 10 mm. Despite this, high enbloc (> 90 %) and R0 (87 %) rates were maintained, with a stable curative rate (76 %) and low complication rate.

Our experience shows that a structured regional ESD service in the UK, supported by specialist MDT discussion, can achieve excellent outcomes comparable to international standards while safely managing increasingly complex cases.

eP1120 Endoluminal vacuum therapy to treat leaks or perforations in the upper gastrointestinal tract: A meta-analysis

Authors Chon SH[1], Lang S[2], Allo G[2], Kasper P[2], Mahoney C[3], Ahrens J[3], Gupta K[3]

Institutes **1** Klinik und Poliklinik für Allgemein-, Viszeral- und Tumorchirurgie, Köln, Germany; **2** Klinik und Poliklinik für Gastroenterologie und Hepatologie der Uniklinik Köln, Cologne, Germany; **3** Boston Scientific Corporation, Marlborough, United States of America

DOI 10.1055/s-0046-1822447

Aims Anastomotic leakage has been reported in up to 30 % of patients who have esophagectomy or gastrectomy, with an associated morbidity and mortality rate of 20 %–50 % [1]. Treatment options for upper gastrointestinal (UGI) leaks include endoscopic, surgical, and conservative therapy [2]. Endoluminal vacuum therapy (EVT) uses the principles of vacuum-assisted closure of external wounds to improve and accelerate healing by removing infected secretions, reducing edema, increasing local perfusion, and promoting granulation tissue formation [3]. Most studies of EVT for UGI leaks and perforations have been retrospective case series or case reports to date. We conducted a meta-analysis of the efficacy and safety of EVT to treat UGI defects in adults.

Methods An expert librarian conducted searches of the MEDLINE full file (via Ovid) and Embase databases to identify studies of Eso-SPONGE (Boston Scientific Corporation, Massachusetts, USA) published in English January 1, 2008–May 30, 2025. Clinical studies (including meta-analyses & systematic reviews) and case reports/series including more than 10 patients were included. Efficacy and safety outcomes were assessed using a random-effects meta-analysis to estimate the proportion of patients with the outcome. Efficacy outcomes were UGI EVT technical success, clinical success, and reinterventions. The safety outcome was the proportion of patients with ≥ 1 serious adverse event (SAE).

Results Data from 301 patients who participated in 8 observational studies were included in the analysis of all eligible publications. The estimated pooled proportions of patients with technical success and clinical success were 100 % (95 % CI 99.7–100 %) and 77.4 % (95 % CI 65.2 %–87.6 %), respectively. Patients had reinterventions associated with closure management (15.3 %, 95 % CI 8.4 %–23.8 %) or adverse events (8.2 %, 95 % CI 1.2 %, 20.7 %). The estimated pooled proportion of patients with ≥ 1 SAE during the study period was 21.3 % (95 % CI 6.6 %–41.5 %), with a mortality rate of 5.9 % (95 % CI 3.5 %–8.9 %). Among 127 patients with an anastomotic leak from 5 studies with available data, 7 (5.5 %) patients died from one of the following causes: acute respiratory distress syndrome with or without multiorgan failure (2), sepsis (4), pneumonia (1). Among 10 patients with a perforation in a single study, no deaths were reported.

Conclusions EVT using Eso-SPONGE for UGI anastomotic leaks and perforations showed high technical success and good clinical success. High rates of adverse events and mortality occurred in ill patient populations at high baseline risk of complications. (Funded by Boston Scientific Corporation)

eP1121 EUS-guided antegrade transanastomotic intrapancreatic stenting with fully covered metal stent: a novel approach to the management of leaks after pancreaticoduodenectomy

Authors Stegagnini M[1], Forti E[1], Pugliese F[1], Dioscoridi L[1], Cintolo M[1], Bonato G[1], Bravo M[1], Palermo A[1], Gallo C[1], La Mantia A[1], Mutignani M[1]

Institute 1 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy

DOI 10.1055/s-0046-1822448

Aims Pancreatic leak (PL) following pancreaticoduodenectomy (PD) remains one of the most challenging and potentially life-threatening complications in pancreatic surgery. When retrograde endoscopic access to the pancreaticojejuna (PJ) anastomosis is not feasible, treatment options are limited, and surgical revision carries high morbidity and mortality.

Currently, no clear or standardized guidelines exist regarding the optimal endoscopic management of these leaks. In our experience, retrograde approach becomes necessary when the pancreatic fistula coexists with biliary anastomotic dehiscence and/or necrosis of the jejunal limb, as these situations require a complex, multi-target intervention. Conversely, in isolated PLs, retrograde access is often technically demanding and ultimately redundant [1–3].

We aimed to evaluate the feasibility, safety, and clinical outcomes of a novel endoscopic technique for the management of PLs after PD: EUS-guided antegrade transanastomotic intrapancreatic stenting (EUS-ATIS) using a fully covered self-expandable metal stent (FCSEMS).

Methods This was a single-center, retrospective case series (July 2022–August 2025) of consecutive PD patients with PLs secondary to PJ dehiscence who underwent EUS-ATIS. Primary endpoints were technical and clinical success. Secondary endpoints included time to leak closure, adverse events (AEs), need for rescue therapy, recurrence, and follow-up outcomes (▶ **Table 1**).

▶ **Table 1**

Faesability, n	13/15 (86.7)
Indication for surgery, n (%)	Malignant 9 (69); Benign 4 (31)
Sepsis before EUS, n (%)	13 (100)
Associated BDA leak, n (%)	5 (38)
Necrosis of afferent limb/PJ anastomosis, n (%)	7 (53.8)
Therapeutic delay (days), median [IQR]	10 [6,5–13,5]
Technical success, n (%)	13 (100)
Clinical success overall *, n (%)	13 (100)
Median time to PL closure (days), median [IQR]	7 [5.5–11.5]
Leak recurrence, n (%)	0 (0)
Procedure-related mortality, n (%)	0 (0)

Results Fifteen patients were evaluated; EUS-ATIS could not be performed in 2 due to lack of a safe and adequate endosonographic window for puncture, resulting in a feasibility rate of 86.7 %. Thirteen patients underwent successful EUS-ATIS (61.5 % male; median age 68 years [IQR 59–73.5]). All had International Study Group on Pancreatic Surgery (ISGPS) grade B postoperative pancreatic fistula; 10/13 presented with high-output PLs, and all were septic at the time of the EUS intervention. In two cases, shorter FCSEMSs (40 mm in length) were initially placed, resulting in persistent leakage. Leak resolution was achieved after placement of a second, coaxial FCSEMS to extend the intrajejunal segment and divert pancreatic flow further downstream within the jejunal limb. Median endoscopic sessions per patients were 1 (IQR 1-2). Median therapeutic delay was 10 days (IQR 6.5–13.5). Technical success and clinical overall success rates were both 100 %. Median time to leak closure was 7 days (IQR 5.5–11.5). Early AEs occurred in 3/13 (23 %), all non-severe and successfully managed either endoscopically or conservatively. No late AEs or leak recurrences were observed during a median follow-up of 189 days (IQR 95–410). No patient required radiologic or surgical rescue. One death (7.7 %) occurred, unrelated to the procedure or PL persistence. Pancreaticogastrostomy stents were removed in 7/13 patients after a median of 3 months (IQR 2–3). FCSEMS were removed in only 2 patients, as retrograde endoscopic access was often unfeasible.

Conclusions To our knowledge, this represents the first reported use of EUS-ATIS with FCSEMS placement for the treatment of PLs caused by PJ dehiscence after PD. This innovative approach provides a safe, effective, and minimally invasive alternative to surgery by restoring anastomotic continuity, diverting pancreatic flow from the dehiscence site, and promoting definitive healing. Early outcomes are favorable. Continued patients' enrollment and longer follow-up will be essential to confirm long-term safety and reproducibility.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1122 First results of therapeutic response of the EUS-guided intra-tumoral implantation of Radioactive Phosphorus (32P) in seventeen patients with Local Advanced Pancreatic Cancer

Authors Kontos A[1], Kypraios D[1], Alexakis N[2], Zografos G[2]

Institutes 1 Saint Savvas Oncology Hospital of Athens, Athens, Greece; 2 Hippocration General Hospital, University of Athens, School Of Medicine, Athens, Greece

DOI 10.1055/s-0046-1822449

Aims Radioactive phosphorus (^{32}P) is an innovative therapy for locally advanced pancreatic cancer that is implanted through endoscopic ultrasound (EUS). One of the most innovative therapies is the implantation of radioactive phosphorus-32 which is a type of brachytherapy. It is indicated for the treatment of patients with Locally Advanced Pancreatic Cancer (LAPC) in combination with gemcitabine-based chemotherapy. The primary goal of this study is to determine the safety of the intra-tumoral implantation of radioactive phosphorus (^{32}P) through EUS and the complications of the procedure of implantation. The secondary goals are to determine the Local Disease Control Rate (LDCR) at 16 weeks and the effectiveness of the implantation of radioactive phosphorus by measuring Overall Survival (OS), Progression Free Survival (PFS) and Local Progression Free Survival (LPFS). They receive gemcitabine-based

chemotherapy in combination with an intra-tumoral therapy with radioactive phosphorus (^{32}P) through a 22-gauge FNA needle guided by EUS [1–3].

Methods The adverse events of the implantation are evaluated by the Common Terminology Criteria for Adverse Events (CTCAE) version 4.0. The LDCR is evaluated at 16 weeks and the alteration of Tumor Volume every two months for the first year after implantation and every three months the second year after implantation according to RECIST 1.1.

Results We currently have made the implantation in seventeen patients (10 male and 7 female) with similar clinical and demographic features who suffer from locally advanced pancreatic cancer. All the procedures (median age of patients:67,9 years) were unremarkable and no complication during the procedures was noted. The patients did not have any major adverse events during the day of the procedure. 13 out of 17 patients (76,4 %) revealed mild abdominal pain on the second day which recovered with typical pain killers. The LDCR, for all patients, at 16 weeks, was 100 %. Two of the patients had a major reduction in the tumor and underwent surgery (resection rate 12 %) – R0 100 %. Three patients died after a median overall survival of 20,3 months. 12 patients showed stable disease (70,6 %) and 5 showed partial response (29,4 %) during the eight months of follow-up. During the first four months the median reduction of the tumor was 0,64cm.

Conclusions We must include more patients to conduct more useful results, but the initial results look promising.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1124 Impact of ESGE key performance measures on ERCP quality and safety: a multicenter study

Authors Ruwisch L[1], Braadt L[2], Tischendorf M[3], Meister T[4], Floer WM[4], Heinzow H[5], Ellrichmann M[6, 7], Trebicka J[8], Domagk D[9]
Institutes **1** Josephs-Hospital Warendorf, Warendorf, Germany; **2** Josephs Hospital Warendorf, Warendorf, Germany; **3** Münster University Hospital, Münster, Germany; **4** Klinikum Ibbenbüren, Ibbenbüren, Germany; **5** Krankenhaus Bamherzigen Brüder, Trier, Germany; **6** University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany; **7** Department of Internal Medicine III – Gastroenterology, University Hospital Oldenburg, Oldenburg, Germany; **8** Department of Medicine B, Münster University Hospital, Münster, Germany; **9** Clemenshospital Münster, Düesbergweg, Münster, Germany, Münster, Germany
DOI 10.1055/s-0046-1822451

Aims The aim of this study is to investigate the impact of the ESGE quality improvement initiative with respect to the performance in ERCP in multicenter setting. We strived to evaluate whether there have been any changes in clinical outcomes, particularly in the incidence of post-ERCP pancreatitis, since the guideline was introduced in 2017.

Methods A total of six hospitals are included in this multicenter study: three academic teaching (Warendorf, Ibbenbueren, Trier) and three university hospitals (Muenster, Kiel, Oldenburg). The study examined how the introduction of the ESGE guideline affected defined quality indicators [1].

Three groups were formed:

- Group I: Examinations prior to implementation of the guideline (retrospective, until 2017)
- Group II: Studies after implementation of the guideline (retrospective, 2018–2023)
- Group III: Studies after implementation of the guideline (prospective, from 2024)

The primary endpoint was the occurrence of post-ERCP pancreatitis (PEP). Secondary endpoints were the bile duct cannulation rate, stent placement in cases of biliary obstruction, and the success rate of stone extraction.

In addition, a subgroup analysis was performed to assess the relationship between the number of examiners and the frequency of PEP.

The study is approved by the local Ethics Committee of University in Muenster and registered at ClinicalTrials.gov (NCT06727851).

Results Data from over 1,200 ERCPs from four clinics are currently available. The incidence of post-ERCP pancreatitis was significantly reduced in the prospective cohort to < 5 %, thereby achieving the primary endpoint of the study. The bile duct cannulation rates in all clinics met the threshold value of over 90 % required by the ESGE. The further secondary endpoints, stone extraction and stent placement, were also close to the required target values, but still showed some potential for optimization.

The subgroup analysis revealed that a higher number of examiners and thereby a lower number of investigations per person was associated with a slightly increased incidence of PEP.

Conclusions The introduction of the ESGE guideline with defined key performance measures led to an improvement in quality parameters and a reduction in post-ERCP pancreatitis in the four clinics studied.

By adhering to key performance measurements, we were able to demonstrate that complications were avoided, hospital stays were shorter, and there were fewer repeat examinations.

The observation that a higher number of examiners is associated with a slightly increased incidence of PEP underscores the importance of examiner experience and indicates that the level of training and the supervision structure in endoscopy continue to be of central importance. Further studies should specifically address the question of what level of experience and training characteristics are necessary to ensure consistently high quality and patient safety in ERCP.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822452

Aims Inflammatory disorders of the small bowel represent a heterogeneous spectrum of diseases, in which endoscopic lesions show considerable variability in terms of location, extent, and morphological features. The aim of the

study was to investigate the correlation between capsule endoscopy (SBCE) and double balloon enteroscopy (DBE) in the evaluation of inflammatory lesions of the small bowel [1–5].

Methods This is a retrospective, single-center observational study including all SBCE and DBE performed at an Italian tertiary referral center between January 2018 and June 2025. The selected study period was determined by the availability of complete endoscopic data within the hospital's Picture Archiving and Communication System (PACS) wich ensured a comprehensive and standardized data source for retrospective analysis. Patients with at least one inflammatory small-bowel mucosal lesion on SBCE or DBE were included. These inflammatory findings were defined according to the Delphi consensus on Crohn's disease capsule endoscopy lesions and the I-CARE international consensus on atrophic patterns. Patients with a conclusive diagnosis of neoplasia were excluded. SBCE PillCam SB3 or PillCam Crohn's were used according to clinical indication. Fujifilm DBE was performed antegrade or retrograde based on presumed lesion location. The diagnostic performance of SBCE for inflammatory lesions was assessed using DBE as the reference standard; sensitivity, specificity, and Cohen's kappa were calculated.

▶ **Table 1** SBCE performance compared to DBE.

SBCE	Sensitivity (%)	Specificity (%)	Cohen's Kappa (95% CI)
Aphtoid lesions	100	85	0.376 (0.197 – 0.793)
Deep ulceration	70	85	0.474 (0.189 – 0.715)
Superficial ulceration	50	80	0.300 (0.047 – 0.565)
Stenosis	70	90	0.599 (0.284 – 0.836)
Edema	67	86	0.599 (0.284 – 0.836)
Hyperemia	20	84	0.402 (-0.032 – 0.837)
Denudation	67	92	0.402 (-0.032 – 0.837)
Atrophy	85	87	0.709 (0.520 – 0.857)
Mosaicism	53	97	0.503 (0.189 – 0.800)
Scalloping	70	89	0.602 (0.382 – 0.876)
Fold reduction	0	98	-0.033 (-0.090 – 0.000)
Granular mucosa	0	89	-0.057 (-0.094 – 0.000)

Results 295 endoscopic procedures were analyzed, 195 SBCE (145 PillCam SB3, 50 PillCam Crohn) and 100 DBE (73 anterograde, 27 retrograde). Among these, 102 paired enteroscopies were performed (51 SBCE and 51 DBE) within six months thus allowing comparison of the two techniques. SBCE demonstrated an overall high specificity, greater than 80 %, for all inflammatory lesions. Sensitivity was more variable: high (> 80 %) for aphthoid lesions and villous atrophy, good (70 %) for deep ulceration, stenosis and scalloping, and lower for the other lesions. Agreement was excellent ($\kappa \geq 0.6$) for stenosis, edema and villous atrophy; good (κ 0.4–0.6) for deep ulceration, hyperemia, mucosal denudation and mosaicism; and only fair to weak for aphthous lesions and superficial ulcerations. Fold reduction and granular mucosa showed very low κ values, probably due to the small number of cases. Data are reported in the ▶ **Table 1**.

Conclusions SBCE demonstrated an overall good performance in the evaluation of inflammatory lesions of the small bowel. It showed good agreement with DBE, the reference standard for enteroscopy, in detecting most inflammatory lesions, including both ulcerative–stenosing and atrophic patterns. Further multi-center studies with larger sample sizes and external validation in different study populations are needed to confirm these findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1126 Endoscopic and EUS features of deep infiltrating intestinal endometriosis: novel diagnostic markers and clinical implications

Authors Dubrovin V[1], Senchilo S[2], Malkov V[3]

Institutes 1 Saint-Petersburg, Russia; 2 Spbgu, Saint Petersburg, Russia; 3 Saint-Petersburg State University, Saint-Petersburg, Russia

DOI 10.1055/s-0046-1822453

Aims Deep infiltrating endometriosis (DIE) of the bowel remains an under-recognized challenge in endoscopic practice. Lesions frequently mimic subepithelial tumors or infiltrative neoplasia, leading to diagnostic errors reported in up to 60–70 % of reviews and resulting in delayed diagnosis. Rectosigmoid involvement predominates, whereas small-bowel and duodenal disease are exceptionally rare. The absence of reproducible endoscopic criteria and the infrequent use of EUS further complicate preoperative recognition, contributing to misclassification as malignancy.

Aims: To describe reproducible endoscopic and EUS markers of bowel DIE with histological confirmation and to evaluate the role of EUS-FNB in diagnosing atypical subepithelial lesions.

Methods Two patients with histologically confirmed intestinal DIE complicated by gastrointestinal bleeding were analyzed. A comprehensive correlation of endoscopic, EUS, and histopathological findings was performed, including EUS-guided fine-needle biopsy (FNB).

A structured literature search and analysis were conducted using PubMed, Embase, and Scopus databases (2019-2025), focusing on bowel endometriosis and its endoscopic visualization.

Results 1. Sigmoid involvement

Colonoscopy: segmental wall rigidity, concentric luminal narrowing, mucosal deformation with preserved epithelium.

EUS: hypoechoic thickening of the muscularis propria with mesenteric involvement.

Histology: confirmed DIE.

2. Duodenal involvement (exceptionally rare)

EGD: nodular, bleeding protuberant lesions distal to the major papilla.

EUS: deep hypoechoic infiltrate with loss of wall stratification and extension into paraduodenal tissue.

EUS-FNB: morphological confirmation of endometriosis (PAX8 + , ER +).

Morphologically verified cases of duodenal DIE diagnosed by EUS-FNB are exceedingly rare or absent in the published literature.

3. Literature data

Bowel DIE occurs in ~5-12 % of patients with endometriosis, predominantly affecting the rectosigmoid segment.

EUS demonstrates high sensitivity for assessing depth of infiltration (~82–94 % in clinical series), whereas standard endoscopy remains limited in detecting submucosal disease.

Practical implications / Reproducible markers

Based on clinical observations and literature analysis, the following reproducible endoscopic and EUS markers of bowel DIE were identified:

1. Wall rigidity and luminal narrowing without ulceration.
2. Mucosal deformation with preserved epithelial surface.
3. Atypical bleeding nodular lesions in the duodenum.
4. Hypoechoic infiltrative contour on EUS with involvement of adjacent tissues.

These markers emphasize the diagnostic value of combined endoscopy and EUS, supporting accurate preoperative recognition of bowel DIE and reducing the risk of misinterpretation as neoplasia.

Conclusions These observations enhance clinical awareness of endoscopic and EUS features of bowel DIE and demonstrate the diagnostic value of EUS-FNB even in extremely rare duodenal involvement. The findings may serve as a foundation for developing standardized imaging criteria and for future multicenter prospective validation under the auspices of ESGE.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1127 Dysplasia and Malignancy Risk in Resected Hamartomatous Polyps in Peutz-Jeghers Syndrome: A Case Series

Authors Varley R[1, 2], Connolly Y[1], O'Hara F[1, 2], McNamara D[1, 2]
Institutes **1** Tallaght University Hospital, Dublin, Ireland; **2** Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin, Ireland
DOI 10.1055/s-0046-1822454

Aims Introduction: Peutz Jeghers Syndrome (PJS) is a rare, autosomal dominant hereditary polyposis syndrome characterised by hamartomatous polyps, mucocutaneous pigmentation and confirmatory testing of a genetic mutation of serine/threonine kinase 11 or liver kinase B1 (STK11/LKB1). PJS is recognised as a cancer predisposition syndrome with a very high relative risk of gastrointestinal cancers. Some studies, including meta-analysis have suggest a relative risk of up to 13 % of small bowel cancers in PJS patients compared to less than 1 % of the general population. However, the European Hereditary Tumour Group Guideline caution that the described risks are likely to be an overestimation due to retrospective review and selection bias. The malignant potential of hamartomatous polyps in PJS has been debated in the literature, controversy exists but presently PJS hamartomatous polyps are not considered precancerous lesions [1–7].

Aim: To evaluate the presence of dysplasia or malignancy in resected PJS polyp specimens in our tertiary referral centre.

Methods We performed a retrospective review of our histological specimens from patients with a clinical or histological diagnosis of PJS between 2008 to 2025. The histological database was screened for keywords such as "Peutz-Jeghers" "PJS" "Peutz-Jegher's Syndrome" and "hamartomatous polyps". Baseline demographic data and histological findings were extracted from electronic patient record and pathology reports.

Results Seventeen patients with confirmed PJS were identified, with a male predominance (70 %). The median patient age was 31years (range 12-72). The median follow-up time was 64 months (range 1-135), accounting to 90.6 patient years. There were 65 polyp specimens of which 47 (72 %) were consistent with hamartomatous PJS polyps. The table below characterises the location of the polyps.

PJS polyps: The median patient age for PJS-type polyps was 26 (12-72). The median polyp size for PJS polyps was 20mm (range 4-100mm). 56 % of procedures (n = 34) for PJS polyps were via device assisted enteroscopy (n = 22), ADBE (n = 17), RDBE (n = 5) remainder were obtained via OGD(n = 9), Colonoscopy (n-3). Indications for procedures included polypectomy based on size criteria, symptomatic polyps for intussusception, anaemia and surveillance. The majority (62 %) of these procedures were performed for polypectomy of a polyp ≥ 15mm (n = 21), two cases were performed for anaemia; the remainder of the cases were part of routine surveillance procedures. Following MDT consensus review, no polyps demonstrated dysplasia or malignancy, resulting in an estimated incidence of 0 per patient year (95 % CI: 0–0.033) (▶ **Table 1**).

▶ **Table 1**

Location	PJS polyps n = 47	Non-PJS polyps n = 18
Stomach	2	3
Duodenal	7	3
Jejunal	13	0
Ileal	14	0
Undifferentiated Small Bowel	8	1
Colon	3	11

Non PJS polyps: Of the non PJS polyps; the histological morphology was predominately hyperplastic (50 %, n = 9). Other morphology included; Tubular adenoma with LGD (n = 2), Serrated adenoma (n = 1), Pseudopolyp (n = 1), epithelial atypia favoured reactive (n = 1) normal small bowel mucosa (n = 4). The median age in the non-PJS polyps' group was 59 (19-66), for those who had adenomas the median age was 62 (range 59-66). Adenomatous polyps were present in 16.7 % (95 % CI: 4.6 %–38.9 %).

Conclusions Our study found that our cohort of PJS patients had no evidence of dysplasia or malignancy in any of their polyp specimens over 91 patient years in our tertiary referral centre. This study supports previously published studies from PJS registries and supports the argument from the European Hereditary Tumour Group who suggest that previous studies may overestimate risk of cancer due to selection bias and retrospective analysis.

eP1128 Sporadic Duodenal Adenomas: An Alert on Associated Risk Factors

Authors Abreu Marques I[1, 2, 3], Rui V[2, 3, 1], Cláudia M[1, 2, 3], Pedro C[1, 2, 3], José C[1, 2, 3]

Institutes **1** Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Portugal, Guimaraes, Portugal; **2** Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Guimaraes, Portugal; **3** ICVS/3B's – PT Government Associate Laboratory, Guimaraes, Portugal

DOI 10.1055/s-0046-1822455

Aims Sporadic duodenal adenomas are uncommon in comparison to other gastro-intestinal adenomas and often an incidental finding in upper gastrointestinal endoscopy. Recent studies indicate an increasing incidence of these lesions.

Methods A retrospective review of upper endoscopies performed over the past 10 years was conducted to identify cases of duodenal adenomas. Patients with polyposis syndromes and ampullary adenomas were excluded, resulting in a sample of 41 patients with sporadic duodenal adenomas. In addition, a control group of 41 randomly selected individuals from the same 10-year span, matched by age and gender, was used for comparison. Potential risk factors for duodenal adenomas were collected [1, 2].

Results The prevalence of duodenal adenomas was 0.22 %. The mean age of affected individuals was 69 years, out of which 24 were males. Most of the adenomas were endoscopically removed (68.3 %), three patients had recurrent adenomas and one progressed into adenocarcinoma. A significant association was observed between smoking and the presence of duodenal adenomas ($p = 0.037$). Family history of gastrointestinal neoplasia was related to the occurrence of duodenal adenomas ($p = 0.043$). In addition, in comparison to the control group, the duodenal adenoma group had a significantly higher number of affected family members with gastrointestinal neoplasia ($p = 0.001$). Furthermore, the duodenal adenoma group had a significantly higher number of colorectal adenomas compared to the control group ($p < 0.001$). No statistically significant associations or differences to the control group were found amongst other variables.

Conclusions Although sporadic duodenal adenomas are rare, their potential for recurrence and progression to adenocarcinoma warrants careful surveillance. Smoking and family history of gastrointestinal neoplasia appear to be potential risk factors for sporadic duodenal adenomas. Additionally, the higher prevalence of colorectal adenomas in these patients highlights the importance of colorectal cancer screening in this population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1129 Ten-Year EUS Surveillance of Gastric and Duodenal GISTs: Implications for ESGE Recommended Intervals

Authors Dimassi A[1], Leahy A[1], Shariff M[1]

Institute **1** Watford General Hospital, West Hertfordshire Teaching Hospitals NHS Trust, Watford, United Kingdom

DOI 10.1055/s-0046-1822456

Aims Current ESGE guidance advises early gastroscopy within a few months of diagnosis for small subepithelial lesions, followed by periodic long-term surveillance with shorter intervals for larger lesions. These recommendations are based on low-quality evidence, and the true growth behavior of GISTs remains uncertain. Our 10-year review of EUS-detected gastric and duodenal GIST aims to assess growth patterns and evaluate whether current surveillance intervals are justified or could be safely extended.

Methods A retrospective study was conducted at a district general hospital, reviewing EUS examinations of endoscopically or biopsy-confirmed gastric and duodenal GISTs between January 2015 and October 2025. For patients with at least one qualifying EUS, any prior EUS before 2015 was included to preserve surveillance continuity. Data collected includes lesion size, location, EUS intervals, biopsy status, and management plan. Lesions were grouped by baseline size (≤ 10 mm, > 10–15 mm, > 15–20 mm, and > 20 mm). Growth was defined as an increase of ≥ 5 mm or ≥ 20 % in maximal diameter between first and last EUS. Event rates per person-year were calculated to estimate growth incidence, with 95 % confidence intervals (CI) derived using binomial or Poisson methods.

Results A total of 105 patients (274 EUS procedures) were reviewed and categorized by initial GIST size.

For lesions ≤ 10 mm, 11 of 17 patients underwent more than one EUS, representing 32.8 person-years. No growth events were recorded (0/11; 0 %, 95 % CI 0–27.3 %). The event rate per person-year was therefore 0 (upper 95 % bound = 0.0915 per person-year). Using this upper confidence limit to model the worst plausible scenario, the theoretical cumulative probability of growth was estimated at ≤ 24 % over 3 years and ≤ 31 % over 4 years. These values represent the statistical ceiling implied by zero events, not observed risk. In practice, all ≤ 10 mm lesions remained entirely stable.

For lesions > 10–15 mm, 12 of 32 patients had serial follow-up representing 40.8 person-years. One lesion (1/12; 8.3 %, 95 % CI 0.2–38.5 %) enlarged from 15 mm to 30 mm after 24 months, yielding an event rate of 0.0246 per person-year (95 % CI 0.0006–0.136). The modeled upper 95 % cumulative risk was 7.23 % at 3 years and 9.52 % at 4 years. Although the upper cumulative risk is numerically smaller than that for the ≤ 10 mm group, this reflects narrower statistical uncertainty from one observed event; the true growth probability in ≤ 10 mm lesions is lower, but its confidence interval is wide due to the absence of events.

In the > 15–20 mm category, 9/22 patients had serial EUS (25.2 person-years). 3 patients had growth events (3/9; 33.3 %, 95 % CI 7.5–70.1 %), giving an event rate of 0.119 per person-year (95 % CI 0.025–0.347), corresponding to an upper 95 % cumulative risk of about 30 % at 3 years and 40 % at 4 years.

Among lesions > 20 mm, 11 of 50 patients had serial EUS (35.2 person-years). 8 patients had growth events (8/11; 72.7 %, 95 % CI 43–90 %). The event rate was 0.228 per person-year (95 % CI 0.098–0.450), equivalent to an upper 95 % cumulative growth risk of 74.08 % at 3 years and 83.47 % at 4 years.

Conclusions This review demonstrates that GISTs ≤ 10 mm show no measurable growth. Although Poisson modeling allows a theoretical 31 % risk at 4 years, this reflects statistical uncertainty rather than clinical risk. The absence

Endoscopy 2026; 58: S1–S1041

of any true growth events supports extending surveillance for ≤ 10 mm GISTs every 3–4 years. For 10–15 mm lesions, a single event over 40 person-years corresponds to a modeled cumulative risk of 9.52 % at 4 years, making the current ESGE recommendation justified. Lesions > 15 mm showed substantially higher event rates, confirming that shorter surveillance remains appropriate for this subgroup.

DOI 10.1055/s-0046-1822457

Aims Despite the increasing number of individuals diagnosed with Lynch syndrome, few studies have reported prospective follow-up data in this high-risk population. While colorectal surveillance is well established, international consensus remains limited regarding optimal surveillance strategies for other organ systems, largely due to a lack of robust evidence.

Methods This study is based on a retrospective analysis of prospectively collected data from a single prevention-oriented center. All included individuals were confirmed carriers of a pathogenic or likely pathogenic variant in one of the mismatch repair (MMR) genes associated with Lynch syndrome and were followed according to a structured surveillance protocol.

The primary objective of this study was to estimate the incidence of cancers diagnosed during prospective follow-up in this genetically defined population. The secondary objective was to assess the concordance between observed cancers and current organ-specific surveillance recommendations as outlined in regional French guidelines.

Results 517 patients carrying a P/LP variant in an MMR gene and enrolled in prospective follow-up. A total of 201 cancers were diagnosed during prospective follow-up.

203 patients (39.3 %) carried MSH2 or EPCAM P/LP variant, 181 had MLH1 (35 %), 90 (17.4 %) had MSH6 and 42 (8.1 %) had PMS2. One patient carried two distinct variants affecting both EPCAM and MLH1. The median age at inclusion was 43 years (IQR: 32–52 years), and was 52 years (IQR: 40–64 years) at last follow-up. 52.8 % were males and 47.2 % were females, with a median follow-up duration of 8 years (IQR: 4–13 years). A total of 281 patients were cancer-free at the start of surveillance.

132 were subject to specific recommendations based on the underlying genetic predisposition. These included tumors of the upper and median GI tract (stomach, duodenum, jejunum, n = 14), lower GI tract (colon and rectum, n = 84), urinary tract (renal, bladder, and urothelial tumors, n = 27), and gynecologic cancers (n = 7).

The organ-specific incidence rates were as follows:

- Lower GI tract (n = 84): 1.74 % (95 % CI, 1.37–2.11)
- Urinary tract (n = 27): 0.56 % (95 % CI, 0.35–0.77)
- Upper and median GI tract (n = 14): 0.29 % (95 % CI, 0.14–0.44)
- Gynecologic cancers (n = 7): 0.15 % (95 % CI, 0.04–0.25)

Outside of the recommended surveillance organs, 69 cancers were diagnosed (1.43 %; 95 % CI 1.09–1.77). The most frequent sites were skin-related tumors (cutaneous, sebaceous, basal cell, or melanoma; n = 26; 0.54 %; 95 % CI 0.33–0.75), followed by breast (n = 12; 0.25 %; 95 % CI 0.11–0.39), pancreas (n = 7; 0.15 %; 95 % CI 0.04–0.25), and prostate (n = 6; 0.12 %; 95 % CI 0.03–0.22).

Urinary tract tumors were predominantly diagnosed in an asymptomatic setting (n = 21) through surveillance imaging, cytology, or incidental findings, while 2 cases were diagnosed due to symptoms. Among upper GI tumors (n = 14), 6 were detected during routine endoscopic surveillance, and the remaining 8 were identified in symptomatic contexts. Of the 84 lower GI tumors, the vast majority (n = 71) were diagnosed during scheduled surveillance colonoscopies, with only 11 cases detected due to symptoms. Gynecologic cancers (n = 7) included 2 asymptomatic and 5 symptomatic cases.

Characteristics of the study population

Conclusions This study provides robust prospective evidence supporting the value of structured, multidisciplinary surveillance in patients with Lynch syndrome. The majority of cancers covered by recommendations were detected at an asymptomatic stage, particularly in the lower GI and urinary tracts—underscoring the effectiveness of current surveillance protocols. The high rate of symptomatic upper and median GI tumors highlights the need to reassess surveillance strategies for this site. In addition, our findings support the integration of dedicated skin, breast, and prostate surveillance into personalized and comprehensive care plans for patients with Lynch syndrome.

DOI 10.1055/s-0046-1822458

Aims Gastroparesis (GP) is a chronic gastric motility disorder that is frequently underdiagnosed and underestimated, with a major impact on quality of life. The underlying tissue mechanisms remain poorly defined. G-POEM is an emerging endoscopic therapy for refractory GP, but robust predictors of response are lacking. This study aimed to characterize gastric transcriptomic and metatranscriptomic profiles in patients with refractory idiopathic or diabetic GP and to correlate these features with post–G-POEM outcomes.

Methods In this single-center prospective study, we enrolled adults with refractory idiopathic or diabetic GP undergoing G-POEM (clinical cohort). All patients underwent standardized additional mucosal gastric biopsies from the antrum, body, and fundus. Clinical success at 3 months after G-POEM was defined as a ≥ 1.0-point reduction in total GCSI and a ≥ 25 % improvement in at least one GCSI subscale.

A nested molecular cohort (9 GP patients) was selected for RNA sequencing. A control group of patients without GP symptoms, undergoing EGD for non–motility-related indications, underwent the same biopsy protocol; nine controls were age- (± 3 years) and sex-matched to GP cases. Host transcriptomic and microbial metatranscriptomic data were analyzed using differential expression, GSEA, UMAP, cell-type deconvolution, microbial alpha-diversity, and species-level differential analyses. Correlations with G-POEM outcomes were also assessed.

Results Between February 2023 and June 2025, 21 refractory GP patients (57 % idiopathic, 43 % diabetic; median age 52 years; 71.4 % female) undergoing G-POEM and 16 controls were enrolled. Clinical and functional success rates after G-POEM were 47.6 % and 42.9 %, respectively. G-POEM significantly improved GCSI, SF-36, and GES parameters.

In the molecular cohort, a marked and region-specific transcriptional shift was observed in the antrum of GP patients (1,793 genes upregulated and 1,006 downregulated vs controls). Pathway enrichment in the antrum revealed upregulation of programs related to tissue remodeling, cell migration and adhesion, vascular regulation, and neuromuscular organization. Microbial alpha-diversity was preserved across groups and regions, although a distinct, region-specific shift in bacterial community composition at the species level was identified in the antrum of GP patients. No significant correlations emerged between molecular features and G-POEM outcomes.

Conclusions In refractory GP, G-POEM provides a moderate short-term clinical and functional benefit. GP patients exhibit a distinct, antral-specific transcriptomic reprogramming together with localized alterations in bacterial community composition. These findings support the concept of a regionally confined, functionally oriented molecular phenotype in GP, which may contribute to disease mechanisms and help inform future, more personalized therapeutic strategies.

eP1132 Association Between Aortic Valve Diseases and the Risk of Colorectal Polyps and Cancer: A Real-World Cohort Study Using a Global Collaborative Network

Authors Su ML[1], Tsai CY[2]
Institutes 1 Changhua Christian Hospital, Changhua City, Taiwan; 2 Taichung Veterans General Hospital, Taichung, Taiwan
DOI 10.1055/s-0046-1822459

Aims This study aimed to examine the association between aortic valve diseases and the subsequent development of colorectal neoplasia. Specifically, we evaluated whether patients with aortic stenosis (AS) or aortic regurgitation (AR) had higher risks of developing colorectal polyps, benign colorectal polyps, or colorectal cancer compared with echocardiography-confirmed individuals without valvular disease. By leveraging a large real-world dataset from a global collaborative network, we sought to clarify potential links between valvular pathology, systemic inflammation, and colorectal tumorigenesis.

Methods We conducted a retrospective cohort study using the TriNetX Global Collaborative Network. Adults aged 18 years or older who underwent echocardiography between January 1, 2015 and January 1, 2020 were included. Two exposure cohorts, aortic stenosis (AS) and aortic regurgitation (AR), were compared with echocardiography-confirmed controls without valvular disease. Patients with inflammatory bowel disease, acute abdomen, prior colectomy, or preexisting colorectal neoplasia were excluded. The outcomes included incident colorectal polyp, benign polyp, and colorectal cancer. Propensity score matching in a 1:1 ratio was performed to balance demographics, comorbidities, and lifestyle factors. Cox proportional hazards models were used to estimate hazard ratios (HRs) with 95 percent confidence intervals (CIs).

Results After matching, 250,255 patients with AS and 254,023 with AR were analyzed, each matched to an equal number of controls. In the AS cohort, risks were significantly higher for colorectal polyp (HR 1.21; 95 % CI 1.17–1.24; $p < 0.0001$), benign polyp (HR 1.19; 95 % CI 1.16–1.22; $p < 0.0005$), and colorectal cancer (HR 1.20; 95 % CI 1.13–1.29; $p = 0.0008$). Similarly, in the AR cohort, risks were elevated for colorectal polyp (HR 1.17; 95 % CI 1.14–1.21; $p < 0.0001$), benign polyp (HR 1.21; 95 % CI 1.18–1.24; $p = 0.0083$), and colorectal cancer (HR 1.07; 95 % CI 1.00–1.15; $p = 0.034$). Kaplan–Meier analysis showed consistently lower event-free survival among AS and AR groups compared with controls (log-rank $p < 0.001$ for most outcomes).

Conclusions Both aortic stenosis and aortic regurgitation were associated with increased risks of colorectal polyps and malignancy, suggesting potential shared inflammatory or hemodynamic mechanisms linking valvular disease and colorectal neoplasia. Further studies integrating molecular and hemodynamic parameters are warranted to elucidate causal pathways.

DOI 10.1055/s-0046-1822460

Aims The optimal endoscopic resection technique for non pedunculated colorectal polyps 15-20mm in size remained unclear. This study therefore aimed to evaluate the efficacy of snare tip precutting endoscopic mucosal resection (STP-EMR) compared to conventional EMR (C-EMR) for these lesions

Methods This prospective randomized comparative study recruited 126 patients with 128 colorectal neoplasms of 15-20 mm in size and randomly assigned them in a 1:1 ratio to undergo STP-EMR or C-EMR at four university hospitals from June 2022 to November 2023. The primary outcomes were en bloc resection rate (EBR) and complete resection rate (CRR), determined by gastrointestinal pathologists based on histopathological findings. Adverse events and procedure time were also carefully analyzed.This prospective randomized comparative study recruited 126 patients with 128 colorectal neoplasms of 15-20 mm in size and randomly assigned them in a 1:1 ratio to undergo STP-EMR or C-EMR at four university hospitals from June 2022 to November 2023. The primary outcomes were en bloc resection rate (EBR) and

Endoscopy 2026; 58: S1–S1041

complete resection rate (CRR), determined by gastrointestinal pathologists based on histopathological findings. Adverse events and procedure time were also carefully analyzed (▶ **Table 1**).

▶ **Table 1**

variables	C-EMR(n = 65)	STP-EM-R(n = 63)	P value
En bloc resecion, no(%)	46(70.8)	55(87.3)	0.022
Number of resected pieces, mean(±SD)	1.35 ± 0.62	1.22 ± 0.68	0.257
Complete resection, no(%)	38(58.5)	48(76.2)	0.033
Pathologic findings			0.730
Serrated lesions	22 (33.8)	26 (41.3)	
Adenoma	42 (64.6)	36 (57.1)	
Carcinoma in situ	1 (1.5)	1 (1.6)	
Submucosal cancer	0	0	
Total procedure time, mean(±SD), min	5.0 ± 3.9	8.1 ± 2.5	< 0.001
Precut time, mean(±SD), min		4.8 ± 1.8	
Admission rate, no(%)	34 (52.3)	48 (76.2)	0.005
Hospital stays, , mean (±SD)	1.92 ± 0.973	2.14 ± 0.820	0.169
post polypectomy bleeding, no(%)			0.480
Immediate(< 24h)	7 (10.8)	6 (9.5)	
Delayed(≥ 24h)	1 (1.5)	0	
Perforation, no(%)	0	1 (1.6)	0.492

Results A total of 128 eligible colorectal neoplasms were successfully resected using C-EMR and STP-EMR. The overall mean lesion size, EBR, and CRR were 17.2 ± 1.9 mm, 78.9 %(101/128), and 67.1 %(86/128), respectively. The baseline characteristics such as location, size, morphology, and histologic findings of the polyps showed no significant differences between the two groups. The EBR and CRR were significantly higher in the STP-EMR group compared to the C-EMR group. Additionally, the mean total procedure time was significantly longer in the STP-EMR group. There were no significant differences in the post-procedural bleeding rate and hospital stays between the two groups. A perforation occurred in the STP-EMR group , but this was not statistically different from the C-EMR group.

Univariate analysis revealed that the resection method was the sole significant factor associated with both EBR and CRR. Pathologic findings and polyp type also significantly influenced CRR. In the multiple logistic regression analysis, the resection method remained the only significant factor of both EBR and CRR (OR 3.03, 95 % CI 1.29-7.07, P = 0.011).

Conclusions STP-EMR seems to significantly improve en bloc and complete resection compared to C-EMR for non-pedunculated colorectal polyps of 15-20 mm, even though the procedure time of STP-EMR was longer than that of C-EMR.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1134V Presence of mucin droplets during endoscopic submucosal dissection at the submucosa and beyond

Abstract Text

Mucinous adenocarcinoma is an uncommon subtype of colorectal cancer (10–20 %), defined by extracellular mucin comprising more than half of the tumor and is associated with increased lymphatic involvement in early stages. Endoscopically, mucin may appear as “droplet-like” material, a nonspecific but important finding during endoscopic submucosal dissection (ESD). We present two cases in which mucin droplets were visualized in the resection plane, with different distribution and histology. In the first case, a recurrent 30-mm rectal lesion contained mucin infiltrating deeper layers, and histology confirmed mucinous adenocarcinoma. In the second case, a 30-mm colonic lesion showed mucin confined to the submucosa; en bloc resection revealed high-grade dysplasia with mucin-draining glands. Mucin during ESD may indicate malignancy, although it can also occur in benign lesions [1–3].

DOI 10.1055/s-0046-1822462

Aims In inflammatory bowel disease (IBD) surveillance, current ESGE guidelines recommend a minimum neoplasia detection rate of > 8 %, whilst desirable detection rates have not been defined. [1] These recommendations, however, are based on a limited number of studies, predominantly carried out in academic referral centres. We therefore aimed to evaluate neoplasia detection rates in IBD surveillance at a nationwide level, assessing performance across all endoscopists to determine whether existing detection rate thresholds should potentially be adjusted. Furthermore, to assess if conventional adenoma detection rate (ADR) in colorectal cancer screening correlates with neoplasia detection rate in IBD surveillance.

Methods We utilized data from the Swedish Registry for Colorectal Cancer Screening and Colonoscopy (SveReKKS), a prospectively entered, web-based national register. Data were retrieved for the period April 2019 to October 2025.

Variables extracted from the registry included indication for colonoscopy, bowel preparation, ileocecal intubation, presence of suspected malignancy, polyp detection, biopsy or removal of polyp, and corresponding histopathological results. Neoplasia detection was defined as dysplasia in lesions that were removed or biopsied. Data were not available for lesions that were not classified as polyps or cancer in the registry, nor for cases of "invisible" dysplasia (i.e., dysplasia in random biopsies). Adequate bowel preparation was defined as Boston Bowel Preparation Scale score > 6 in total, with an individual segment score of ≥ 2.

Results In total, 8,757 IBD surveillance colonoscopies were performed by 333 endoscopists. After excluding endoscopists that had registered less than 50 IBD surveillance colonoscopies, 3,386 endoscopies and 40 endoscopists remained. The mean age of the patients in the cohort was 53 (SD 15) years and the proportion of males was 58 %. Bowel preparation was adequate in 95 % of colonoscopies and ileocecal intubation was achieved in 97 %. The overall neoplasia detection rate was 8.8 % (95 % CI 7.9, 9.8 %), and cancer detection rate was 0.15 % (95 % CI 0.05, 0.34 %). Endoscopist-specific detection rates ranged from 0.8 % to 21.8 %. The second-highest quintile (60–80 %) and highest quintile (80–100 %) of endoscopists had detection rates of 9.6–13.0 % and 13.2–21.8 %, respectively. Overall, 22 endoscopists registered more than 50 colonoscopies for both colorectal cancer screening and IBD surveillance. Among these endoscopists, adenoma detection rate (ADR) and neoplasia detection rate demonstrated a moderate-to-strong correlation ($R^2 = 0.59$; $\beta = 0.37$ [95 % CI 0.23–0.52]). However, among endoscopists with a neoplasia detection rate < 8 %, ADR still ranged widely from 32 % to 58 %.

Conclusions These results indicate that the current European guidelines for neoplasia detection in IBD surveillance seem reasonable, however, higher detection rates can be achieved. Therefore, raising the minimum neoplasia detection threshold in IBD surveillance, and setting desirable thresholds, can be considered. Furthermore, although a high ADR in colorectal cancer screening correlated with neoplasia detection, this correlation was not absolute, suggesting that deidicated training in neoplasia detection in IBD surveillance may be required.

eP1136 Cost-Effectiveness of a Universal Rectal Endoscopic Submucosal Dissection Strategy Compared with Selective Resection Practice

Authors Clancy J[1], Khalaf K[1], Li H[1], Gupta S[1], Calo N[1], Mosko J[1], Teshima C[1], May G[1]

Institute 1 St. Michael's Hospital, Toronto, Canada

DOI 10.1055/s-0046-1822463

Aims Endoscopic submucosal dissection (ESD) provides superior en-bloc and curative resection rates for rectal neoplasia but at higher upfront cost. The cost-effectiveness of a universal rectal ESD strategy compared to EMR/ESD is unexplored within western practice. To evaluate the cost-effectiveness of universal rectal ESD compared with the current mixed EMR/ESD practice from St. Michael's Hospital in Toronto, Ontario, Canada (▶ **Table 1**).

▶ **Table 1** Base-Case and Sensitivity Analysis Results Comparing Universal Rectal ESD versus Current EMR/ESD Practice

Outcome	Status Quo (EMR/ESD mix)	Universal Rectal ESD	Incremental Difference (ESD – SQ)
Expected cost per patient (CAD)	$2,650	$7,850	+ $5,200
Recurrence rate	10.6 %	3.1 %	− 7.5 %
Hospital admission	30 % (weighted)	80.8 %	—
En-bloc resection	19.1 %	75.8 %	—
R0 resection	95.5 %	96.4 %	—
Curative resection (carcinoma)	9.3 %	74.3 %	—
ICER (CAD per recurrence avoided)	$34,700		
Probability cost-effective of $50,000 WTP	72 %		

Methods A decision-analytic model was developed using rectal outcomes from an institutional registry (n = 195; EMR = 89, ESD = 106). Inputs included weighted probabilities of adverse events, admission, and recurrence. Costs were derived from micro-costing and provincial reimbursement schedules (Ministry of Health Schedule of Benefits 2024 in CAD). The primary outcome focused on cost per recurrence avoided within a 12-month horizon. Sensitivity analyses examined admission policy, recurrence rates, and resource costs; uncertainty was explored using 5,000 Monte Carlo simulations.

Results Base procedural costs were $1,348 (EMR) and $7,007 (ESD). Incorporating adverse events and retreatments, the mean expected cost per patient was $2,650 for the current practice and $7,850 for universal ESD. Recurrence for ESD decreased from 10.6 % to 3.1 % (Δ = 0.075), yielding an ICER of $34,700 per recurrence avoided. In a one-way analysis, ESD was cost-saving when admission probability fell below 25 % or when EMR recurrence exceeded 13 %. Probabilistic analysis demonstrated ESD to be cost-effective in 72 % of iterations at a willingness-to-pay threshold of $50,000 per recurrence avoided.

Conclusions Universal rectal ESD substantially reduces recurrence and retreatment risk compared to current practice. Although associated with higher upfront procedural cost, it is cost-effective in centers with optimized anesthesia and selective admission protocols. These findings support expansion of rectal ESD capacity where procedural expertise and resources are available.

Endoscopy 2026; 58: S1–S1041

Aims Endoscopic submucosal dissection (ESD) is an effective but technically challenging treatment for esophageal neoplasms, with significant complication risks. To address these limitations, various tissue traction techniques have been developed. This study evaluates the feasibility and efficacy of a novel retractable robotic traction device designed to facilitate tissue traction during esophageal ESD.

Methods Three endoscopists performed ESD procedures on live porcine esophagus using both the robotic device and the conventional technique. Artificial lesions involving 50 % and 30 % of the esophageal circumference were created in both the mid and lower esophagus and assigned to either group. Primary outcomes included procedure time, dissection speed, incidence of procedure-related adverse events, and blind dissection rate.

Results We performed 12 robotic ESDs (RESD) and 12 conventional ESDs (CESD) across six pigs. RESD showed a significantly shorter total procedure time (30.1 ± 13.1 minutes) compared to CESD (42.3 ± 17.4 minutes, $p < 0.05$). RESD also achieved a significantly higher submucosal dissection speed (48.3 ± 7.8 mm^2/min versus 20.2 ± 7.4 mm^2/min, $p < 0.05$), along with a lower rate of blind dissection (8.5 % ± 2.7 % versus 24.2 % ± 11.1 %, $p < 0.05$) and muscle damage (3.0 ± 1.4 versus 5.9 ± 3.2 %, $p < 0.05$). The advantage of RESD over CESD was more pronounced in lesions involving 50 % of the esophageal circumference than in those involving 30 %.

Conclusions The robotic gripper facilitated efficient ESD by providing controlled, multidirectional traction. These findings suggest the device may enhance procedural performance and overcome technical challenges of ESD, particularly in large esophageal lesions.

eP1138 Withdrawal time and CADe are independent predictors of Adenoma Detection Rate: Result from a national prospective study

Authors Olabintan O[1, 2], George R[1], Arimoro O[3], Marynina A[1], Choong LM[1], Adeyeye A[1], Emmanuel A[1], Gulati S[2], Haji A[2], Hayee B[1]

Institutes **1** King's College Hospital, London, United Kingdom; **2** King's Institute of Therapeutic Endoscopy, King's College Hospital NHS Foundation Trust, London, United Kingdom; **3** University of Calgary, Calgary, Canada

DOI 10.1055/s-0046-1822465

Aims Withdrawal time (WT) is a key quality indicator and technical determinant of colonoscopy performance. The integration of artificial intelligence (AI), particularly computer-aided detection (CADe) systems, has demonstrated potential to enhance adenoma detection rate (ADR). However, the interaction between the CADe and procedural dynamics, including its potential to inadvertently prolong WT, remains poorly understood. In this study, we sought to evaluate the independent and combined effects of CADe and WT on ADR in a real-world multicentre setting.

Methods Data were analysed from the NAIAD trial, a prospective, stepped-wedge, multicentre study conducted across 25 hospitals involving 4,514 colonoscopies. The study comprised three phases: Phase 1 (baseline), Phase 2 (CADe active), and Phase 3 (post-intervention). Changes in WT were examined across phases. Mixed-effects logistic regression was employed to assess the independent contributions of CADe (Phase 2 vs Phases 1 + 3) and WT (per minute) to ADR, adjusting for patient age, endoscopist expertise and gender, bowel preparation quality, and hospital type, with random effects for site and endoscopist.

Results Implementation of CADe (Phase 2) was associated with increased procedural duration and improved detection. Mean WT increased from 10.2 ± 5.5 minutes at baseline to 10.9 ± 5.7 minutes during AI-assisted colonoscopy, accompanied by an ADR increase from 30.0 % to 34.8 % ($p < 0.001$). In multivariable mixed-effect regression analysis, both CADe use and WT were independent predictors of ADR. CADe use increased the odds of adenoma detection by 17 % (aOR 1.17; 95 % CI, 1.01–1.35; $p = 0.040$), while each additional minute of WT increased ADR by 11 % (aOR 1.11; 95 % CI, 1.09–1.13; $p < 0.001$). Following CADe withdrawal (Phase 3), mean WT and ADR declined to 8.9 minutes and 27.6 %, respectively, below baseline levels.

Conclusions CADe implementation and withdrawal time independently and synergistically improve adenoma detection. Although AI use incidentally prolongs WT, its impact on ADR extends beyond this effect. The decline in WT and ADR after CADe withdrawal suggests a transient behavioural adaptation. While CADe can augment endoscopic performance, sustained meticulous withdrawal technique remains fundamental to high-quality colonoscopy.

eP1139 High volume training of fellows in colorectal endoscopic submucosal dissection is feasible and safe in western centres

Authors Emmanuel A[1], Olabintan O[2, 3], Eqbal A[1], Judge C[1], Campion J[1], Lim A[1], Homira A[1], Adeyeye A[1, 4], Gulati S[1, 2], Hayee B[1, 2], Haji A[1, 2, 3]

Institutes **1** King's College Hospital, London, United Kingdom; **2** King's Institute of Therapeutic Endoscopy, King's College Hospital NHS Foundation Trust, London, United Kingdom; **3** King's College Hospital NHS Foundation Trust, London, United Kingdom; **4** Afe Babalola University , Ado Ekiti, Nigeria, Federal Republic of

DOI 10.1055/s-0046-1822466

Aims Adoption of ESD has been limited and gradual in western centres due to the complexity of the procedure, a long learning curve, limited opportunities to train and a lack of standard guidelines for training. Most ESD practitioners embark on training "in-post" after specialisation and ESD fellowships are scarce. There are no reports from western centres of high volume ESD training of endoscopy fellows. The ESGE have published a recommended curriculum for ESD training, including a recommendation for 10 ESDs to be completed under mentorship before independent practice. We report the experience of ESD training in a structured fellowship toward achieving this standard.

Methods Patients who underwent colorectal ESD at a tertiary referral centre were included. Data recorded included procedure time, en bloc and R0 resection, complications and proficiency of resection in cm^2/hr. Outcomes of ESD performed by fellows were reported and time to achieve 10 independent resections under mentorship was calculated for those following a dedicated ESD training program

Results 1077 lesions were treated using ESD. Fellows performed part or complete ESD of 277 lesions at an average of 23 cases per fellow (range 3-105). 80 % of fellow performed ESD were rectal lesions *versus* 57 % of expert performed ESD. En bloc and R0 resection rates for ESD involving fellows were 99 % and 85 %. There was no difference in complications ($p = 0.75$) between trainers and fellows. Mean proficiency of ESD involving fellows was 8.3cm^2/hr, 5 of 12 fellows who performed ESD followed a dedicated ESD training program, all achieving 10 independently performed ESDs. 2 had interrupted training periods due to research and other commitments. For the rest, the time from first ESD experience in patients of any kind to completing the 10th independent ESD was 46, 52, and 33 weeks

Conclusions Conclusion In one of the first reports of fellow training in significant volume of ESD in western centres, we demonstrate that structured training consistently results in achieving ESGE ESD training curriculum requirements within an acceptable fellowship period. Training can be achieved with high quality outcomes and acceptable proficiency without compromising patient safety.

eP1140 Role of Preprocedural Biopsies in Upper Gastrointestinal Tumors Undergoing Endoscopic Submucosal Dissection (ESD) and Impact on Fibrosis and Resection Rates

Authors Youssef M[1], Ching Hui Yee C[2], Ghobrial S[3], Khalaf K[1], Bechara R[4]
Institutes **1** St. Michael's Hospital, Toronto, Canada; **2** McGill University, Montréal, Canada; **3** University of Manitoba, Winnipeg, Canada; **4** Queen's University, Kingston, Canada
DOI 10.1055/s-0046-1822467

Aims Endoscopic submucosal dissection (ESD) is a minimally-invasive procedure widely used for resection of upper gastrointestinal lesions (GI) including esophageal and gastric tumors. Although preprocedural biopsies are routinely performed, their role is limited due to sampling error and risk of fibrosis which may impact technical outcomes of ESD. This study aims to evaluate the diagnostic performance of pre-ESD biopsies and the associated risk of fibrosis as well as the impact on technical outcomes of ESD.

Methods This is a retrospective cohort study of all patients who underwent ESD for upper GI lesions at Kingston Health Sciences Center (KHSC) between October 2016-September 2025. We analyzed clinical, endoscopic, and histopathologic characteristics of lesions as well as patient outcomes. Histological diagnoses were categorized using the WHO Classification criteria for GI lesions, 5th edition. Rates of concordance and upstaging were calculated comparing the initial and final resected pathology. Univariate analysis between the presence of fibrosis and technical outcomes such as resection time, procedural efficiency, en-bloc, R0, curative resections, and adverse events were used to calculate odds ratios with 95 % confidence intervals. P-value of < 0.05 was considered statistically significant.

Results This cohort study included 183 patients with upper GI lesions (esophageal = 120, gastric = 63) that underwent ESD at KHSC. 158/183 (86.3 %) of patients had preprocedural biopsies prior to their ESD at KHSC. The overall histologic concordance rate between tissue biopsy and ESD specimens was 48.4 % (38.8 % for esophageal and 68.0 % for gastric lesions). 46.4 % (n = 71) of lesions were upstaged from initial biopsy with 84.5 % (n = 60) of those final resections being neoplastic lesions. The risk of fibrosis was similar between patients with and without pre-ESD biopsies (23.9 % vs 36.0 %, p = 0.115). Lesions with fibrosis affected the procedural effiicency (mean 11.2 min/cm^2 vs. 7.4 min/cm^2, p = 0.026). However, the presence of fibrosis did not have a statistically significant impact on en-bloc resections (p = 1.00), R0 resections (p = 0.763), curative resections (p = 0.647), or on periprocedural adverse events (p = 0.719). Subgroup analysis showed that fibrosis did affect ESD efficiency in gastric lesions (14.0 min/cm2 vs 6.1 min/cm2, p = 0.005) but not in esophageal lesions (p = 0.296). Technical outcomes and adverse events remained consistent between site-specific analyses and the overall cohort.

Conclusions Preprocedural biopsies have poor concordance rate with post-ESD tissue histology. Biopsies of upper GI lesions do not seem to increase the risk of fibrosis. Fibrosis may limit ESD procedural efficiency but does not impact ESD technical outcomes or periprocedural adverse events.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1141 Endoscopic band ligation in randomized controlled trials of primary prophylaxis of variceal bleeding: Influence of study and patient characteristics on event outcomes

Authors Kalafateli M[1], Papantoniou K[2], Lekakis V[3], Aggeletopoulou I[2], Triantos C[2]
Institutes **1** Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom; **2** Division of Gastroenterology, Department of Internal Medicine, University of Patras, 26504, Patras, Greece; **3** Academic Departement of Gastroenterology, Laiko General Hospital, Athens, Greece
DOI 10.1055/s-0046-1822468

Aims Both endoscopic band ligation (EBL) and non-selective beta-blockers are used for primary prophylaxis of variceal bleeding, but the performance of EBL may vary across trials. We aimed to evaluate how study design and patient characteristics influence EBL-related outcomes in this context [1–6].

Methods We performed a comprehensive search of MEDLINE, Embase, Cochrane Library, and major conference proceedings from 1995 to April 2025 to identify randomized controlled trials comparing EBL with placebo or alternative interventions. Sample-weighted univariate and multivariate linear regression models were applied to examine factors associated with bleeding events, variceal eradication, and mortality. Weighting was based on the number of patients undergoing ligation in each study.

Results Forty RCTs were included, comprising 2055 patients treated with EBL. The pooled incidence of procedure-associated bleeding was 3 % (95 % CI 2–4 %), while post-ligation bleeding occurred in 11 % (95 % CI 9–15 %). In multivariate models, overtube use was independently associated with increased procedure-related bleeding (β = 0.710; 95 % CI 5.389–26.124; p = 0.007). Alcohol-related liver disease showed a borderline association with higher post-ligation bleeding risk (β = 0.427; 95 % CI −0.019–0.324; p = 0.078). Variceal eradication was achieved in 94 % of cases (95 % CI 88–97 %), and a higher prevalence of red wale marks correlated with improved eradication rates (β = 0.537; 95 % CI 0.002–0.335; p = 0.048). The overall mortality estimate was 18.3 % (95 % CI 14.0–22.2 %), with longer follow-up duration significantly linked to higher mortality (β = 0.651; 95 % CI 0.366–1.072; p < 0.001).

Conclusions Outcomes of EBL for primary prophylaxis show substantial heterogeneity across trials. Procedural factors, patient profiles, and follow-up duration significantly influence bleeding, eradication, and mortality outcomes. Recognizing these determinants is essential for designing and interpreting future EBL studies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1142 Unveiling The Risk Of Esophageal Squamous Cell Carcinoma In Achalasia: End-Stage Disease Carries a Markedly Higher Prevalence and Incidence. A Single-Referral Center Study With Systematic Review And Meta-Analysis

Authors Salvador R[1], Forattini F[1], Barberio B[1], Nezi G[1], Moletta L[1], Provenzano L[1], Capovilla G[1], Pierobon ES[1], Zanchettin G[1], Pittacolo M[1], Savarino E[1], Valmasoni M[1]

Institute 1 Department of Surgical, Oncological and Gastroenterological Sciences, University of Padova, Padova, Italy

DOI 10.1055/s-0046-1822469

Aims Achalasia is a rare esophageal motility disorder defined by impaired lower esophageal sphincter (LES) relaxation and complete aperistalsis of the esophageal body. Its incidence is estimated at ~1/100,000 per year, with a prevalence near 10/100,000. A recognized long-term complication is esophageal squamous cell carcinoma (ESCC), occurring at rates ranging from 0.4 % to 9.2 % and significantly exceeding that of the general population. Despite compelling evidence of elevated risk, international guidelines still do not recommend routine endoscopic surveillance for achalasia patients. This study quantifies ESCC risk in end-stage achalasia — defined by longstanding stasis and sigmoid-shaped megaesophagus — and evaluates whether surgical correction mitigates cancer risk. We report a single-center cohort of patients undergoing Laparoscopic Heller-Dor (LHD), supplemented by a systematic review and meta-analysis of published literature.

Methods All consecutive patients with radiologically confirmed end-stage achalasia undergoing LHD at the University of Padova between 2000–2025 were enrolled. Pre-operative diagnostics included endoscopy, barium swallow, and manometry. Post-operative surveillance consisted of endoscopy one year after surgery and every two years thereafter, aimed at detecting malignant transformation. Cancer prevalence and incidence rates were calculated. We additionally conducted a systematic search of MEDLINE, EMBASE, and the Cochrane Library (from inception to January 2025) to identify studies reporting ESCC in achalasia. Pooled prevalence, pooled incidence, rate ratios, and 95 % confidence intervals (CIs) were estimated according to PRISMA standards.

Results Among 1,782 patients who underwent LHD for achalasia, 115 exhibited radiological stage IV disease (median age 55 y, IQR 42–63). After a median follow-up of 8.2 years (IQR 5.1–15.6), 4 patients (3.47 %) developed ESCC, only one at early stage despite systematic postoperative endoscopic surveillance (▶ **Table 1**). Three cases arose more than 10 years after surgery, and one occurred in a patient with persistent dysphagia after failed surgical outcome. By contrast, no ESCC cases were detected among the remaining 1,667 patients with stage I–II–III disease (median follow-up 10.2 y).

The systematic review identified 26 eligible studies spanning 13 countries, comprising 12,962 achalasia patients. Overall ESCC prevalence in achalasia was ~2 %, with an incidence of 173 cases per 100,000 patient-years. Stratified analysis demonstrated substantially higher risk in end-stage disease, with an incidence of 724 vs 114 cases per 100,000 patient-years (rate ratio 6.34; 95 % CI 3.24–12.38). Most tumors occurred in males (81 %) and predominantly in the mid-thoracic esophagus (52 %).

Conclusions Conclusion: Patients with end-stage achalasia and sigmoid megaesophagus exhibit a significantly elevated ESCC risk that persists even after surgical correction. These findings support reconsideration of current guidelines and emphasize the need for structured, targeted endoscopic surveillance in this high-risk subgroup. Further prospective studies are warranted to define evidence-based surveillance strategies and to refine risk-stratification thresholds for early detection.

eP1143 Spectrum, Etiology, and Outcomes of Esophageal Strictures in Patients Presenting With Dysphagia: A Three-Year Endoscopic Experience From a Resource-Limited Tertiary Care Center

Author samad A[1]

Institute 1 Department of Gastroenterology, Hamdard University Hospital Karachi Pakistan, karachi, Pakistan

DOI 10.1055/s-0046-1822470

Aims To evaluate the frequency, etiological patterns, and clinical outcomes of esophageal strictures diagnosed on endoscopy in patients presenting with dysphagia, and to highlight challenges in management within a resource-limited environment [1, 2].

Methods This prospective observational study was conducted at Naimat Begum Hamdard University Hospital from January 2022 to January 2025. A total of 200 consecutive patients presenting with dysphagia (120 males, 80 females) underwent upper gastrointestinal endoscopy. Findings were categorized into stricturing lesions and non-stricturing causes (candida esophagitis, motility disorders, or normal examination). Patients with strictures were further clas-

▶ **Table 1**

Patient	Years after LHD	Tumor Location	Stage	Outcome
1 (M)	2	Upper third	IIA (pT2N1M0)	Disease-free after esophagectomy + adjuvant chemotherapy
2 (M)	14	Middle third	IIIB (pT4aN1M0)	Deceased 2 years after esophagectomy + adjuvant chemotherapy
2 (F)	13	Middle third	IA (pT1aN0M0)	Disease-free after esophagectomy
4 (F)	13	Lower third	IVB (cT4N2M1)	Palliative chemotherapy

sified by etiology, clinical presentation, need for repeated dilatation, complications, and requirement of palliative interventions.

Results Of the 200 dysphagia patients, **130 (65 %)** were found to have esophageal strictures. Among these:

- **55 (42.3 %)** had benign peptic strictures related to chronic GERD.
- **43 (33.1 %)** had malignant strictures, predominantly in the mid and distal esophagus.
- **5 (3.8 %)** had radiation-induced strictures following treatment for head and neck cancer.
- **9 (6.9 %)** had corrosive strictures secondary to caustic ingestion.
- **18 (13.8 %)** had proximal smooth strictures/webs linked to iron deficiency anemia.
- Patients with corrosive and peptic strictures frequently required multiple sessions of endoscopic dilatation. **Five patients (3 corrosive, 2 peptic)** developed perforations during dilatation. Tumor-related strictures typically presented late, with most patients requiring **palliative self-expandable metal stent placement** due to inoperability.

Conclusions Esophageal strictures constitute a major cause of dysphagia in our population, with peptic and malignant strictures being the most prevalent etiologies. Corrosive and peptic strictures pose significant management challenges, often requiring repeated interventions and carrying a risk of perforation. Late presentation of malignant strictures limits curative options, necessitating palliative stenting. In resource-constrained settings, **early referral and timely endoscopy are essential to improve outcomes and reduce morbidity**.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1144 Impact of the Double Scope Method on Incomplete LES Myotomy and the Occurrence of Blown-out Myotomy During POEM

Authors Shiwaku H[1], Akio S[1], Kosuke Y[1], Suguru H[1]

Institute 1 Fukuoka University Faculty of Medicine, Fukuoka, Japan

DOI 10.1055/s-0046-1822471

Aims The Double Scope Method (DS), performed during peroral endoscopic myotomy (POEM) for esophageal achalasia, is a technique used to objectively confirm complete myotomy of the lower esophageal sphincter (LES). Although several reports have demonstrated the usefulness of DS, no studies have investigated its association with the development of blown-out myotomy (BOM). In this study, we retrospectively evaluated the impact of DS on incomplete LES myotomy and the occurrence of BOM in POEM cases at our institution.

Methods We included 490 patients who underwent POEM at our institution between September 2011 and November 2023 and had at least two years of postoperative follow-up. BOM was defined according to Joseph et al. (GIE 2021) as "a distal esophageal diverticulum corresponding to the previous myotomy site, characterized by a wide opening > 2 cm and ≥ 50 % dilation of the esophageal body." Patients with pre-existing diverticula were excluded. DS was introduced in the 109th case in January 2015 and thereafter performed routinely except in technically difficult cases. Patients were divided into a DS group (n = 380) and a non-DS group (n = 108). We compared the rates of incomplete LES myotomy, overall BOM occurrence, and BOM caused by incomplete LES myotomy between groups. Fisher's exact test was used for statistical comparisons, with $p < 0.05$ considered statistically significant.

Results The success rate of DS was 99.5 % (380/382). The rate of incomplete LES myotomy was 0 % (0/380) in the DS group and 3.7 % (4/108) in the non-DS group, with a significantly lower rate in the DS group ($p = 0.002$). The incidence of BOM was 0.5 % (2/380) in the DS group and 0.9 % (1/108) in the non-DS group, with no significant difference ($p = 0.53$). BOM attributable to incomplete LES myotomy was not observed in the DS group (0 %) but occurred in 0.9 % (1/108) of the non-DS group; however, this difference was not statistically significant ($p = 0.22$). No severe adverse events associated with DS were observed.

Conclusions DS is a reliable technique for objectively confirming complete LES myotomy during POEM, and routine use is advisable. The introduction of DS significantly reduced the incidence of incomplete LES myotomy. Although the overall incidence of BOM in this series was lower than previously reported and statistical significance regarding the impact of DS on BOM occurrence was not demonstrated, the reduction in incomplete LES myotomy suggests that DS may theoretically contribute to preventing BOM. Further accumulation of cases is warranted to clarify this relationship.

eP1145 Double Trouble, Double Myotomy: Simultaneous D-POEM for Two Blown-Out Myotomy Segments Post-POEM

Authors Mangiola F[1], Landi R[1], Blasi V[1], Marchitto SA[2], Perri V[1], Spada C[1], Familiari P[1]

Institutes 1 Digestive Endoscopy Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; 2 Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy

DOI 10.1055/s-0046-1822472

Introduction Blown-out myotomy (BOM) is a rare complication following Heller myotomy or Peroral Endoscopic Myotomy (POEM), characterized by pseudodiverticular dilation at the site of the previous myotomy [1, 2]. It results from mucosal herniation through the muscular defect and can lead to food stasis and symptom recurrence. Risk factors include type III achalasia, elevated integrated relaxation pressure (IRP), and inadequate myotomy extension [3–5]. Diverticular-Peroral Endoscopic Myotomy (D-POEM) has emerged as a promising minimally invasive treatment [6, 7].

Case Presentation A 68-year-old man with type III achalasia, who had previously undergone an anterior POEM in 2017, presented with recurrent dysphagia, retrosternal pain, and mild weight loss (Eckardt score 7). Upper GI endoscopy revealed two pseudodiverticular ectasias—BOMs—in the middle and distal esophagus. Barium swallow confirmed esophageal dilation. The patient underwent endoscopic treatment utilizing a D-POEM approach involving double septotomy.

Procedure Under general anesthesia, endoscopy revealed food debris inside the BOMs, which was removed using a Roth-Net. A mucosal incision was performed 8 cm above the squamocolumnar junction. Submucosal tunneling and full-thickness myotomy were extended 8 cm (with 3 cm on gastric side), including the distal diverticular septum. Mucosal closure was achieved with four endoclips.To address the middle BOM, a second mucosal entry was created. A 7 cm tunnel and septotomy were performed in a similar manner, followed by clip closure.

Outcome Postoperative endoscopy after 24 hours confirmed proper clip placement and mild mucosal trauma. The patient resumed oral intake within 24 hours and was discharged on postoperative day 2. At three-month follow-up, symptoms had resolved (Eckardt score 2).

Conclusion This is the first reported case of simultaneous double D-POEM for BOM in two esophageal segments. D-POEM is safe, effective, and should be considered for symptomatic BOM.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1146 SECONDARY BILIARY CIRRHOSIS — The Tip Of Iceberg: Our Experience, Insights, And Evolving Perceptions

Authors Jhajharia A[1], Gaur V[1], Ashdhir P[1], Nagauri M[1]
Institute 1 Sawai Man Singh Hospital (SMS), Jaipur, India
DOI 10.1055/s-0046-1822473

Aims : Secondary biliary cirrhosis (SBC) arises from sustained obstruction of the biliary tract, culminating in progressive cholestatic injury and fibrosis. Despite its clinical significance, literature delineating its etiological spectrum, onset chronology, and biochemical–radiological characteristics remains remarkably scarce. Emerging evidence suggests that timely and appropriate biliary intervention may partially reverse fibrosis. Our aim is to elucidate the prevalence, delineate the relative contribution of benign and malignant causes, determine the temporal evolution from disease onset to cirrhosis, and evaluate post-interventional outcomes [1–2]

Methods The study was conducted at Gastroenterology Department of a major tertiary referral centre in north-west India. Among all admitted 1950 extrahepatic biliary obstruction (EHBO) patients, patients of SBC were selected. Primary objective of this study is to assess prevalence of SBC in all EHBO patients. Secondary objectives were to assess sociodemographic pattern, clinico-biochemical characteristics, aetiological spectrum, duration of onset of secondary biliary cirrhosis, radiological presentation, severity of cirrhosis and outcomes of biliary decompression

Results Out of a total of 1,950 individuals enrolled, 149 patients developed SBC & prevalence came out to be 7.6 %. Among them, 53.7 % patients were females & 46.3 % were males. 33.6 % patients were benign ones while the rest, 66.4 % were of malignant aetiologies. Most common aetiology repercussion into SBC is carcinoma gall bladder which accounts for 33.6 % cases. Among benign aetiologies, common bile duct (CBD) stricture is the most common one reported with 23.5 % cases. Median duration for the development of SBC is less for malignant aetiologies which is 2(2-4) months, whereas for benign causes it is 96 (57-123) months with significant p value of <0.001. In all benign aetiologies of SBC, free fluid was present in all patients. The frequency of intervention varied significantly between the two groups with p value 0.01. The decrease in liver stiffness measurements (LSM) over the 12 months period was statistically significant in cholangiocarcinoma, carcinoma head of pancreas, metastatic lymphadenopathy and among all benign aetiologies with p value <0.05.

Conclusions In summation, SBC exhibited a conspicuous predilection for the female cohort, with malignant aetiologies predominating and demonstrating a truncated latency to overt manifestation. Notably, the institution of biliary drainage engendered a marked attenuation of LSM, corresponding to fibrosis, across both investigative arms, underscoring its potent therapeutic efficacy and capacity to ameliorate disease trajectory.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1147 Global lifetime risks of developing and dying from pancreatitis from 1990 to 2050: a cross-sectional analysis from the Global Burden of Disease Study 2021

Authors Liu M[1], Yuhao L[2], Xin T[3], Rui-Xi G[3], Zhaoshen L[3], Shengfeng W[2], Lianghao H[3]
Institutes 1 Naval Medical University, shanghai, China; 2 Department of Epidemiology and Biostatistics, School of Public Health, Peking University, Peking, China; 3 Changhai hospital, Naval medical university, Shanghai, China
DOI 10.1055/s-0046-1822474

Aims Limited research has been conducted on the lifetime risks of pancreatitis, defined as the chance of developing or dying from the disease over one's lifetime. This study aims to estimate the global lifetime risks of pancreatitis from 1990 to 2021 [1–3].

Methods We used the Global Burden of Disease (GBD) Study 2021 estimates of pancreatitis incidence and the competing risks of death from any cause other than pancreatitis to calculate the cumulative lifetime risks of pancreatitis. Regional and gender disparities, health inequalities, temporal trends, and future projections were explored.

Results In 2021, the global lifetime risks of developing and dying from pancreatitis were 2.93 % (95 % CI: 2.92 %–2.94 %) and 0.16 % (95 % CI: 0.16 %–0.16 %), respectively. The Socio-demographic Index (SDI) was positively correlated with lifetime incidence risk ($r = 0.707$, $p < 0.001$) and exhibited a weak positive correlation with lifetime mortality risk ($r = 0.248$, $p < 0.001$). Eastern Europe and High-income North America had the highest lifetime risk of developing pancreatitis, while Eastern Europe had the highest mortality risk. The male-to-female lifetime risk ratios were 1.04 (95 % CI: 1.03–1.04) for incidence and 1.24 (95 % CI: 1.20–1.28) for mortality. The mortality risk after age 70 accounted for 56 % of the overall lifetime risk. Between 1990 and 2021, Western Europe experienced the largest increase in incidence risk, while Eastern Europe had the largest increase in mortality risk.

Conclusions The lifetime risk of developing pancreatitis is approximately 1 in 34, with geographic variations and higher risks in males. Targeted prevention in high-risk areas and focused management among the elderly are essential to reducing the future burden of pancreatitis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1148 Outcomes and Adverse Events of EUS-Guided Rendezvous Technique at Our Institution

Authors Ito S[1], Okuzono T[1]
Institute 1 Sendai Kousei Hospital, Sendai, Japan
DOI 10.1055/s-0046-1822475

Aims The EUS-guided rendezvous technique（EUS-RV）is a useful salvage method for cases in which biliary cannulation during ERCP is difficult. However, the procedure has not been standardized, and technical approaches vary among institutions. Although adverse events such as bile leakage and bleeding have been reported, detailed analyses remain limited. At our institution, puncture of the intrahepatic bile duct (B2/B3) from the stomach is the first-line approach, whereas puncture of the common bile duct from the second portion of the duodenum (D2 position) is selected when intrahepatic bile duct dilation is insufficient. This study evaluated the outcomes and adverse events associated with EUS-RV performed at our institution.

Methods A total of 106 EUS-RV procedures were performed at our institution between November 2018 and October 2025. The puncture route, technical success rate, time to biliary cannulation, and adverse events were retrospectively analyzed. Technical success was defined as successful bile duct cannulation. Cannulation time was defined as the interval from ERCP failure to successful cannulation with EUS-RV. Adverse events were defined as those directly attributed to the EUS-RV procedure.

Results The median age was 77 years, and 54 patients were male. Primary diseases included common bile duct stones (n = 44), intrahepatic stones (n = 3), pancreatic cancer (n = 29), distal cholangiocarcinoma (n = 10), hilar cholangiocarcinoma (n = 6), ampullary cancer (n = 3), and others (n = 11). Puncture routes were B2/B3 in 60 cases, the D2 position in 44 cases, and the D1 position (push position at the duodenal bulb) in 2 cases. The technical success rate was 82.1 % (n = 87/106). Causes of technical failure included insufficient bile duct dilation (n = 7), inability of the guidewire to pass through the papilla or biliary stricture (n = 11), and failure of the duodenoscope to reach the papilla after guidewire placement (n = 1). The mean cannulation time was 29 minutes. EUS-RV related adverse events occurred in 5 cases (4.7 %), consisting of bile leakage (n = 2) and intraductal bleeding (n = 3). Bile leakage occurred in one case punctured from the D1 position and in another case punctured from the duodenal bulb with stretch position. Bleeding events were attributed to B3 puncture. All adverse events improved with conservative management, and no additional interventions were required.

Conclusions Adverse events related to EUS-RV occurred in 4.7 %. Puncture from the duodenal bulb may increase the risk of bile leakage and should be avoided when possible. Technical refinements and representative adverse event cases from our experience will be presented with video.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1149 Microbial and Metabolic Signatures in Locally Advanced Pancreatic Ductal Adenocarcinoma: Insights from V1–V9 Sequencing and Metabolomics

Authors Marcozzi G[1, 2], Pozzi C[1], Gatti A[1], Terrin M[1], Spadaccini M[2, 1], Rescigno M[2], Zerbi A[1, 2], Hassan C[1, 2], Repici A[1, 2], Carrara S[1, 2]
Institutes 1 Humanitas Research Hospital, Rozzano, Italy; 2 Humanitas University, Pieve Emanuele, Italy
DOI 10.1055/s-0046-1822476

Aims Pancreatic Ductal Adenocarcinoma (PDAC) remains one of the most lethal malignancies, projected to become the second leading cause of cancer death by 2040. The poor and heterogeneous prognosis, particularly in the Locally Advanced PDAC (LAD-PDAC) subgroup, highlights the urgent need for robust pre-treatment predictive biomarkers. Recent evidence implicates the intratumoral microbiota and metabolic reprogramming in disease progression and therapeutic response. This study aimed to characterize and integrate the microbial and metabolic signatures in pre-treatment tumor biopsies of LAD-PDAC patients, leveraging high-resolution sequencing to improve taxonomic clarity.

Methods A prospective cohort of LAD-PDAC patients (n = 65) undergoing Endoscopic Ultrasound-Guided Fine Needle Biopsy (EUS-FNB) was enrolled. The microbial community structure was characterized using 16S rRNA gene sequencing of the extended V1–V9 regions to achieve higher species-level resolution compared to standard protocols. Untargeted metabolomics analysis was performed to identify the functional chemical landscape. Alpha and Beta diversity metrics were correlated with clinical and morphological variables, including surgical status, tumor size reduction following neoadjuvant therapy, and basal glucose levels.

Results High-resolution sequencing successfully identified 267 genera and 767 species, enriched for taxa typically associated with the skin, oral cavity, and gut (e.g., C. acnes, K. pneumoniae, S. aureus, H. pylori, E. faecalis). The metabolomic profiling revealed 413 known metabolites, dominated by lipids and lipid-like molecules (~22.6 %) and organic acids and derivatives (~23.6 %). Crucially, the Beta-diversity of the microbial community emerged as a significant pre-treatment determinant: the microbial composition was significantly distinct in patients who later underwent surgical resection compared to those who did not (p = 0.026). Furthermore, patients who showed a dimensional reduction in tumor size post-therapy presented a significantly different microbial profile compared to non-responders (p = 0.031). No single microbial taxa or metabolite was found to be significantly discriminant after correction for multiple comparisons.

Conclusions Our findings demonstrate that the overall structure and diversity of the intratumoral microbiota, rather than specific single markers, is a pre-existing biological feature significantly associated with critical clinical outcomes (resectability and response) in LAD-PDAC. The use of V1–V9 sequencing validated a highly complex microbial ecosystem. These results strongly advocate for the development of integrated multi-omics and Network Analysis models to uncover the functional interplay between microbes and metabolites, ultimately paving the way for personalized therapeutic stratification.

eP1150 Balancing Symptom Relief and Intervention Burden: A Case Series of Single-Session Endoscopic Ultrasound-Guided Double Bypass for Malignant Gastric Outlet and Biliary Obstruction

Authors Ko A[1], Maher B[2], Tehami N[3]
Institutes 1 University of Southampton, Southampton, United Kingdom; 2 Interventional Endoscopy Unit, University Hospital Southampton, Southampton, United Kingdom; 3 Interventional endoscopy Unit, University Hospital Southampton, Southampton, UK, United Kingdom
DOI 10.1055/s-0046-1822477

Aims Pancreaticoduodenal malignancies commonly present with simultaneous biliary and duodenal obstruction, resulting in jaundice, vomiting, nutritional decline, and marked deterioration in quality of life. Most affected patients are unsuitable for surgery. Conventional management often requires multiple staged interventions, including ERCP, duodenal stenting, percutaneous biliary drainage, and surgical gastrojejunostomy.
Endoscopic ultrasound (EUS)-guided gastrojejunostomy (GJ) and biliary drainage (BD) have emerged as effective palliative strategies. Performing both in a

Endoscopy 2026; 58: S1–S1041

single session offers an efficient method to relieve double obstruction while minimising procedural burden.

This study evaluates the technical success, clinical success, and safety of single-session EUS-guided double bypass for palliation of malignant biliary and duodenal obstruction. We hypothesised that this approach would achieve high technical and clinical success, improve symptoms rapidly, reduce the need for multiple procedures and prolonged hospitalisation, and maintain an acceptable safety profile.

Methods This single-centre, retrospective observational cohort study was conducted at University Hospital Southampton, United Kingdom, from September 2023 to September 2025. Primary outcomes were technical success (successful completion of both EUS-guided bypass procedures) and clinical success (reduction in bilirubin and improvement in obstructive symptoms). Secondary outcomes included procedural safety and early recovery metrics. Statistical analysis was performed using Stata.

Results Eighteen patients were screened, and sixteen met inclusion criteria. The cohort comprised 6 males and 10 females, with a median age of 63.6 years. Underlying malignancies included pancreatic adenocarcinoma and duodenal cancers: head of pancreas (40 %), duodenum (40 %), and ampulla (20 %).

All 16 patients underwent single-session EUS-GJ and EUS-BD. Biliary drainage techniques included EUS-GJ + choledochoduodenostomy (CDD; n = 4) and EUS-GJ + hepatogastrostomy (HGS; n = 12).

- **Technical success:** 16/16 (100 %)
- **Clinical success:** 16/16 (100 %)
- **Median time to oral intake:** 3 days
- **Median length of stay:** 3.6 days

Adverse events occurred in 2 patients (12.5 %): one bile-leak biliary peritonitis and one probable ischaemic injury following EUS-HGS. The 30-day mortality was 30 %, predominantly related to underlying disease progression rather than procedural complications.

Conclusions Single-session EUS-guided double bypass appears to be a safe, feasible, and highly effective palliative option for patients with malignant biliary and duodenal obstruction. The high technical and clinical success rates, early return to oral intake, and acceptable adverse-event profile suggest that this approach may reduce the need for multiple invasive procedures and streamline palliative care pathways.

eP1151 The possibility of obtaining good quality and quantity RNA from EUS-FNA samples of PanNENs: a prospective study

Authors Tacelli M[1], Petrone MC[1], Rossi G[1], Zaccari P[1], Archibugi L[1], Arcidiacono PG[1], Capurso G[1]

Institute **1** San Raffaele Hospital, Milano, Italy

DOI 10.1055/s-0046-1822478

Aims The biological progression of pancreatic neuroendocrine neoplasms (PanNENs) is significantly influenced by their grading. Endoscopic ultrasound (EUS) is the gold standard for PanNENs' grading evaluation but inconsistent EUS/surgery Ki67 agreement rates have been found. This inconsistency underscores the need for improved diagnostic techniques in EUS. The aim of the project is to evaluate the feasibility of extracting RNA in sufficient quantity and quality to perform genomic analyses from specimens obtained through EUS-fine needle aspiration (EUS-FNA) of PanNENs, comparing three methods of RNA preservation and extraction.

Methods This study prospectively evaluated patients undergoing EUS for suspected PanNENs. A uniform biopsy procedure using a 25-gauge Menghini needle with a slow-pull technique was applied. Sample adequacy was assessed on-site by a cytopathologist. For cases deemed adequate and suspicious of malignancy, an additional biopsy was performed, and RNA preservation and extraction were conducted using three distinct methods: Snap frozen plus Trizol (Method 1), Fresh tissue plus 1-Thioglycerol buffer solution (Method 2), and Snap frozen followed by 1-Thioglycerol buffer solution (Method 3). RNA integrity and concentration were measured using the 2100 Bioanalyzer

Results The study included 37 PanNEN patients, predominantly male (62.2 %), with a median age of 59 years. The median Ki67 proliferation index was 2 %, with most tumors graded as G2 (62.2 %). RNA extraction yielded a median global RNA concentration of 11,000 pg/ul, and the median RNA Integrity Number (RIN) was 3.7. Method 1 resulted in the highest median RNA concentration, while Method 3 produced the highest median RIN value. Significant differences were observed between the methods in terms of RNA concentration and RIN. Univariate linear regression analysis considering various patient and tumor characteristics found no significant associations with RNA quantity or quality.

Conclusions Successfully extracting high-quality RNA from EUS-FNA samples of PanNENs represents a significant advancement in the molecular profiling of these tumors. This development is crucial in the context of modern oncology, where molecular characterization increasingly informs treatment and prognostic evaluations.

DOI 10.1055/s-0046-1822479

Aims Small (< 2 cm), asymptomatic gastric subepithelial lesions (SELs) arising from the muscularis propria are frequently managed conservatively through follow-up, since most represent gastrointestinal stromal tumors (GISTs) with a favorable prognosis or benign lesions. This study aimed to evaluate the role of endoscopic ultrasound (EUS) in the long-term surveillance of such lesions [1–5].

Methods We conducted a retrospective multicenter study including patients with incidentally detected, asymptomatic, gastric SELs ≤ 20 mm arising from the muscularis propria who underwent EUS-based surveillance. Clinical outcomes (iron deficiency anemia, epigastric pain, weight loss) and EUS changes (mucosal ulceration, enlargement ≥ 25 % of the initial main diameter as suggested by previously published studies, change in the EUS pattern of the lesions) were analyzed together with risk factors for size increase and diagnosis of GISTs.

Results A total of 150 patients (38.7 % male; median age 62 [IQR 55-68] years) were followed for a median of 49 (IQR 22–96) months. No patient developed lesion-related symptoms. Thirty-five lesions (23.3 %) demonstrated a ≥ 25 % increase in size, which was significantly associated with age (P = 0.02), a ≥ 5 % size increase at 1 year (P < 0.001) and histologically confirmed GIST (P = 0.001). Histological diagnosis was obtained in 42 cases, with 22 confirmed GISTs. On multivariate analysis predictors of GIST included location in the gastric fundus or cardia (OR 0.94 (0.86 – 0.98); P = 0.05), baseline diameter for each mm (OR 1.17 (1.03 – 1.38); P = 0.01), ≥ 5 % enlargement at 1 year (OR 4.7 (1.1 – 20.5); P = 0.04), and size increase during follow-up for each % (OR 1.02 (1.01 – 1.04); P = 0.02). A resulting composite model was developed to predict the risk of having a GIST according to SEL location (fundus = 0 points; body or antrum = 1 point),

basal SEL size (≥ 10 mm = 1 point), 5 % increase at 1-year (2 points). The prevalence of GIST was 0 %, 4.4 %, 6.3 %, 34.8 %, 43.8 % in case of scores = 0, 1, 2, 3, 4 respectively; patients with a composite score > 2 showed an Odd ratio 13.3 (95 % confidence interval 4.39 – 39.9; P value < 0.001) for a diagnosis of GIST.

Conclusions Our multicenter study confirms that EUS-based surveillance is a safe and effective strategy for small, asymptomatic gastric SELs of the muscularis propria. Most lesions remain stable over time, but younger age, baseline size > 1 cm, location in the fundus and early growth identify patients at higher risk of clinically relevant progression or GIST diagnosis. In such cases, closer EUS follow-up and tissue acquisition should be prioritized, while resection may be considered. Emerging techniques such as contrast-enhanced EUS, elastography and the incorporation of artificial intelligence in EUS image interpretation may further refine the risk stratification, but histology remains essential to guide management.

eP1153 Life-Saving Endoscopic Management of Stapfer Type II Perforations Using Fully Covered Metal Stents

Authors Kenarlı K[1], ÖDemiş B[1], Macif A[2], Ünver NG[1]

Institutes 1 University of Health Science, Ankara Bilkent City Hospital, Ankara, Türkiye; 2 Ankara Bilkent City Hospital, Ankara, Türkiye

DOI 10.1055/s-0046-1822480

Aims Stapfer type II perforations, defined by periampullary injury with retroperitoneal leakage, represent the most frequent form of ERCP-related perforation. Despite their clinical relevance, optimal management remains debated. The aim of this study was to evaluate the clinical success of endoscopic treatment of Stapfer type II perforations, including cannulation success, early perforation recognition rate, and the need for surgery or percutaneous drainage.

Methods This retrospective study included patients diagnosed with Stapfer type II perforation between 2019 and 2025 at a high-volume tertiary referral center. Type II perforation was defined as retroperitoneal free air detected intra-procedurally or confirmed post-procedurally on contrast-enhanced CT. When perforation was recognized during ERCP, FcSEMS was placed in the same session. Patients diagnosed after ERCP underwent repeat ERCP within 24 hours, and FcSEMS was deployed if technically feasible. Endoscopic clinical success was defined as the avoidance of surgical exploration. In two patients with failed cannulation, percutaneous transhepatic biliary drainage (PTBD) was performed, followed by rendezvous-assisted FcSEMS placement.

Results Between 2019 and 2025, a total of 14,576 ERCPs and 8,094 sphincterotomies were performed. Sphincterotomy-related Stapfer type II perforation developed in 24 patients (0.29 %). The median age was 61.5 years (range 23–90), and 16 patients (66.6 %) were female. The most frequent indication for ERCP was common bile duct stones in 16 patients (66.6 %). Perforation was recognized during the index procedure in 20 patients (83.3 %), while 4 patients (16.7 %) were diagnosed post-procedurally by CT. Standard sphincterotomy was the cannulation technique attempted in 13 patients (54.2 %). Cannulation was successful in 22 patients (91.7 %). In two patients with unsuccessful cannulation, PTBD followed by rendezvous-assisted stent placement was performed. Due to post-procedural recognition of perforation (n = 4) or failed initial cannulation requiring PTBD (n = 2), a total of 6 patients (25 %) underwent a repeat ERCP within 24 hours. FcSEMS was successfully placed in 23 patients (95.8 %). One patient (4.2 %) with primary sclerosing cholangitis-related dominant stricture was treated with nasobiliary drainage because stent placement was not technically possible. Retroperitoneal fluid collection developed in 8 patients (33.3 %), 6 of whom were in the group requiring a second-session procedure. None of the patients required percutaneous drainage or surgical intervention. No mortality occurred in the entire cohort. All patients demonstrated rapid clinical improvement following endoscopic therapy, and no stent-related adverse events such as migration or occlusion were recorded during follow-up.

Conclusions FcSEMS placement is a highly effective treatment modality for Stapfer type II ERCP perforations. In all technically suitable patients, FcSEMS should be deployed immediately once perforation is recognized. In cases of failed cannulation, PTBD-assisted rendezvous enables successful stent placement and prevents the need for surgery. When perforation is diagnosed post-procedurally, early repeat ERCP and prompt FcSEMS deployment within 24 hours are critical to prevent clinical deterioration. Early recognition and timely treatment appear to reduce the likelihood of developing retroperitoneal fluid collections, which were predominantly observed in patients requiring delayed intervention. Our findings support the early, systematic use of FcSEMS for Stapfer type II perforations and highlight the importance of immediate detection, successful cannulation, and rapid biliary decompression to optimize outcomes and avoid invasive procedures.

eP1154 From accuracy to adoption: closing the real-time gap in gastric AI for MAPS III

Authors Stefani Donati D[1], Venturini A[1], Visaggi P[1], Gambaccini D[1], Natali V[1], Bolognesi V[1], Pancetti A[1], Tapete G[1], Marciano E[1]

Institute 1 Digestive Endoscopy Unit, Azienda Ospedaliera Universitaria Pisana, Ospedale Nuovo Santa Chiara, Pisa, Italy

DOI 10.1055/s-0046-1822481

Aims MAPS III recommends using AI where available to enhance exam quality, but surveillance decisions remain based on Kimura–Takemoto, EGGIM, OLGA/OLGIM, and histology/risk factors—not on AI outputs. Many gastric AI systems show strong performance, yet most are offline and rarely report patient-level outcomes aligned with MAPS [1–4].

Methods Systematic search of PubMed/Embase (through Oct-2025) for adult EGD-AI studies targeting: (i) CAG detection/classification, (ii) IM detection or EGGIM scoring, (iii) OLGA/OLGIM prediction, versus histology or expert endoscopy. Because patient-level 2 × 2 data were uncommon, we performed a narrative synthesis, extracting per-patient accuracy metrics when available and mapping outputs to MAPS tasks.

Results We screened 214 records, assessed 32 full texts, and included 20 studies. Evidence clustered into three MAPS-relevant areas:

1. CAG (per-patient): accuracy ≈ 91 %, sensitivity ≈ 88 %, specificity ≈ 94 % vs histology.

2. IM/EGGIM (risk stratification): per-patient accuracy 88 % (95 %CI ~80–96) with sensitivity 100 % for EGGIM ≥ 5 (no high-risk cases missed) and specificity ~85 %; per-image accuracy ~87 % on large NBI datasets.
3. Atrophy/histologic risk: AI correlated with Kimura–Takemoto and OLGA/OLGIM (AUC ~0.67–0.75), supporting proof-of-concept more than deployable staging.

Most studies were offline, and < 15 % reported MAPS-ready, patient-level outputs (confusion matrices or explicit CAG/EGGIM/OLGA reporting); real-time validation and routine VCE/standardized scoring were inconsistent.

Conclusions Gastric AI already reaches MAPS-relevant accuracy, but it must support—not replace—Kimura–Takemoto, EGGIM, and OLGA/OLGIM. Adoption hinges on multicentre real-time trials proving: (i) non-inferiority in missing high-risk disease (EGGIM ≥ 5 / advanced OLGA–OLGIM), (ii) better consistency of MAPS scoring, and (iii) standardized patient-level reporting aligned with MAPS III.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1155 Study of the CagPAI gene for gastric virulence factor of Helicobacter pylori

Authors Baatar G[1], Khasag O[2], Boldbaatar G[3]
Institutes **1** ShinonMed Hospital, Ulaanbaatar, Mongolia; **2** Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia; **3** Mongolian National University of Medical Sciences , Ulaanbaatar, Mongolia
DOI 10.1055/s-0046-1822482

Aims The Helicobacter pylori (*H. pylori*) is considered as the major cause of gastric cancer. This can be explained by the differences in the genotype of the CagA toxicity and the genes of the CagPAI assembly.

Methods A case control study was conducted among Mongolian adult patients. Gastric endoscopy, gastric histology, *H. pylori* isolation, and its gene sequence were performed in gastric cancer and non-gastric cancer cases. The diagnosis of gastric cancer was determined by the Lawrence classification. After culturing *H.pylori* infection DNA was extracted. Based on whole genome database the CagPAI complex genes were extracted and statistically processed [1–8].

Results A total of 54 patients were included in the study, with a male-to-female ratio of 1:1. Among the participants, 27.8 % (n = 15) were diagnosed with gastric cancer and 72.2 % (n = 39) had non-cancer cases. According to the updated Sydney classification, 66.7 % (n = 26) of non-cancer cases were low-risk and 33.3 % (n = 13) were high-risk for gastric cancer. Cancer prevalence differed by sex: 13.3 % of women (n = 4) and 45.8 % of men (n = 11) had cancer, indicating a significantly higher risk in men with *H. pylori* infection (p = 0.009).

Analysis of the *H. pylori* CagPAI gene revealed that 64.8 % (n = 35) of cases had complete gene sequences, 20.4 % (n = 11) were incomplete, and 14.8 % (n = 8) were negative. Full CagPAI expression was observed in 46.2 % of low-risk, 61.5 % of high-risk non-cancer groups, and 100 % of cancer cases, demonstrating a significant association with gastric pathology (p = 0.005). Full gene expression correlated with tumor presence and increased Sydney scores, reflecting greater histopathological changes in the gastric antrum (monocyte score p < 0.0001, neutrophil score p < 0.001).

Full CagPAI gene expression was associated with a 1.75-fold increased risk of gastric cancer (OR = 1.75, 95 % CI 1.3–2.3). Individuals over 40 years old with *H. pylori* infection had a 10.8-fold higher risk (OR = 10.8, 95 % CI 1.3–90.5), and men with *H. pylori* infection had a 5.5-fold higher risk compared to women (OR = 5.5, 95 % CI 1.5–20.7).

Conclusions

1. Among *H. pylori*–positive patients, 66.7 %(n = 26) of non-cancer cases were low-risk and 33.3 %(n = 13) were high-risk according to the updated Sydney classification.
2. Full CagPAI gene expression was observed in 46.2 %(n = 12)of low-risk, 61.5 %(n = 8) of high-risk, and 100 % of cancer cases, indicating a strong association with gastric cancer development (*p = 0.005*).

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1156 Impact of the "TOGAS" Study on Gastroscopy Key Performance Indicators in a Tertiary Referral Centre: An Interim Comparative Analysis

Authors Casey O[1], Deane C[2], Hegarty C[1], Costigan C[1], Semenov S[1], Nally F[1], Hazel K[1], O'morain C[1], Kelly O[1]
Institutes **1** Connolly Hospital Blanchardstown, Dublin, Ireland; **2** Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland
DOI 10.1055/s-0046-1822483

Aims Introduction TOGAS (TOwards GAstric Cancer Screening Implementation in the EU) is a large EU-funded study providing preliminary data to inform implementation of gastric cancer screening. "Pilot 2" focuses on participants aged 50-74 years-old undergoing FIT-positive/surveillance colonoscopy. Patients are offered additional gastroscopy at time of scheduled colonoscopy to determine prevalence of *Helicobacter pylori* infection, precancerous lesions and gastric cancer.

Aim To determine whether preliminary evidence supports an improvement in gastroscopy key performance indicators (KPIs) following the introduction of the TOGAS pilot study in Ireland, similar to the established KPI enhancements seen in colonoscopy after the initiation of the Irish BowelScreen programme [1,2].

Methods Reports from 100 gastroscopies performed before the start of the TOGAS study were reviewed. Data were collected on photographic documentation, use of anti-bubble solution, biopsies taken, and whether precancerous lesions such as intestinal metaplasia (IM) or atrophy were noted. These findings

were then analysed and compared with reports from 91 gastroscopies conducted during the TOGAS study. P values were determined using Fisher's exact test.

Results In the pre-TOGAS cohort, the average number of photographs taken was 12, compared with the minimum of 15 obtained in the TOGAS cohort. Complete photographic documentation of the antrum, body, and incisura was achieved in all TOGAS gastroscopies, but in only 22 (22 %) of pre-TOGAS procedures (P < 0.0001). Photographic evidence of examination under NBI was completed in every TOGAS gastroscopy, in comparison to less than half of the pre-TOGAS cohort. Use of anti-bubble solution was not documented in any pre-TOGAS gastroscopy. Full Sydney protocol biopsies were performed in all TOGAS procedures, compared with just two in the pre-TOGAS group (P < 0.0001). Comments on the presence or absence of intestinal metaplasia or gastric atrophy were included in 28.26 % of TOGAS reports, but only 4 % of pre-TOGAS reports (P < 0.0001).

Conclusions Adherence to the MAPS 2 (management of epithelial precancerous conditions and lesions in the stomach) and Sydney protocol was much more prevalent in the TOGAS cohort in comparison to the pre-TOGAS group. This may suggest that participation in the TOGAS study results in improved quality of upper GI endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822484

Aims EUS-FNA/B represents a key diagnostic modality for the evaluation of gastric subepithelial lesions, which are often incidentally identified and comprise a heterogeneous group of pathologies. However, the diagnostic performance of EUS-FNA/B is affected by lesion-specific features, procedural factors, and operator expertise. This study aimed to identify the factors associated with the diagnostic yield of EUS-FNA/B in two tertiary centers in Greece.

Methods Data from consecutive patients with gastric subepithelial lesions who underwent EUS-FNA/B between 2017 and 2025 were retrospectively collected. Variables collected included patient demographics, needle type and diameter, number of needle passes, lesion size, and final cytological diagnosis. Associations between lesion size, needle characteristics, number of passes, and diagnostic cytology were assessed.

Results A total of 118 EUS-FNA/B were performed in 118 consecutive patients, 56 (47 %) males and 63 (53 %) females, with a median age of 67,5 years (range: 29–90). Cytology was diagnostic in 100 cases (85 %) and non-diagnostic in 18 cases (15 %). Of the diagnostic samples, 88 (88 %) were reported as neoplastic while 11(11 %) were non-neoplastic. In the neoplastic category, the predominant diagnosis was of gastrointestinal stromal tumor (53,4 %), followed by leiomyoma (39,7 %). In the non-neoplastic category, the most common diagnosis was pancreatic rest (18 %). Lesion size > 19 mm (OR = 0.29, 95 % CI: 0.12–0.72, p = 0.007), ≥ 2 needle passes (OR = 5.99, 95 % CI: 2.20–16.3, p < 0.001) and use of EUS-FNB needle (OR = 4.21, 95 % CI: 1.57–11.3, p = 0.004) were associated with a higher diagnostic yield.

Conclusions The results of our study suggest that performing two or more needle passes, targeting lesions > 19 mm, and the use of EUS-FNB needles were independently associated with a significantly higher diagnostic yield in the evaluation of gastric subepithelial lesions.

eP1158 Capsule Endoscopy for Treat-to-Target Monitoring in Crohn's Disease: A Systematic Review and Meta-Analysis

Authors Marmo C[1], Puca FS[1], Marmo R[2], Spada C[1], Scaldaferri F[1], Riccioni ME[1]

Institutes **1** Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; **2** Presidio ospedaliero Luigi Curto di Polla, Polla, Italy

DOI 10.1055/s-0046-1822485

Aims To evaluate the role of small bowel and pan-enteric capsule endoscopy in treat-to-target monitoring of Crohn's disease.

Methods We conducted a systematic review and meta-analysis of studies assessing capsule endoscopy for mucosal healing in Crohn's disease from database inception to November 2025. We searched PubMed, Embase, Google Scholar, and the Cochrane Library to identify studies performing a baseline capsule examination followed by repeat capsule after medical therapy. Two reviewers independently screened titles, abstracts, and full texts. Reference lists were also examined to identify additional eligible studies. Pooled effect estimates and risk of bias assessments were computed using STATA 19.

Results The search yielded 829 records, of which nine studies met the inclusion criteria, enrolling a total of 348 patients. Among these, 91 % (95 % CI, 74 % 100 %) showed positive findings on baseline capsule endoscopy. The weighted mean age was 30.5 years (95 % CI, 28.8 32.2 years), and 44 % (95 % CI, 37 % 51 %) were male. Small-bowel visualization was complete in 91 % (95 % CI, 73 %100 %) of cases, with no reported capsule retention. Capsule endoscopy detected active inflammation at baseline in 89 % of patients. A modification of medical therapy occurred in 97 % of patients (95 % CI, 88 % 100 %). After a weighted mean of 33.5 weeks, the pooled rate of mucosal healing was 26 % (95 % CI, 0.16 0.37; I^2 = 77.40 %; p < 0.001). No statistically significant small-study effects were identified by Egger's test (p ≥ 0.89). 40 % of patients demonstrated reduced inflammation scores (95 % CI, 0.33–0.48; p < 0.001; I^2 = 24.35 %; p = 0.23). Meanwhile, the proportion of patients without mucosal healing or mucosal improvement was 33 % (95 % CI, 0.23–0.45; p < 0.001; I^2 = 76.8 %).

Conclusions In the cohort of patients with small bowel Crohn's disease, capsule endoscopy was a safe and accurate tool for disease monitoring. These findings support incorporating Capsule Endoscopy into treat-to-target strategies to guide therapeutic decision-making in Crohn's disease with small bowel involvement.

eP1159 Artificial Intelligence and Endoanal Ultrasound: Multicenter Validation of Automated Detection and Differentiation of Benign Lesions

Authors Almeida MJ[1], Mascarenhas M[1], Martins M[1], Mendes F[1], Mota J[1], Araújo C[1], Frias J[1], Mendes B[2], Macedo G[1], Poças F[3]
Institutes **1** Department of Gastroenterology, São João University Hospital, Porto, Portugal; **2** Faculty of Engineering – University of Porto, Porto, Portugal; **3** Hospital Geral de Santo António, Porto, Portugal
DOI 10.1055/s-0046-1822486

Aims Benign anal canal conditions are common, clinically impactful, and frequently associated with proctological symptoms and functional impairment, creating a substantial burden for patients. Precise diagnostic assessment is essential to guide appropriate therapeutic planning and ensure optimal outcomes. Endoanal ultrasonography (EAUS) remains the reference modality for evaluating the sphincteric complex, yet its operator dependency, steep learning curve, and variability in image interpretation continue to limit consistency and reduce interobserver agreement. Artificial intelligence (AI) offers a compelling opportunity to address these constraints by enhancing image interpretation, reducing reliance on individual expertise, and strengthening diagnostic standardization. This study aims to validate an AI model capable of automatically detecting and characterizing benign anal lesions in EAUS exams, reinforcing the need for more consistent, scalable, and clinically dependable evaluation in anal disorders.

Methods A bicentric retrospective study evaluated 13 787 EUAS radial-probe exams between April 2022 and January 2024. A total of 13787 frames were classified into fissures (632), external lacerations (1989), and internal lacerations (1687), intersphincteric fistula (5163), transsphincteric fistula (3581) and internal atrophy (735), after expert review. The dataset was divided into 90 % for training and 10 % for testing. Performance metrics included sensitivity, specificity, and accuracy.

Results For external lacerations, the CNN achieved 94.1 % sensitivity, 99.6 % specificity and 98.9 % accuracy. For internal lacerations, achieved 95.0 % sensitivity, 98.4 % specificity and 98.4 % accuracy. In the case of anal fissures, achieved 98.4 % sensitivity, 98.6 % specificity and 98.7 % accuracy. Regarding inter and transsphincteric fistulas, sensitivity was 92.5 % and 96.9 %, specificity was 99.5 % and 97.8 %, and accuracy was 97.0 % and 97.4 %, respectively. For internal atrophy, sensitivity was 97.5 %, specificity was 99.9 % and accuracy was 99.9 %.

Conclusions Our findings demonstrate that AI can reliably support the detection and characterization of benign lesions on EAUS and highlight its capacity to improve diagnostic consistency in this setting. In addition to enhancing accuracy and reducing operator dependency, AI may drive meaningful standardization and function as a valuable educational tool for clinicians in training. By guiding interpretation and emphasizing key anatomical structures, it has the potential to shorten the demanding learning curve associated with EAUS. Although these results are encouraging, they represent an early milestone in a wider developmental pathway. Future work will focus on integrating three dimensional network reconstruction to deliver richer anatomical insight and further elevate diagnostic precision.

eP1160 Prucalopride is Associated with Higher Completion Rate and Shorter Transit Times in Colon Capsule Endoscopy: Results from a Large Danish Cohort

Authors Radic Eskemose S[1, 2], Baatrup G[1], Koulaouzidis A[3, 2], Bjørsum-Meyer T[1], Kaalby L[1], Schelde-Olesen B[1], Deding U[1]
Institutes **1** Odense University Hospital, Odense, Denmark; **2** Department of Clinical Research, University of Southern Denmark, Odense, Denmark; **3** Department of Surgery, SATC-C, OUH Svendborg Sygehus, Svendborg, Denmark
DOI 10.1055/s-0046-1822487

Aims Colon capsule endoscopy (CCE) is a minimally invasive alternative to colonoscopy for colorectal cancer screening and diagnostic evaluation of the colon. A major limitation of CCE is incomplete examination, with reported complete CCE rates typically ranging from 60 to 80 %, depending on bowel preparation regimen and patient-related factors. In an interim analysis of the CareForColon2015 trial, oral administration of 2 mg prucalopride (a selective 5-HT4 receptor agonist) appeared to increase the complete CCE rate and reduce both total (mouth to anus) and colonic (caecum to anus) transit times [1]. This study aimed to validate these findings in the full cohort, asses self-reported side effects, and identify predictors of fast colonic capsule transit.

Methods We conducted a non-randomised comparison of participants enrolled in the CareForColon2015 trial, which was conducted in Denmark from August 2020 to December 2022 [2]. The first 680 participants underwent a standard 2-day polyethylene glycol-based (Movicol and Moviprep, Norgine Danmark A/S, Herlev, Denmark) bowel preparation. The subsequent 1350 participants additionally received 2 mg prucalopride 45 to 60 minutes prior to capsule ingestion. The main exclusion criteria were conditions related to CCE contraindications, e.g. history of abdominal surgery, cardiac pacemaker, and renal insufficiency. The primary outcome was complete CCE rate defined as adequate bowel cleansing in all colorectal segments, no more than short technical interruptions, and visualization of both the caecum and anal cushions. Secondary outcomes included complete transit, conclusive CCE rate, self-reported side effects, polyp detection rate, total and colonic transit times, and overall bowel cleansing quality. Data were obtained from the capsule reports generated by the capsule readers or from participant questionnaires. Outcomes were compared between those who received prucalopride to those who did not using X^2 tests, Fisher's exact tests, Student's t-tests, or Mann-Whitney U tests depending on data type and normality.

Results Out of 2,031 participants, 2,024 were eligible for inclusion and complete data was available for 1,915 (94.3 %). Prucalopride administration was associated with a higher complete CCE rate (63.2 % versus 69.1 %, $p = .008$). Median total transit time was decreased from 304 minutes (IQR 211 to 400) in the control group to 182 minutes (IQR 108 to 274, $p < .001$), representing a 40.1 % reduction. Median colonic transit time was reduced by 27.5 %, going from 153 minutes (IQR 97 to 248) in controls to 111 minutes (IQR 44 to 184, $p < .001$). Adequate overall bowel cleansing increased from 72.9 % to 78.2 % ($p < .001$). Prucalopride was associated with higher detection of polyps > 9 mm ($p = .037$) but not detection of any polyps of any size ($p = .070$). Participants receiving prucalopride more frequently reported diarrhoea, headache, and fatigue. All self-reported side effects were of mild to moderate clinical significance despite potentially being relevant for patients and their acceptability of undergoing CCE. Predictors of fast colonic transit times included male sex ($p < .001$) for transits < 20 minutes, and male sex ($p < .001$), older age ($p = .015$), and higher BMI ($p = .016$) for transits < 40 minutes.

Conclusions Oral administration of 2 mg prucalopride 45 to 60 minutes prior to CCE was associated with higher complete CCE rate and shorter total and colonic transit times. Prucalopride may be a simple and effective addition for CCE completeness with little self-reported side effects. The main limitation is the non-randomised study design while the primary strength is the large sample size. Randomised trials investigating optimal patient-specific dosing strategies and tolerability are warranted [3].

eP1161 Endoscopic features of colon cancer at early restaging colonoscopy predicts response to neoadjuvant immunotherapy in colon cancer

Authors Bulut M[1, 2], Chieng M[1], Souchon A[1], Gögenur I[1, 2]
Institutes **1** Zealand University Hospital, Køge, Denmark; **2** University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark
DOI 10.1055/s-0046-1822488

Aims Reliable predictors of clinical complete response (CR) are lacking for colon cancer (CC) patients treated with immunotherapy. Optical biomarkers have been used in other contexts for staging and response assessment, presenting a promising strategy for this purpose. This study aims to externally validate an optical evaluation framework for predicting CR.

Methods We conducted a retrospective, multi-reader, multi-case study involving 28 international endoscopists and 75 cases of stage I-III CC, treated with a single dose of pembrolizumab. Endoscopists assessed response using a published optical framework and provided confidence ratings for each case. Evaluations were based on still images from re-staging colonoscopies, with accuracy compared to biopsy and surgical pathologic specimens.

Results The optical evaluation performed with comparable accuracy to routine biopsy (72.7 % vs. 74 % OR = 0.94, p = 0.80) with moderate inter-observer agreement (κ = 0.522). Reader confidence significantly correlated with accuracy. High confidence (HC) evaluations demonstrated a marked increase in diagnostic accuracy and AUROC compared to low-confidence (LC) evaluations (0.799 vs 0.582, p = < 0.0001). The addition of biopsy data doubled the odds of accurate LC-optical predictions (OR 2.01, p = < 0.0001), but significantly decreased accuracy in HC cases (OR 0.53, p = < 0.0001).

Conclusions Confidence-weighted optical assessment accurately predicts CR in CC. HC-optical evaluations matched biopsy accuracy and were not improved by addition of biopsy data, supporting a selective biopsy approach. LC-optical predictions of CR improved with biopsy confirmation, highlighting its role in uncertain cases. This framework provides an accurate, reliable and efficient strategy for disease restaging.

eP1162 Correlation between gastrointestinal PET-FDG uptake and subsequent endoscopic findings: a single centre retrospective study

Authors Coccia M[1], Orlando D[2], Coppola M[3], Stigliano V[3]
Institutes **1** Azienda ospedaliero – universitaria Sant'Andrea, Rome, Italy; **2** Digestive Endoscopy Unit, IRCCS Regina Elena National Cancer Institute, Roma, Italy; **3** Digestive Endoscopy Unit, IRCCS Regina Elena National Cancer Institute, Rome, Italy
DOI 10.1055/s-0046-1822489

Aims The primary aim of our study is to determine the correlation between the incidental PET-FDG uptake in the gastrointestinal tract (GIT) and the subsequent endoscopic findings. Secondary outcomes are to analyze the differences among the types of 18-FDG uptake patterns and to evaluate the role of the maximum standardized uptake value (SUVmax) in differentiating among the different kind of findings [1–3].

Methods We conducted a single center retrospective study in a cohort of patients who underwent an endoscopic examination after a PET-scan showed abnormal uptake at some level in the GIT. All the patients included had a non GIT malignancy, or the FDG accumulation was in a different site than the pre-existing GIT-malignancy. All the endoscopic procedures were performed at Istituto Regina Elena in Rome, while some of the radiological exams were performed in other centers and then reviewed by our expert radiologists. The analysis of the differences of SUVmax values among the different groups was performed using the Kruskal-Wallis test with Dunn's post-hoc pairwise comparisons adjusted by the Bonferroni method, due to non-normal data distribution. Continuous variables were summarized as medians with interquartile ranges (IQR). Statistical significance was set at $p < 0.05$.

Results We analyzed the data from 267 patients who underwent an endoscopic procedure between April 2018 and November 2024. 57.7 % were females, with a median age of 66 years (range 32-89). 68.5 % of patients underwent lower-GI endoscopy, 19.9 % gastroscopy, and 11.6 % underwent both examinations. 113 patients had a positive endoscopic finding (42.3 %), in particular: 34 malignant lesions; 55 pre-malignant lesions (either colonic adenomas > 10 mm in diameter, with low grade or high grade dysplasia, or gastric intestinal metaplasia) and 26 inflammatory conditions of various kind. In 237 patients we could analyze the pattern of uptake in the radiological exam being a focal pattern in 166, diffuse in 36 and focal on diffuse in 35 cases. The diffuse pattern was associated with the higher grade of false positives (33 out of 36, 91.7 %), while a focal captation was more frequently correlated with a significant endoscopic finding (86/166, 51.8 % in the focal pattern and 13/35, 37.1 % in the focal on diffuse pattern). In 242 out of 267 patients (90.6 %) the SUVmax value was reported on the radiological exam. SUVmax median value significantly differed among malignant (15.7), premalignant (10.7), inflammatory lesions (8.16) and false positives (8.05) (Kruskal–Wallis H = 36.97, $p < 0.001$). Post-hoc Dunn analysis showed that malignant lesions had significantly higher SUVmax compared with inflammatory lesions ($p < 0.001$) and PET false positives ($p < 0.001$), while the difference with premalignant lesions did not reach statistical significance ($p = 0.196$).Premalignant lesions showed higher SUVmax values compared with PET false positives ($p < 0.001$), but not with inflammatory lesions ($p = 0.109$). No difference emerged between inflammatory lesions and PET false positives.

Conclusions In our study 42.3 % of the patients had a positive endoscopic finding (either neoplastic, premalignant or inflammatory) which corresponded to the segment of the abnormal FDG-PET uptake in the majority of the cases, with the focal uptake pattern being the most specific one in identifying clinically relevant conditions compared to the diffuse pattern. The median SUVmax value in the group with malignant lesions was higher if compared to the inflammatory lesions or the false-positive PET-scan group, and the difference was statistically significant suggesting a role of this parameter in the decision of performing the endoscopic exam after incidental PET captation in the GIT. There are no guidelines on the subject yet and the decision whether to proceed with further investigations should be made on a case-by-case basis, also taking in consideration the patient's prognosis and comorbidities.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822490

Aims Recurrent colorectal neoplasia at anastomotic sites after colorectal surgery poses a significant risk for subsequent cancer and is challenging to treat endoscopically due to severe fibrosis. Evidence on the feasibility of endoscopic submucosal dissection (ESD) in this setting remains limited. This study aimed to assess clinical and procedural outcomes of ESD for colorectal anastomotic-site lesions [1–3].

Methods A retrospective analysis was conducted on 17 patients who underwent ESD for anastomotic-site lesions at two high-volume western referral centers between January 2018 and June 2025. Tumor characteristics (location, morphology, size, histology, invasion depth) and procedural outcomes (technical success, en bloc and R0 resection rates, procedure time, and adverse events) were evaluated.

Results Mean patient age was 62 years (range 41–84); six patients had hereditary syndromes (Lynch n = 3; FAP n = 3). Lesions occurred at ileocolic (n = 1), colocolic (n = 3), colorectal (n = 8), coloanal (n = 1) anastomoses, and in the ileal pouch (n = 4). Median tumor size was 38 mm. Morphology included three protruded lesions, nine granular, and five non-granular LSTs. Technical success was 82 % (14/17): two procedures were aborted due to severe fibrosis (both in the ileal pouch), and one lesion in the rectal cul-de-sac was inaccessible. Histology showed adenomas (LGD n = 4; HGD n = 7) and invasive cancer (n = 3). Median procedure time was 75 minutes. En bloc and R0 resection rates were 85.7 % and 71.4 %, respectively. One perforation occurred during one of the aborted procedure.

Conclusions ESD for colorectal anastomotic-site lesions is feasible, achieving high en bloc resection rates with acceptable safety despite technical difficulty from dense fibrosis. Ileal pouch lesions represent the most challenging subgroup. ESD may serve as an effective organ-preserving alternative to repeat surgery in selected patients.

eP1164 Endoscopic Submucosal Dissection Versus Endoscopic Laryngopharyngeal Surgery for Superficial Head and Neck Tumors

Authors Furukawa K[1], Hirose T[2], Miyahara R[1], Funasaka K[1], Furune S[1], Suzuki T[1], Shibata H[1], Kurata Y[1], Fukuzawa K[1], Oshitani Y[1], Ishikawa E[1], Sawada T[2], Maeda K[1], Yamamura T[2], Kawashima H[1]

Institutes **1** Department of Gastroenterology and Hepatology, Nagoya University Graduate School of Medicine, Nagoya, Japan; **2** Department of Endoscopy, Nagoya University Hospital, Nagoya, Japan

DOI 10.1055/s-0046-1822491

Aims Endoscopic laryngopharyngeal surgery (ELPS) and endoscopic submucosal dissection (ESD) are minimally invasive endoscopic techniques for the treatment of head and neck tumors. ELPS is performed by otolaryngologists under gastrointestinal endoscopic guidance, whereas ESD is conducted by gastroenterologists with laryngeal exposure provided by otolaryngologists. Both procedures are performed collaboratively by gastroenterologists and otolaryngologists under general anesthesia, enabling organ preservation and favorable therapeutic outcomes. This study aimed to compare the clinical outcomes of ESD and ELPS for superficial head and neck tumors.

Methods A total of 120 patients with 129 lesions who underwent endoscopic treatment for head and neck tumors between June 2014 and December 2024 were retrospectively analyzed. Parameters assessed included (1) patient demographics and lesion characteristics, (2) short-term therapeutic outcomes, (3) procedural accidents, and (4) recurrence rates.

Results (1) Among the 120 patients, 110 were male and 10 female, with a median age of 69 years (range, 45–82). Lesions were located in the hypopharynx (n = 111), oropharynx (n = 9), and larynx (n = 9). Macroscopic types were 0-Is (n = 10), 0-IIa (n = 25), 0-IIb (n = 82), and 0-IIc (n = 12), with a median tumor size of 15 mm (range, 3–70). Pathological diagnoses included pTis (n = 47), pT1 (n = 59), pT2 (n = 18), pT3 (n = 3), and dysplasia (n = 2). (2) ESD was performed in 33 patients with 36 lesions, and ELPS in 88 patients with 93 lesions. The median resection speed, calculated as (long diameter × short diameter) / procedure time (mm^2/min), was 13.9 (range, 2.2–32.7) in the ESD group and 11.3 (range, 1.1–73.9) in the ELPS group, with no significant difference (p = 0.38). The R0 resection rate was significantly higher in the ESD group (88.9 %, 32/36) than in the ELPS group (48.4 %, 45/93) (p < 0.0001). In the ESD group, horizontal margin indeterminate (HMX) status was observed in four lesions, due to tumor or dysplasia near the margin (n = 2), thermal denaturation (n = 1), and specimen incision (n = 1). In the ELPS group, HM1, HMX, VM1, and VMX statuses were noted in 15, 32, 2, and 6 lesions, respectively. Causes of HMX included tumor or dysplasia near the margin (n = 16), specimen crush or epithelial detachment (n = 8), thermal denaturation (n = 7), and specimen incision (n = 1). VMX was attributed to thermal denaturation (n = 5) and specimen crush (n = 1). (3) Procedural accidents occurred in seven patients (21.2 %) in the ESD group, including aspiration pneumonia (n = 2), tongue injury (n = 2), laryngeal edema (n = 1), hypoglossal nerve palsy (n = 1), and vocal cord paralysis (n = 1). In the ELPS group, complications were observed in 16 patients (18.2 %), including aspiration pneumonia (n = 6), laryngeal edema (n = 5), dysphagia (n = 2), free jejunal perforation (n = 1), tongue/oral floor swelling (n = 1), and prerenal failure (n = 1). There was no significant difference in the incidence of procedural accidents between the ESD and ELPS groups (p = 0.71). (4) In the ELPS group, local residual or recurrent lesions were observed in five cases (5.4 %) and distant metastases in four cases (4.3 %), whereas no such events occurred in the ESD group. There were no significant differences between the two groups in the

rates of local residual or recurrent lesions (p = 0.16) and distant metastases (p = 0.21).

Conclusions Although resection speed, incidence of procedural accidents, and frequency of residual or recurrent lesions were comparable between ESD and ELPS, the significantly higher R0 resection rate observed in the ESD group suggests that ESD may offer superior curative potential in the management of superficial head and neck tumors.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1165 Virtual reality in teaching non-technical skills (NTS) for ERCP – Real life experience from a JAG accredited ERCP training centre in the United Kingdom

Authors Elhusseiny R[1], Selvaraj E[1], Esmaily S[2], Sethia R[1], Mathur R[1], Dores C[2], Machan D[1], Easton K[1], Dwarakanath D[1], Mitra V[3]

Institutes **1** University Hospital of North Tees, Hardwick, United Kingdom; **2** COUNTY DURHAM AND DARLINGTON NHS FOUNDATION TRUST, Newcastle upon Tyne, United Kingdom; **3** University Hospital of North Tees, Hardwick Road, Stockton-on-tees, United Kingdom

DOI 10.1055/s-0046-1822492

Aims Virtual reality (VR) technology is increasingly used in ERCP training to enable early acquisition of skills in a safe environment. While its role in developing technical skills in ERCP is recognised, evidence for its impact on generic non-technical skills (NTS) —including communication, teamwork, leadership, situational awareness, and emotional regulation—is limited. We evaluated the use of fully immersive VR to teach generic NTS during the Joint Advisory Group (JAG) approved Basic Skills ERCP course at University Hospital of North Tees [1–4].

Methods Three ERCP-based VR scenarios (complex stone disease, post-sphincterotomy bleeding, and oversedation during ERCP) were developed with support from a VR development team. Participants (consultants, trainees, and ERCP nurses) viewed the scenarios using immersive headsets (Red Box) and took part in facilitated group debriefs. A post-session electronic questionnaire assessed realism, usefulness for NTS, decision-making, emotional control, and overall value.

Results Seventeen delegates completed the questionnaire (7 doctors [4 consultants, 3 registrars] and 10 nurses). Thirty-five percent had prior exposure to more than 200 ERCP procedures. Perceptions of VR were highly positive: 76.5 % strongly agreed and 23.5 % agreed that sessions were realistic. VR improved understanding of NTS in ERCP (88.2 % strongly agree, 11.2 % agree), decision-making (58.8 % strongly agree, 41.2 % agree), confidence and emotional control in challenging cases (70.6 % strongly agree, 29.4 % agree) and the ability to manage unexpected limitations (70.6 % strongly agree, 29.4 % agree). Debrief discussions were rated useful by all participants (88.2 % strongly agree, agree 11.2 %). Overall session rating was excellent in 76.5 % and very good in 23.5 %. All participants recommended ongoing use of VR as an adjunct to ERCP training.

Conclusions Fully immersive VR is a promising tool for teaching non-technical skills in ERCP, providing a realistic platform for developing situational awareness, communication, and confidence within a controlled environment.

Integrating VR into a standardised ERCP curriculum may accelerate the acquisition of both technical and non-technical skills. Further multi-centre studies are needed to determine its broader educational impact.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822493

Aims Amber-red color imaging (ACI) is a novel image-enhanced endoscopic modality designed to improve visualization of blood-rich and submucosal structures. This study aimed to evaluate whether ACI improves in a clinical setting the clarity of identification of submucosal vessels, submucosal and muscle layers compared with white light imaging (WLI) in a standardized, video-based setting [1].

Methods In this prospective video-based study, third-space endoscopy clips, including endoscopic submucosal dissections (ESD) and peroral endoscopic myotomies (POEM), were analyzed. Each clip included matched WLI and ACI segments in randomized order. Six expert and six non-expert endoscopists independently rated vessel, submucosal and muscle layer clarity on a 10-point Likert scale.

Results Clips from 35 ESD and 20 POEM were analyzed. For submucosal vessels mean scores improved from 7.33 ± 0.89 to 8.55 ± 0.85 for non-experts and from 7.96 ± 0.86 to 9.63 ± 0.51 for experts (both $p < 0.001$); non-experts with ACI outperformed experts with WLI ($p < 0.01$). For submucosal layer non-experts improved from 6.37 ± 1.51 to 8.14 ± 1.29, and experts from 7.82 ± 0.87 to 9.80 ± 0.40 (both $p < 0.001$), with non-experts achieving expert WLI performance ($p = 0.2$). For muscle layer non-experts improved from 5.31 ± 1.16 to 7.12 ± 1.17, and experts from 7.75 ± 0.73 to 9.51 ± 0.57 (both $p < 0.001$).

Conclusions ACI enhances recognition of submucosal vessels, submucosal and muscle layers in ESD and POEM, benefiting both experts and non-experts, and may serve as a valuable adjunct in third-space endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Transmural gastrointestinal (GI) defects—including perforations, anastomotic leaks, and fistulae—carry significant morbidity and mortality. Salvage operations – esophagectomy, duodenal diversion, or major colorectal resection are associated with prolonged recovery and high complication rates. Modified Endoscopic vacuum therapy (mEVT) has emerged as an organ-preserving alternative that promotes granulation, drainage, and controlled defect collapse. In our centre, a modified EVT platform (mEVT) was developed to enhance adaptability, allow custom sponge/ioban configurations, and improve negative-pressure delivery in anatomically challenging locations. This study evaluates the clinical performance, safety, and organ-preserving impact of mEVT across a wide spectrum of GI defects.

Methods A retrospective analysis of a prospectively maintained database was performed for all patients treated with mEVT. The mEVT device was assembled using a fenestrated NGT wrapped with gauze and antimicrobial incise drape or sponge, secured with three-point suturing for stability and positioning. Multiple 18G perforations enhanced uniform suction.The device was placed endoscopically and connected to continuous wall suction, with incise-drape sealing and a 20F catheter used to maintain stable negative pressure. All patients underwent EGD and contrast-enhanced CT to delineate leak size, location, associated cavities, and debris burden. Data retrieved included demographics, timing of presentation, comorbidities, etiology, leak chronicity, EVT placement technique (intraluminal, intracavitary, or combined), number of sponge exchanges, adjunctive endoscopic therapy, vacuum pressure settings, and clinical outcomes. Primary outcome was clinical success, defined as complete leak resolution. Secondary outcomes included organ preservation, requirement for rescue surgery, EVT-related complications, and adjunctive therapy utilization (▶ **Table 1**).

▶ **Table 1**

Types	Etiology
Post-surgical N = 6	Whipple's leak, LAR leak, ileorectal leak, duodenal ulcer repair, post–percutaneous drainage
Endoscopic / Iatrogenic N = 5	Post-EFTR (D3), post-POEM Boerhaave-type leak, , iatrogenic transmural tear
Spontaneous / Traumatic / Idiopathic N = 7	Spontaneous Boerhaave, traumatic,foreign-body esophageal injury traumatic duodenal fistula, idiopathic TEF

Results Eighteen patients underwent mEVT (mean age 54.22 ± 20.47 years; males 94.44 %). Acute leaks accounted for 72.22 % (13/18) and chronic defects for 27.78 % (5/18). Comorbidities included DM (27.77 %), HTN (27.77 %), and IHD (22.22 %). Prior therapy had failed in five patients. Successful closure was achieved in 10/13 (76 %) acute leaks and 3/5 (60 %) chronic leaks. Organ-specific healing rates were esophageal 6/8 (75 %), duodenal 5/7 (71.4 %), and colonic 2/3 (66.7 %). Importantly, all successfully treated patients avoided major morbid surgery, preserving esophageal, duodenal, and colonic continuity. mEVT placement was intraluminal in 61.11 % (11/18), intracavitary in 16.67 % (3/18), and combined in 22.22 % (4/18). Adjunctive endoscopic therapy included necrosectomy (2/18), endoscopic suturing (1/18), OTSC (1/18), haemoclips (5/18), specialized TTSC (1/18), and bovine pericardial patch (2/18). Only one patient required rescue surgical intervention. One patient was lost to follow-up; three deaths occurred, all unrelated to mEVT.Only 50 % required sponge exchanges (mean 6.22 ± 4.99). Median hospital stay was 21.5 days. Mean vacuum pressure was 145 mmHg ± 40. No major EVT-related complications were observed.

Conclusions mEVT is a safe, effective, and strongly organ-preserving treatment for GI transmural defects. In this cohort, it achieved meaningful closure rates across esophageal, duodenal, and colonic injuries while preventing major salvage surgery in nearly all responders. The modified system's adaptability and adjunctive endoscopic options broaden its utility and justify further prospective evaluation.

eP1168 Do we need to endoscopically reassess patients with Eosinophilic Oesophagitis if they have no symptoms? A prospective real-world cohort study

Authors Kumar R[1], Mcdonald H[1], Shaw K[1], Santa E[1], Cole F[1], Baker P[1], Morris D[1]

Institute 1 East & North Hertfordshire NHS Trust, Stevenage, United Kingdom

DOI 10.1055/s-0046-1822495

Aims Symptoms correlate only modestly with endoscopic and histological activity in Eosinophilic Oesophagitis (EoE). Real-world data show that symptoms detect histological remission with only ~60 % accuracy (AUC 0.60–0.61) [1]. Persistent histological activity is potentially associated with progression to fibrostenotic disease, highlighting the importance of detecting subclinical inflammation. UK, US, and European guidelines therefore recommend reassessment after induction or treatment change to detect unrecognised persistent inflammation [2–4]. Whether all symptom-free patients require routine gastroscopy in real-world practice remains uncertain.

This study aims to determine whether clinical remission predicts histological remission in treated EoE, and whether a targeted rather than universal reassessment strategy may be appropriate.

Methods We conducted a prospective single-centre cohort study from September 2023 to November 2025. Adults with confirmed EoE underwent reassessment after ≥ 8 weeks of stable therapy (food elimination diet, proton pump inhibitor, budesonide orodispersible tablets (BOTs), or combinations). All patients completed the Dysphagia Symptom Questionnaire (DSQ) and underwent same-day capsule sponge cytology (Endosign) and gastroscopy with biopsies, as part of another study. Clinical remission was defined as DSQ = 0. Histological remission was defined as highest peak eosinophil count < 15 eos/hpf on capsule sponge or histology. Fisher's exact test, Mann–Whitney U testing, sensitivity, specificity, predictive values and Cohen's kappa were calculated.

Results A total of 66 patients underwent paired symptom and tissue assessment. Median age was 50 years (IQR 36.5–57.0); 64 % were male and 91 % were White or White British. Of the 66 patients, 29 had DSQ = 0 and 37 had DSQ ≥ 1. Histological remission occurred in 55/66 (83.3 %).

Among DSQ = 0 patients, 24/29 (82.8 %) were in histological remission and 5/29 (17.2 %) had active eosinophilia (median 20 eos/hpf, IQR 19–30). In the DSQ = 0 group, the median total EREFS score was 2 in histological remission, and 4 in those with active disease. Of the 5 DSQ = 0 patients with active eosinophilia at follow-up, 2 reported variable compliance with Jorveza, 2 had marked symptomatic improvement despite persistent inflammation, and 1 had insufficient dietary elimination.

Among DSQ ≥ 1 patients, 31/37 (83.8 %) were in histological remission and 6/37 (16.2 %) were histologically active (median 30 eos/hpf, IQR 27–37.5). In the DSQ ≥ 1 group, the median total EREFS score was 2 in both remission and active disease. Within the DSQ ≥ 1 group, DSQ scores were significantly higher in histologically active patients compared with those in histological remission (median 34.5 [IQR 18–42] vs 9 [IQR 3–14]; Mann–Whitney U p = 0.016).

Median treatment duration was 16.3 weeks (IQR 13.0–19.6) for DSQ = 0 patients and 14.9 weeks (IQR 10.4–21.9) for DSQ ≥ 1 patients.
Clinical remission did not correlate with histological remission (Fisher's exact p = 0.76; κ = –0.04). Using DSQ ≥ 1 to detect histologic activity gave a sensitivity of 55 %, specificity 44 %, PPV 16 %, and NPV 83 %.

Conclusions Despite clinical remission, 17.2 % of asymptomatic patients had persistent eosinophilic inflammation. As these are a minority of DSQ = 0 patients demonstrated active disease, these findings could support a targeted reassessment strategy, reserving gastroscopy for individuals with higher-risk features i.e. Higher EREFS at index endoscopy. The results also highlight the potential role of less invasive monitoring tools, such as capsule sponge cytology, and the need for biomarkers beyond eosinophil counts alone.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822496

Aims Flexible endoscopic septotomy (FES) is the gold standard for the endoscopic treatment of Zenker's diverticulum (ZD), although limitations of the technique remain. We report the first experience with a novel FES-based approach, termed Submucosal INjection-Guided septotomy (SING) technique [1].

Methods In this retrospective analysis of prospectively collected data, all consecutive patients with ZD referred to three Italian centers between October 2019 and August 2024 were treated by the SING technique and included. SING procedure includes a classic septotomy, a mucosal incision with a Hook-Knife along the midline of the septum, and a cricopharyngeal myotomy extending along the entire length of the diverticulum and at least 10mm into the esophageal muscular layer. During septotomy, a submucosal injection is performed on both the esophageal and diverticular sides, enhancing visualization of the muscular layer and guiding a complete myotomy. This represents the innovative aspect of the technique and an improvement over the traditional septotomy. The primary outcome was clinical success (CS), defined as a Kothari-Haber Scoring system score (KHSS) < 2 at 3 months. Secondary outcomes included technical success (TS), procedural time, and adverse events (AEs). Time to recurrence was estimated using the Kaplan–Meier method.

Results A total of 102 patients underwent the SING procedure (median age 74 years [IQR 68–81]; 69.7 % male). Median diverticulum depth was 30 mm (IQR 25–40), and median baseline KHS score was 4 (IQR 3–6). CS was achieved in 98 % (100/102) of patients, and, after a median follow-up of 370 days (IQR, 297–747), the recurrence of symptoms was 7 %. The probability of remaining recurrence-free was 93.5 % at 6 months, 92.0 % at 12 months, and 92.0 % at 24 months. TS was obtained in all cases, with a median procedural time of 30 minutes (IQR, 25–45 minutes). AEs occurred in 3 patients (2.9 %) and were all managed endoscopically. Sixty-three patients (61.8 %) underwent the conventional SING technique (C-SING), while 39 patients (38.2 %) were treated with the diverticuloscope-assisted variant (D-SING). AEs occurred more frequently in the D-SING group (7.7 % vs 0 %, p = 0.04), including the only case of perforation, which was attributed to mechanical trauma from the distal end of the diverticuloscope. Recurrence was more frequent in the D-SING group compared to the C-SING group, although this difference did not reach statistical significance (12.8 % vs 3.3 %, p = 0.06. Seventy-eight patients (76.5 %) had large diverticula (> 25 mm), while 24 patients (23.5 %) had small diverticula (< 25 mm). was similarly high (L-SING 97.4 % vs S-SING 100 %, p = 0.43). No significant differences in AEs (3.8 % vs 0 %, p = 0.62) and recurrence rates (7.9 % vs 4.2 %, p = 0.53) were observed. TS was 100 % in both groups (p = 1.00).

Conclusions SING appears to be a safe and effective technique for the endoscopic treatment of ZD, potentially offering technical advantages and improved outcomes over conventional FES.

eP1170 Impact of Endoscopy Timing, Predictors of mortality and rebleeding in Variceal bleeding

Authors Dragomir I[1, 2], Cristina P[2, 3], Rednic NV[2], Seulean E[2, 1], Mercea V[2, 1], Cavasi E[2], Cristina B[2], Munteanu L[2, 1], Mercea V[1, 2], Mocan T[2, 1], Crăciun R[1, 2], Tantau M[2, 1], Pop T[2, 1], Mosteanu O[1, 2], Buzas C[2, 1], Tefas C[1, 2], Damian D[2], Orzan RI[2, 1], Seicean A[1, 2]

DOI 10.1055/s-0046-1822497

Aims Acute variceal bleeding (AVB) is the complication of portal hypertension associated with the highest mortality. Standard endoscopic treatment consists of esophageal band ligation (EBL) for esophageal varices (EV) or GOV1 varices, and cyanoacrylate (CYA) injection for gastric varices (GOV1–2 or IGV1–2). Early rebleeding carries significant morbidity, mortality, and prolonged hospitalization. Baveno guidelines recommend early consideration of transjugular intrahepatic portosystemic shunt (TIPS) placement in patients at high risk of rebleeding, such as those with active bleeding, hepatic venous pressure gradient (HVPG) > 20 mmHg, or Child-Pugh score ≥ 8. Because HVPG is not universally available, identification of less invasive predictors of early rebleeding is required.

Methods Patients presenting with AVB between January 2021 and March 2024 were included. Demographic data, clinical parameters, type of varices, timing

of endoscopy (early intervention < 12 h; delayed intervention > 12 h), rebleeding within 5 days, 30-day mortality, and overall mortality were recorded. Patients follow-up was until the end of the study or until death.

Results A total of 91 patients were included, 86 males and 5 females, with a mean age of 59.5 ± 12.1 years. Cirrhosis accounted for 90.1 % of portal hypertension, while 9.9 % had prehepatic etiologies (portsinusoidal vascular disease or portal vein thrombosis). AVB was caused by EV in 81 cases (89 %) and by GV in 10 cases (11 %). EBL was performed in 82 patients, and CYA injection in 9. Mean systolic arterial pressure was 123.9 ± 21.1 mmHg, mean hemoglobin 8.8 ± 2.4 g/dL, mean INR 1.66 ± 0.54, and mean platelet count 134.18 ± 92.5 × 10^9/L. Early endoscopy was performed in 77 patients (84.6 %), while 14 (15.4 %) underwent endoscopy > 12 hours. Rebleeding occurred in 15 cases (16.4 %). Thirty-day mortality was 16.4 %, while overall mortality reached 31.8 %, mainly related to multiple organ dysfunction syndrome.

Rebleeding ($p < 0.01$) was associated with CYA injection and with FFP transfusion ($p < 0.05$) with statistical significance. For 30-day mortality, CYA injection, infection, low albumin, and coagulopathy were identified as significant predictors ($p < 0.001$). Altough patients undergoing delayed endoscopy showed higher mortality rates (30,7 % versus 14,5 %), the difference did not reach statistical significance. No difference was seen in rebleeding rates based on endoscopy timing.

Conclusions Rebleeding rates are higher in patients with gastric varices treated with CYA injection and in those who received FFP transfusion. Thirty-day mortality is increased in patients with gastric varices, infection, low albumin levels, or elevated INR.

DOI 10.1055/s-0046-1822498

Abstract Text

Intraprocedural bleeding in third-space endoscopy remains a major technical challenge, and no universal pre-sealing strategy has been established.

We present the first comparison of two electrosurgical settings for vessel pre-sealing: Forced Coagulation (FC) (Effect 0.3) in CO_2 and Swift Coagulation (Effect 3.0) in saline immersion.

In the high-impedance CO_2 environment, Forced Coagulation (Effect 0.3) successfully minimized spark formation, ensuring a safe pre-sealing effect. Conversely, in the low-impedance saline medium, Swift Coagulation achieved progressive tissue heating and successful coagulation.

Crucially, FC failed in saline due to the drop of impedance. These findings demonstrate that a similar pre-sealing outcome can be achieved with different modes across different settings, emphasizing the necessity of matching the electrosurgical setting to the procedural environment

eP1172 Role of Endoscopy in the Management of Complicated Forms of Hepatic Hydatid Cyst

Authors Aksim H[1], Belhamdiya M[1], Gharbi K[1], Akka R[1]

Institute **1** L'hôpital militaire Avicenne, Marrakesh, Morocco

DOI 10.1055/s-0046-1822499

Aims Rupture of a hepatic hydatid cyst (HHC) into the biliary tract is the most frequent and serious complication, leading to significant morbidity. Traditionally, management relied on surgery, but the advent of endoscopic retrograde cholangiopancreatography (ERCP) has considerably modified practices over the past decades. The objective of our study was to evaluate the contribution of ERCP in the management of complicated forms of HHC, particularly those fistulized into the biliary tract [1–3].

Methods We conducted a retrospective descriptive study within the Department of Hepato-Gastroenterology over the period from January 2021 to August 2025. Data were collected from ERCP records and concerned patients with complicated hepatic hydatid cysts.

Results A total of 85 cases of fistulized HHC were included. The mean age of patients was 38 years, with a male-to-female ratio of 1.8. Reported medical histories included prior surgery for HHC (28 %), cholecystectomy (13 %), and known uncomplicated HHC (9 %). Clinically, obstructive jaundice was the predominant symptom (81 %), followed by hepatic colic (41 %); fever > 38.2 °C was present in 59 %.

Radiological investigations (ultrasound, CT, MRI) showed dilatation of the common bile duct (CBD) in 71 % of cases and of the intrahepatic bile ducts in 48 %. Hydatid material within the CBD was found in 69 % of patients.

The main indications for ERCP were: acute cholangitis (63 %), postoperative or post-drainage biliary fistula (33 %), and acute biliary pancreatitis (4 %). Endoscopic sphincterotomy was performed in all patients (100 %).

Post-ERCP evolution showed resolution of jaundice within 5–15 days on average, and closure of biliary fistulas within 10–16 days. Complications were rare: two cases of post-ERCP pancreatitis (2.3 %) and one case of procedure-related bleeding (5.2 %). The relative risk of bleeding after sphincterotomy was significantly lower in patients without a history of HHC surgery (RR = 0.439; p = 0.01).

Conclusions ERCP is an effective and safe therapeutic modality in the management of complicated hepatic hydatid cysts. It ensures rapid resolution of jaundice and closure of fistulas, with a satisfactory safety profile (bleeding RR: 0.43). These results highlight the central role of ERCP in the therapeutic arsenal for complicated HHC, as a complement or an alternative to surgery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims According to the Revised Atlanta Classification, walled-off pancreatic necrosis (WOPN) is a late complication of acute pancreatitis, diagnosed > 4 weeks after disease onset. Up to 40 % of WOPN cases develop secondary infections, which significantly worsen clinical outcomes and increase mortality up to five-fold compared with sterile necrosis. While endoscopic drainage is the preferred treatment, data on the microbiological characteristics of infected WOPN remain limited [1].

This study aims to characterise the microbial pathogens and their antibiotic resistance patterns in patients undergoing endoscopic stent placement for suspected infected WOPN at a single tertiary care centre the aim of this study is to describe the microbiological profile in infected WOPN. Secondary objectives were to assess antimicrobial resistance patterns, evaluate the effectiveness of empiric antibiotic therapy, and document therapy modifications.

Methods Between October 2021 and October 2025, we performed 3337 endoscopic procedures, including 1705 EUS examinations. During this period, a total of 75 WOPN cases were identified, comprising 40 LAMS insertions, 11 conventional plastic stent insertions, and 24 cases of spontaneous regression. This retrospective analysis included 51 patients with WOPN who underwent EUS placement of either a plastic or a metal stent. Samples from the WOPN cavity and blood cultures were obtained and sent for microbiological evaluation. We recorded the isolated organisms, resistance profiles, and corresponding antimicrobial therapies

Results Among 51 patients, 37 had infected WOPN (72.5 %; median age 57 [42-69], 32.4 % female) and 14 had sterile WOPN (27.5 %; median age 64 [54.8-73], 57.1 % female). Polymicrobial infection was present in 35/37 infected cases (94.6 %), while the remaining two patients had monomicrobial infection. The most frequently isolated organisms included Enterococcus spp. (56.75 %), Klebsiella spp. (45.9 %), and Pseudomonas spp. (43.2 %). Fungal organisms, predominantly Candida spp., were identified in 19 patients (51.3 %).

Empiric imipenem was administered to 19 patients (51.3 %), with therapy modification required in 16 (84.2 %), including 13 modifications due to confirmed imipenem resistance (68 %). Overall, imipenem resistance was detected in 24 out of the 37 infected cases (64.8 %), and antibiotic modification was required in 19 patients (51.3 %).

Conclusions This study highlights the high rates of bacterial and fungal infections in WOPN, as well as the high prevalence of imipenem resistance, underscoring the need to recognise pathogen profiles to improve treatment protocols and strengthen antimicrobial stewardship in managing necrotising pancreatitis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims The optimal treatment of pancreatic duct strictures and stones due to chronic pancreatitis remains challenging considering the heterogeneity in etiology, morphology and patient burden. Endoscopic therapy offers a minimally invasive option. However, endoscopic therapy, especially since the introduction of pancreatoscopy, varies between centers and countries due to availability and preference. Current guidelines offer limited guidance for treatment decisions. This study aims to provide an overview of practice variation across Europe and its influence on treatment outcomes, focusing on quality of life.

Methods This multicenter prospective snapshot study was conducted in 14 hospitals from 8 European countries. Between the 1st of June 2021 and the 9th of August 2023, patients undergoing endoscopic therapy for chronic pancreatitis were included. Patients were followed for at least 2 years. Primary outcomes were type of therapy performed and clinical success, defined as partial or complete pain relief following endoscopic therapy after 2 years. Secondary outcomes were total number of interventions, quality of life and post-interventional events. The Pancreatitis Quality of Life Instrument (PANQOLI), Izbicki and 12-Item Short-Form (SF-12) were performed at baseline and after 1, 3, 6, 12, 18 and 24 months post-intervention.

Results 96 patients were included (mean age 54 years (14.7), 66 (68.8 %) men), median symptom duration of 7 months (3.0-23.0), 33 (34.4 %) patients had current opioid use, of which 14 (42.4 %) longer than 6 months and the most common etiology toxic/metabolic (N = 49, 51.6 %). The mean Izbicki score was 52.7 (SD 24.6) following 81 responses. The primary indication for intervention was pain (N = 70, 56.5 %). Overall, 102 treatments were performed, 6 patients receiving multiple modalities. Of these, 55 (53.9 %) were only classic Endoscopic Retrograde Cholangiopancreatography (ERCPs), 23 (22.5 %) extracorporeal shockwave lithotripsy (ESWL) + /- ERCP, 20 (19.6 %) ERCPs assisted with pancreatoscopic lithotripsy and 4 (3.9 %) Endoscopic ultrasound-guided access (i.e. rendezvous). A median of 3 (IQR 2.0-5.0) endoscopic interventions were performed in the two year follow-up. Clinical success following only endoscopic therapy was achieved in 56 (58.3 %) patients. After 2 years, the median Izbicki score was 18.1 (IQR 1.2-33.9) in the overall population, following 36 responses.

Endoscopy 2026; 58: S1–S1041

Nineteen patients used opioids (19.8 %). Four patients died, one caused by endoscopic complications, one due to an infected pseudocyst and two following other/unknown causes. Additional pancreatic surgery was performed in 21 (21.9 %) patients and planned in two (2.1 %). Explorative univariate logistic regressions showed no correlation of treatment related factors and patient related factors on clinical success. Additional quality of life outcomes are currently being analyzed and results are expected beginning of 2026.

Conclusions This snapshot study shows substantial treatment variation across Europe, with currently a limited role for pancreatoscopic lithotripsy. This treatment variation in combination with a clinical success rate in about 6 out of 10 cases, underlines the need for standardization of endoscopic management of chronic pancreatitis. Although several studies have shown superior outcomes of surgery, minimally invasive endotherapy should not be dismissed. Future studies should focus on optimal patient selection, further standardizing endotherapy based on morphologic traits and creating unity in European treatment standards.

DOI 10.1055/s-0046-1822502

Aims EUS-guided hepaticogastrostomy (EUS-HGS) is among the preferred rescue techniques for biliary drainage when ERCP fails or when the papilla is inaccessible due to altered anatomy or neoplastic invasion. Although the majority of published experience originates from Eastern centers, and despite its demonstrated technical feasibility and clinical effectiveness, safety concerns have limited widespread adoption of EUS-HGS in Western practice, even among expert institutions. Recently, however, growing experience with EUS-guided interventions and accumulating evidence supporting the superiority of this technically demanding approach in select clinical scenarios have highlighted the need for robust data from Western centers.

Methods We conducted a retrospective study of all consecutive patients who underwent EUS-HGS at six Italian institutions from 2017 to October 2025. Technical outcomes were technical success rate and procedure time. Clinical outcomes included the rates of clinical success—defined as a ≥ 50 % bilirubin reduction within two weeks for malignant disease or resolution of the underlying condition for benign indications—and adverse events, which were defined and graded according to the ASGE lexicon.

Results A total of 183 patients underwent attempted EUS-HGS: 142 for malignant and 41 for benign conditions. Most procedures (n = 98, 53.6 %) were performed from January 2024 onward. In 116 patients, the papilla was inaccessible due to duodenal or pyloric strictures (n = 61) or altered anatomy (n = 55). Adequate transmural stent placement was achieved in 174 cases (95.1 %), with a mean procedure time of 50.2 ± 26.3 minutes. Following bile duct puncture, a cystotome was the preferred device for tract creation. Dedicated stents were used in 110 cases. Among the 174 technically successful procedures, clinical success was achieved in 146 patients (83.9 %). Twenty-three patients (12.5 %) experienced adverse events, ranging from moderate (n = 16) to severe (n = 7) according to the modified ASGE lexicon. Cholangitis was the most common complication. One patient required surgery for biliary peritonitis, and two procedure-related deaths occurred due to post-procedural cholangitis leading to septic shock.

Conclusions EUS-HGS is increasingly adopted in tertiary centers and demonstrates high technical and clinical success rates, particularly considering that these procedures are performed in patients with limited—and often clinically ineffective—alternative options. Nevertheless, the incidence and severity of adverse events underscore the need for careful pre-procedural patient counseling and emphasize that EUS-HGS should be performed exclusively by experienced endoscopists in centers equipped to manage complications within a multidisciplinary framework.

eP1176 Breaking the size barrier: Endoscopic Submucosal Dissection of a massive flat Gastric Neuroendocrine Tumour

Authors Giunta M[1], Bravi I[1], Galtieri A[1], Maregatti M[1], Ravizza D[1], Soru P[1], Trovato C[1], De Roberto G[1]

Institute **1** European Institute of Oncology, Milan, Italy

DOI 10.1055/s-0046-1822503

Abstract Text

Type I gastric neuroendocrine tumors (gNETs) arise in chronic atrophic gastritis under hypergastrinemic stimulation, are typically indolent, with negligible metastatic potential. They present as multiple, small, mucosal (rarely submucosal) yellowish lesions with ectasic vessels. As most are small, superficial and without distant spread, the mainstay of treatment is endoscopic resection, while ENETS guidelines recommend considering surgery for lesions > 2 cm or high grade.

We report an exceptionally rare case of a type I gNET with an extremely unusual morphology—flat and involving almost the entire gastric body—successfully treated by endoscopic submucosal dissection (ESD).

A 56-year-old woman with autoimmune atrophic gastritis underwent gastroscopy. High-definition white-light and virtual chromoendoscopy revealed a subtle, completely flat (Paris 0-IIb) lesion with preserved glandular pattern but prominent, irregular "corkscrew-like" vessels, extending continuously from the proximal to the distal gastric body (≈ 100 mm).

Targeted biopsies showed low-grade gNET (Ki-67 1 %). Somatostatin receptor PET/CT with ^{68}Ga-DOTA-peptides and contrast-enhanced CT excluded metastases. Endoscopic ultrasound (EUS) demonstrated mucosal thickening without submucosal or muscularis involvement.

Given the lesion's remarkable size, the case was discussed at our multidisciplinary neuroendocrine tumor board. The absence of deeper invasion or metastasis supported an endoscopic approach, and ESD was performed. The lesion margins were carefully marked and en-bloc resection was achieved, yielding a 140 × 35 mm specimen. Histopathologic examination confirmed a well-differentiated, G1 multifocal NET with negative lateral and vertical margins and no vascular invasion. Remarkably, serial sectioning revealed more than 40 microfoci of neuroendocrine proliferation ranging from 0.5 to 5 mm.

Postoperative recovery was uneventful. Follow-up endoscopies at two and six months showed a retracted scar with no recurrence or symptoms.

To our knowledge, this is the first reported case of a giant, completely flat type I gNET successfully removed by ESD. In gNETs, lesion size correlates with lymph-

node metastatic risk, typically guiding, for lesion larger than 2 cm, surgical management. However, in this case, careful correlation of morphology, cross-sectional imaging, and EUS findings supported localization limited to the mucosal layer, justifying an endoscopic approach. Definitive histology confirmed confinement to the mucosa and absence of lymphovascular invasion
This case highlights the importance of individualized, multidisciplinary evaluation in gNETs and demonstrates that, even for unusual very large lesions, advanced endoscopic resection can achieve curative results and avoid unnecessary surgery.

eP1177 Is EUS with FNB an adequate method for the preoperative prognostic stratification of GIST?

Authors Terrin M[1], Spadaccini M[2, 1], Franchellucci G[1], Colombo M[1], Fugazza A[1], Andreozzi M[1], Fantin A[3], Lisotti A[4], Donato G[5], Renne SL[6], Bertuzzi AF[7], Cananzi FCM[8], Hassan C[1, 2], Repici A[2, 1], Carrara S[2, 1]

DOI 10.1055/s-0046-1822504

Aims The Miettinen-Lasota scoring system is the cornestone for prognostic stratification of gastrointestinal stromal tumors(GISTs), based on mitotic count and tumor size. Guidelines lack indications about the optimal sample that should be used for mitoticcount assesment, only specifying that at least 50 high-power fields (HPF) must be evaluated. It is generally believed that, due totumor heterogeneity and the limited sample size obtained, endoscopic ultrasound-guided tissue acquisition (EUS-TA) is unreliable,particularly when using traditional cytology needles. However, only few data are available regarding the use of histology (FNB) needles in this context. Nevertheless, the ability to correctly stratify patients preoperatively is a critical factor in GIST management. The primary aim of this multicenter retrospective study was to evaluate the concordance between EUS-FNB andsurgical specimens in assessing the GIST prognostic score. Secondary endpoins were the adequacy of FNB samples forimmunohistochemistry (IHC) and mutational analysis [1–4].

Methods We included all histologically confirmed GISTs from a prospective registry (NCT02855151). Concordance for mitotic count and tumor size measurements was evaluated using Bland-Altman plots, calculating bias (mean difference between FNB and surgical specimens) and limits of agreement (LoA). Agreement in prognostic score classification was calculated as a percentage.

Results Among a cohort of 68 GISTs, we included 32 cases in which complete histopathological data from both EUS-FNB and surgical specimens were available. The diagnostic concordance between EUS-FNB and surgical pathology was 100 %. IHC was successfully performed in all FNB samples (100 %). The mitotic count showed a bias of -1.19 mitoses, with LoA ranging from + 3.02 to -5.4. For tumor size, the bias was -0.96 mm, with LoA ranging from + 21.28 to -23.2 mm. Miettinen-Lasota score concordance between EUS with FNB and surgery showed 72 % agreement (23/32): in 5 cases, EUS underestimated the score, while in 4 cases, it overestimated it. Mutational analysis was performed in 62.5 % of the cases.

Conclusions EUS with new FNB needles appears to be reasonably accurate for preoperative GIST evaluation and is certainly a useful tool for diagnosis and mutational analysis. However, its concordance with surgical findings is still suboptimal in terms of prognostic evaluation. On one hand, performing multiple needle passes, together with fanning technique, could improve the representativeness of tumor heterogeneity and increase the amount of material provided to the pathologist. On the other hand, greater attention should be addressed to tumor size measurement in EUS, as this can sometimes lead to score variations. The study's limitations include its retrospective nature and the heterogeneity of mitotic count assessment. Prospective studies with dedicated protocols are warranted, along with an evaluation of the adequacy of the collected material for mitotic count on 50 HPF, as suggested by the guidelines.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1178 Performance of elementary endoscopic lesions for predicting helicobacter pylori infection

Authors Hafi S[1], Mohamed G[2], Bizid S[2], Bouali R[2], Ben Abdallah H[2]
Institutes **1** Military hospital, Tunis, Tunisia; **2** The Military Hospital of Tunis, Tunis, Tunisia
DOI 10.1055/s-0046-1822505

Aims The Kyoto classification was introduced to standardize the endoscopic description of chronic gastritis associated with Helicobacter pylori (H. pylori). The diagnostic value of elementary endoscopic lesions has not been evaluated in our setting, where the prevalence of infection is high.
The aim of our study was to assess the diagnostic performance of each elementary endoscopic lesion for predicting H. pylori status.

Methods This was a single-center, cross-sectional study conducted over a six-month period. Included patients were H. pylori–treatment naïve and had not received recent antibiotics or proton pump inhibitors. Endoscopic evaluation focused on eight elementary lesions. H. pylori status was determined by histological examination. Diagnostic performance for each lesion was assessed by sensitivity (Se), secificity (Sp), positive predictive value (PPV), and negative predictive value (NPV).

Results Among the 300 included patients, 228 (76.0 %) were H. pylori positive (mean age 40.2 ± 13.3 years; 54.4 % women). The most frequent lesions were diffuse redness (94.3 %), nodularity (50.4 %), and atrophy (46.9 %). Diagnostic performance was as follows:

- Diffuse redness: Se = 94.3 %, Sp = 8.3 %, PPV = 76.5 %, NPV = 31.6 %
- Nodularity: Se = 50.4 %, Sp = 86.1 %, PPV = 92.0 %, NPV = 35.4 %
- Atrophy: Se = 46.9 %, Sp = 43.1 %, PPV = 72.3 %, NPV = 20.4 %
- Fold hypertrophy: Se = 24.6 %, Sp = 83.3 %, PPV = 82.4 %, NPV = 25.9 %
- Adherent mucus: Se = 30.3 %, Sp = 75.0 %, PPV = 79.3 %, NPV = 25.4 %
- Spotty erythema: Se = 9.2 %, Sp = 94.4 %, PPV = 84.0 %, NPV = 24.7 %
- RAC absence/presence: Se = 32.5 %, Sp = 29.2 %, PPV = 59.2 %, NPV = 12.0 %
- Fundic gland polyp: Se = 3.1 %, Sp = 94.4 %, PPV = 63.6 %, NPV = 23.5 %

Conclusions Nodularity is the most specific lesion and the strongest predictor of H. pylori infection (PPV = 92.0 %). Conversely, the absence of diffuse redness—owing to its high sensitivity (Se = 94.3 %)—is a good indicator for ruling out infection. Fundic gland polyp is highly specific for excluding H. pylori infection (Sp = 94.4 %), but its very low prevalence (3.1 %) limits its practical value.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1179 Accuracy Of Lesion Size Estimation In Gastric Endoscopic Submucosal Dissection: A Comparison Between Community And Expert Endoscopists

Authors Pedro M[1], Costa C[1], Ferreira R[1], Teixeira P[1], Freitas T[1], Ponte A, Carlos J[1], Rolando P[1]
Institute 1 Unidade Local de Saúde de Gaia e Espinho, Vila Nova de Gaia, Portugal
DOI 10.1055/s-0046-1822506

Aims Accurate pre-procedural lesion size estimation is crucial in endoscopic submucosal dissection (ESD) to guide treatment decisions. This study aimed to compare the accuracy of lesion size estimation by community endoscopists and hospital-based expert endoscopists against the actual lesion size measured from resected ESD specimens.

Methods A total of 250 paired pre-procedural lesion size estimates were analyzed from community endoscopists and from hospital based expert endoscopists. These estimates were compared with the actual lesion size using Bland-Altman analysis, Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), and Lin's Concordance Correlation Coefficient (CCC). Regression analysis was performed to assess proportional bias and trends over time, while ANOVA tests were used to determine whether lesion classification (Paris classification) or anatomical location influenced estimation errors.

Results Hospital-based endoscopists demonstrated superior accuracy compared to community endoscopists, with a lower bias of 5.22 mm, narrower limits of agreement, and a higher concordance correlation coefficient (CCC) of 0.785. Lesions larger than 11.5 mm were associated with increased estimation errors, particularly in community endoscopist estimates, which exhibited significant proportional bias ($p < 0.001$). Among hospital-based endoscopists, neither Paris Classification nor anatomical location showed a significant association with estimation errors. However, for community endoscopists, lesions located in the greater curvature were significantly overestimated ($p = 0.019$), with an average overestimation of 8.50 mm. No significant improvement in estimation accuracy over time was observed, suggesting that error rates have remained stable despite potential advancements in training or experience.

Conclusions These findings highlight the need for standardized measurement techniques and underscore the potential benefits of enhanced training programs and adjunctive imaging technologies to improve pre-procedural lesion size assessment in endoscopic practice

eP1180 Biologic Behaviour of Carcinoma Differs Across the Colorectum: Real-World Validation in an All-Comers Observational Cohort from a Tertiary Care Center

Authors Khalaf K[1], Li H[1], Bucheeri MAGA[1], Jugnundan S[1], Nishimura T[1], Hanna Y[1], Devloo R[1], Abu Shawish W[1], Brar G[1], Gupta S[1], He T[1], Zhang L[1], Harb M[1], Fujiyoshi Y[1], Clancy J[1], Calo N[1], May G[1], Mosko J[1], Teshima C[1]
Institute 1 St. Michael's Hospital, Toronto, Canada
DOI 10.1055/s-0046-1822507

Aims Prior reports [1] suggest that distal colorectal lesions harbour carcinomas at higher rates than proximal (right-sided) lesions. Newer data [2], after adjusting for lesion size and morphology, posit that lesion location is not a significant predictor of carcinoma. As such, there is conflicting evidence on the role of lesion location in the risk of carcinoma and thus the choice of endoscopic resection technique. Thus, we sought to characterize real-world cancer behaviour by colorectal sub-site. We leveraged detailed endoscopic and histopathologic correlation to assess whether a universal ESD strategy is superior to a selective resection algorithm (SRA). To determine how the frequency, depth, and curability of carcinoma differ across anatomical regions of the colorectum (rectum, distal colon, proximal colon), and to examine associations with lesion morphology, optical classification, and histologic risk features.

Methods From July 2019-2025, all 6,449 colorectal lesions assessed endoscopically at St. Michael's Hospital, Toronto, Canada were screened. After excluding polyps less than 10mm (n = 4,871), 1,578 lesions with endoscopic features warranting resection were evaluated. Choice of endoscopic resection technique was determined using our previously presented SRA [3]. Thirty-two high-risk lesions were referred directly for surgery, leaving 1,546 endoscopic resections attempted: EMR n = 1,364; ESD n = 182.

Results Carcinoma was identified in 110 (7.1 %) of specimens, with marked variation by anatomical sub-site: carcinoma was most frequent in the rectum (33/195, 16.9 %), followed by the distal colon (32/291, 11.0 %) and proximal colon (45/1,060, 4.3 %). By Vienna classification, low-grade dysplasia (LGD) was the predominant histologic grade (48.8 %), followed by high-grade dysplasia (33.3 %), intra-mucosal carcinoma (1.2 %), and submucosal carcinoma (5.9 %). On histopathological review, lesions with carcinoma were more commonly removed with ESD than EMR (15.4 % vs 4.6 %, $p < 0.0001$). Among the carcinomas, well-differentiated histology predominated (61.8 %), though poor differentiation was more frequent in ESD vs EMR specimens (11.4 % vs 1.3 %, $p = 0.002$). LVI was observed in 36.4 % of all carcinomas and was more common in ESD vs EMR (51.4 % vs 29.3 %, $p = 0.025$). Among the carcinomas, positive deep (6.6 % vs 0.2 %, $p < 0.0001$) and lateral (4.9 % vs 0.2 %, $p < 0.0001$) margins were higher in ESD vs EMR. Curative resection for carcinoma was markedly higher with ESD vs EMR (74.3 % vs 9.3 %, $p < 0.0001$). Notably, 26.5 % of EMR lesions with submucosal invasive carcinomas fulfilled curative histologic criteria and would have been cured endoscopically had they been resected by ESD. Multivariable logistic regression confirmed anatomical location as a key determinant of carcinoma risk. Compared with the proximal colon, lesions in the rectum (OR 2.48, 95 % CI 1.24–4.97, $p = 0.01$) and distal colon (OR 2.56, 95 % CI 1.50–4.38, $p = 0.0006$) were significantly more likely to harbor carcinoma. Non-granular pseudo-depressed LSTs showed the strongest association with invasion (OR 4.94, 95 % CI 1.72–14.16, $p = 0.003$), whereas granular homogeneous LSTs were least likely to harbor carcinoma (OR 0.18, 95 % CI 0.07–0.49, $p = 0.0009$). When compared to lesions measuring 30–50 mm, those larger than 50 mm had significantly higher odds of harboring carcinoma (OR 0.50, 95 % CI 0.29–0.85; $p = 0.01$), indicating roughly a two-fold increase in carcinoma risk. Furthermore, optical prediction (JNET) of carcinoma performed significantly worse in the rectum: the odds of correctly identifying carcinoma endoscopically were 6-fold lower in rectal vs colonic lesions (OR 0.159, 95 % CI 0.084–0.304; $p < 0.0001$), consistent with lower discriminative performance in the rectum (AUC 0.67, [95 % CI 0.59-0.75] vs 0.71, [95 % CI 0.61-0.81] in the colon), supporting a higher prevalence of covert invasion in rectal lesions despite careful optical assessment by JNET (AUC 0.88, 95 % CI 0.86-0.90) of all colorectal lesions.

Conclusions Rectal lesions, while more frequently found to harbor carcinoma, exhibited a covert pattern of invasion that was less reliably detected endoscopically. This underscores the need for heightened suspicion and an aggressive approach to *en-bloc* resection in this location. Recognizing these segmental differences is essential for refining a selective resection algorithm that balances curative potential, procedural complexity, and patient safety.

Problem to solve Spray Coagulation (SprayCoag) is a noncontact thermoablative mode producing superficial tissue effects and operating on the same principles as Argon plasma coagulation (APC). Although SprayCoag has long been used for hemostasis in Surgery and dissection in ESD or POEM, its use in first-space endoscopy remains limited. A recent case series suggested that SprayCoag applied with a conventional polypectomy snare tip across different gastrointestinal locations may be a safe, economical, and less polluting alternative to APC (1). However, a major gap that should be filled is the lack of documented SprayCoag settings for first-space endoscopy [1].

Innovation We propose SprayCoag as an alternative to APC for ablating rectal angiodysplasias in chronic radiation proctitis (CrP). Accordingly, we conducted a single-blind randomized controlled trial using an *ex-vivo* porcine rectal model to identify the SprayCoag settings that most closely replicate APC-induced tissue effects. **Intervention:** Two electrosurgical units (ESU), the VIO-300D (Erbe Elektromedizin GmbH, Tübingen, Germany) and the ESG-300 (Olympus, Tokyo, Japan) were used for both APC and SprayCoag. APC was set according to recommended settings for CrP and SprayCoag was tested at 3 settings (effect/power): VIO-300D-Erbe: 2/50, 1/60 and 1/50; ESG-300-Olympus: 1/40, 2/30 and 2/40. All electrofulgurations were performed by the same endoscopist and tissue effects were blindly assessed by the same anatomopathologist. **Main outcome measure:** The tissue effects of SprayCoag.

Results Four rectums were included. For each rectum and generator, 3 APC and 3 SprayCoag electrofulgurations per setting were performed (N = 96).

VIO-300D-Erbe: APC produced mean thermal injury of 2.4mm (2.0-2.7) in diameter and 1.3mm (0.2-1.8) in depth, Volume: 2.0mm^3 (0.3-2.8). These values were similar to SprayCoag-1/50: 2.6mm (2.2-2.8) in diameter and 1.4mm (0.7-2.0) in depth, Volume: 2.3mm^3 (1.2-3.5), p = 0.272 (95 %CI -3.3-1.1), p = 0.251 (95 %CI -0.2-0.9), p = 0.525 (95 %CI -1.6-3.2), respectively. SprayCoag-2/50 and 1/60 caused significantly higher damage.

ESG-300-Olympus: APC produced injury of 2.3mm (1.8-2.6) in diameter and 1.2mm (0.3-1.7) in depth, Volume: 1.8mm^3 (0.3-2.9) similar to SprayCoag-2/30: 2.5mm (1.9-2.8) in diameter and 1.2mm (0.9-1.8) in depth, Volume: 1.9mm^3 (0.8-3.3), p = 0.217 (95 %CI -0.3-1.2), p = 0.386 (95 %CI -0.3-0.7), p = 0.417 (95 %CI -0.8-1.9), respectively. SprayCoag-1/40 showed a trend toward greater volume damage: 2.2mm^3 (0.6-4.1), p = 0.271 (95 %CI -0.6-2.1) and a more erratic effect, 3/12 (25 %) yielding no measurable injury. SprayCoag-2/40 produced significantly greater thermal damage in diameter and volume: 2.8mm (2.5-3.2), p = 0.021 (95 %CI 0.1-1.6) and 3.3mm^3 (2.0-4.7), p = 0.017 (95 %CI 0.3-3.1), respectively. No electrofulguration reached the muscle layer.

Conclusions SprayCoag 1/50 with the VIO-300D and SprayCoag 2/30 with the ESG-300 produce tissue injury comparable to APC and may therefore be suitable alternatives for the treatment of chronic radiation proctitis.

eP1182 Comparative Efficacy and Technical Performance of Submucosal Injection Solutions for Colorectal Endoscopic Mucosal Resection: A Network Meta-analysis of Randomized Trials

Authors Patel RH[1], Parikh C[2, 3], Patel PD[4], Confer B[4], Khara H[5]
Institutes **1** St. Mary Medical Center, Langhorne, United States of America; **2** Hospital of the University of Pennsylvania – Cedar Avenue, Philadelphia, United States of America; **3** Mercy Fitzgerald Hospital, Darby, United States of America; **4** Geisinger Medical Center, Danville, United States of America; **5** Geisinger Medical Center, Danville, PA, United States of America
DOI 10.1055/s-0046-1822509

Aims Submucosal injection solutions are essential for safe and effective colorectal endoscopic mucosal resection (EMR), yet comparative evidence across available agents is limited. Viscous and hypertonic solutions have been proposed to improve technical performance and resection quality. This study evaluates the comparative efficacy of submucosal injectates using a network meta-analysis (NMA) of complete resection and a structured synthesis of secondary technical and safety outcomes.

Methods Nine randomized trials were included in the study. Three colorectal EMR trials with extractable complete resection (R0/CRR) data contributed to the connected NMA network of normal saline (NS), hyaluronic acid (HA), 50 % dextrose (DEX), and indigo carmine–mixed saline (IC) (total 564 lesions). A fixed-effect contrast-based NMA was used to generate risk ratios (RRs). Secondary outcomes, including submucosal elevation durability, injection volume, procedure time, and adverse events, were synthesized from all relevant colorectal trials.

Results Primary NMA: Compared with NS, HA significantly improved complete resection (RR 1.21; 95 % CI 1.02–1.45), DEX showed comparable efficacy (RR 1.26; 95 % CI 0.97–1.65), and IC showed no advantage over NS (RR 0.96; 95 % CI 0.89–1.05). Treatment ranking favored HA ≈ DEX > NS > IC.
Secondary Outcomes: Direct comparative evidence demonstrated that both hydroxyethyl starch (HES) and 50 % dextrose substantially prolonged submucosal elevation and reduced reinjection volume versus NS. HES also modestly shortened procedure time and reduced EMR-related bleeding in large laterally spreading tumors. HA-based solutions exhibited a bleeding risk comparable to NS, whereas indigo-carmine saline and 0.13 % HA did not significantly influence bleeding or procedural safety. In a separate comparison unconnected to the saline-based network, Eleview required significantly less injectable volume and improved Sydney Resection Quotient compared with hetastarch, without clear adverse event differences. Across all colorectal trials, perforation was rare, and no injectate demonstrated a consistent safety liability.

Conclusions In this colorectal EMR NMA, hyaluronic acid was the only agent that showed a statistically significant improvement in complete/curative resection compared to normal saline. Dextrose 50 % showed a similar effect but with less precision. Secondary comparative analyses indicate that HES, dextrose, and Eleview each enhance technical performance by improving cushion durability or lowering injection volume, whereas bleeding and perforation rates remain low across agents. These results show that viscous and hypertonic solutions, especially HA and DEX, are good injectants for clinical use. HES and Eleview also have some technical advantages in certain situations. Additional well-designed randomized controlled trials are required to standardize efficacy and safety assessments across all injectable categories.

eP1183 Significant proportion of young patients under the age of 50 years found to have premalignant and advanced colorectal polyps – Critical Juncture

Authors Rameshshanker R[1, 2], Badat S[3]
Institutes **1** The Hillingdon Hospital NHS Foundation Trust , London, United Kingdom; **2** The Brunel Medical School, London, United Kingdom; **3** The Hillingdon Hospitals NHS FoundationTrust, London, United Kingdom
DOI 10.1055/s-0046-1822510

Aims To evaluate the adenoma detection rate (ADR) in patients under 50 years of age undergoing colonoscopy and to characterize the features of adenomas/polyps in this population.

Methods A retrospective analysis was conducted of colonoscopy procedures performed between 2022-2023 in patients under 50 years of age at a district general hospital in the UK. Data collected included patient demographics, procedure indications, colonoscopy findings, and histopathological results. Adenoma and polyp characteristics including location, histological type, and grade of dysplasia were recorded and analyzed (▶ **Table 1**).

▶ **Table 1** Adenoma Characteristics (n = 35)

Characteristics	n	%
Location *		
Caecum + ascending colon	13	37.1
Transverse colon	13	37.1
Descending + sigmoid colon	16	45.7
Rectum	9	25.7
Size		
< 5mm	16	45.7
6-9mm	10	28.6
≥ 10mm	11	31.4
Size range (mm)	2-30	-
Histological subtype		
Tubular	29	85.7
Tubular villous	5	14.3
Dysplasia grade		
Low-grade dysplasia	31	88.6
High-grade dysplasia	3	8.6
Adenocarcinoma	1	2.9
Advanced adenomas†	9	25.7

Results A total of 3800 colonoscopies were carried out during this time. 234 colonoscopies performed in patients under 50 years of age. Patients with inflammatory bowel disease and polyposis syndrome were excluded.

Overall adenoma detection rate was 14.96 % (35/234). The mean age of patients with adenomas was 38.12 years (range 33-49) with a 22:13 M: F of 1.7:1. One patient was found to have an adenocarcinoma.

Common indications for colonoscopy included: rectal bleeding (15/35, 42.9 %), altered bowel habits (13/35, 37.1 %), abdominal pain (9/35, 25.7 %), and anaemia (7/35, 20 %).

Overall serrated polyp detection rate was 4.27 % (10/234).

ADR plus (defined as the proportion of patients with at least one adenoma or serrated polyp) was 18.4 % (43/234).

Advanced adenomas were found in 25.7 % (9/35).

Conclusions This study demonstrates a significant ADR of 15 % in patients under 50 years of age undergoing colonoscopy. Adenomas were relatively evenly distributed throughout the colon, with slight left-sided predominance (45.7 %). The presence of high-grade dysplasia in 8.6 % of cases and one adenocarcinoma highlights the clinical significance of evaluating significant symptoms in younger patients. These findings support the value of colonoscopy in symptomatic patients under 50 and contribute to evidence informing screening strategies for younger populations.

eP1184 Development Of A Vision-based Large Language Model For An Automated Ambient Endoscopic Report Scribe: A Scalable Approach With Clinical Potential

Authors Wang Y[1], Kumbhari V[1], Huang Y[1], Wallace M[1]
Institute **1** Mayo Clinic, Jacksonville, United States of America
DOI 10.1055/s-0046-1822511

Aims Endoscopic reporting has traditionally required physicians to manually document findings, procedural maneuvers, and recommendations—a time-consuming task that contributes to physician burnout. Recent advances in ambient clinical documentation have reduced this burden, enabling greater focus on high-value, skill-based activities. Emerging large language models (LLMs) with vision-language capabilities offer the potential to further streamline workflows and enhance diagnostic accuracy through automated image interpretation. This study evaluated the performance of a state-of-the-art vision-language LLM for endoscopic image classification and report generation.

Methods We fine-tuned Google's MedGemma-4B LLM using the HyperKvasir dataset, comprising 9,808 labeled GI endoscopic images across 23 categories representing both anatomical landmarks and pathological findings from upper and lower GI examinations. Images were randomly divided into training/validation (80 %; 7,686/854) and testing (20 %; 2,122) sets. The model underwent supervised fine-tuning, and performance metrics were assessed before and after training.

Results Fine-tuning yielded large performance gains across the full test set (Figure 1). On all samples, overall accuracy increased from 0.13 at baseline to 0.86 after fine-tuning, with macro-averaged F1 rising from 0.07 to 0.54; discrimination approached ceiling performance with area under the receiver operating characteristic curve (AUROC) improving from 0.96 to 0.99. For labels with ≥ 100 training images, performance was uniformly strong, with both accuracy and macro-F1 near 0.97 and AUROC ≈ 0.996. In contrast, classes with < 100 training images showed greater variability (Figure 2). Visually dis-

tinctive but infrequent findings, such as impacted stool and ulcerative colitis with Mayo endoscopic score 3, remained accurately classified despite limited sample size.

Conclusions Supervised fine-tuning of LLM substantially enhanced endoscopic image classification, achieving near-ceiling discrimination for well-represented classes, with variable performance for underrepresented labels. These results support immediate utility for focused tasks such as Boston Bowel Preparation Scale grade assignment, anatomic landmark recognition, and polyp identification, with anticipated gains with additional training data. Future work should incorporate unstructured textual inputs and free-text label prediction to better mirror clinical documentation. The framework's scalability, adaptability to heterogeneous inputs, and flexibility in outputs position it for clinically relevant applications (e.g., automated endoscopy reporting) and for academic use in large-scale curation of image repositories. Extension to multimodal data streams may enable predictive analytics (e.g., pathology forecasting), offering a promising avenue for translational research.

eP1185 A human factors-based analysis of reported patient safety incidents involving significant harm in endoscopy care in England and Wales to inform the generation of team-based in-situ simulations

Authors Little S[1, 2], Tawn J[1], El-Sawy D[1], Saghir A[1], Debasish D[1, 2], Kadri S[3], Andrew C[1, 2], Peerally MF[1, 2], O'reilly M[1]

Institutes **1** University of Leicester, Leicester, United Kingdom; **2** Kettering General Hospital, Northampton, United Kingdom; **3** Leicester Royal Infirmary, Leicester, United Kingdom

DOI 10.1055/s-0046-1822512

Aims Gastrointestinal (GI) endoscopy is widely regarded as safe, yet patient safety incidents (PSIs) do occur, with scarce information on contributory factors (CF). [1] This study aims to systematically identify contributory factors (CFs) across the endoscopy pathway using narrative reports from the National Reporting and Learning System (NRLS) in England and Wales, mapped to the Systems Engineering Initiative for Patient Safety (SEIPS) 2.0 human factors framework. By capturing latent risks across its various domains, we seek a system-wide understanding of where, in the endoscopy journey, significant patient harm occurs and why. We also seek to translate these insights into team-based simulations, delivered in-situ, designed to reflect real-world risks.

Methods We retrospectively analysed relevant PSI narrative reports submitted to the NRLS between 2017 and 2022, focusing on significant incidents, resulting in moderate or severe harm or death. Incidents were characterised by procedure type, urgency, and stage of patient care. Using a mixed inductive and deductive approach we identified CFs, based on the SEIPS 2.0 domains using established content analysis principles. [2] High-yield in situ simulation scenarios were developed by translating key descriptors and CFs into realistic, contextually grounded scenarios. These scenarios reflected system vulnerabilities and provided a foundation for exploring team communication and adaptive decision-making in complex, real-world settings.

Results Analysis of 1,442 PSI reports revealed that incidents most commonly occurred during oesophago-gastro-duodenoscopies (31.2 %), colonoscopies (29.4 %), and Endoscopic Retrograde Cholangio-Pancreatography (16.4 %). Elective procedures accounted for 44.8 %, with emergencies comprising 17.0 %. PSIs were most frequently reported peri-endoscopically (44.5 %), followed by pre- (28.3 %) and post-endoscopy (27.3 %) phases.

Content analysis of 1,057 reports identified 1,484 CFs. The Person domain predominated (52.0 %), with communication failures (50.6 %) and gaps in knowledge, competence, or skills (33.7 %) most commonly reported. Organisational factors (18.7 %) reflected resource availability, staffing, and workflow challenges, while Task factors (17.5 %) related to procedural complexity and patient-specific considerations. Tools and Technology (7.3 %) and External factors (3.7 %, mainly COVID-19–related) were less frequently reported CFs

These findings were translated to create team-based in-situ simulation scenarios addressing real-world vulnerabilities (such as management of complex patients with comorbidities and anticoagulation, navigating incomplete or conflicting documentation, responding to peri-procedural complications such as perforation, withdrawal of consent). Each scenario was explicitly mapped to CFs identified from the analysis and are currently being used as a basis to study endoscopy team communication and adaptive capacity in participating centres.

Conclusions This content analysis of at least moderate harm incident reports in GI endoscopy highlights that PSIs arise from complex interactions across the entire work system, with Person and Organization domains most frequently reported. Communication failures accounted for over half of person-related CFs, often occurring across teams, with patients, or via incomplete documentation. This highlights a mismatch between current endeavours to improve safety in endoscopy care—typically focused on improving individual technical performance—and where harm actually originates. Latent system vulnerabilities amplify seemingly minor errors into significant adverse events, including delayed diagnosis, missed pathology, or lost surveillance.

Addressing these risks requires a reconceptualization of safety that extends beyond the procedure room to encompass the entire multidisciplinary team. To address some of those challenges, we have developed and delivered multi-centre, in-situ team-based simulations based on those real-life risks. These simulations are now being used to study team communication and adaptive capacity, offering an evidence-informed, proactive approach to improving patient safety and fostering resilient endoscopy systems.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1186 Development of a Simulated Soft-Gel Upper Gastrointestinal Endoscopy Training Device and Matching Lesion Training Modules

Authors Zhang J[1], Ren B[1], Liu B[1]

Institute **1** The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

DOI 10.1055/s-0046-1822513

Aims To address the limitations of current gastrointestinal endoscopy training systems—such as abstract modeling, low anatomical fidelity, and lack of support from adjacent organs—this study aimed to develop a high-fidelity upper gastrointestinal endoscopy training platform based on real imaging data, along with replaceable lesion training modules.

Methods Three-dimensional reconstruction and optimized design were performed using patient CT images, preserving the upper gastrointestinal tract, adjacent organs, and bony structures. The outer shell and positioning framework were fabricated via 3D printing using TPU material, followed by rubber casting and overall assembly to form a complete human simulation model with a fixation system. According to training requirements, matching lesion modules for foreign body removal, polypectomy, and ESD were developed, enabling modular quick replacement and scenario expansion.

Results A simulated upper gastrointestinal endoscopy trainer was constructed that covers the pharynx, esophagus, stomach, duodenum, and pancreatobiliary system, integrating adjacent structures such as the liver, spleen, pancreas, diaphragm, and spine, together with a stable fixation system. Multiple compatible lesion training modules were successfully developed to meet training needs ranging from basic to advanced procedures.

Conclusions This trainer achieves high-fidelity design based on realistic anatomical structures, significantly enhancing the spatial perception and tactile

feedback of endoscopic operations. It provides a reproducible and expandable solution for endoscopy education and skill training.

eP1187 Short-term PEG (stPEG) mortality risk stratification using machine learning

Authors Haller F[1, 2], Zottl J[1, 2], Jetzinger K[2], Perný V[1], Oschmautz AH[1], Schwientek A[1], Ortner M[1, 2], Koutny F[1, 2, 3], Maieron A[1, 2, 3], Prosenz J[1, 2, 3]

Institutes **1** Karl Landsteiner University of Health Sciences, Krems, Austria; **2** University Hospital St. Pölten, Department of Internal Medicine 2 Gastroenterology & Hepatology, St. Pölten, Austria; **3** Paracelsus Medical University, Medical Science Research Program, Salzburg, Austria

DOI 10.1055/s-0046-1822514

Aims Patients receiving endoscopic percutaneous endoscopic gastrostomy (PEG) are usually at elevated risk of short-term mortality due to concurrent morbidity. Risk stratification algorithms to identify patients with no or elevated risk might assist appropriate patient selection. The aim of this study was to develop a machine learning-based risk stratification model for short-term (< 30 days) mortality prediction.

Methods All PEG implantations between January 2017 and December 2023 were retrospectively included. Exclusion criteria comprised age below 18 years, multiple PEG procedures (≥ 2), follow-up shorter than 30 days and PEG indications due to dementia or palliative treatment. Spearman correlation with Bonferroni multiple comparison correction was used to identify feature variables. A time-based split (4:1) was applied to define the training (80 %) and validation cohort (20 %). After feature engineering, imputation of missing variables using K-nearest neighbour method and compensation of class imbalance with SMOTE, a logistic regression-based machine learning model was trained using the training cohort. Monte Carlo cross-validation-based (100-fold stratified random splitting with a 25 % validation proportion) threshold selection was used to pre-define a rule out threshold achieving a sensitivity > 80 % while maximizing the true negative classifications within the training data. This rule-out threshold was then applied to the validation data. Performance metrices were calculated and an internal validation was conducted using bootstrap analysis (n = 2000). To assess for differences between the training and validation cohort a Mann–Whitney U test was used for continuous non-parametric variables and a Fisher's exact test for categorical variables. Python alongside different packages (e.g. NumPy, pandas, SciPy, scikit-learn) with the support of Chat GPT-5 was used to develop the algorithm and to perform the statistical analysis.

Results A total of 689 PEG implantations met the inclusion criteria. Median age of patients was 68 (IQR 60-78) years, 39 % were female. The most common PEG indication was a cancer (n = 314), either due to dysphagia or prophylactic (oncological), followed by stroke/cerebral haemorrhage (n = 242) and neurological disease (n = 133). Approximately 7.7 % of patients died within 30 days after PEG placement. Spearman correlation analysis demonstrated a significand correlation between 30-day mortality and C-reactive protein (r = 0.21), Charlson Comorbidity Index (r = 0.163), prothrombin time (r = -0.16), age (r = 0.12), leucocyte count (r = 0.12) and haemoglobin (r = -0.12). ASA score was also associated with short-term mortality (30-day mortality: ASA1 = 0 %; ASA2 = 3.1 %; ASA3 = 8.2 %; ASA4 = 8.9 %). To identify patients with no or elevated risk a machine learning based approach was developed. No differences between the training (n = 551) and validation cohort (n = 138) were found. A logistic regression-based machine learning model was trained utilizing the features identified and listed above. To reduce overfitting, as indicated by learning curves, leucocytes were excluded from the final model. Evaluation of the model demonstrated good discrimination with an area under the receiver operating characteristic curve of 0.81 (95 %CI 0.70-0.92). SHAP analysis indicated that PEG indication had only minimal predictive value (mean absolute SHAP < 0.01). Utilizing the pre-calculated rule-out threshold in the validation cohort, patients without short-term mortality could be identified with a negative predictive value and sensitivity of 100 % (true negative = 91; false negative = 0; true positive = 6; false positive = 41). Given the low prevalence of short-term mortality, a reliable rule-in threshold could not be defined. Thus, the rule out threshold was used to stratify into rule out (mortality = 0 %) and elevated-risk groups (mortality = 14.6 %).

Conclusions This logistic regression-based machine learning model enables stratification of patients receiving PEG implantations. Patients classified as rule out have no mortality risk. Future research should focus on external and possibly prospective validation and further refining the model for better stratification of high-risk patients.

DOI 10.1055/s-0046-1822515

Aims In patients with cirrhosis, gastroesophageal varices (EV) due to clinically significant portal hypertension (CSPH) are associated with an increased risk of liver decompensation. Non-invasive tests (NITs) are increasingly used in clinical practice for assessing the risk for CSPH with EV, but chronic hepatitis Delta (CHD) specific studies are missing. We investigated the performances of NITs-based criteria to predict EV in CHD patients (▶ **Table 1**).

▶ **Table 1**

Criteria	Specificity	Positive Predictive Value	Sensitivity	Negative Predictive Value
LSM or PLT	24.0 %	31.6 %	**95.7 %**	**93.8 %**
SSM	47.3 %	37.0 %	**89.5 %**	**92.9 %**
LSM > 18.7 kPa	**68.1 %**	**40.9 %**	60.2 %	82.4 %

Methods Untreated patients with HDV-related compensated cirrhosis and available liver stiffness measurement (LSM) and esophagogastroduodenoscopy (EGD) enrolled in the multicenter SAVE-D and D-SHIELD studies were included. In a subgroup of patients, spleen stiffness measurement (SSM) was also available. EGD and transient elastography (TE) were performed prior to Bulevirtide (BLV) start. Baveno VI/VII and AASLD criteria were applied to identify patients in which screening endoscopy could have been avoided (LSM < 20 kPa + platelets [PLT] count > 150x10^9/L). Regarding SSM, the Baveno VII criteria of SSM ≤ 40 kPa was implemented to identify patients who could have been spared of screening endoscopy. NITs' performances were assessed calculating for each criteria Sensibility (Sn), Specificity (Sp), Positive Predictive Value (PPV), Negative Predictive Value (NPV), and accuracy. The diagnostic performance of the continuous LSM variable was evaluated using Receiver Operating Characteristic (ROC) curve analysis [1, 2].

Results 347 patients were included in this analysis (median age 54, 56 % males): 93 (27 %) showed high risk varices (HRV). Avoiding screening endoscopy in patients with LSM < 20 and PLT > 150 x10^9/L resulted in 4 (9 %) missed high risk varices (HRV) (Sensitivity [Sn] 95.7 %, Negative Predictive Value [NPV] 93.8 %). In patients with available SSM, the rate of missed HRV dropped to 7 %, while Sn was reduced 89.5 % and NPV to 92.9 %. ROC analysis to identify patients harboring varices retrieved an optimal LSM cut-off of 18.7 kPa, with an AUROC of 0.620 (0.550-0.690), Sn of 60.2 % and a false positive rate (1 – Sp) of 0.319, corresponding to a Sp of approximately 68.1 %. The corresponding PPV was 40.8 %.

Conclusions In patients with untreated HDV-related cirrhosis, applying the Baveno VII criteria to identify patients who could avoid screening EGD reports a rate of missed HRV higher than the acceptable threshold. Avoiding screening endoscopy based on NITs in CHD patients could lead to misclassify patients who have HRV and are at higher risk of decompensating events.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1189 Acetic Acid-Enhanced Linked Color Imaging May Improve the Color-Based Visibility of Barrett's Neoplasia

Authors Kim DG[1], Latorre G[1], Bechara R[1]
Institute 1 Queen's University, Division of Gastroenterology, Kingston Health Sciences Centre, Kingston, Canada
DOI 10.1055/s-0046-1822516

Aims Acetic acid chromoendoscopy and linked color imaging demonstrate significant clinical utility in enhancing the visibility of Barrett's neoplasia during endoscopy. However, there are limited data examining the incremental benefit of utilizing these imaging modalities in combination. The aim of this study is to assess the effect of acetic acid-enhanced linked color imaging (AA-LCI) on enhancing Barrett's neoplasia visibility, compared with acetic acid chromoendoscopy alone [1–5].

Methods We retrospectively examined paired endoscopic images of 17 lesions from 17 consecutive patients with Barrett's neoplasia who underwent endoscopic submucosal dissection between April 2023 and March 2025 at a single Canadian tertiary referral centre. Images of each lesion were captured under acetic acid chromoendoscopy and AA-LCI during index endoscopy. Within these images, neoplastic and non-neoplastic Barrett's mucosa were identified and demarcated by an expert endoscopist, and ten 50-by-50-pixel regions of interest were randomly selected from each of the demarcated mucosal zones using image analysis software (ImageJ, NIH, Bethesda, MD, USA). We then quantified the mean color contrast (ΔE^*) between the neoplastic and non-neoplastic regions of interest for each lesion, using the Commission Internationale de l'Eclairage (CIE) lab color system. We also performed exploratory analyses of the geometric and textural contrast between the lesion and adjacent non-neoplastic mucosa using the Sobel operator and grey-level co-occurrence matrix, respectively. Paired differences in color, geometric, and textural contrast between acetic acid chromoendoscopy and AA-LCI were analysed using a Wilcoxon signed-rank test.

Results Overall, 680 regions of interest were analysed across 17 neoplastic lesions with paired acetic acid chromoendoscopy and AA-LCI images (340 neoplastic and 340 adjacent non-neoplastic). Quantitative image analysis demonstrated that AA-LCI produced a moderate increase in the lesion-to-background color contrast when compared to acetic acid chromoendoscopy alone (median paired difference 2.8 ΔE^*; $Z = 2.34$, $p = 0.017$, $r = 0.57$). Differences in geometric contrast did not favor either modality (median paired difference −0.68 units; $Z = 0.78$, $p = 0.459$, $r = 0.19$), and textural contrast similarly showed no significant advantage for AA-LCI (median paired difference − 1.33 units; $Z = 0.59$, $p = 0.579$, $r = 0.14$).

Conclusions In this single-centre review of Barrett's neoplasia treated with ESD, AA-LCI was associated with a moderate increase in color contrast between neoplastic lesions and adjacent non-neoplastic Barrett's mucosa when compared to acetic acid chromoendoscopy alone. We did not observe significant differences in geometric or textural metrics between modalities, suggesting that the potential benefit of AA-LCI in this context may be driven principally by color contrast rather than by changes in edge or texture features. These findings support AA-LCI as a useful adjunct for enhancing color-based delineation of Barrett's neoplasia. However, this study was limited by its small sample size and the absence of endoscopist visibility scores, diagnostic performance measures, or clinical outcome data. Larger studies are needed to further evaluate whether AA-LCI meaningfully improves the optical detection of Barrett's neoplasia.

Conflicts of Interest Dr. Robert Bechara is a consultant for Olympus and Vantage Endoscopy.

eP1190 Predictive factors for pressure ulcer resolution after esophageal variceal ligation in cirrhotic patients

Authors Chafif O[1], Cherkaoui Malki M[2], S.saoud S[2], Mechhor S[2], Mghyly F[2], Cherkaoui Malki O[2], Nadia B[3], Errabih I[3], El Bacha H[3]
Institutes **1** CHU IBN SINA RABAT, RABAT, Morocco; **2** CHU Ibn Sina, Rabat, Morocco; **3** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco
DOI 10.1055/s-0046-1822517

Aims Hemorrhage from sloughing of the esophageal slough, which has a severe prognosis, is a rare complication of esophageal variceal ligation (EVL) in cirrhotic patients. The aim of this study was to identify risk factors for hemorrhage associated with this complication at the time of EVL.

Methods This retrospective study included patients with cirrhotic portal hypertension who underwent esophageal ligation between April 2021 and October 2025. A retrospective analysis of these patients was performed, followed by a case-control study comparing patients who experienced a first bleeding episode due to sloughing of the esophageal ulcer during their first esophageal ligation (EVL) session (13 cases) with 120 cirrhotic patients (controls) treated during the same period during their first EVL. Univariate and multivariate analyses were conducted to determine predictive factors for bleeding from sloughing of the esophageal ulcer after EVL. The procedure was performed under propofol-induced general anesthesia. Eleven patients experienced a bleeding episode following EVL. Post-EVL sloughing of the esophageal ulcer was confirmed in all cases endoscopically by the presence of active bleeding at one or more sites of post-EVL esophageal ulceration .

Results Bedsore sloughing occurred in 13 patients with a mean age of 54 years [34; 75], with a
M/F sex ratio of 1.5.
All of the patients were admitted through the emergency department for gastrointestinal bleeding.
Cirrhosis was non-B/non-C in 8 patients (61.5 %), of viral origin (Hepatitis B) in 3 patients (23 %), of alcoholic origin in 1 patient (7.6 %), and of dysmetabolic origin in 1 patient (7.6 %).
Seven patients (53.8 %) had child-onset C , 4 patients (30.7 %) had child-onset B, and 2 patients (15.3 %) had child -onset A.
Hemorrhage from sloughing of eschar occurred within an average of 6 days, inducing hemodynamic instability in 2 patients (15.3 %) requiring transfusion. This complication induced severe bleeding in all patients and was significantly associated in the case-control study with the presence of gastroesophageal reflux ($p < 0.001$), a history of gastrointestinal bleeding ($p = 0.02$), a low prothrombin level ($p = 0.01$), a high Child- Pugh score ($p = 0.02$), and elevated C-reactive protein. protein ($p = 0.04$) and units of fresh plasma transfused ($p = 0.03$). Two patients (15.3 %) died following this complication. In multivariate analysis, a history of gastrointestinal bleeding (OR: 1.2), the presence of gastroesophageal reflux (OR: 4.5), an APRI score greater than 3.3 (OR: 1.54), and a prothrombin level less than 46 % (OR: 0.54) were independent predictors of post-LVO eschar sloughing bleeding.

Conclusions In conclusion, hemorrhage from sloughing of post-LVO eschar in cirrhotic patients is a severe complication with independent risk factors including a history of gastrointestinal bleeding, gastroesophageal reflux , a high APRI score and a low prothrombin level.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1191 Long-term outcomes of endoscopic treatment for zenker's diverticulum in patients with prior failure treatments: a retrospective analysis in a high-volume western center

Authors Alfarone L[1], De Deo D[1, 2], Minini F[2, 1], Capogreco A[1], Massimi D[1], de Sire R[3, 1], Spadaccini M[1, 2], Maselli R[4, 2], Hassan C[1, 2], Repici A[2, 1]

DOI 10.1055/s-0046-1822518

Aims Endoscopic treatment is an established treatment of Zenker's diverticulum. However, evidence on endoscopic retreatment of ZD after prior treatment failure is limited. We aimed to compare long-term outcomes of endoscopic treatment of ZD in patients with and without previous endoscopic or surgical treatments.

Methods This is a retrospective analysis of a prospectively maintained cohort of patients who underwent endoscopic treatment for ZD at a single high-volume center between March 2019 and March 2025. Patients who had completed at least 6 months of follow-up were included. Baseline data included demographics, symptom duration, and septum size. Procedural data included type of treatment (flexible endoscopic septotomy (FES) vs peroral endoscopic septotomy (POES), sedation, procedural time, adverse events and length of hospitalization. The primary outcome was clinical failure (defined as Kothari-Haber Dysphagia Score ≥ 2) during overall follow-up. The effect of previous treatment on clinical failure was estimated using inverse-probability-of-treatment weighting (IPTW) with a Cox model, accounting for relevant influencing factors. A sensitivity analysis used 1:1 propensity-score matching (PSM) followed by Cox regression was performed.

Results 250 patients underwent endoscopic treatment for ZD during the study period. 224 patients (median age 74 years; 70.5 % male; median ASA score 2; median septum 20 mm; median symptom duration 12 months) with at least 6 months of follow-up were included in the analysis. 50 patients (22.3 %) had undergone previous treatment. No difference between the two groups in terms of baseline characteristics and procedural data (median procedural time 20 min; adverse events 3.1 %) were reported. Over a median follow-up of 36 months, clinical failure was comparable in the two groups (10.4 % naïve vs 14.0 % previous; $p = 0.53$). A conventional multivariable Cox model stratified by technique (FES vs POES) found prior failure treatment did not significantly predict clinical failure (HR 1.06; 95 %CI 0.46–2.42; $p = 0.887$). In the IPTW–Cox analysis, previous treatment was not associated with clinical failure (HR 1.34; 95 %CI 0.56–3.22; $p = 0.508$), with good post-weighting balance across covariates. The PSM–Cox sensitivity analysis yielded concordant results (HR 1.35; 95 %CI 0.61–2.97; $p = 0.46$). Among previously treated patients, a subgroup analysis by prior modality (endoscopic vs surgical) showed no association with clinical failure (endoscopic: HR 0.78, 95 % CI 0.28–2.23, $p = 0.65$; surgical: HR 1.63, 95 % CI 0.63–4.22, $p = 0.31$).

Conclusions Endoscopic treatment for ZD after prior intervention failure remains feasible, safe, and effective, achieving clinical results comparable to treatment-naïve patients even in the long-term. These findings support offering endoscopic treatment as the first-line therapy for ZD irrespective of previous failure history.

eP1192 Hepatic Decompensation After ERCP in Cirrhotic Patients: A Retrospective Cohort Study from a Tertiary Eastern European Center

Authors Haja M[1], Tefas C[2, 1]
Institutes 1 Iuliu Haţieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; 2 Institutul Regional de Gastroenterologie şi Hepatologie Prof. Dr. Octavian Fodor, Cluj-Napoca, Romania
DOI 10.1055/s-0046-1822519

Aims To evaluate the frequency, type, and predictors of hepatic decompensation following endoscopic retrograde cholangiopancreatography (ERCP) in patients with liver cirrhosis, and to assess the impact of baseline clinical and biochemical parameters on post-procedural outcomes.

Methods We retrospectively analyzed 67 cirrhotic patients who underwent ERCP between January 2021 and December 2023 at a tertiary referral center. Child–Pugh and MELD-Na scores were recorded pre- and post-procedure. Variables analyzed included demographics, etiology of cirrhosis, indication and type of ERCP intervention, and post-procedural complications such as ascites, hepatic encephalopathy (HE), variceal bleeding, jaundice, and hepatorenal syndrome (HRS). Statistical analysis included Wilcoxon, Chi-square, ANOVA, and univariate logistic regression tests.

Results The study cohort included 49 men (73 %) and 18 women (27 %), mean age 65 ± 10.9 years. The predominant etiology was alcoholic cirrhosis (61 %). ERCP indications were choledocholithiasis (60 %), malignant biliary stricture (28 %), benign biliary stricture (8 %), and pancreatic disease (4 %). Post-procedural deterioration in hepatic function was significant (Child–Pugh $p = 0.008$; MELD-Na $p = 0.006$). Hepatic decompensation occurred in 25 % of patients, most commonly ascites and HE. Logistic regression identified post-ERCP Child–Pugh (OR 2.35; $p < 0.001$) and MELD-Na (OR 1.19; $p = 0.001$) as independent predictors of complications.

Conclusions ERCP in cirrhotic patients carries a substantial risk of post-procedural hepatic decompensation, particularly in advanced disease stages. Careful patient selection, pre-procedural optimization, and close post-procedural monitoring are essential to mitigate risk and improve outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1193 Explaining outcome variability in endoscopic treatment of post–liver transplant biliary leaks

Authors Stefani Donati D[1], Gambaccini D[1], Natali V[1], Venturini A[1], Tapete G[1], Bolognesi V[1], Pancetti A[1], Visaggi P[1], Marciano E[1]
Institute 1 Digestive Endoscopy Unit, Azienda Ospedaliera Universitaria Pisana, Ospedale Nuovo Santa Chiara, Pisa, Italy
DOI 10.1055/s-0046-1822520

Aims Endoscopic therapy is first-line for biliary leaks after liver transplantation (LT), yet contemporary series report success from ~55 % to > 90 %. We assessed which technical/anatomical factors explain this variability.

Methods We searched PubMed/Embase (Jan 2015–Oct 2025) for peer-reviewed studies on endoscopic treatment of post-LT (or post-hepatic surgery including LT) bile leaks with extractable patient-level outcomes or multivariable analyses. Three studies met criteria (Oh 2015; Sendino 2018; Obata 2025). Management was classified as bridging (stent or nasobiliary tube beyond the leak) vs non-bridging/pressure-reduction only. Additional 2025 LT series/review were screened qualitatively but not pooled (no per-technique denominators).

Results Across the three pooled studies, endoscopic closure was 190/244 (77.9 %). Bridging drainage was the strongest, most consistent predictor: in a two-centre LT series, success was 44/47 (93.6 %) with stent vs 19/33 (57.6 %) with sphincterotomy alone (OR 8.36; $p = 0.007$); a large postoperative cohort likewise found bridging stent independently associated with closure (OR 12.2; $p < 0.001$). Anatomical complexity reduced success: an LT cohort showed leak-only 17/22 (77.3 %) vs leak + anastomotic stricture 10/20 (50.0 %). Recent 2025 series confirmed high success (> 85 %) for stent and ENBD when the leak could be crossed, supporting the bridging effect [1–10].

Conclusions Bridging the leak is the decisive driver of success in post-LT bile leaks: ≈ 84 % when the drainage crosses the defect vs ≈ 55 % when it does not. The variability seen between studies is largely explained by three elements—bridging, absence of an anastomotic stricture, and technical success at the index ERCP. Future reports should mandate "bridged vs not bridged" to make outcomes comparable and actionable.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1194 Endoscopic ultrasound- guided gastroenterostomy performed with novel lumen- apposing metal stent with electrocautery-enabled delivery system- a single center study

Authors Karagyozov P[1], Velikova T[2], Kavrakov D[3]
Institutes 1 Acibadem City Clinic University Hospital Tokuda , Sofia, Bulgaria; 2 Medical Faculty, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria; 3 Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofia, Bulgaria
DOI 10.1055/s-0046-1822521

Aims Background: Endoscopic ultrasound- guided gastroenterostomy (EUS-GE) is a new treatment modality for gastric outlet obstruction, demonstrating advantages over enteral stenting and surgical bypass. The majority of reported

procedures have been performed with only one electrocautery- enhanced lumen-apposing stent (LAMS) and data about other LAMSs are scarce. There is paucity of data in the literature about long-term symptom relief and factors associated with outcomes and adverse events.

Aim: To evaluate the safety and efficacy of EUS-GE to treat gastric outlet obstruction (GOO) using a novel electrocautery- enabled LAMS (Niti-S Hot SPAX-US, Taewoong Medical, Goyang, South Korea). Primary endpoints were adverse events (AEs) and factors associated with their occurrence. Secondary endpoints were technical success (establishment of an anastomosis), clinical success (tolerating semisolid food at 48 hours), procedure time, hospital stay and long term follow up data on symptom relief.

Methods Methods: Retrospective single center study over a 2-year period. Demographic characteristics, procedure-related and follow-up data were collected.

Results Results: Forty patients were included. The most common indication was malignancy (87.5 %), predominantly pancreatic cancer (55 %), followed by gastric cancer (10 %) and groove pancreatitis (7.5 %). Technical success was achieved in 97.5 %. Stent misdeployment (SM) occurred in 10 % and was more frequent in younger (p = 0.0067) and female (75 % vs. 25 %) patients. SM occurred exclusively in malignant indications (11.4 % vs. 0 %). There was no correlation with the presence of ascites, site of obstruction, technique, shape of target loop, previous interventions or surgically altered anatomy. All the cases were salvaged endoscopically. SM did not prolong the hospital stay (p = 0.481) and was only associated with prolongation of the procedure time. Immediate AEs (< 24 hours) were reported in 2.5 % and happened more frequently in younger age and peritoneal carcinomatosis (p = 0.046). The rate of short-term AEs (< 30 days) was 10 % (n = 4) occurring more frequently in the presence of ascites (p = 0.078), in malignant etiology (p = 0.048) and peritoneal carcinomatosis (p = 0.046). Long-term AEs (> 30 days) were reported in 15.8 % and were significantly associated with malignant etiology (p = 0.021). Most adverse events were managed conservatively or were not clinically significant, only two patients required surgery. The median procedure time was 35 minutes (IQR 30–40), and the median hospital stay was 3 days (IQR 2–3) The clinical success was 92.5 %, indicating high rate of early functional recovery. Six-month follow-up data were available for 15 patients (37.5 %). Among them, 86.7 % demonstrated complete clinical resolution. Late functional outcomes assessed using the gastric outlet obstruction scoring system (GOOSS score) showed that 94.9 % of patients achieved a GOOSS of 3 or 2, indicating the ability to tolerate a full or almost full diet at longest follow-up. These findings suggest sustained symptomatic improvement in most patients with available follow-up data. Two patients are alive at 12 months and both tolerate normal diet.

Conclusions Conclusions: We demonstrated that EUS-GE using a novel electrocautery- enabled LAMS is a safe and highly effective procedure. The majority of patients tolerate normal diet at long term follow-up. SM happened rarely, mostly in young female patients with malignant indications but did not affect the outcome and was related only with prolonged procedure time. Malignant etiology and presence of peritoneal carcinomatosis are strongest risk factors for adverse events.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1195 Lumen-apposing metal stent with or without coaxial double pigtail plastic stent for EUS-guided gallbladder drainage in case of acute cholecystitis or distal malignant biliary obstruction: a multicentre study (COALA study) on behalf of I-EUS group

DOI 10.1055/s-0046-1822522

Aims EUS-guided gallbladder drainage (EUS-GBD) with lumen-apposing metal stent (LAMS) reported high technical/clinical success but not negligible adverse events (AEs) and stent dysfunction (SD). Based on evidence from pancreatic fluid collection drainage and EUS-choledochoduodenostomy, the placement of a coaxial double-pigtail plastic stent (DPPS) within the LAMS may reduce these events. This study aimed to assess whether inserting a DPPS coaxially through the LAMS during EUS-GBD decreases the risk of AEs and stent dysfunction.

Methods This is an interim analysis of an ongoing multicentre study conducted across eight centres, including consecutive adult patients (2018–2025) who underwent successful EUS-GBD with LAMS for acute cholecystitis or distal malignant biliary obstruction. Patients with perforated gallbladder or with contained perforation, coagulopathy, non-patent cystic duct (in case of DMBO) were excluded. As the target sample size has not yet been reached, analyses represent a direct comparison without propensity-score matching. Stent dysfunction was defined as a composite endpoint including recurrent jaundice, obstruction, migration, buried stent, cholangitis or new onset/recurrent AC during follow-up The primary endpoint was the effectiveness of coaxial DPPS placement in reducing overall AEs and SD. Secondary endpoints included identifying risk factors associated with AEs and SD.

Results A total of 273 patients were included (141 M; mean age 80 ± 12 years); 216 underwent EUS-GBD for acute cholecystitis. Coaxial DPPS placement was performed in 41 patients, predominantly via a trans-gastric approach. Overall, AEs occurred in 9/41 (22 %) patients in LAMS + DPPS group and 42/230 (18.3 %) in LAMS alone group. Kaplan–Meier analyses revealed no significant differences between the LAMS + DPPS and LAMS-alone groups in AE-free survival (log-rank test, p = 0.49) or SD-free survival (log-rank test, p = 0.10) (Fig.1;Fig.2). Binary logistic regression identified previous percutaneous transhepatic biliary drainage (PTBD) (OR 3.197; 95 %CI 1.00–2.32; p = 0.048) and the presence of perihepatic ascites (OR 0.210; 95 %CI 0.00–1.00; p = 0.050) as predictors of AEs. The transgastric route showed a trend toward increased AEs (OR 0.515; 95 %CI 0.03–1.36; p = 0.061).

Conclusions In this interim analysis, coaxial DPPS within LAMS did not reduce AEs or SD. Notably, prior PTBD, ascites and a transgastric approach were identified as potential risk factors for AEs. A larger cohort with propensity-score matching or a RCT is necessary to verify this hypothesis.

eP1196 Gastrointestinal Complications of Continuous Levodopa–Carbidopa Enteral Therapy: A Five-Year Multicenter Experience

Authors Achemlal A[1,2], Coelho J[2], Popa I[2], Robleh H[2], Grabli D[3], Meneret A[3], Mantisi L[3], Letrillart H[3], Amiot X[2]

Institutes **1** Mohammed V Military Training Hospital, Rabat, Morocco; **2** Tenon Hospital, Paris, France; **3** University Hospitals Pitié Salpêtrière, Paris, France

DOI 10.1055/s-0046-1822523

Aims The primary objective of our study was to report our experience with the placement and management of complications in patients with advanced Parkinson's disease (PD) treated with continuous intestinal infusion of levodopa-carbidopa gel (LCIG) via gastrojejunostomy tube (PEG-J). This work was conducted through close collaboration between a neurology unit and a gastroenterology department. In addition, factors associated with system persistence, the occurrence of complications, and the need for device replacement were also analyzed.

Methods This was a retrospective observational study conducted in patients with long-standing, advanced PD who had a PEG-J tube placed for LCIG therapy between December 2019 and June 2025. The treatment decision, made by the neurology department based on clinical status, treatment history, and patient preferences, followed a thorough discussion of potential benefits and risks. After obtaining informed consent, PEG-J placement was performed endoscopically, and LCIG therapy was initiated and adjusted during a short hospitalization period. A scheduled annual tube replacement was implemented to prevent complications, while patients and their caregivers received training on preventive measures. Malfunctions or complications were managed on an emergency basis, with or without endoscopic intervention. Statistical analysis was performed using Jamovi software, version 2.3.

Results A total of 91 patients were included, accounting for 361 procedures performed over a five-year period. The male-to-female ratio was 2.37, and the mean age at the time of intervention was 68.5 ± 8.7 years. Most PEG-J tubes placed were 15 French in diameter (96.1 %). The median propofol dose per procedure was 245 mg [186; 346].

Among the procedures performed:

- 57 (15.8 %) corresponded to initial tube placements,
- 140 (38.8 %) to scheduled annual replacements,
- 67 (18.6 %) to complete endoscopic repairs under anesthesia,
- 92 (25.5 %) to repairs performed without anesthesia,
- and 5 patients (1.4 %) required complete tube removal due to lack of therapeutic efficacy.

One or more complications were reported in several patients, leading to partial or total device replacement (▶ **Table 1**). The median device survival at one year, prior to scheduled replacement, was estimated at 308 days (cf. Survival Curve Analysis).

▶ **Table 1**

Adverse Events / Complications		N (%)
Stoma-related	Wound infection	2 (0.9)
	External blockage	9 (4.2)
Gastrointestinal complications	Buried Bumper Syndrome (BBS)	6 (2.8)
	Bezoar	5 (2.3)
	Digestive ulceration	4 (1.9)
	Other gastric lesions	1 (0.5)
Device-related	J-tube migration	37 (17.2)
	Hardware displacement	11 (5.1)
	Dislocation	7 (3.3)
	Obstruction (loop, knot, etc.)	52 (24.2)
Severe complications	Peritonitis	2 (0.9)
	Aspiration pneumonia	1 (0.5)
Other	Accidental device removal	78 (36.3)

Conclusions Complications related to PEG-J tubes used for LCIG therapy in advanced Parkinson's disease are frequent but generally mild. Optimal management relies on close collaboration between neurologists, gastroenterologists, healthcare providers, and caregivers to ensure early detection and effective management of complications, thereby maintaining treatment continuity and improving clinical outcomes.

eP1197 The Evolution of Capsule Endoscopy Procedure Over Two Decades: A Single-Center Experience (2002–2025)

Authors Leventaki F[1], Stasinos I[1], Kouimtsidis I[1], Chachopoulos C[1], Pujante A[1], Sorotou A[1], Theofanopoulou A[1], Kalantzis C[1], Tsibouris P[1], Apostolopoulos P[1]

Institute **1** NIMTS Medical Institution Military Shareholder Fund, Athina, Greece

DOI 10.1055/s-0046-1822524

Aims Small-bowel capsule endoscopy (SBCE) has undergone substantial technological evolution over the past two decades, accompanied by changes in clinical indications and referral patterns. From 2002–2013, the PillCam SB1/SB2 platforms were used at our center, while from 2014–2025 the PillCam SB3 system—offering higher image resolution, adaptive frame rate, and prolonged battery life—was introduced. The aim of this study is to compare indications, completion rates, transit times, and diagnostic yield of SBCE across two consecutive 11-year periods (2002–2013 and 2014–2025).

Methods We performed a retrospective analysis of 1.484 consecutive SBCE examinations (1.048 in 2002–2013 and 436 in 2014–2025). Indications were classified according to ESGE/ASGE guidelines as "appropriate" (obscure GI bleeding, iron-deficiency anemia [IDA], Crohn's disease, inherited polyposis syndromes, imaging abnormalities, and celiac disease) or "low-yield" (abdominal pain, diarrhea, malabsorption). Indications outside ESGE/ASGE criteria were also recorded. Diagnostic yield was defined as the presence of clinically relevant findings at the time of examination. Statistical analysis was performed using t-test and chi-square testing [1].

Results Significantly more SBCEs were performed in the first period than in the second (1,048 vs. 436, $p < 0.001$). Patients examined in the later period

Endoscopy 2026; 58: S1–S1041

were significantly older (mean age 60 vs. 66 years, p < 0.001). IDA and obscure GI bleeding became more frequent indications in the second period (IDA: 39 % vs. 54 %; GI bleeding: 14 % vs. 25 %; both p < 0.001), whereas Crohn's disease was significantly less common (13 % vs. 5 %, p < 0.001). Examinations performed outside ESGE/ASGE guidelines decreased markedly from 2.76 % to 0.07 % (p < 0.01). Completion rate improved substantially from 76 % to 94 % (p < 0.00001), and small-bowel transit time increased from 281 to 321 minutes (p = 0.0001). Estimated diagnostic yield decreased significantly in the second period for GI bleeding (86 % to 61 %, p < 0.001), IDA (78 % to 53 %, p < 0.001), and Crohn's disease (75 % to 45 %, p < 0.01).

Conclusions Over the last two decades, stricter adherence to guideline-based indications, refined interpretation criteria, and technological enhancements of SBCE have resulted in fewer but more targeted examinations, improved completion rates, and more reliable evaluation. Despite technological advancements, diagnostic yield decreased, likely reflecting increasingly selective patient referral and more stringent diagnostic thresholds rather than diminished test performance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1198 EUS-guided Enteroenterostomy via a Small Bowel Ostomy for Recurrent Malignant Small Bowel Obstruction in a Highly Palliative Setting: a two-case feasibility report

Authors Cahyadi O[1], Ewald P[1], Torres Reyes C[1], Zeidler C[1], Ayoub M[1], Schellen S[1], Ebigbo A[1]

Institute 1 St. Josef-Hospital, Ruhr-University Bochum, Bochum, Germany

DOI 10.1055/s-0046-1822525

Abstract Text

Patients with peritoneal carcinomatosis frequently develop small bowel obstruction (SBO), resulting in significant morbidity due to severe nausea, vomiting, pain, leading to reduced quality of life. Surgical bypass or ostomy creation is the traditional approach; however, obstructions proximal to the ostomy or bypass can recur. Further treatment becomes difficult, especially in patients with low performance status not amenable to surgery. In this setting, endoscopic ultrasound–guided enteroenterostomy (EUS-EE) using a cautery-enhanced (CE) Lumen-apposing metal stent (LAMS) through a pre-existing small bowel ostomy could be a potential alternative, but data are scarce. We report two cases of patients with peritoneal carcinomatosis and recurrent malignant SBO proximal to a small bowel ostomy in whom EUS-EE was performed via the ostomy.

Case 1: a 60-year-old man with metastatic colon cancer and peritoneal carcinomatosis underwent jejunostomy for ileus two years prior. After a long stable phase under chemotherapy he presented with absent stoma output, vomiting, and melena without any oral intake. CT-scan revealed dilated small-bowel loops proximal to the ostomy, consistent with ileus. As surgery was not feasible, EUS-EE was performed by advancing a linear echoendoscope through the jejunostomy. A 15/10 mm CE-LAMS was deployed 15 cm proximal to the stoma. Subsequently stoma output improved and oral intake (soft solid) was tolerated. He was discharged after five days and died four weeks later due to disease progression.

Case 2: A 63-year-old man with metastatic pancreatic cancer and a prior ileostomy, presented with intermittent absent stoma output, abdominal pain ,and reduced oral intake. CT-scan confirmed ileus about 20 cm proximal to the stoma. An EUS-EE through the ostomy with deployment of a 20/10 mm CE-LAMS 10 cm proximal to the ostomy resulted in immediate bowel decompression. During the procedure, he aspirated gastric content, from which he fully recovered. He tolerated oral intake (full diet) for four weeks before the obstructive symptoms recurred. He declined further intervention and was discharged to hospice care.

Conclusion: These two cases suggest that EUS-guided enteroenterostomy via an existing small bowel ostomy is technically feasible. and may offer short-term palliation in carefully selected patients with recurrent malignant SBO who are not surgical candidates. Larger series are needed to better define safety, durability, and patient selection.

eP1199V Combined endoscopic decompression using EUS-guided entero-colostomy (EUS-EC) through a colonic stent for a double lower intestinal malignant obstruction (LIMO)

Authors López Torres LM[1], Sánchez-Ocaña R[1], Cobreros del Caz M[1], Marcos-Carrasco N[1], Ortiz Chimbo DS[1], Sanjosé Crespo A[1], Martinez-Cuevas C[1], Perez-Miranda M[2]

Institutes 1 Rio Hortega University Hospital, Valladolid, Spain; 2 Hospital Universitario Rio Hortega, Valladolid, Spain

DOI 10.1055/s-0046-1822526

Abstract Text

EUS-EC is a palliative alternative for LIMO not amenable to enteral stenting. Synchronous rectosigmoid and jejunal LIMO precluding EUS-EC was overcome by same-session colonic stenting, facilitating rectal passage of the echoendoscope over a guidewire. A frail patient with mid-jejunal implant of CRC. A 7F irrigation catheter is left in the jejunum using a pediatric colonoscope peroraly. A malignant sigmoid stricture precluding passage is bridged with a 22x90 uncovered stent, which is then 20-mm balloon dilated. The echoendoscope is passed over the wire through the stent into the descending colon supported by a transrectal overtube. After fluoroscopic confirmation of proximity, the jejunum is maximally distended. Jejuno-colostomy is uneventfully performed with a Hot 15x10 mm LAMS. The patient maintains oral tolerance 4 months later.

eP1201 Transfusion strategy in acute non-variceal upper gastrointestinal bleeding among high-risk cardiac patients: a 3-year prospective monocentric study from Marrakech, Morocco

Authors Aouroud H[1], Aouroud M[1], NACIR O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute 1 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco

DOI 10.1055/s-0046-1822528

Aims Patients with ischemic heart disease (IHD) are at increased risk of upper gastrointestinal bleeding (UGIB), mainly due to antiplatelet therapy. International guidelines recommend a restrictive transfusion strategy for most UGIB patients, but suggest considering a more liberal threshold in high-risk cardiac patients, who may require higher hemoglobin levels to maintain adequate myocardial oxygen supply.

Aim To compare restrictive versus liberal transfusion strategies in high-risk cardiac patients admitted for acute non-variceal UGIB in a Moroccan tertiary center.

Methods A prospective randomized monocentric study was conducted at CHU Mohammed VI, Marrakech, between January 2022 and January 2025.A total of 76 high-risk cardiac patients with acute non-variceal UGIB were included.High-risk cardiac status was defined briefly as:a history of myocardial infarction, coronary stents, coronary bypass surgery, ongoing/recent ischemia, reduced left ventricular ejection fraction (< 40 %), significant arrhythmias, or dual antiplatelet therapy.

Patients were randomized into:

- Restrictive strategy: transfusion when Hb ≤ 8 g/dL
- Liberal strategy: transfusion when Hb ≤ 10 g/dL, in accordance with recommendations for cardiac high-risk patients

The primary endpoint was 30-day rebleeding. Secondary outcomes included mortality, cardiovascular events, and hospital stay duration.

Results Of the 76 included patients, 38 received restrictive transfusion and 38 received liberal transfusion. Baseline characteristics were comparable between groups.

30-day rebleeding:

- Restrictive: 18.4 %
- Liberal: 13.2 %($p > 0.05$, not significant)

30-day all-cause mortality: no significant difference.

Hospital stay: slightly shorter in the liberal group (mean 6.8 vs 7.4 days).

Major cardiovascular events:

- Restrictive: 15.8 %
- Liberal: 7.9 %Liberal transfusion was associated with fewer heart-failure episodes and acute coronary syndromes.

Conclusions In this 3-year Moroccan monocentric cohort of high-risk cardiac patients with acute non-variceal UGIB, a liberal transfusion strategy (Hb ≤ 10 g/dL) did not increase rebleeding or mortality.It was associated with:

- fewer major cardiovascular events,
- and a slightly shorter hospital stay.

These findings support the use of a more liberal transfusion threshold in high-risk cardiac patients, in line with international recommendations.

DOI 10.1055/s-0046-1822529

Aims Pre-resection biopsy is usually performed for gastric lesions and non-ampullary duodenal adenomas. However, the final histological diagnosis often diverges, revealing the presence of high-grade dysplasia or carcinoma not previously detected. We aimed to assess the agreement between biopsy and definitive histopathological diagnosis in this setting.

Methods We performed a retrospective analysis of gastric and non-ampullary duodenal lesions submitted to endoscopic resection. Patients' and lesions' characteristics were prospectively collected. A descriptive analysis was performed [1–3].

Results We collected 135 lesions (54 % F, mean age 75.6 years) treated by endoscopic resection and previous biopsy with forceps, performed between January 2021 and October 2025 at Forlì-Cesena Gastroenterology Unit. Gastric (71 %) and duodenal (29 %) lesions were included, with mean dimensions of 20 mm, respectively submitted to Endoscopic Submucosal Dissection (ESD) and Endoscopic Mucosal Resection (EMR) according to European Guidelines.

In 35 % of cases we observed disagreement between biopsies and definitive histology ; in details, for gastric lesions understaging rate was 41 % and among them carcinoma was diagnosed in one third of cases not previously detected. Notably 5 % emerged as mixed type gastric cancer including signet ring cells, leading to a significant change in the oncological approach.

Conclusions In our experience and in accordance with previous literature, pre-resection sampling showed a low prediction rate of definitive histology despite its economic and ecological burden, as well potential delay in therapeutic decisions. In this setting, a future change in the diagnostic algorithm for upper GI lesions, especially gastric ones, should be considered. The adoption of artificial systems and chromoendoscopy could strengthen this approach.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1203 Dieulafoy's Lesion in Clinical Practice: A 30-Year Analysis of Diagnostic Accuracy and Overdiagnosis

Authors Georgakopoulou N[1], Kotzagiannidou E[1], Thanos C[1], Ntailianas D[1], Piskopou D[1], Georgiou E[1], Triantafyllou M[1], Tsitsigiannis K[1], Kalakos N[1], Mpraimakis A[1], Michalopoulos G[1], Striki A[1], Argyropoulos T[1], Karoumpalis I[1]

Institute **1** General Hospital of Athens "G. Gennimatas", Athens, Greece

DOI 10.1055/s-0046-1822530

Aims Dieulafoy's lesion is an uncommon vascular anomaly characterized by a dilated submucosal artery that can cause severe upper gastrointestinal bleed-

ing in the absence of underlying mucosal disease. It accounts for approximately 1–2 % of all gastrointestinal hemorrhage.Endoscopic diagnosis relies on specific criteria: (1) active arterial spurting or micropulsatile bleeding from a small (< 3 mm) mucosal defect or through normal mucosa; (2) a visible protruding vessel with or without active bleeding from a tiny mucosal defect; or (3) a densely adherent clot with a pinpoint attachment on otherwise normal mucosa. Despite these criteria, overdiagnosis remains under-reported, and the extent of misinterpretation in real-world endoscopy practice is unclear. We aimed to evaluate both diagnosis and overdiagnosis of Dieulafoy's lesions over a 30-year period in a tertiary hospital [1, 2].

Methods We reviewed all gastroscopy reports from our department between September 1993 and January 2024 in which the term "Dieulafoy" appeared. Demographic data (age, sex) were collected, and all reports underwent detailed reassessment. We evaluated stomach contents, completeness of mucosal inspection, and the presence of alternative bleeding sources such as ulcers, varices, erosions, or angiodysplasia. Each report was reassessed to determine whether the standard endoscopic diagnostic criteria for Dieulafoy's lesion were clearly documented. For confirmed cases, the endoscopic hemostatic modality used was recorded.

Results A total of 59 reports were retrieved, corresponding to 52 patients (mean age 70 years; 71 % male), all presenting with upper gastrointestinal bleeding. Lesions were most commonly described in the fundus (28,8 %), followed by the duodenal bulb (21 %), the lesser curvature (11 %) and the posterior wall of the gastric body (11 %). Overall, 42,3 % of lesions labeled as "Dieulafoy" did not fulfil the diagnostic criteria, indicating substantial overdiagnosis. Nearly half of the procedures (57,6 %) were performed in a stomach contaminated with blood or clots, limiting mucosal visualization. Apart from the lesions described as Dieulafoy, other mucosal abnormalities potentially responsible for bleeding were present in 34,6 % of cases. Several lesions initially labeled as Dieulafoy's were reinterpreted as ulcers (19 %). Hemostasis was achieved using adrenaline injection, ethanolamine injection (used until 2005), APC, thermal coagulation probes, hemoclips, or combination therapy (53 %). Successful hemostasis was reported in 96,6 % of confirmed Dieulafoy cases. Five patients underwent second-look endoscopy; outcome data for the remaining patients were not available.

Conclusions Dieulafoy's lesions remain a significant diagnostic challenge. Limited visualization and inconsistent application of standard diagnostic criteria contribute to substantial overdiagnosis. This 30-year review underscores the importance of rigorous documentation and strict adherence to the recognized endoscopic criteria to improve diagnostic accuracy and guide appropriate treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1204 Impact of Position Change on Polyp Detection During a Second Look at the Right Colon: A Multicenter, Randomized Controlled Trial

Authors Soh J[1], Yoon J[2]

Institutes **1** Hallym University Sacred Heart Hospital, Anyang, Republic of Korea; **2** Kangdong Sacred Heart Hospital, Seoul, Republic of Korea

DOI 10.1055/s-0046-1822531

Aims Detection and removal of colorectal polyps are important for the prevention of colorectal cancer. Among various strategies to enhance the polyp detection, a second-look examination of the right colon can improve the adenoma detection rate (ADR) in the proximal colon. This study aimed to determine whether a second look with patient position change improves ADR compared with a second look without a position change [1, 2].

▶ **Table 1** Comparison between the first observations and the first + second observations in the control and position change group

	Second look with position change group (n = 327)			Second look without position change group (n = 332)		
	First exam	**Frist and second exams**	***p*-value**	**First exam**	**Frist and second exams**	***p*-value**
Overall ADR for right colon, %	67 (20.5)	99 (30.3)	0.005	63 (19.0)	88 (26.5)	0.026
Overall ASR for right colon, %	15 (4.6)	22 (6.7)	0.310	15 (4.5)	25 (7.5)	0.142
Overall PDR for right colon, %	101 (30.9)	159 (48.6)	< 0.001	103 (31.0)	154 (46.5)	< 0.001
MAP, n	0.3 ± 0.6	0.4 ± 0.8	0.012	0.3 ± 0.6	0.4 ± 0.7	0.030
MSP, n	0.0 ± 0.2	0.1 ± 0.3	0.101	0.1 ± 0.3	0.1 ± 0.4	0.165
MAPP, n	0.4 ± 0.8	0.8 ± 1.0	< 0.001	0.4 ± 0.8	0.7 ± 1.0	< 0.001

ADR, adenoma detection rate; ASR, SSL detection rate; PDR, polyp detection rate; SSL, sessile serrated lesion; MAP, mean number of adenomas per patient; MSP, mean number of SSLs per patient; MAPP, mean number of all polyps per patient.

Methods A total of 659 patients undergoing colonoscopy at six institutions were randomly assigned to one of two groups. In the second-look without position change group, the right colon was examined twice in the same position. In the second-look with position change group, the right colon was examined once, the patient's position was changed (from left lateral to supine or from supine to left lateral), and the segment was re-examined. Each observation lasted at least one minute. Colorectal lesions detected during the examinations were analyzed for each group.

Results The second-look with and without position change groups included 327 and 332 patients, respectively. Changing the patient's position during the second look did not result in a significantly higher ADR compared with no position change (30.3 % vs. 26.5 %; $p = 0.324$) (▶ **Table 1**). However, in both groups, the second look identified additional missed lesions, increasing ADR by 9.8 % ($p = 0.005$) and 7.5 % ($p = 0.026$), respectively, and increasing the polyp detection rate by 17.7 % and 15.5 %, respectively ($p < 0.001$). No increase in the detection of sessile serrated lesions was observed.

Conclusions A second-look examination of the right colon significantly increased ADR and polyp detection rates regardless of position change. Similar outcomes in both groups suggest that the effect of position change may be offset when a second look is routinely performed.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1205 Comparative Evaluation of Multimodal Large Language Models for Computer-Assisted Endoscopic Assessment in Ulcerative Colitis

Authors Zhao X[1], Sun J[1], Zhan Q[1]
Institute 1 Wuxi People's Hospital, Wu Xi Shi, China
DOI 10.1055/s-0046-1822532

Aims To systematically compare the diagnostic accuracy of five contemporary multimodal large language models (MLLMs: Gemini-2.5-Pro, Grok-4, GPT-4o, GPT-5, and Qwen-VL-Max) in evaluating the Mayo Endoscopic Score (MES) for ulcerative colitis (UC), and to explore their consistency and performance across various intestinal segments and MES categories [1–12].

Methods A total of 402 authentic endoscopic images from patients with UC were collected, covering the entire colon location from the ileocecal region to the rectum. Three experienced inflammatory bowel disease (IBD) experts independently reviewed and unanimously graded these images and finally 283 images with consensus on regrades. These images were among the second stage of research and the grade as the reference standard. These images were randomly presented to MLLMs and two senior IBD physicians without specifying the intestinal segment, and then randomly presented to MLLMs with segmental information before grade. Model and physician performance were compared, and stratified analyses were conducted by intestinal segment and MES grade.

Results The diagnostic accuracies (Acc) of the two IBD physicians were 81.6 % and 78.4 %, respectively, with strong inter-observer agreement ($\kappa = 0.692$). Among these MLLMs), GPT-5 achieved the highest overall performance (F1: GPT-5 0.720 > GPT-4o 0.602 > Gemini-2.5-Pro 0.480 > Grok-4 0.415 > Qwen-VL-Max 0.338), and its diagnostic accuracy was comparable to that of human physicians (GPT-5 Acc 71.7 % vs. Senior Physician 2 Acc 78.4 %, $P = 0.068$). The other models exhibited significantly lower diagnostic performance compared with experienced IBD physicians (all $P < 0.001$). When additional segmental information was provided, the sigmoid colon was the most accurately assessed region (mean F1 across models 0.682), whereas the rectum and ileocecal region remained the most challenging (0.447 and 0.493, respectively). The provision of segmental information significantly enhanced the performance of the lower-performing models. Moreover, both the models and human physicians showed the lowest accuracy at MES = 1(physicians mean Acc ≈ 60.3 %, models mean Acc ≈ 39.4 %), indicating that the mild-activity grade remains the most challenging to classify due to its inherent subjectivity.

Conclusions GPT-5 demonstrated diagnostic performance comparable to that of senior IBD physicians in MES grading, whereas other MLLMs require further optimization. In terms of intestinal segments, the rectum and ileocecal region, and in terms of disease severity, mild activity (MES = 1), represented common challenges for both physicians and models. Future efforts should focus on targeted training for these challenging segments and grades, and on integrating additional clinical multimodal data to advance the clinical implementation of intelligent endoscopic assessment.

DOI 10.1055/s-0046-1822533

Aims Endoscopic submucosal dissection (ESD) is increasingly used to achieve 'en bloc' resection of large non-pedunculated colorectal polyps (LNPCPs). However, accurate pre-procedural identification of patients at risk of local- or high-risk resections, which fall within the spectrum of non-curative ESD (NC-ESD), remains challenging. This study aimed to develop and validate machine-learning (ML) models to predict NC-ESD using pre-procedural variables.

Methods We retrospectively analyzed a prospective multicenter database including consecutive patients aged ≥ 65 years who underwent colorectal ESD for LNPCPs in 10 Italian tertiary centers (2019–2023). Forty baseline clinical and endoscopic features were collected. The primary outcome was NC-ESD, defined according to ESGE criteria. A supervised ML pipeline with 5-fold stratified cross-validation was implemented using support vector machine (SVM), random forest (RF), extreme gradient boosting (XGBoost) and multi-layer perceptron (MLP) classifiers, optimized for F1-weighted score. Model explainability was assessed with Local Interpretable Model-Agnostic Explanations (LIME).

Results Overall, 1022 patients (median age 74 years) were included. NC-ESD occurred in 16.5 %. T1 cancer was found in 13.4 % cases, with a deep submucosal invasion in 91 % cases. SVM achieved the highest accuracy (0.82) with an F1-score of 0.77, whereas RF yielded an accuracy of 0.81 with the highest F1-score (0.80). XGBoost and MLP showed good, comparable performance (accuracy 0.78–0.79; F1-score 0.77–0.78). LIME consistently identified JNET pattern, lesion size, location, antithrombotic therapy, age and ASA class as the most influential predictors of NC-ESD.

Conclusions In older patients undergoing colorectal ESD, ML models based on clinical and endoscopic variables provided accurate pre-procedural prediction of NC-ESD. These tools may support treatment planning while complementing, rather than replacing, expert endoscopic judgement.

eP1207 Prospective clinical and economic analysis of a universal ESD resection strategy for non-pedunculated colonic polyps ≥ 20 mm

Authors Ayoub M[1], Zeidler C[1], Cahyadi O[1], Quast D[1], Torres Reyes C[1], Stögbauer M[1], Ewald P[1], Ebigbo A[1]
Institute 1 St. Josef-Hospital, Ruhr-University Bochum, Bochum, Germany
DOI 10.1055/s-0046-1822534

Aims Large non-pedunculated colonic polyps (≥ 20 mm) can be resected either by piecemeal endoscopic mucosal resection (pEMR) or endoscopic submucosal dissection (ESD). Macroscopic assessment of flat polyps for invasive cancer often has limited sensitivity, especially in borderline lesions. A universal ESD strategy in the colon offers high en bloc, and R0 resection rates with low recurrence rates. In contrast to pEMR, curative ESD obviates the need for endoscopic surveillance for benign lesions and surgical completion therapy for low-risk malignant polyps. On the other hand, colorectal ESD is associated with higher complication rates and longer procedure times. This study aimed to perform a clinical and economic evaluation of a universal ESD strategy for non-pedunculated colonic polyps ≥ 20 mm at a tertiary referral center.

Methods In a universal ESD approach, all non-pedunculated colonic polyps ≥ 20 mm resected between March and October 2025 were treated by ESD. All procedure- and hospital-related costs (materials, staff, length of stay, complications, surveillance colonoscopies, and additional treatments) were recorded and compared using propensity score matching with a historical pEMR cohort from previous years.

Results Forty patients with non-pedunculated colonic polyps ≥ 20 mm (range 22–112 mm) were treated within the universal ESD strategy. Lesions were located in the caecum (n = 6), ascending colon (n = 9), transverse colon (n = 9), descending colon (n = 2), and sigmoid colon (n = 14). En bloc and R0 resection rates were 100 % and 97.5 %, respectively. Histology revealed 10 LGD, 24 HGD, five early cancers with low-risk features, and one cancer with high-risk features (L1, positive vertical margin). The overall complication rate was 2.5 % (n = 1; post-polypectomy syndrome). Mean procedure time was 113 minutes (range 43–430). In the initial cost analysis of the first 10 patients , immediate ESD costs were higher than those of pEMR (2,059.6 € vs. 1,469.2 €; Δ = + 590.4 €). However, mandatory surveillance colonoscopies in the pEMR group generated additional costs of 886.4 €, resulting in higher 24-month total costs for pEMR compared to ESD (2,355.6 € vs. 2,059.6 €; Δ = –296.0 €). Analysis of the full cohort is still ongoing. Potential costs which would be generated by additional surgery were not part of this evaluation but should also be taken into consideration.

Conclusions This single-center analysis of a universal ESD strategy for non-pedunculated colonic polyps ≥ 20 mm demonstrates excellent clinical outcomes. The exploratory health-economic evaluation and the propensity score–based comparison with a historical pEMR cohort suggest that, due to required surveillance procedures, pEMR becomes more expensive than ESD over time. Final cost-effectiveness results, including avoided surgical treatment, are pending.

eP1208 Assessing the Reliability of the S2T2 Tool for Scoring Technical Difficulty and Educational Value of Endoscopy for Suspected Upper GI Bleeding

Authors Hawkes N[1], Davies O[2], Nigam G[3]
Institutes 1 Royal Glamorgan Hospital, Ynysmaerdy, United Kingdom; 2 University Hospital of Wales, Cardiff, United Kingdom; 3 Translational Gastroenterology and Liver Unit, Oxford, United Kingdom
DOI 10.1055/s-0046-1822535

Aims Accurately assessing technical difficulty in acute upper gastrointestinal bleeding (AUGIB) endoscopy is essential for training, triage, and service planning. The S2T2 scoring tool integrates four domains: Setting, Site, Type, and Treatment, to generate a total score between 0 and 10, stratified into easy, moderate, and difficult cases. This study evaluated the inter- and intra-observer reliability of the S2T2 tool among endoscopy trainees and trainers, and explored its relationship with perceived educational value (EDV).

Methods Twenty-three raters (12 trainees, 11 trainers) scored 15 anonymised AUGIB cases (5 easy, 5 moderate, and 5 difficult) across two rounds two weeks apart. Case order was randomised and blinded between rounds. Each rater independently applied the S2T2 score to each case. Inter- and intra-observer reliability of total S2T2 scores was assessed using intraclass correlation coefficients (ICCs; two-way, agreement, single measures), stratified by case difficulty and by rater type. Domain-level ICCs were calculated for each S2T2 component. Intra-observer agreement between rounds was evaluated using a Bland–Altman plot and summarised using mean absolute score differences. The association between S2T2 scores and perceived EDV was analysed using Spearman's rank correlation.

Results Overall inter-observer reliability was excellent, with an ICC of 0.938 (95 % CI: 0.888–0.974) in Round 1 and 0.919 (95 % CI: 0.856–0.966) in Round 2. Stratified analyses showed strong agreement for difficult cases (ICC > 0.8) and easy cases (ICC ~ 0.72–0.86), while moderate cases showed greater variability, particularly among trainees (ICC 0.41 vs 0.25). Intra-observer reliability across rounds was also strong (ICC = 0.938, 95 % CI: 0.924–0.950), with a mean absolute score difference of 0.51 (SD 0.99). The Bland–Altman plot demonstrated minimal bias and narrow limits of agreement. Domain-specific reliability was highest for Treatment (ICC = 0.985), followed by Setting (0.910), Type (0.890), and Site (0.657). EDV ratings demonstrated substantial inter-rater agreement (Fleiss' κ = 0.757), and S2T2 scores showed a strong positive correlation with EDV (Spearman's ρ = 0.81, p < 0.001).

Conclusions The S2T2 tool is a reliable and valid measure of technical difficulty in AUGIB endoscopy, demonstrating excellent inter- and intra-observer agreement, particularly in clearly easy or difficult cases. The strong correlation between S2T2 scores and perceived educational value supports its use for case selection in training, performance assessment and certification, and service benchmarking.

DOI 10.1055/s-0046-1822536

Aims Non-invasive video capsule endoscopes (VCE) are widely used for gastrointestinal (GI) imaging. Usually, excretion of VCE occurs within 2 weeks. However, excretion is not always observed by the patient and rare cases of capsule retention for years have been reported. Magnet Resonance Imaging (MRI) with incorporated VCE is considered a contraindication due to possible adverse interaction with the ferromagnetic components of VCE. While single case reports with incidental MRI have documented no clinically evident harm due to VCE, systematic experimental data are lacking. This study aims to quantify magnetically induced displacement forces and torque on VCE within the electromagnetic environment of a 3 Tesla (T) MRI scanner according to internationally recognized ASTM standards.

Methods This experimental study used a 3T whole-body MRI scanner (Magnetom Vida, Siemens Healthcare, Erlangen, Germany). Eleven commercially available VCEs (PillCamSB3, PillCamColon2, OMOM HD, OMOM RC, OMOM CC, NaviCam, NaviCam Colon, CapsoCam Plus, MiroCam 1200, MiroCam 2000, MiroCam Navi) designed for imaging of the small bowel, upper GI tract, or colon were tested. For displacement force measurement, each capsule was suspended by a string near the MRI bore entrance at the position of maximum spatial magnetic field gradient (ASTM F2052-21). The deflection angle relative to the vertical axis was measured using a protractor setup. A deflection angle greater than 45 ° was defined as exceeding gravitational force, thus failing the MRI safety criterion.Torque was measured with the pulley method (ASTM F2213-17). Each capsule was mounted in a test apparatus allowing free rotation and connected to a calibrated force gauge. The maximum tensile force and lever arm radius were recorded to calculate torque. For VCE with excessive displacement, qualitative assessments and torque estimations based on displacement data were performed. Data were compared with MRI safety limits described in ISO/TS 10974:2018(E). Length of the paramagnetic interior parts of each VCE was calculated from the measured length and the ratio of internal ferromagnetic parts to the outer surface on X-ray images.

Results All VCE except NaviCam Colon demonstrated deflection angles greater than 45 °, indicating displacement forces exceeding gravitational forces within the 3 T static magnetic field. The cutoff for MRI safety was therefore not met in 10 of 11 tested devices. Capsules containing small permanent magnets allowing gastric navigation by external magnets, exhibited significantly higher displacement forces compared to VCE without magnet (2338 mN vs. 168.1 mN; $p < 0.0001$). In contrast, mean gravity was 36.4 mN.Torque measurements were successfully performed for eight VCE models, ranging from undetectable to 54.0 mNm. All but one capsule (NaviCam Colon) exceeded the individual gravity-induced torque safety limit (mean 1.04 mNm). For the three magnet-containing capsules torque measurement was not possible due to strong displacement forces. Instead, estimated torque values based on displacement measures were calculated, ranging from 271.95 to 293.90 mNm. Mean X-ray assisted length estimation of internal paramagnetic parts was 21.3 mm (range 18.2 – 25.4 mm).

Conclusions This study provides the first systematic experimental evaluation of magnetic displacement force, and torque acting on VCE in a 3T MRI environment. Induced forces on all but one tested capsules exceed safety thresholds defined for passive medical implants, especially for VCE containing integrated permanent magnets. Estimated length of paramagnetic VCE parts was within or only slightly above the limit of 24 mm for dynamic thermal effects in a 3T MR environment. Furthermore, VCE include air and a protective plastic cover likely protecting from thermal damage. Hence no direct thermal measurements were performed.Although the measured and calculated forces remain below those reported to cause bowel perforation, the findings highlight a potential safety hazard in clinical practice. Interdisciplinary awareness of these risks is critical for clinicians and MRI staff. Future research should include in-vivo and clinical safety assessments, as well as manufacturer-specific labeling, consideration of MR compatibility by engineers, and improved workflow for device identification before MRI procedures.

eP1210 To re-scope or not to re-scope? — The gastric ulcer dilemma

Authors Garcia AC[1], Bordalo Ferreira F[1], Alexandrino G[1]

Institute **1** Hospital Fernando Fonseca, Amadora, Portugal

DOI 10.1055/s-0046-1822537

Aims The increasing demand on endoscopy units in Portugal requires optimization of the diagnostic yield of procedures. Routine endoscopic re-evaluation is based on limited evidence. Recent studies support an individualized approach, reserving repeat endoscopy for patients at higher risk.

To assess the incidence of malignant gastric ulcer in a cohort of patients undergoing upper gastrointestinal endoscopy and to identify clinical, endoscopic, and histological predictors of malignancy that may guide the need for endoscopic re-evaluation [1–4].

Methods Retrospective observational study conducted in the Gastroenterology Department, including patients with gastric ulcer diagnosed on upper endoscopy between January and December 2024. Demographic, clinical, endoscopic, and histological data from index and follow-up endoscopies were collected. Descriptive and univariate analyses were performed using Microsoft Excel.

Results A total of 101 patients were included (mean age 69 years; 72 % male); 59 % of endoscopies were elective, and biopsy was performed in 75 % of index procedures. Seven malignant ulcers (6.9 %) were identified, 71 % diagnosed at the index endoscopy. Among 53 ulcers reassessed endoscopically, most showed mucosal healing (79 %).Endoscopically suspicious ulcers represented 27 % of cases, of which 26 % were malignant. Among ulcers deemed benign, only 1/74 (1.3 %) was later found to be malignant (late malignancy rate 2.7 %).The strong-

est predictors of malignancy were endoscopic suspicion—particularly excavated base and/or elevated borders (OR 17.2; 95 %CI 0.8–372)—and non-antral location, especially the incisura (OR 4.03; 95 %CI 0.75–16.6; p = 0.12), showing a trend toward increased risk. Ulcer size was also a strong and independent predictor: ulcers > 20 mm were significantly associated with malignancy (OR 12.5; 95 %CI 2.0–78.0; p = 0.0026).Comorbidities most strongly associated with malignancy included cardiovascular disease (OR 3.22), chronic kidney disease (OR 4.64), antiplatelet therapy (OR 6.26), and smoking (OR 6.03).Helicobacter pylori at index endoscopy showed a non-significant trend toward lower malignancy risk (OR 1.8; p = 0.12).A benign initial histology was a strong predictor of benign disease.The presence of multiple ulcers (≥ 2), including duodenal ulcer, was associated with a lower probability of malignancy (OR 0.10; 95 %CI 0.005–1.76; p = 0.043), supporting the observation that malignant ulcers tend to present as single lesions.All malignant cases occurred in patients aged > 50 years, but age ≥ 50 did not reach statistical significance (OR 1.86; 95 %CI 0.10–35.0; p = 1.00). Sex was not associated with malignancy (OR 0.85; 95 %CI 0.18–4.05).Presentation with overt bleeding at index endoscopy was not significantly associated with malignancy.

Conclusions In this cohort, 7 % of gastric ulcers were malignant, most diagnosed at the index endoscopy with adequate histological sampling. The diagnostic yield of routine re-evaluation after benign biopsies was low. The combination of benign histology and absence of suspicious endoscopic features was sufficient to exclude malignancy in most patients, supporting a risk-stratified approach.These findings align with current international guidelines (MAPS III, ESGE/AGA/ASGE) and support a strategy that may reduce costs, optimize resource allocation, and improve the sustainability of endoscopy services. Validation in larger, multicenter cohorts is warranted.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1211 Multi-Center Evaluation of Novel Point-Of-Care Blood Detection Capsule: Advancing Clinical Decision-Making and Optimizing Resource Utilization

Authors Hayat H[1], Szvarca D[1], Walradt T[1], Soleymanjahi S[1], Ryan M[1], Zeid HA[2], Storm A[2], Lee L[1]

Institutes **1** Brigham and Women's Hospital, Boston, United States of America; **2** Mayo Clinic, Rochester, United States of America

DOI 10.1055/s-0046-1822538

Aims Esophagogastroduodenoscopy is the gold standard for evaluating suspected upper gastrointestinal bleeding but delays in access may complicate triage and resource management. PillSense, an FDA-approved ingestible capsule that detects presence of blood through optical absorption, provides a rapid and non-invasive diagnostic option with results available within ten minutes. This study assessed the real-world impact of this device on clinical decision-making and resource allocation while evaluating its safety profile.

Methods A multicenter retrospective analysis was performed across two academic medical centers, including only patients with documented PillSense result. Patients were excluded for gastrointestinal obstruction, motility disorders, dysphagia, pregnancy, or implanted electromedical devices. Outcomes were compared between patients with positive and negative capsule results, including Glasgow Blatchford Score (GBS), transfusion requirements, hemodynamic instability, length of stay, thirty-day readmission, and adverse events. The influence of capsule findings on clinical management was recorded (▶ **Table 1**).

▶ **Table 1**

	Patients (n = 75)			
Mean Age	60.2 years			
Gender (n, %)	Male (54, 72 %)			
Symptoms*n*(%)				
Melena	51 (68 %)			
Hematochezia	17 (28 %)			
Hematemesis	15 (30 %)			
Coffee Ground Emesis	9 (12 %)			
Symptomatic Anemia	40 (53 %)			
Outcomes		**Negative** (n = 51)	**Positive** (n = 24)	*P value*
Length of stay (days)	*Mean (se)*	3.87 (0.82)	14.83 (5.58)	0.02*
GBS score at presentation	*Mean (se)*	7.62 (0.86)	11.68 (1.29)	0.005**
Units of Blood Transfused	*Mean (se)*	1.45 (0.50)	10.00 (6.12)	0.04*
Hemodynamically Unstable	*n (%)*	7 (21 %)	8 (47 %)	0.03*
Active bleeding on EGD	*n (%)*	4 (6 %)	18 (75 %)	0.01*

Results Seventy-five patients met inclusion criteria, of whom 24 (32 %) had a positive capsule and 51 (68 %) had a negative result. Patients with a positive result demonstrated substantially higher GBS (11.68 vs 7.62), required significantly more blood transfusions during hospitalization (mean 10.00 units vs 1.45 units), and experienced markedly longer hospital stays (14.83 days vs 3.87 days). The capsule was deployed in Emergency Department for 39 patients (52 %) and in inpatient setting for 36 patients (48 %) of which 12 were in intensive care unit (16 %). Capsule findings influenced management in 70 % of cases, including avoidance of EGD in 25 %, prioritization of urgent EGD in 12 %, and improved resource allocation in 63 % (ED observation discharges n = 18, step-down bed assignment due to early detection of GI bleeding n = 10, colonoscopy instead of EGD when upper GI bleed was excluded n = 9); among patients who did not undergo EGD (n = 12), there were no 30-day readmissions or adverse events.

Conclusions This study demonstrates that the blood detection capsule is a safe and clinically valuable point-of-care tool for suspected upper gastrointestinal bleeding. Capsule results correlate meaningfully with bleeding severity, support more accurate triage, and reduce unnecessary procedures. Incorporation of this technology into routine practice may meaningfully decrease health care burden by improving diagnostic efficiency and supporting earlier and more appropriate allocation of endoscopic and inpatient resources.

DOI 10.1055/s-0046-1822539

Aims Eosinophilic oesophagitis (EoE) is a chronic, immune-mediated disease characterised by eosinophilic inflammation of the oesophagus with peak eosinophilic count > 15 cells per high power field that may lead to remodelling and fibrotic changes and impaired oesophageal function. [1] We aim to characterize the current practices in the diagnosis, management, and follow-up of EoE at Aberdeen Royal Infirmary.

Methods We conducted a retrospective analysis of electronic data records from 2022 to 2024. This involved identifying EoE cases using histology confirmation, clinical presentation, and mode of treatment at Aberdeen Royal Infirmary, Scotland.

Results In our cohort, we found 162/690 patients had histology biopsies confirmed EoE. Most patient were Male (125/162). The median age group was 30-40 years old. We found that the most common mode of presentation was dysphagia (63 %) followed by food bolus (16.3 %). The most recognised endoscopic finding was furrows (21.6 %).

37.24 % received both Proton pump inhibitors and Jorveza (oral Budesonide dispersable tablets). 45.2 % achieved histological remission. There were 20 patients who had strictures and 10 of these patients underwent endoscopic ballon dilation. Although 74 patients had clinical follow up, there was no standardisation of management across the board with fast majority of patients had no follow up (88). Therefore, we believe that this data should raise the awareness of the importance of establishing an EoE clinic for standard medical practice and better patient outcomes.

Conclusions This audit has highlighted the importance of establishing EoE clinic for standardisation of medical practice, prevent future complications and repeat hospitalisations.

Abstract Text

Esophageal adenocarcinoma (EAC) treatment is challenging in patients unfit for surgery. We report an 84-year-old male with Barrett's esophagus (BE) who underwent ESD for a 3-cm pT1bN0M0 EAC. Histology revealed deep submucosal invasion, perivascular infiltration, negative horizontal and positive vertical resection margins, rendering the resection non-curative. Given surgical ineligibility, the patient underwent cryoballoon ablation six months later for recurrent intramucosal carcinoma proximal to the ESD scar. At three months, surveillance endoscopy revealed residual BE with low-grade dysplasia. This case highlights the feasibility and safety of cryoballoon ablation as salvage therapy after non-curative ESD in inoperable EAC. This represents the first report of salvage CbFAS in T1bN0M0 EAC, underscoring the need for further studies to define its role in multimodal management of EAC.

eP1214 Use of EndoRotor as Salvage Therapy for Refractory Barrett's Neoplasia in a High-Risk Patient

Authors Irfan B[1], Haboubi H[1]

Institute 1 Cardiff and Vale University Health Board, Cardiff, United Kingdom

DOI 10.1055/s-0046-1822541

Aims Endoscopic eradication therapy (EET) is established as first-line management for dysplastic Barrett's esophagus (BE) and early oesophageal adenocarcinoma. Although most patients respond to a combination of endoscopic

mucosal resection (EMR) and radiofrequency ablation (RFA), a proportion develop residual or non-lifting lesions that remain difficult to treat. Such cases are particularly challenging when patients are unsuitable for esophagectomy or chemoradiotherapy. The EndoRotor non-thermal mechanical resection system has demonstrated feasibility in removing BE mucosa, including fibrotic or previously treated tissue [1], and early evidence supports its safety profile [2]. We present a case illustrating its role as salvage therapy after failure of standard modalities.

Methods A 76-year-old man with long-segment BE (C11M12) was diagnosed with moderately differentiated oesophageal adenocarcinoma, with no worrying features on PET-CT and EUS. He had a history of two renal transplants for glomerulonephritis and was maintained on lifelong immunosuppression, as well as significant cardiac risk factors, rendering him high risk for surgery or chemoradiotherapy. Therefore, an endoscopic approach was favoured following multidisciplinary discussion.

He developed multi-focal neoplasia and required six EMR sessions with an excellent macroscopic response, eventually achieving Prague C0M0 status with only 2–3 residual Barrett's islands. A persistent lesion at the 5 o'clock position exhibited a Paris IIa morphology and was non-lifting, making it unsuitable for further EMR or ESD. Biopsies demonstrated high-grade dysplasia (HGD). Hybrid APC was performed (selected due to preference to perform a "deeper ablation", but dysplasia persisted, consistent with previously described RFA-refractory disease as described in the literature [3, 4]. Subsequent repeat CT-scans demonstrated stable imaging without progression, EndoRotor therapy was selected as salvage intervention.

Results Here we demonstrate EndoRotor resection as technically successful technique, enabling non-thermal mechanical removal of previously treatment-resistant Barrett's mucosa. Histopathology confirmed intramucosal carcinoma (IMCA). Follow-up endoscopy demonstrated further regression of the remaining Barrett's island with improved appearance and reduced surface irregularity. Small areas of residual mucosa remained, and a repeat EndoRotor session was planned. No immediate or delayed adverse events occurred, consistent with reported low complication rates [2]. Repeat radiological surveillance showed no local progression, nodal involvement, or distant metastasis.

Conclusions This case highlights the value of EndoRotor as a salvage modality for refractory Barrett's neoplasia when Endoscopic resection modalities (EMR or ESD) and Ablation techniques (RFA or APC) are insufficient, particularly in patients unable to undergo surgery or oncologic therapy. Its non-thermal mode of action appears advantageous in previously ablated or fibrotic tissue, allowing targeted resection while limiting thermal injury. Emerging evidence supports its feasibility, safety, and potential utility in complex or treatment-resistant Barrett's pathology [1–4]. EndoRotor may represent an important adjunct in the evolving management paradigm for advanced or refractory BE.

eP1215V Alligator-assisted esophageal ESD in a compact and extensive early Barrett's cancer lesion

Authors Tvaradze G[1], Groth S[1], Lleshi D[1], Ewerton MM[2], Schneider PM[1], Tanabe M[3], Yamamoto K[3], Inoue H[3], Seewald S[1]
Institutes **1** GastroZentrum Hirslanden – Swiss Digestive Health Center – Klinik Hirslanden, Zürich, Switzerland; **2** medica MEDICAL LABORATORIES Dr. F. KAEPPELI AG, Zürich, Switzerland; **3** Showa University Koto Toyosu Hospital, Tokyo, Japan
DOI 10.1055/s-0046-1822542

Problem to solve Endoscopic submucosal dissection (ESD) of large and compact esophageal lesions is technically demanding, especially in the later stages of the procedure. The partially dissected specimen often becomes floppy and obscures the dissection field. This loss of visualization and traction limitation makes precise submucosal dissection challenging. Conventional traction methods, especially at this stage of the procedure, provide only limited axis movements and cannot be easily repositioned.

Innovation The novel EndoRobotics Alligator (ROBOPERA & TraCloser) device is designed for flexible multipoint traction. The device provides true four-axis independent movements (grip, wrist, arm, and rotational movements), enabling multidirectional traction. The operator can lift, rotate, pull, or push the lesion in multiple directions and reposition at any time, maintaining continuous exposure of the submucosal layer and preventing the partially dissected specimen from obstructing the field. This multidirectional control improves visualization, optimizes tissue tension, facilitates efficient and precise dissection, and allows safe en-bloc specimen retrieval using the same device.

We report the first case of an EndoRobotics Alligator–assisted esophageal ESD of an 11 cm early Barrett's adenocarcinoma extending over 70 % of the circumference, with a compact component of 3–4 cm. The use of this novel device was authorized by the Institutional Review Board.

Results After circumferential incision and completing dissection of 70 % of the lesion, visualization and access to the dissection plane worsened. The Alligator device was used at this later stage of the procedure to lift the compact specimen in order to re-visualize the dissection plane, maintain tension, and finalize the dissection.The lesion was successfully resected en bloc. R0 resection was histologically confirmed. No intra- or post-procedural adverse events occurred.

Conclusions Alligator-assisted robotic traction is a valuable tool during esophageal ESD, particularly in challenging cases involving large or compact lesions. By providing dynamic multidirectional traction, it complements conventional ESD techniques and enhances visualization, stability, and dissection efficiency. This case demonstrates that integrating robotic traction into ESD can support safer and more controlled tissue handling.

eP1216 Clinical outcomes and ph-impedance results predicting recurrence rates of circumferential Barrett's Esophagus after successful Treatment with Radiofrequency Ablation

Authors Maione F[1], Chini A[1], Maione R[1], Ricchiuti M[1], Pesce M[1], Sarnelli G[1]
Institute **1** Azienda Ospedaliera Universitaria Federico II – "Policlinico", Napoli, Italy
DOI 10.1055/s-0046-1822543

Aims Radiofrequency ablation (RFA) is an effective treatment for circumferential Barrett's esophagus (BE). However, recurrence of BE after initially successful RFA is common, and outcomes following recurrence not well described. The aim of this study is to find clinical signs and ph-impedence results able to predict circumferential Barrett's esophagus recurrence following initially successful RFA

Methods In 15 patients undergoing a single session of circumferential Radiofrequency Ablation (BarrX 360 °) on proton pump inhibitor (PPI) therapy, clinical symptoms are investigated and 24h-pH-impedance measurements were performed after 3 months of treatment. On pH monitoring, total acid exposure time (AET) > 6 % was defined as pathological reflux [1–3]

Results Pathological reflux was identified in 6 patients (40 %), of whom only 2 patients referred reflux symptoms. Other 3 patients of 15 referred reflux symptoms, but their ph-impedance measurements didn't show pathological values of acid exposure.

Conclusions 30 % of asymptomatic patients treated for BE with circumferential Radiofrequency ablation exhibit pathological reflux on pH-monitoring despite PPI treatment. Conversely, clinical symptoms of reflux is not necessarily linked

to pathological acid exposure and therefore to an increased risk of post-ablation BE recurrence

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822544

Aims To assess the efficacy and safety of a bipolar knife in POEM.

Methods Single-center retrospective study including patients undergoing POEM between October 2023 and May 2025, using the Speedboat knife and the CROMA energy platform (Creo Medical, UK). Categorical variables were presented as frequencies and percentages. Continuous variables were summarized using median and interquartile range (IQR). To compare the pre- and post-POEM Eckardt scores we used the Wilcoxon signed-rank test for paired samples. The Speedboat knife has an insulating cover on one side that reduces the risk of accidental mucosal injury, is 1:1 rotatable, and incorporates a needle/injection channel. The CROMA platform provides bipolar radiofrequency cutting as well as microwave coagulation, making the use of a hemostatic forceps hardly necessary.

Results Seventy-five patients were included (median age 52 years, 61.3 % male, 83.8 % ASA I–II). Achalasia was the most frequent indication (86.6 %). Forty-six point seven per cent had undergone previous treatment (29.3 % with one technique and 17.3 % with more than one technique). The median length of the submucosal tunnel was 11 cm (IQR 11–15). In most cases, the myotomy was posterior (89.3 %) and full-thickness (97.3 %), with a median length of 5 cm (IQR 5–8) in the esophagus and 2.5 cm (IQR 2–3) in the stomach. The location of the gastric myotomy was determined by visual inspection in 98.7 % of cases. A total of 5 clips (IQR 4–5) were used for mucosotomy closure. Technical success was 100 %, and clinical success (post-POEM Eckardt score ≤ 3) was 93.3 % after 24 months follow-up (IQR 12–24). The median Eckardt score decreased from 6 (IQR 3–8) pre-POEM to 1 (IQR 0–2) post-POEM ($p < 0.0001$). Proton pump inhibitors use increased from 34.7 % pre-procedure to 75.7 % after POEM. Complications occurred in 5 cases (6.7 %): 1 inadvertent mucosotomy, 1 bleeding, 2 pneumonias, and 1 esophagopleural fistula. Median hospital stay was 3 days (▶ **Table 1**).

▶ **Table 1**

BASELINE PATIENT CHARACTERISTICS	N	Median (IQR) or N (%)
Age (years)	75	52 (37-63)
Sex		
Male		46 (61.3 %)
Female	75	29 (38.7 %)
ASA		
I-II		62 (83.8 %)
III-IV	74	12 (16.2 %)
Indication		
Achalasia		65 (86.6 %)
Type I		6 (8 %)
Type II		43 (57.3 %)
Type III		7 (9.3 %)
Unknown type		9 (12 %)
Distal esophageal spasm		3 (4 %).
Hypercontractile esophagus		1 (1.3 %)
Other	75	6 (8 %).
Prior treatment		
No		40 (53.3 %)
1 technique		22 (29.3 %)
>1 technique	75	13 (17.3 %)
Duration of prior symptoms (months)	44	24.3-120
Sigmoid esophagus	75	26 (34.7 %)
Pre-POEM Eckardt score	63	6 (3-8)
Pre-POEM PPIs use	75	26 (34.7 %)
Pre-POEM IRP	45	22 (15.1-31.6)

Conclusions Performing POEM with a bipolar knife seems as effective and safe as using a monopolar knife and may provide additional theoretical advantages regarding the energy delivery (lower risk of peripheral tissue damage, no interference with implanted devices).

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1218 Biliary strictures in liver transplantation recipients: recurrence risk factors after treatment with fully-covered self-expanding metal stents via ERCP

Authors Romero Martínez M[1], Gómez Gómez A[1], Fernández Nievas R[1], López-Picazo García M[1], Bógalo Romero C[1], Sánchez Roncero FJ[2], Madrigal Bayonas L[2], Calatayud Vidal G[3], Ana PL[1], Martinez Caselles A[1], Egea Valenzuela J[1], Alberca De Las Parras F[1]

Institutes 1 Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; 2 Rafael Méndez University General Hospital, Lorca, Spain; 3 Rafael Méndez Hospital, Lorca, Spain

DOI 10.1055/s-0046-1822545

Aims Biliary complications after liver transplantation (LT) occur between 5 % and 25 % of patients in some studies. Out of those, biliary strictures (BS) are the most frequent. Such can be divided into anastomotic or non-anastomotic and early or late regarding to its location in the biliary tract and time of onset. Standard treatment is the placement of a fully-covered self-expanding metal stent (FC-SEMS) via endoscopic retrograde cholangiopancreatography (ERCP) for six months, although there are no clear recommendations in guidelines. However, some patients present a BS recurrence after FC-SEMS withdrawal. Although risk factors for BS have been studied, no studies analyse risk factors for recurrence [1–3].

Methods We collected, retrospectively, our center's ERCP data from January 2012 to July 2023. Out of 2647 ERCPs, 1036 of them identified BS. After careful revision of those, 136 procedures were done on LT recipients with BS. Out of those, patients who were treated with FC-SEMS were selected as the study population (▶ **Table 1**).

▶ **Table 1** Simplified statistical results comparing patients with recurrent BS (column 2) to patients without recurrent BS (column 3) and Odds Ratio.

	Patients with recurrent BS after first ERCP (n = 33)	Patients without recurrent BS after first ERCP (n = 17)	Calculated Odds Ratio (IC 95 %)
Sex (M/F)	26 / 7	14 / 3	0.79 (0.18 – 3.57)
Cardiovascular risk factors	15/33	10/17	0.59 (0.18 – 1.91)
CMV incompatibility in serological test	3/33	1/17	1.60 (0.15 – 16.67)
Hepatic artery stenosis	14/33	5/17	1.77 (0.51 – 6.18)
Use of T-tube	4/33	5/17	0.33 (0.08 – 1.45)
Early biliary leak	10/33	2/17	3.26 (0.62 – 17.01)

▶ **Table 1** Simplified statistical results comparing patients with recurrent BS (column 2) to patients without recurrent BS (column 3) and Odds Ratio.

	Patients with recurrent BS after first ERCP (n = 33)	Patients without recurrent BS after first ERCP (n = 17)	Calculated Odds Ratio (IC 95 %)
Early biliary stricture	24/33	6/17	4.89 (1.39 – 17.16)
Early post-LT infection	13/33	7/17	0.93 (0.28 – 3.06)
Early post-LT CMV infection	6/33	1/17	3.56 (0.39 – 32.27)

50 patients were included in this study, 33 presenting recurrence of BS (case group) while 17 did not develop a recurrence (control group). Patient selection is summarized in Figure 1. Factors related to the surgical procedure (use of biliary T-tube), patient (sex, age, LT indication, cardiovascular risk factors) and transplant (AB0 incompatibility, DSA incompatibility, CMV serological incompatibility, early biliary leak, early BS, hepatic artery stenosis, early post-LT infection and early post-LT CMV infection) were considered. Early BS was considered when the diagnosis was established within the first month after the LT after literature review, as well as the other early factors, although it has not been formally defined.

Results Early BS was associated with a higher risk of recurrence with an OR 4.89 (CI 95 %: 1.39 – 17.16). Other factors such as early CMV infection, early biliary leak or arterial hepatic pathology showed strong, but not statistically significant associations.

Conclusions Patients with early BS have a higher risk of recurrence after FC-SEMS for six months and may benefit from early follow-up. Recurrence of BS in the context of LT is a pathology that needs further studies to establish treatment strategies. For instance, in patients with early BS, to implant a second FC-SEMS after the withdrawal of the first in six months.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1219 EUS-guided Celiac Plexus Interventions in Pancreatitis and Pancreatic Cancer: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Authors Hu M[1], Khalaf K[1], Yuan Y[2], Nishimura T[1], Li H[1], Bucheeri MAGA[1], May G[1], Mosko J[1], Calo N[1]

Institutes 1 St. Michael's Hospital, Toronto, Canada; 2 McMaster University, Hamilton, Canada

DOI 10.1055/s-0046-1822546

Aims Chronic abdominal pain is a major source of morbidity for patients with chronic pancreatitis and pancreatic cancer, and effective pain management

options are limited. Endoscopic ultrasound (EUS)-guided celiac plexus interventions are minimally invasive procedures designed to alleviate severe upper abdominal pain associated with these conditions, however, data reporting the effect of these interventions are scarce and based in small reports. This systematic review and meta-analysis evaluates the effectiveness and safety of EUS-guided celiac plexus interventions for managing abdominal pain in patients with chronic pancreatitis and pancreatic cancer.

Methods A comprehensive search of OVID MEDLINE, EMBASE, and Cochrane CENTRAL was conducted from inception to September 1st, 2025. We included full-text randomized controlled trials (RCTs) evaluating EUS-guided celiac plexus block (CPB), celiac plexus neurolysis (CPN), or celiac ganglion neurolysis (CGN) in patients with chronic pancreatitis or pancreatic cancer. The primary outcome was the proportion of patients experiencing pain relief. Secondary outcomes included duration of pain relief, reduction in opioid consumption, and adverse events. Subgroup analyses were performed based on patient diagnosis and intervention type.

Results Fourteen RCTs (n = 596 patients) met the inclusion criteria. Four studies evaluated EUS-CPB in patients with chronic pancreatitis, and ten studies evaluated EUS-CPN or EUS-CGN in patients with pancreatic cancer. The overall pooled proportion of patients with pain relief was 70 % (95 % CI: 0.60-0.79), with significant heterogeneity (I^2 = 80 %). In subgroup analyses, the pooled proportion of pain relief was 73 % (95 % CI: 0.50-0.91) for patients with chronic pancreatitis and 68 % (95 % CI: 0.57-0.78) for patients with pancreatic cancer. Complete pain response was reported in five studies with a pooled proportion of complete pain response of 23 % (95 % CI: 0.09-0.41). The mean duration of pain relief, reported in four studies, was 89.8 days, and seven studies reported on changes in opioid consumption with a pooled reduction of opioid use by 39 % (95 % CI: 0.20-0.58). Unilateral versus bilateral technique for EUS-guided interventions did not have any significant differences in pain reduction. Serious adverse events were infrequent; three studies reported a total of three major events (one upper gastrointestinal bleed, one irreversible paralysis, and one hematoma). Furthermore, two studies reported that six patients required hospitalization or an emergency department visit for severe abdominal pain.

Conclusions EUS-guided celiac plexus interventions are safe and provide significant pain relief for patients with abdominal pain secondary to chronic pancreatitis and pancreatic cancer. These findings support their use as a key component in a multimodal pain management strategy for this challenging patient population. However, significant heterogeneity across studies and few RCTs with small sample sizes highlights the need for larger, well-designed RCTs. Future research should focus on standardizing endoscopic techniques, identifying key predictors of response, and evaluating long-term effects on opioid consumption reduction and quality of life to better define the role of these interventions.

eP1220V Cholangioscopy-guided Radiofrequency Ablation to Treat Biliary Intraductal Papillary Mucinous Neoplasia

Authors Bracken L[1], Craig P[1]
Institute **1** St George Hospital, Kogarah, Australia
DOI 10.1055/s-0046-1822547

Abstract Text

Bile duct intraductal papillary mucinous neoplasia (BD-IPMN) is a pre-malignant precursor to cholangiocarcinoma traditionally managed by surgery with limited data on endoscopic management. We present a case of an elderly comorbid patient with long segment BD-IPMN containing high grade dysplasia who declined surgery. Cholangioscopic and fluoroscopic videos demonstrate characteristic BD-IPMN morphology, application of cholangioscopy-guided radiofrequency ablation (RFA), post-treatment appearances, and subsequent recurrence. In this case, RFA did not achieve complete eradication but substantially reduced the overall disease length, permitting a more conservative surgical resection approach. This video highlights key diagnostic features, technical considerations, and the potential role and limitations of RFA in selected patients with BD-IPMN who are poor surgical candidates [1–4].

Aims Current guidelines recommend delaying endoscopic drainage until at least 4 weeks after the onset of acute necrotizing pancreatitis. However, in clinical practice, "early" drainage is sometimes considered for acute infected collections, despite a lack of strong supporting evidence. The primary objective of this study was to compare the clinical efficacy and safety of “early” versus “delayed” endoscopic drainage of necrotic pancreatic collections [1–4].

Methods Patients with necrotizing pancreatitis and pancreatic collections treated with "early" endoscopic drainage (< 4 weeks) in a multicentre retrospective cohort (2010–2025) were compared with patients undergoing "late" drainage (≥ 4 weeks) from a recent multicentre randomized controlled trial (PROMETHEUS, NCT03100578). A propensity score analysis using Inverse Probability of Treatment Weighting (IPTW) was performed to minimize confounding (age, sex, infection status, ASA score). The primary outcome was the need for surgical rescue. Secondary outcomes included clinical success, number of endoscopic sessions, procedure-related adverse events, and mortality (▶ **Table 1**).

Results From a total of 648 patients screened who underwent endoscopic drainage, 107 were included in the analysis: 43 in the "early" group and 64 in the "late" group. Median age was 60–65 years in both groups. The predominant aetiology was biliary pancreatitis. Confounding factors were adequately balanced after IPTW adjustment. In descriptive analysis, the need for surgical rescue was numerically higher in the "early" group, but this difference was not significant after propensity score adjustment. Early and overall adverse events were higher in the "late" group, reaching statistical significance in the propensity analysis but not in the descriptive analysis. No significant differences in mortality or clinical success were observed in either analysis. The necrosectomy rate was significantly higher in the "early" drainage group in both descriptive and propensity-adjusted analyses.

Conclusions Clinical outcomes were comparable between early and late endoscopic drainage in terms of surgical rescue, clinical success, and mortality. The "early" group required a greater number of endoscopic sessions and more frequent necrosectomy. Major adverse events were more frequent in the "late" group on propensity analysis. These findings suggest that early drainage may be a reasonable option in selected patients, although the comparison of retrospective data with RCT data represents an inherent limitation that warrants cautious interpretation.

Aims To prospectively evaluate the accordance rate between contrast-enhanced Endoscopic Ultrasound (CE-EUS) and Endoscopic Retrograde Cholangiopancreatography (ERCP) in defining intraductal tumor extension and endoscopic resectability of ampullary adenomas (AAs). Secondary aims were: to describe a tertiary referral centre's experience with endoscopic papillectomy (EP); to assess the accordance rate between endoscopic tumor size and final histopathology; to evaluate the association between CE-EUS enhancement patterns and final histopathology, including stratification by size; to determine CE-EUS uTNM and final pTNM congruity.

Methods This prospective monocentric interventional study included all consecutive patients referred for EP between January 2024 and June 2025. Inclusion criteria were: age 18–90 years, endoscopic diagnosis of ampullary tumor, absence of lymph node or distant metastases at staging MRI (if performed), ≥ 3-month follow-up, and informed consent. Exclusion criteria included prior sphincterotomy/stenting, altered anatomy, and metastatic disease. All patients underwent CE-EUS before ERCP. EUS evaluation included lesion size, ductal involvement, ductal diameters, depth of invasion, lymph nodes, presence of CBD/PD stones, and CE-EUS enhancement pattern. ERCP was performed by endoscopists blinded to EUS findings; cholangiography and wirsungography assessed intraductal growth before papillectomy. EP was performed with hot-snare resection; stenting was routinely performed except for cases with concomitant IPMN. Diagnostic accuracy of EUS and ERCP was analyzed using ROC curves and compared with DeLong's test. Follow-up duodenoscopy with biopsies was scheduled at 3, 6, and 12 months. Residual intraductal disease was treated with endoscopic resection or intraductal radiofrequency ablation (RFA).

Results To date, a total of 25 patients (52 % male; median age 58 years) were included. Median AAs size was 20 mm. CE-EUS suspected intraductal invasion in 36 % (n = 9), whereas ERCP confirmed it in 32 % (n = 8), with a median intraductal extension of 5 mm. All lesions were resected endoscopically, with en-bloc resection in 56 %. Post-procedural adverse events occurred in 40 %, mainly bleeding, all managed endoscopically or conservatively. Final histopathology showed 17 LGD (68 %), 5 HGD (20 %), 2 no dysplasia (8 %), and 1 adenocarcinoma (uT1bN0M0 / pT1bN0M0). R0 resection was achieved in 56 %, R1 in 20 %, and R2 in 24 %, the latter exclusively in cases with intraductal involvement. Excluding the adenocarcinoma and the two lesions not confirmed as adenomas, 15 out of the 22 confirmed AA (68.2 %), were uTis/uT1a on EUS, whereas 7 (31.8 %) were overstaged as uT1b despite the absence of invasive behavior at final pathology. No significant association emerged between CE-EUS uT staging and dysplasia grade (HGD: 14.3 % in uT1b vs 26.7 % in uTis/uT1a; p = 0.36). EUS and ERCP showed excellent diagnostic accuracy for intraductal invasion (AUC 0.96 vs 1.00; p = 0.9) and high accordance rate (88.9 %). One minimal 5 mm ductal extension suspected by EUS was not confirmed by ERCP or pathology. Tumor size and CE-EUS enhancement pattern were not associated with malignancy (p > 0.1). Kudo and JNET classifications showed limited accuracy (52 %). At 3-month follow-up, residual adenoma was found in 37.5 % of cases, mostly those with initial ductal involvement. Endoscopic retreatment, mainly RFA, yielded an overall clinical success rate of 81 %. No deaths occurred.

Conclusions According to our limited experience, in patients without nodal or metastatic disease at MRI, EUS and ERCP showed very high accordance rate in assessing intraductal extension of AAs. ERCP was slightly more specific, whereas EUS tended to overestimate minimal intraductal involvement. Furthermore, EUS overstaged uT-staging in over 30 % of AAs. CE-EUS enhancement patterns and endoscopic surface classifications were not predictive of malignancy. Routine pre-papillectomy EUS, even with CE, may therefore not be required for all lesions. EP proved to be safe and effective, with high clinical success using a stepwise endoscopic approach including intraductal RFA when required. Lager multicentre studies are needed to refine criteria for EUS selective application.

Aims Chronic and recurrent acute idiopathic pancreatitis remains a clinical challenge, particularly regarding the management of disease flares, interventional therapies and long-term outcomes. This study aimed to identify potential risk and protective factors associated with clinical outcomes and to guide therapeutic management, particularly endoscopic and surgical strategies, in these patients [1–4].

Methods We conducted a retrospective single-centre cohort study at a tertiary university hospital, including 80 consecutive patients with chronic or recurrent acute idiopathic pancreatitis carrying at least one pathogenic or likely pathogenic variant associated with hereditary or genetic pancreatitis. The main outcome was clinical remission, defined as absence of symptoms and no stent dependency at last follow-up, in patients who underwent at least one interventional treatment. Demographic, genetic, morphological and clinical variables were collected. Univariable logistic regression was used to assess predictors of clinical remission. Cox proportional hazards models were applied to evaluate time-to-event outcomes, using death, documented recurrence or ongoing stent dependency as events.

Results Among 80 patients, 32.5 % (n = 26) were children (age at diagnosis < 18 years) and 60 % (n = 48) were female. The median age at diagnosis was 27 years (IQR 13–46), and 9 years (IQR 7–13) among children. A total of 120 genetic variants were identified, including 39 CFTR, 36 PRSS1 and 28 SPINK1 mutations. A positive family history of pancreatitis was present in 28.8 % (n = 23). Pancreas divisium and toxic exposure were each present in 35 % (n = 28). Exocrine and endocrine insufficiency occurred in 33.8 % (n = 27) and 22.5 % (n = 18), respectively. One patient died from pancreatic cancer. Fifty-five patients underwent at least one interventional treatment, with a median of 2 procedures (IQR 0–5). A total of 323 interventions were performed, including 8 pancreatic resections and 7 drainage surgeries. The median disease duration at first interventional treatment was 4 years (IQR 0–9). The median total follow-up was 12.5 years (IQR 4.3–16.8), and the median follow-up after the last interventional treatment was 12 months (IQR 2–24). At the last clinical evaluation, 71 % (n = 39) of treated patients were asymptomatic and free of stenting, with a median post-interventional follow-up of 17 months (IQR 7–37) in this subgroup. In univariable logistic regression, none of the demographic, genetic or clinical variables reached statistical significance for predicting clinical remission. However, older age at diagnosis (OR 1.01; 95 % CI 0.98–1.04; p = 0.59) and longer disease duration at first interventional treatment (OR 1.04; 95 % CI 0.96–1.13; p = 0.36) trended toward higher odds of remission. Conversely, pancreas divisium (OR 0.34; 95 % CI 0.10–1.12; p = 0.076), toxic exposure (OR 0.39; 95 % CI 0.11–1.33; p = 0.13) and endocrine insufficiency (OR 0.43; 95 % CI 0.12–1.54; p = 0.20) trended toward lower odds of remission. In multivariable logistic regression including pancreas divisium, toxic exposure, endocrine insufficiency, disease duration at first treatment and age at diagnosis, none of the variables reached statistical significance (all p > 0.10), although pancreas divisium (adjusted OR 0.44; 95 % CI 0.13–1.50; p = 0.19) and toxic exposure (adjusted OR 0.34; 95 % CI 0.09–1.38; p = 0.13) remained associated with lower odds of remission. In Cox proportional hazards analysis, pancreas divisium was associated with a higher hazard of clinical recurrence (HR 2.83; 95 % CI 1.02–7.87; p = 0.046), whereas no other clinical, genetic or morphological factor showed a robust association with time-to-event outcomes. Although the Cox model suggested a higher hazard of recurrence in patients with pancreas divisium

(HR ≈ 2.8), the log-rank test comparing Kaplan–Meier curves did not reach statistical significance (p = 0.23).

Conclusions Despite the heterogeneity of disease expression, 71 % of treated patients achieved clinical remission, indicating that most individuals derived meaningful benefit from interventional treatment management. Older age at diagnosis and longer disease duration at first interventional treatment tended to be associated with a higher likelihood of remission. Conversely, pancreas divisium, toxic exposure and endocrine insufficiency tended to be associated with a higher risk of recurrence, although these trends did not hold statistical significance.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1224 Synchronous gastric mantle cell lymphoma and early gastric adenocarcinoma: endoscopic diagnosis and curative resection of an exceptionally rare presentation

Authors Reyes Medina G[1], Rey Rubiano AM[1], Rincon R[1], Walker S[1], Gomez-Gutiérrez MA[1], Sierra V[1], Sierra Arango F[1]

Institute 1 Fundación Santa Fe de Bogotá, Bogotá, Colombia

DOI 10.1055/s-0046-1822551

Abstract Text

Synchronous gastric neoplasms are exceptionally rare, with reported coexistence of adenocarcinoma and lymphoma in only 0.08 % to 0.1 % of gastric malignancies [1]. Among them, the association of gastric adenocarcinoma with mantle cell lymphoma (MCL) is exceedingly uncommon with very few cases reported worldwide [2, 3]. Most reported cases have been diagnosed incidentally during endoscopy performed for nonspecific upper gastrointestinal symptoms. Careful endoscopic evaluation and multiple targeted biopsies are therefore crucial to identify distinct lesions that may otherwise be overlooked, highlighting the indispensable role of endoscopy in detecting such complex presentations and, in cases such as this one, enabling curative treatment through endoscopic resection techniques. We present a 68-year-old man with diabetes mellitus and peripheral arterial disease who developed new-onset dyspepsia. Initial endoscopy revealed a 50-mm ulcerated, infiltrative lesion in the antrum. Biopsies showed an atypical lymphoid infiltrate. A second endoscopy demonstrated additional ulcers in the proximal body and antrum. Immunohistochemistry identified small- to large-sized blastoïd lymphoid cells positive for CD20, CD5, and cyclin D1, with Ki-67 around 70 %, and negative for CD3, CD10, and CD23, findings consistent with blastoïd-variant MCL with focal gastric involvement. The surrounding mucosa displayed atrophic follicular gastritis and intestinal metaplasia without Helicobacter pylori. Systemic therapy with R-CHOP was initiated, achieving complete metabolic response after three cycles. Follow-up endoscopic surveillance showed mucosal healing without lymphoid infiltration, a 40 × 40 mm antral scar, and a 0-IIc lesion of 12 mm on the subcardial lesser curvature whose biopsies showed high-grade dysplasia. After multidisciplinary discussion, endoscopic submucosal dissection (ESD) with Flush knife BT 2.0 was performed, yielding a 32 × 20 mm specimen. Histopathology revealed a well-differentiated tubular adenocarcinoma (pT1b, Sm1, 400 µm submucosal invasion) measuring 16 mm, with no lymphovascular invasion and negative lateral and deep margins. The resection was deemed curative, with no indication for gastrectomy. The patient completed R-CHOP for lymphoma and remains under surveillance due to persistent atrophic gastritis and multifocal intestinal metaplasia. At 3-month endoscopic follow-up with biopsies, post-ESD scarring was observed, without new lesions. This rare case highlights the pivotal role of endoscopy across the entire spectrum of care, from early detection and targeted biopsy to curative resection and post-treatment monitoring. Coexistence of gastric MCL and gastric adenocarcinoma may reflect shared mucosal alterations such as atrophy and intestinal metaplasia that predispose to dual neoplasia (1). The use of the Flush knife BT 2.0 facilitated safe and efficient en bloc ESD, consistent with previously reported advantages of this device, including improved hemostasis and maneuverability that allow high R0 resection rates with minimal complications [4]. Accurate endoscopic assessment, histopathologic correlation, and multidisciplinary care allowed organ preservation and favorable outcome. Ongoing surveillance is essential, as both entities carry potential for recurrence or metachronous lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1225 The Risk of Pathological Upgrade for Gastric Low-grade Intraepithelial Neoplasia in A Short Period of Time: A Nomogram Prediction

Authors Han J[1], Tian Z[1], Si S[1], Ding L[1], Ji L[1], Zhan Q[1], Zhou Z[1], An F[1]

Institute 1 Wuxi People's Hospital, Wuxi, China

DOI 10.1055/s-0046-1822552

Aims Gastric low-grade intraepithelial neoplasia (LGIN) carries a risk of progression to gastric cancer (GC) in a short time. Identifying predictors of pathological upgrade is critical for precision treatment.

Methods This retrospective study analyzed 260 LGIN patients undergoing ESD within 90 days after biopsy. Clinical data, lesion characteristics (size, location, morphology, ulceration), and immunohistochemical markers (Ki67, c-MYC, MUC5AC,MUC6, CDX-2, P53, H.pylori, MLH1) were assessed. Bioinformatic

analysis identified DEGs in GIN. A nomogram was developed using multivariable logistic regression and validated via ROC, calibration, and decision curve analysis.

Results In our study, Ki67 positivity > 30 % (OR = 2.47), depressed-type lesions (OR = 2.21), and larger lesion size (OR = 1.33) are the independent risk factors for pathological upgrade. Bioinformatic analysis furtherly confirmed Ki67 is one of the key gene in high-grade lesions. The ROC, calibration, and decision curve analysis showed the nomogram has good discrimination (AUC = 0.73) and calibration for predicting pathological upgrade of LGIN patients.

Conclusions The nomogram incorporating Ki67, lesion morphology and size effectively predicts pathological upgrade of LGIN patients in a short period of time,which helps precision treatment decision-making for gastric LGIN.

DOI 10.1055/s-0046-1822554

Abstract Text

Due to early postoperative anastomotic leak after total gastrectomy, a fully-covered stent was deployed. Given the long-term persisting leak and laparotomic approach, PEJ was indicated and EUS-guided guidance proposed. A linear echoendoscope was advanced across the esophago-jejunal stent. Transillumination identified a compressible abdominal location suitable for PEJ. An endosonographic target was created placing a saline-filled sterile glove on the skin, which was then punctured with a 19G needle. A guidewire was exteriorized and tied to the kit string, which was then pulled across the abdominal wall from the mouth. Then, a standard “pull” technique was used. To increase the distance from the distal margin of the stent, the PEJ was extended distally via an 8Fr feeding tube. Two months later, after fistula healing and stent removal, PEJ was removed.

eP1228 Prevalence and predictive factors of gastric atrophy

Authors Hafi S[1], Mohamed G[2], Bizid S[2], Bouali R[2], Ben Abdallah H[2]

Institutes **1** Military hospital, Tunis, Tunisia; **2** The Military Hospital of Tunis, Tunis, Tunisia

DOI 10.1055/s-0046-1822555

Aims Assessment of gastric atrophy has long relied exclusively on histological evaluation of systematic biopsies according to the Sydney protocol. A paradigm shift is currently underway: endoscopy is emerging as a standalone diagnostic tool. The validated Kimura Takemoto classification allows real-time diagnosis of gastric atrophy, mapping of its extent, and targeted biopsy sampling. Current recommendations advocate an integrated endoscopy–histology approach with dual risk stratification. In cases of discordance, the higher associated risk dictates surveillance.

The aim of our study was to evaluate the prevalence and predictive factors of gastric atrophy.

Methods This was a single-center, cross-sectional study conducted over six months. Included patients were naïve to Helicobacter pylori eradication therapy and had not received recent antibiotics or proton pump inhibitors (PPIs). After excluding cases of isolated fundic atrophy on histology, 289 patients were analyzed. Endoscopic evaluation of atrophy was performed using the Kimura–Takemoto classification. Biopsies were obtained according to the Sydney protocol. H. pylori infection was diagnosed by histology.

Results The mean age was 46 ± 10 years, with a male-to-female ratio of 1.2 and a mean BMI of 25.4 ± 3.7 kg/m². H. pylori infection was detected in 73.3 % of cases. Endoscopic atrophy was present in 35.6 % of patients, compared with 5.2 % for histological atrophy. No significant association was found between atrophy and H. pylori status (p = 0.79 for endoscopy; p = 0.76 for histology). In multivariate analysis, age was the only independent factor associated with gastric atrophy. Each additional year of age increased the probability of endoscopic atrophy by 3 % (OR = 1.03; 95 % CI [1.01–1.05]) and histological atrophy by 6 % (OR = 1.06; 95 % CI [1.02–1.11]). Cohen’s kappa coefficient measuring agreement between endoscopy and histology was low (κ = 0.15; 95 % CI [–0.03; 0.33]), indicating no significant correlation between both methods.

Conclusions Age is the main determinant of gastric atrophy, potentially reflecting the cumulative mucosal damage over time. The low prevalence of histological atrophy compared with published data from regions with similar H. pylori prevalence may be explained by intrinsic limitations of histology: under-sampling inherent to the Sydney protocol, subjective interpretation, and low sensitivity for early atrophy. The absence of association with H. pylori was unexpected and warrants further investigation. Our findings support the relevance of a combined endoscopy–histology approach with dual stratification to optimize gastric cancer risk assessment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1229 Updated Diagnostic Approach to Autoimmune Gastritis (AIG): Highlighting Typical Endoscopic Findings

Authors Kashin S[1], Kuvaev R[2]

Institutes **1** Yaroslavl Regional Cancer Hospital, Department of Endoscopy, Yaroslavl, Russia; **2** Endoscopy Department, Yaroslavl Regional Cancer Hospital, Yaroslavl, Russia

DOI 10.1055/s-0046-1822556

Aims AIG remains relatively uncommon on a global scale, with epidemiological studies suggesting a prevalence ranging from approximately 0.5 % to 4.5 % in the general population. A considerable diagnostic gap persists, as the true number of undiagnosed or misdiagnosed AIG cases is still unclear, partly due to non-specific symptomatology in early stages. This underscores the critical importance of mastering its endoscopic recognition. The ability to accurately identify characteristic endoscopic features is therefore paramount, serving as a cornerstone for enhancing diagnostic detection rates, enabling timely intervention, and improving long-term patient management strategies.

Methods This study analyzed data from 149 patients diagnosed with AIG at two medical centers between January 2022 and June 2025. Clinical and endoscopic records were reviewed. The study involved a meticulous review of all available clinical records, laboratory data, and, most importantly, detailed endoscopic documentation (Table 1). A standardized endoscopic protocol was employed for all subjects: each patient underwent high-definition gastroscopy. The primary aim of this methodological approach was to systematically identify, document, and analyze the key endoscopic markers pathognomonic or highly suggestive of AIG.

Results The demographic profile of the studied cohort revealed a mean patient age of 59.9 years, with a marked female predominance, as women constituted 73.5 % of the group. Diagnosis was primarily based on endoscopic evaluation. Common reasons for referral included refractory iron deficiency anemia and

previously diagnosed neuroendocrine tumors (NET). Typical endoscopic findings comprised "reverse atrophy" (97.3 % of cases), dense mucus (89.2 %), and remnants of oxyntic mucosa (53.7 %). Additional observations were: white globe appearance (53.0 %), glomus-like lesions (53.6 %), type 1 NET (38.2 %), size less than 5 mm lesions (57.9 %), gastric adenocarcinoma (4.0 %), and adenomas (4.0 %)

Conclusions The study highlights key clinical and endoscopic features that facilitate accurate diagnosis of AIG, including in outpatient settings. The integration of advanced imaging modalities allows precise detection of small, early-stage type 1 NET, thereby enabling proactive management. The documented spectrum of findings—from benign inflammatory patterns to pre-neoplastic and neoplastic lesions—directly contributes to a more nuanced and individualized oncologic risk stratification for patients with AIG. This, in turn, provides a solid evidence base to guide subsequent therapeutic decisions, surveillance intervals, and patient counseling. The ongoing prospective accumulation and analysis of clinical cases within this dedicated cohort are anticipated to further enhance diagnostic precision, validate the observed patterns, and potentially uncover new correlations, ultimately refining the standard of care for this condition.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822557

Aims To demonstrate the feasibility and real-world effectiveness of KAR and STER techniques for endoscopic resection of rectal subepithelial tumors, excluding neuroendocrine tumors (NETs).

▶ **Table 1** Patients' Demographics and Clinical Indications for Resection

Variable	n (%)
Type of Hospital$_a$	Private: 10 (18.2 %); Public: 42 (76.4 %); Not specified: 3 (5.4 %)
Type of Hospital$_b$	University: 17 (30.9 %); Non-university: 27 (49.1 %); Not specified: 11 (20 %)
Gender	Male: 33 (60.0 %); Female: 22 (40.0 %)
Age, years, median (range)	60 (27–87)
ASA score	I: 24 (43.6 %); II: 28 (50.9 %); III: 3 (5.5 %)
Charlson Comorbidity Index, median (range)	2 (0–4)
Indication for endoscopic resection	Malignant potential: 19 (34.5 %); Diagnostic resection: 17 (30.9 %); Symptom-related: 19 (34.5 %)
Symptoms	None: 32 (58.2 %); Obstruction: 7 (12.7 %); Pain: 8 (14.5 %); Bleeding: 8 (14.5 %)

Methods A retrospective, multicenter study was conducted between January 2017 and October 2025. Data were collected using a standardized case report form (CRF) distributed to all participating centers. Descriptive and comparative analyses were performed to evaluate key outcomes, namely en bloc resection and adverse events, using R software (version 4.4.2).

Results Fifty-five patients were included (30 males, 55 %), with a median age of 60 years (range 27–87), from 11 centers across 9 countries (▶ **Table 1**). Diagnostic pre-resection sampling was available in 26 cases (47.3 %), most commonly obtained with EUS-FNA/FNB (41.8 %). The main indications for resection were malignant potential (34.5 %) and symptoms (34.5 %) (▶ **Table 1**). On EUS, the layer of origin was the muscularis propria in 27 cases (49.1 %), the submucosa in 18 (32.7 %), and the muscularis mucosa in 4 (7.3 %). The majority of lesions demonstrated a partially (49.1 %) or mainly endoluminal (38.2 %) growth pattern, while a mainly extraluminal component was noted in 5 cases (9.1 %). KAR was performed in 33 patients (60.0 %), STER in 20 (36.4 %), and 2 patients (3.6 %) underwent knife-assisted hybrid techniques (circumferential incision with snare resection or full-thickness resection using a knife). Lesion size, location, distance from the dentate line, and growth pattern were comparable between groups, whereas muscularis propria origin was more frequent in STER [12/20 (60 %)] than in KAR [14/33 (42 %)], p = 0.005. The median distance from the dentate line was 6.0 cm in both groups, while the median tumor size was 20 mm (range 10–58) for KAR and 29 mm (range 9–64) for STER (p = 0.07). During dissection, the plane was purely submucosal in 18 cases (32 %), intramuscular in 30 (55 %), and extended into the perirectal fat in 7 (13 %). All tumors were removed en bloc, with no septic complications. The predominant histology was GIST (34.5 %), followed by leiomyoma (21.8 %), lipoma (16.4 %), and schwannoma (9.1 %). Most GISTs were very low or low risk, and five patients received adjuvant Tyrosine Kinase Inhibitor therapy. The median procedure duration was 52.5 minutes (range 15–181). Two adverse events were recorded (3.6 %), neither directly attributable to the endoscopic intervention: one urinary tract infection and one ischemic stroke requiring ICU admission. The median hospital stay was 1 day (range 0–7). Two early recurrences in GIST cases were recorded, one managed endoscopically and the other under surveillance [1–3].

Conclusions KAR and STER appear safe and effective for rectal subepithelial tumor resection. High en bloc rates, low complications, and short hospital stay support their minimally invasive role. Prospective studies are needed to confirm these retrospective findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822558

Aims Delayed bleeding (DB) after endoscopic mucosal resection (EMR) of large non-pedunculated colorectal lesions (LNPCL ≥ 20 mm) is a frequent clinically relevant adverse event in patients with intermediate–high bleeding risk according to the GSEED-RE2 score (≥ 4). Covergel is a thermosensitive bioadhesive gel designed to seal post-EMR defects and may reduce bleeding risk. This interim analysis of the multicentre study COVER-PIC01-2023 evaluates the preliminary efficacy and safety of Covergel for preventing DB after EMR of intermediate-high risk LNPCL [1, 2].

Methods This prospective, multicentre, single-arm investigation plans to enrol 121 patients. Adults with ≥ 1 LNPCL ≥ 20 mm and GSEED-RE2 ≥ 4 underwent complete EMR followed by uniform application of Covergel using the Covercat catheter. Adjunctive clip placement could be performed at the discretion of the endoscopist. Follow-up occurred at 24–72 h, 15 ± 3 days, and 30 ± 3 days. The primary endpoint was clinically relevant DB occurring > 24 h and ≤ 30 days, defined as bleeding requiring hospitalisation, transfusion, therapeutic colonoscopy, radiological intervention, or surgery. Expected DB risk was calculated with the GSEED-RE2 model and compared with observed incidence using an exact one-sided binomial test. This interim analysis includes 69 consecutive patients with complete 30-day follow-up.

Results A total of 69 patients with ≥ 1 LNPCL ≥ 20 mm were analysed. The mean GSEED-RE2 score was 5.4 ± 1.4, corresponding to a mean predicted DB risk of 7.22 % (range: 4.1–19.8 %). Clips were placed in 39/69 patients (56.5 %). Only one DB event occurred (1.45 %), corresponding to an absolute risk reduction of 5.77 % and a relative reduction of 79.9 % compared with the expected risk; the reduction was statistically significant (exact binomial p ≈ 0.04). The single DB episode occurred in a patient with GSEED-RE2 = 9 and no clip placement. No DB occurred in the Clip + Covergel subgroup (0/39), recognising that the study is not powered for between-group comparisons. No perforations, severe post-polypectomy syndrome, or device-related adverse events were identified (▶ **Table 1**).

▶ **Table 1** Summary of interim outcomes (n = 69)

Variable	Result
Mean predicted delayed bleeding risk	7.22 %
Observed delayed bleeding	1/69 (1.45 %)
Absolute risk reduction	5.77 %
Relative risk reduction	79.9 %
Clip + Covergel cases	39/69
Delayed bleeding in Clip + Covergel group	0/39
Serious adverse events	0

Conclusions In this interim analysis, prophylactic application of Covergel after EMR of intermediate-high risk LNPCL was associated with a significant reduction in delayed bleeding compared with GSEED-RE2–predicted risk and showed a favourable safety profile. The absence of delayed bleeding in patients treated with both Covergel and selective clip placement is clinically promising, although not definitive in this non-comparative interim analysis. Recruitment is ongoing toward the target of 121 patients, and final results will be presented at ESGE Days 2026.

Conflicts of Interest V. Lorenzo-Zúñiga is co-inventor of a patent related to the Covergel technology.

DOI 10.1055/s-0046-1822559

Problem to solve Serrated polyposis syndrome (SPS) carries an elevated colorectal cancer (CRC) risk. Serrated lesions involving the appendix (SLAs) are relatively frequent in SPS but remain challenging to treat. Endoscopic mucosal resection and endoscopic submucosal dissection are hampered by limited visualization of the deep appendiceal margin, resulting in a high risk of incomplete resection and perforation. Endoscopic full-thickness resection (EFTR) improves R0 rates but typically cannot achieve complete removal of the appendix and carries a substantial risk of post-procedural appendicitis, likely due to impaired appendiceal drainage. Meanwhile, standard laparoscopic appendectomy may leave residual peri-orificial serrated mucosa. A laparoscopic appendectomy extended to the cecum can theoretically ensure wider margins, but defining an adequate lateral boundary without jeopardizing the ileocecal valve is difficult, often leading to ileocecal resection. In summary, no current strategy reliably combines complete resection, anatomical preservation and procedural safety for SLAs in patients with SPS [1–3].

Innovation We propose a laparoscopic–endoscopic cooperative surgery (LECS) approach combining, in a single session, an endoscopic full-thickness

resection performed with an over-the-scope full-thickness resection device and a laparoscopic appendectomy. Endoscopic delineation and full-thickness excision of the serrated lesion allow a radical resection while preserving ileocecal anatomy. The subsequent complete removal of the appendix prevents post-EFTR appendicitis.

Results Among 1,936 patients undergoing colonoscopy within the CRC screening program of Friuli Venezia Giulia (2021–2025), 18 (1:108) met the 2019 World Health Organization criteria for SPS. 7 of these patients (39 %) had a SLA and underwent LECS. All achieved en bloc full-thickness resection with R0 margins. Median postoperative stay was 3 days, and no postoperative complications were observed. In 3 patients (43 %), histology revealed an additional serrated lesion within the laparoscopically resected appendiceal stump, concomitant to the SLA treated, suggesting that endoscopic removal alone would not have achieved complete eradication of the disease.

Conclusions In SPS patients, SLAs remain difficult to manage with standard endoscopic or surgical approaches. Our results show that a LECS strategy enables safe and radical full-thickness resection while preserving ileocecal anatomy and eliminating the risk of post-EFTR appendicitis through complete appendiceal removal. Histology revealed additional serrated lesions within the surgicallly resected appendix in 3 patients, underscoring the multifocal nature of appendiceal involvement in SPS and the diagnostic and therapeutic value of complete appendectomy, and reinforcing the concept that the appendix represents a blind spot in the endoscopic surveillance of SPS. Therefore, LECS proved safe and effective for the complete resection of appendiceal and periappendiceal serrated lesions in SPS. These findings support considering LECS as a promising therapeutic option for SLAs in this setting.

DOI 10.1055/s-0046-1822560

Aims Computer-aided detection (CADe) systems based on artificial intelligence can assist endoscopists in identifying colorectal neoplasia. Although CADe has been consistently associated with increases in the adenoma detection rate (ADR)—a key quality indicator—its benefit in detecting sessile serrated lesions is uncertain, raising questions about its actual impact on reducing colorectal cancer (CRC) incidence. Moreover, how CADe integrates with existing advanced imaging techniques and distal attachment devices is still unclear.

Methods In this systematic review and network meta-analysis, we conducted a comprehensive search of PubMed/MEDLINE, Embase, and Scopus from inception to November 30, 2024 for randomised controlled trials evaluating the effectiveness of high-definition (HD) white-light endoscopy, chromoendoscopy, add-on devices to enhance mucosal visualisation (e.g., cuffs, caps, balloons), CADe alone, or CADe combined with other strategies, for detecting colorectal neoplasia. Outcomes included ADR and sessile serrated lesion detection rate (SDR). We performed a frequentist random-effects network meta-analysis comparing HD white-light endoscopy, chromoendoscopy, mucosal exposure systems, CADe, and combined strategies, and estimated odds ratios (ORs) with 95 % CIs. Heterogeneity and inconsistency were assessed. Risk of bias and certainty of evidence were assessed using the GRADE framework.

Results A total of 107 randomised controlled trials, comprising 84493 participants, were included in the main analysis. Compared with HD white-light endoscopy, ADR was significantly higher with CADe (OR 1.41 [95 % CI 1.29–1.53]), chromoendoscopy (OR 1.22 [95 % CI 1.13–1.31]), mucosal exposure systems (OR 1.23 [95 % CI 1.15–1.32]), and combined strategies (OR 1.74 [95 % CI 1.48–2.04]). Combined strategies ranked as the most effective approach for adenoma detection and showed significant improvements compared with each individual strategy (vs CADe: OR 1.23 [95 % CI 1.04–1.47]; vs chromoendoscopy: OR 1.43 [95 % CI 1.20–1.67]; vs mucosal exposure: OR 1.41 [95 % CI 1.19–1.67]). Combined strategies also ranked first for detecting sessile serrated lesions and were the only approach to significantly outperform HD white-light endoscopy (OR 1.93 [95 % CI 1.06–3.50]). However, they did not show statistically significant superiority when compared directly against individual strategies.

Conclusions Combining CADe with other endoscopic strategies yields the highest detection rates for both adenomas and sessile serrated lesions. These findings support broader implementation of CADe in endoscopy services, while also highlighting that CADe alone may be insufficient to achieve optimal performance for subtle, high-risk precursors. The combination of CADe with complementary strategies may therefore better meet the clinical need for maximizing diagnostic yield.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1234 Combining different strategies improves colonoscopy advanced adenoma detection performance: a systematic review and network meta-analysis

Authors Spadaccini M[1, 2], Assis Rezende RA[1, 2], Azizullah B[3], Ramai D[4], Massimi D[1, 2], de Sire R[5, 1], Alfarone L[1], Luca DS[2, 1], Rizkala T[2, 1], Menini M[1, 2], Capogreco A[1], Antonelli G[6], Mori Y[7], Rex DK[8], Repici A[2, 1], Hassan C[2, 1]

DOI 10.1055/s-0046-1822561

Aims Computer-aided detection (CADe) systems based on artificial intelligence can assist endoscopists in identifying colorectal neoplasia. Although

CADe has been consistently associated with increases in the adenoma detection rate (ADR)—a key quality indicator—its benefit in detecting advanced adenomas remains uncertain, raising questions about its actual impact on reducing colorectal cancer (CRC) incidence. Moreover, how CADe integrates with existing advanced imaging techniques and distal attachment devices is still unclear.

Methods In this systematic review and network meta-analysis, we conducted a comprehensive search of PubMed/MEDLINE, Embase, and Scopus from inception to November 30, 2024 for randomised controlled trials evaluating the effectiveness of high-definition (HD) white-light endoscopy, chromoendoscopy, add-on devices to enhance mucosal visualisation (e.g., cuffs, caps, balloons), CADe alone, or CADe combined with other strategies, for detecting colorectal neoplasia. The primary outcome was advanced adenoma detection rate (aADR). We performed a frequentist random-effects network meta-analysis comparing HD white-light endoscopy, chromoendoscopy, mucosal exposure systems, CADe, and combined strategies, and estimated odds ratios (ORs) with 95 % CIs. Heterogeneity and inconsistency were assessed. Risk of bias and certainty of evidence were assessed using the GRADE framework.

Results From a pool of 107 randomised trials, 48 trials (n = 46406) reporting advanced adenoma detection were included in this sub-analysis. Unlike general ADR, where individual technologies consistently outperformed white-light endoscopy, results for advanced adenomas were distinct. Combined strategies ranked first and were the sole approach to significantly outperform HD white-light endoscopy (OR 1.43 [95 % CI 1.15–1.78]) for aADR. Furthermore, combined strategies showed significant superiority when compared head-to-head against every individual technique (vs CADe: OR 1.30 [95 % CI 1.04–1.63]; vs chromoendoscopy: OR 1.27 [95 % CI 1.00–1.61]; vs mucosal exposure: OR 1.31 [95 % CI 1.03–1.66]).

Conclusions Across the available literature, combining CADe with other endoscopic strategies results in higher detection rates for colorectal neoplasia and uniquely enhances the detection of advanced adenomas. These findings support broader implementation of CADe in endoscopy services, while also highlighting that CADe alone may be insufficient to achieve optimal performance for lesions with the highest malignant potential. The combination of CADe with complementary strategies may therefore better meet the clinical need for improving detection of high-risk lesions.

eP1235 Comparative Analysis of Pocket Creation Method Versus Traction-assisted Colorectal Endoscopic Submucosal Dissection

Authors Aslan F[1], Ozer S[1], Aktas O[1], Hatipoglu A[1], Ak B[1], Saka B[1]
Institute 1 Koç University Hospital, Istanbul, Türkiye
DOI 10.1055/s-0046-1822562

Aims While both traction-assisted (TRC) and pocket creation method (PCM) techniques have been developed to facilitate colorectal endoscopic submucosal dissection (ESD), yet comparative data remain limited. This study aimed to compare clinical outcomes between TRC and PCM, with a particular focus on dissection speed and factors influencing it.

Methods 256 consecutive colorectal ESD procedures were retrospectively analyzed at our institution (145 PCM, 111 TRC). Primary outcomes included en bloc resection, R0 resection, curative resection rates, and dissection speed. Secondary outcome includes adverse events. Statistical analysis included Fisher's exact test and the Chi-squared test for categorical variables and the Mann-Whitney U test for continuous variables. Multivariable Firth logistic regression adjusted for lesion size, lateral spreading tumor (LST) classification, anatomical location, gender, invasion depth, and fibrosis.

Results Both techniques achieved 100 % en bloc resection with comparable R0 (98.6 % PCM vs 100 % TRC, p = 0.214) and curative resection rates (91.0 % PCM vs 96.4 % TRC, p = 0.088). Notably, mean dissection speed showed no statistical difference (48.6 ± 29 mm²/min PCM vs 49.9 ± 34.9 mm²/min TRC, p = 0.722) with similar mean dissection times (43.7 vs 42.2 min, p = 0.218). In univariate analysis, technique choice was not a significant determinant of dissection speed (p = 0.344), while multivariable analysis revealed F2 fibrosis as the strongest determinant of dissection speed (p < 0.001), and larger dissection size associated with faster speed (p = 0.021). No significant differences were observed in adverse events (perforation: 0.7 % PCM vs 1.8 % TRC, p = 0.581). PCM was predominantly used for rectal lesions (36.6 % vs 6.3 %, p < 0.001), while TRC was preferred for colonic lesions. The PCM group had more carcinomas (33.8 % vs 14.4 %, p < 0.001) and invasive lesions (17.2 % vs 5.4 %, p = 0.004). LST morphology distribution differed significantly (p = 0.017).

Conclusions Both PCM and TRC techniques demonstrate equivalent efficacy in terms of en bloc, R0, curative resection, and safety profile, but neither technique provided a speed advantage. These findings support both PCM and TRC as valuable, complementary tools in colorectal ESD and indicate that technique choice should be guided by lesion characteristics rather than expectations of faster and safer dissection.

eP1236 The AGREE classification for gastrointestinal endoscopy-related adverse events: three-year evaluation and extended recommendations

Authors van Bokhorst QNE[1], Bierma H[1], Nass KJ[2], Dekker E[1], Van Der Vlugt M[1], Fockens P[1, 3]
Institutes 1 Department of Gastroenterology and Hepatology, Amsterdam UMC, Amsterdam, Netherlands; 2 Department of Gastroenterology and Hepatology, Rijnstate Hospital, Arnhem, Netherlands; 3 Department of Gastroenterology, Waikato Hospital, Hamilton, New Zealand
DOI 10.1055/s-0046-1822563

Aims In 2021, a new classification for grading adverse events (AEs) related to gastrointestinal (GI) endoscopy was introduced: the AGREE classification [1]. This classification aimed to minimize subjectivity in AE assessment and severity grading compared to existing classifications, and allow for easier and more robust comparisons of endoscopic and surgical interventions. The aim of this review was to evaluate the impact and status of the classification three years following its introduction.

Methods We performed a systematic scoping review to identify articles referencing the original AGREE publication [1] up to March, 2025. Articles were reviewed to evaluate the classification's global uptake, use for intra- and interdisciplinary comparisons, and comparability with other classifications. Moreover, identified articles were screened to identify complex AE scenarios, defined as (potentially) incorrectly graded AEs, and AEs for which assignment of a severity grade based on the case description was considered challenging. Complex scenarios were discussed in a consensus meeting involving the lead authors of the original AGREE publication. For all scenarios, consensus on grading was reached through discussion among three of the lead authors (K.N., M.V., P.F.) of the original AGREE publication. A selection of illustrative complex scenarios was made and additional recommendations for grading of these scenarios were established. Additionally, articles were screened for AE reporting practices that may impede the accurate definition, interpretation, and comparison of AEs. The identified reporting practices were used to develop a new checklist to guide more standardized AE reporting using the AGREE classification.

Results A total of 167 unique articles referencing the original AGREE publication were identified, involving 33 countries across five continents. A notable year-over-year increase in annual citations was observed (range: 8 to 83). In

terms of intradisciplinary comparisons, the AGREE classification was proven feasible for direct comparison of AEs across (i) different endoscopic treatment modalities in similar patient groups (21 studies), (ii) similar endoscopic treatment modalities in different patient populations or performed by endoscopists with different levels of expertise (8 studies), and (iii) endoscopy units (1 study). In terms of interdisciplinary comparisons, the AGREE classification facilitated comparison of AEs related to endoscopic interventions with both surgical (3 studies, 3 study protocols) and radiology-guided alternatives (1 study). Moreover, a significant correlation between AE severities as graded by the AGREE classification and the American Society for Gastrointestinal Endoscopy (ASGE) classification was reported (2 studies). Concordance in AE severities among clinicians was greater for AEs assessed using the AGREE compared to the ASGE classification (κ = 0.80 vs. 0.60) [2]. In terms of complex scenarios, nine illustrative scenarios were selected, for which consensus-based recommendations were established. Based on identified (variability in) AE reporting practices, a checklist to guide standardized AE reporting was composed (key recommendations included in ▶ **Table 1**).

▶ **Table 1**

▢ 1. Describe the used definition for AEs
▢ 2. Describe how AEs were identified and where AEs were registered or recorded
▢ 3. Describe the timeframe during which AEs were monitored (+ preferably adhere to the recommended 30 post-procedural days timeframe; if not, provide rationale)
▢ 4. If applicable, describe the different groups for which AEs were evaluated
▢ 5. Report the incidence, type and severity of all AEs (+ avoid subjective terminology)
▢ 6. Consider reporting relevant events not meeting the criteria for an AE as "incidents"
▢ 7. Consider reporting additional textual information on any unexpected or unusual AEs

Conclusions This review illustrates the rapid uptake of the AGREE classification and outlines its feasibility to facilitate intra- and interdisciplinary comparisons, along with greater interobserver agreement in AE severity grading when compared to other classifications. Findings of this review highlight the potential of the AGREE classification to serve as a widely accepted classification for GI endoscopy-related AEs. The extended recommendations provided in this review could help to further standardize the identification, grading, and reporting of AEs, thereby increasing opportunities for evaluating and optimizing quality of GI endoscopy.

eP1237 Optimizing Anticoagulant Resumption After Gastrointestinal Bleeding: A Prospective Single-Center Cohort of 162 Patients

Authors Aouroud M[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute 1 CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco

DOI 10.1055/s-0046-1822564

Aims Resuming anticoagulant therapy after gastrointestinal bleeding is a frequent and critical clinical dilemma. Early resumption may increase recurrent bleeding, whereas delayed resumption raises thromboembolic risk. Prospective data evaluating timing and structured protocols remain limited.

Methods We conducted a prospective single-center cohort study including 162 consecutive adult patients presenting with gastrointestinal bleeding over two years, confirmed endoscopically. Exclusion criteria were hereditary hemorrhagic telangiectasia, portal hypertensive gastropathy, radiation-induced vascular lesions, inflammatory bowel disease, post-endoscopic duodenal bleeding, and incomplete follow-up. Patients were managed according to a standardized anticoagulant resumption protocol, stratifying timing into < 7 days, 7–14 days, and > 14 days post-bleeding. Recurrent bleeding was defined as new hematochezia or melena, hemoglobin drop ≥ 2 g/dL, need for transfusion, or endoscopic confirmation. Follow-up included scheduled visits, electronic records, and structured telephone contact. Kaplan-Meier curves estimated recurrence-free survival and Cox proportional hazards models identified predictors.

Results Recurrent bleeding occurred in 28 patients (17.3 %). Recurrence was highest in patients resuming anticoagulants < 7 days (12/42, 28.6 %), intermediate for 7–14 days (10/68, 14.7 %), and lowest for > 14 days (6/52, 11.5 %; log-rank p = 0.03). Cox regression identified early resumption (< 7 days, HR 2.3, 95 % CI 1.1–4.9, p = 0.03), chronic kidney disease (HR 1.9, 95 % CI 1.0–3.5, p = 0.04), and age > 75 years (HR 1.8, 95 % CI 1.0–3.2, p = 0.05) as independent predictors of recurrence. No thromboembolic events were observed during follow-up in patients with delayed resumption (7–14 or > 14 days). The standardized resumption protocol allowed individualized risk stratification and guidance for clinical management.

Conclusions This prospective single-center study demonstrates that timing of anticoagulant resumption critically impacts recurrent gastrointestinal bleeding. Early resumption within 7 days is associated with the highest recurrence. A structured resumption protocol enables safer, evidence-based management, allowing clinicians to tailor therapy while minimizing bleeding risk. These findings provide practical guidance for daily clinical decision-making and can inform multicenter validation studies.

eP1238 Evaluation of Procedural Simulation as a Teaching Method in Diagnostic Digestive Endoscopy

Authors Aouroud M[1], Bouhdoud N[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute 1 CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco

DOI 10.1055/s-0046-1822565

Aims Procedural simulation is an innovative educational method that provides a safe environment for learning diagnostic digestive endoscopy techniques. It complements traditional apprenticeship-based clinical training, thereby reducing risks to patients. Since the introduction of simulators at the Simulation Center in Marrakech, this approach has been integrated into gastroenterology resident training.

The objective of this study was to evaluate the effectiveness of procedural simulation-based learning for residents in diagnostic digestive endoscopy.

Methods This prospective cross-sectional study involved 13 first- and second-year gastroenterology residents aged 26 to 28 years. Training was con-

ducted at the Simulation Center using low-fidelity simulators under the supervision of experienced instructors. The training protocol included repeated and progressive practical sessions, followed by two types of assessments. Self-assessment was performed by the residents before and after training. External assessment was conducted by instructors to evaluate technical skills, including endoscope handling, navigation, and anatomical recognition, as well as behavioral competencies.

Results Results showed that all 13 residents reported significant improvement in technical skills in the self-assessment, with an average gain of 45 percent. Instructor evaluation confirmed notable progress in mastering technical gestures, with improved performance in both upper and lower endoscopy. The average satisfaction score among participants, measured on a scale from 1 to 5, was 4.3 ± 0.6, indicating high perceived effectiveness and usefulness of the training. Instructors also noted improvement in relational skills and professional behavior. Only one resident reported minimal progression, perceiving no change in skills after the training.

Conclusions In conclusion, procedural simulation is an effective educational method that allows gastroenterology residents to rapidly acquire the technical skills required for diagnostic digestive endoscopy. Residents demonstrated significant progress in a safe learning environment with high satisfaction, supporting the systematic integration of procedural simulation into gastroenterology training programs.

eP1239 Sellick Maneuver Improves Gastric Visualization in Patients with Weak LES

Authors Ketenci YB[1], Bektaş A[1], Demiröz H[1], Akca M[1], Bilgin S[1]
Institute 1 Ondokuz Mayıs University – Faculty of Medicine, Samsun, Türkiye
DOI 10.1055/s-0046-1822566

Aims The Sellick maneuver (cricoid pressure) is traditionally used to prevent aspiration during intubation. This study aimed to evaluate the safety and efficacy of the Sellick maneuver in improving gastric visualization and diagnostic yield in patients with weak lower esophageal sphincter (LES) during sedated gastroscopy (▶ **Table 1**).

Methods This prospective study included 43 patients (ASA 1-2, Hill Grade 2-4) who underwent deep sedation EGD between July 2024 and July 2025. Patients demonstrating inadequate gastric inflation due to air reflux were included. A cricoid pressure of approximately 30 Newtons was applied by the anesthesiologist. We compared gastric mucosal fold visibility scores (scored 0-1 for greater curvature, lesser curvature, and fundus), air reflux presence, vital signs (SpO2, heart rate), and procedure duration before and during the maneuver. Statistical analysis was performed using McNemar and paired samples t-tests [1–3].

Results total of 43 patients (22 males, 21 females; mean age 58.2 ± 2.7 years) were analyzed. The distribution of Hill Grades was Grade II (23.3 %), Grade III (53.5 %), and Grade IV (23.3 %). The Sellick maneuver successfully provided adequate gastric distension in 93 % (n = 40) of patients, while failure in 3 cases was attributed to incomplete esophageal closure. The total gastric mucosal fold spreading score improved significantly from a baseline of 0.46 ± 0.59 to 2.79 ± 0.55 during the maneuver ($p < 0.001$). Gastroesophageal air reflux, which prevented visualization in all patients initially, was completely eliminated during the maneuver ($p < 0.001$). Most importantly, the maneuver increased diagnostic yield: new pathological findings not visible during standard insufflation were detected in 41.9 % (n = 18) of patients. These missed lesions included peptic erosions (n = 6), gastric polyps (n = 4), subepithelial lesions (n = 2), Cameron ulcers (n = 1), Dieulafoy lesions (n = 1), and gastric masses (n = 2). Regarding safety, no statistically significant changes were observed in SpO2 (95.83 % vs. 95.69 %, p = 0.52) or heart rate (80.8 vs. 81.3 bpm, p = 0.23). Coughing was absent in 83.7 % of cases, with only minor coughing (1-2 times) observed in 14 % (▶ **Table 2**).

▶ **Table 1**

Pathologic findings	Number
Erosion in the corpus	6
Ulcer in the corpus	1
Cameron ulcers	1
Diealufoy lesion at the corpus	1
Isolated Gastric Varices (IGV)-1	1
Subepithelial lesion at the corpus	2
Mass at the corpus greater curvatur	1
Polyp at the corpus	3
Polyp at the antrum	1
Mass at the antrum lesser curvatur	1

▶ **Table 2**

scoring criteria	No Sellick maneuver	Sellick maneuver	P-value
Esophageal closur status	0,00	1,77 ± 0,57	p < 0.001
Greater curvature fold	0,47 ± 0,21	0,90 ± 0,29	p < 0.001
Gastric lesser curvature	0,07 ± 0,25	0,88 ± 0,32	p < 0.001
Gastric fundic mucosa	0,37 ± 0,48	1,00 ± 0,00	p < 0.001
Total score of vision	0,46 ± 0,59	2,79 ± 0,55	p < 0.001
Reflux findings	0,35 ± 0,48	0	p < 0.001

Conclusions The Sellick maneuver is a highly effective, safe, and readily available technique for optimizing gastric distension in patients with hiatal hernia or weak LES. By preventing retrograde air escape, it significantly enhances mucosal visualization, allowing for the detection of critical benign and premalignant lesions that are otherwise missed during standard sedated gastroscopy. The procedure does not induce hemodynamic instability or significant adverse events. Therefore, the Sellick maneuver should be considered a standard adjunctive tool in cases of suboptimal gastric inflation to avoid repeat procedures and improve diagnostic accuracy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1240 Usefulness of Transnasal Endoscopic Pharyngeal Observation in Surveillance of Esophageal Cancer

Author Kitamura Y[1]
Institute 1 Nara City Hospital, Department of Gastroenterology and Hematology, Nara, Japan
DOI 10.1055/s-0046-1822567

Aims Due to field cancerization, patients with esophageal squamous cell carcinoma (ESCC) have a high risk of synchronous or metachronous head and neck cancer (HNC). Advances in image-enhanced endoscopy and increased awareness among endoscopists have improved detection rates. However, pharyngeal assessment using the transoral Valsalva maneuver often provides insufficient visualization, partly because laryngeal elevation varies widely among individuals. Moreover, anatomical constraints make the tongue base difficult to observe. Since 2025, our institution has introduced systematic pharyngeal observation using a transnasal endoscope (GIF-1200N). For patients scheduled for esophageal ESD who show inadequate pharyngeal visibility despite the transoral Valsalva maneuver, additional preoperative evaluation using a curved laryngoscope is performed in the operating room.

To evaluate the usefulness of transnasal endoscopy for pharyngeal observation by analyzing lesion distribution and diagnostic methods before and after its introduction.

Methods We retrospectively reviewed patients diagnosed with superficial HNC at our department between April 2012 and October 2025. Nineteen patients with 36 lesions were included. The study period was divided into an early phase (2012–2024; 24 lesions) and a late phase (2025; 12 lesions). We compared the methods used at lesion detection, including transoral observation, transoral Valsalva maneuver, transnasal Valsalva maneuver, intra-oropharyngeal U-turn method, and observation using a curved laryngoscope. Endoscope type and lesion location were also evaluated.

Results ll patients were male, with a median age of 74 (range 59–84) in the early phase and 70 (62–82) in the late phase. Observation methods in the early vs. late phase were: transoral observation (17 vs. 4), transoral Valsalva (7 vs. 0), transnasal Valsalva (0 vs. 4), intra-oropharyngeal U-turn (0 vs. 4), and curved laryngoscope (0 vs. 4). Endoscopes used (H260Z / H290Z / 1200N) were 18/6/0 in the early phase and 4/4/4 in the late phase. Lesion locations in the early vs. late phase were: oral cavity (1 vs. 0), oropharynx (4 vs. 3), hypopharynx (15 vs. 2), post-cricoid region (1 vs. 3), epiglottic vallecula (3 vs. 0), and tongue base (0 vs. 4).

Lesion detection increased in the late phase after the introduction of transnasal endoscopy. Notably, tongue-base cancers were not detected in the early phase, whereas four such lesions were identified in the late phase. Transnasal intra-oropharyngeal U-turn provided excellent visualization of the tongue base, leading to improved detection. Many ESCC/HNC high-risk patients had multiple missing teeth, which often limited laryngeal elevation during the transoral Valsalva maneuver. In contrast, the transnasal Valsalva maneuver is unaffected by dentition and therefore enhances pharyngeal visibility. Nevertheless, laryngeal elevation with the transnasal approach also varied among patients. In cases with insufficient visualization, additional observation using a curved laryngoscope enabled identification of lesions—especially in the post-cricoid area—that had previously been difficult to detect.

Conclusions In patients at high risk for head and neck cancer, the transnasal Valsalva maneuver and transnasal intra-oropharyngeal U-turn are highly effective for observing the tongue base and post-cricoid region, which are key blind spots during standard transoral endoscopy. For cases with inadequate laryngeal elevation during the Valsalva maneuver, supplementary evaluation using a curved laryngoscope further improves early detection. Introducing a structured transnasal pharyngeal observation protocol may significantly enhance surveillance accuracy in ESCC patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1241 How can endoscopic yield be improved in young patients with reflux? A large single site UK prospective cohort study

Authors Kumar R[1], Santa E[1], Cole F[1], Shaw K[1], Morris D[1]
Institute 1 East & North Hertfordshire NHS Trust, Stevenage, United Kingdom
DOI 10.1055/s-0046-1822568

Aims Patients < 55yr with Reflux symptoms account for a heavy burden on endoscopy, yet significant endoscopic findings are rare: most have functional heartburn and may be managed without investigation. Oesophageal adenocarcinoma (OAC) and precursor Barrett's oesophagus (BO) are also uncommon hence selective screening is not recommended. However epidemiological studies show increasing incidence of OAC in younger patients often being diagnosed at a later stage. Less invasive tests that identify those younger patients at increased risk of BO/OAC and reassure most patients and referrers without endoscopy are needed. Capsule sponge testing (CS) was introduced in UK national studies with outcomes showing feasibility acceptability and efficacy in detecting BO, reduction in endoscopy and lower costs. Details by age group are not published [1].

Methods This prospective cohort study of patients routinely referred with reflux symptoms to a single UK non-specialist hospital 2020-2023. Patients were offered CS oesophageal cell sampling as part of an early diagnosis pathway. Detailed methods previously published.[1]Only patients with abnormal CS, inadequate samples or ongoing symptoms after treatment advice were offered endoscopy. Records were review in all patients > = 1y follow-up. Endoscopic histology yield of BO were recorded in patient categories of younger (< 50y male/65 female) and older (> = 50 male/65y female) according to previous modelling. Detailed analysis of the younger age group is presented (▶ **Table 1**).

Results 871 patients (median age 54 years) were offered CS of which 572 (65.7 %) were in the younger age group. Abnormal results (TFF3, atypia, p53) were found in 48/507(9.5 %) adequate CS tests, with all 48 having subsequent endoscopy. 65 (11.4 %) had failed or inadequate CS of whom 49 had subsequent endoscopy (16 declined). 115 patients (20.1 %) with normal CS went on to endoscopy due to persistent symptoms. Older age group shown for comparison but not described further here. 11 younger patients were offered surveillance based on current BSG guidelines: 5 having long segments maximal extent > = 4cm. 1 had indefinite for dysplasia.

Atrophic gastritis was also found in 4/212 patients in the young cohort and 6/119 in the older cohort. 360/572 (63 %) patients in the younger and 180/299 (60.2 %) in the older cohort avoided gastroscopy- median follow up 27.2 months.

▶ **Table 1** Histology on patients going on to endoscopy by Age Category

Indication for endoscopy	Yield of BO on Histology < 50y M/ < 65y F (%)	Yield of BO/OAC on Histology > = 50y M/ > 65y F
Abnormal CS	19/48 (37.5%)	18/37 (48.6%)
Inadequate CS	1/49 (2.0%)	2/34 (5.9%)
Negative CS/ persistent symptoms	1/115 (0.9%)	2/48 (4.1%)
Overall Service	21/212 (9.9%)	25/119 (21.0%)*

*p = .005 Chi Sq = 7.85

Conclusions A low overall presumed incidence of BO in younger lower risk cohort is as expected (3.67%), but the yield of histologically confirmed BO is greatly enhanced by using CS triage to 9.9% whilst avoiding endoscopy in 63% patients. A significantly increased yield to 21% is found in older cohorts. This demonstrates the value of a CS pathway in managing younger patients (as well as older) presenting with chronic reflux and may also potentially be valuable in primary care. It can provide prompt reassurance whilst detecting the small number of patients with significant disease and is resource-saving.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1242 Outcomes of a Novel Double-Tunnel Traction (DTT) Technique for Circumferential Endoscopic Submucosal Dissection of the Oesophagus

Authors Gupta S[1], Kim J[1], Lam B[1], Kim YS[1], Hasib A[1], Eitan M[1], Mandarino FV[1], Kerrison C[1], Lee EYT[1], Burgess N[1], Bourke MJ[1]
Institute 1 Westmead Hospital, Westmead, Australia
DOI 10.1055/s-0046-1822569

Aims Circumferential oesophageal endoscopic submucosal dissection (ESD) is technically feasible but frequently inefficient. Although tunnelling and traction strategies improve standard ESD, their benefit in circumferential resections is uncertain. We developed a novel double-tunnel traction (DTT) technique to improve stability and submucosal exposure. This study compared DTT with conventional ESD (cESD).Circumferential oesophageal endoscopic submucosal dissection (ESD) is technically feasible but frequently inefficient. Although tunnelling and traction strategies improve standard ESD, their benefit in circumferential resections is uncertain. We developed a novel double-tunnel traction (DTT) technique to improve stability and submucosal exposure. This study compared DTT with conventional ESD (cESD).

Methods We performed a retrospective analysis of a prospectively maintained registry of ESDs for Barrett's or squamous neoplasia between September 2017 and August 2025. Circumferential cases were analysed, comparing DTT with cESD overall and with traction (C + T) or without traction (C–T). Outcomes included dissection speed (min/cm²), R0 excision, recurrence and adverse events.

Results Among 320 oesophageal ESDs, 51 (15.9%) were circumferential (15 DTT, 36 cESD). Median defect length was 100 mm (range 40–200 mm), with similar baseline characteristics between groups. DTT achieved shorter procedure times than cESD (120 vs 160 minutes; P = 0.009) and faster dissection speed (2.16 vs 3.33 min/cm²; P < 0.001). Dissection speed remained superior to both C + T (3.56 min/cm²; P < 0.001) and C–T (3.07 min/cm²; P = 0.004). En-bloc resection was achieved in all DTT cases. R0 excision was numerically higher with DTT than cESD (86.7% vs 63.9%) and significantly higher than C + T (52.6%; P = 0.035). Luminal recurrence was 0% with DTT versus 20.6% for cESD (P = 0.076) and 27.8% for C + T (P = 0.031). Adverse events were similar between groups.

Conclusions Compared with conventional ESD, DTT improves efficiency and oncological outcomes with regard to R0 excision and luminal recurrence, without compromising safety. DTT offers a reproducible approach for these technically challenging resections.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1243V Over-the-scope clip (OTSC) as salvage therapy for acute esophageal arteriovenous malformation rebleeding

Authors Bokun T[1, 2], Skurla V[1], Milosevic M[1], Huml I[1], Zelenika M[1], Grgurevic I[1, 3, 2]
Institutes 1 University Hospital Dubrava, Zagreb, Croatia; 2 Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia; 3 University of Zagreb School of Medicine, Zagreb, Croatia
DOI 10.1055/s-0046-1822570

Abstract Text

Rendu–Osler–Weber syndrome is characterized by fragile arteriovenous malformations that can lead to recurrent upper gastrointestinal bleeding. In this case, initial endoscopic therapy using standard haemoclips achieved only temporary control, with two subsequent episodes of rebleeding from an oesophageal AVM. During the third bleeding event, bipolar coagulation was insufficient to obtain haemostasis. After removal of previously placed haemoclips, an over-the-scope clip (OTSC) was deployed directly onto the malformation, providing stable mechanical haemostasis. Minor residual mucosal oozing from the top of the tissue grasped by the clip was successfully treated with a bipolar probe. Following this combined intervention, no further bleeding occurred. To our knowledge, this is the first reported use of an OTSC for haemostasis of an oesophageal AVM [1–3].

eP1244 Keeping the fistula open: paradigm shift in the endoscopic management of hepatic hydatid cysts with cystobiliary communication

Authors Ünver NG[1], ÖDemiş B[1], Kenarlı K[1], Macif A[1]
Institute 1 Ankara Bilkent City Hospital, Ankara, Türkiye
DOI 10.1055/s-0046-1822571

Aims In hepatic hydatid disease with biliary communication, ERCP traditionally aims to clear hydatid material from the bile ducts and close the cystobiliary fistula through stenting. In contrast to the conventional approach, this study aimed to investigate the efficacy and safety of complete endoscopic evacuation of the cyst content as a curative treatment in selected patients, with dilation of the fistulous tract when necessary [1].

Methods This retrospective, single-center study included consecutive patients who underwent endoscopic cyst evacuation performed by a single endoscopist. The procedure was carried out in centrally located cysts that were completely surrounded by liver parenchyma, without exophytic extension, and whose cavities could be cannulated endoscopically. In patients whose fistulous tracts were not suitable for endoscopic evacuation, the tract was dilated with a 6–8 mm balloon. The cyst cavity was irrigated with saline and debrided in multiple sessions using endoscopic accessories such as stone extraction balloons and Dormia baskets. At the end of each session, a plastic stent, fully covered metal stent, or nasocystic drain was placed extending into the cyst cavity. Clinical success was defined as endoscopic clearance and reduction in the size of the cyst cavity.

Results Among 102 patients who underwent ERCP for biliary hydatid disease, 37 consecutive patients who received endoscopic cyst evacuation were included in the study. The mean age was 46.8 ± 19.1 years, and the mean cyst diameter was 82.9 ± 36.1 mm. A total of 184 ERCP procedures (median: 5) were performed. Sphincterotomy was performed in all cases. Balloon dilation of the cystobiliary opening orifice was carried out in 19 patients (51.4 %). Nasocystic drainage was performed in 12 patients (32.4 %). A fully covered metal stent was used in four patients (10.8 %) due to dense cyst content. Clinical success was achieved in 36 patients (97.3 %). One patient required surgery (right hepatectomy) due to multiple hepatic abscesses. No recurrence or procedure-related or disease-related mortality was observed during follow-up. Complications occurred in nine procedures (4.8 %), all successfully managed with endoscopic and/or conservative treatment.

Conclusions Endoscopic evacuation provides a safe and effective curative treatment option for hepatic hydatid disease with biliary communication, achieving high success rates with a low risk of complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Endoscopic retrograde cholangiopancreatography (ERCP) is associated with higher rates of adverse events (AEs) than other endoscopic procedures. The European Society of Gastrointestinal Endoscopy (ESGE) and the United European Gastroenterology (UEG) have defined specific ERCP quality performance measures, but prospective national ERCP registries are scarce. The aim of this study was to evaluate compliance with ESGE–UEG quality indicators in the first Spanish ERCP registry and determine incidence, severity and predictors of post-ERCP Aes [1–4].

Methods Prospective, multicenter, nationwide study included consecutive ERCPs performed at 17 Spanish hospitals between October 2024 and October 2025. Demographic, clinical, and technical variables were recorded in a standardized electronic database. All patients underwent telephone follow-up at 7 and 30 days. AEs described by AGREE classification. Descriptive statistics were used to evaluate compliance with quality indicators. Logistic regression analyses were conducted to identify independent risk factors for AEs.

Results A total of 1241 ERCP procedures were included (mean age 70.4 ± 16 years; 48.9 % female). Compliance with quality indicators was high: successful biliary cannulation was achieved in 91.6 %, extraction of stones < 10 mm in 96.2 %, and stent placement for distal biliary obstruction in 100 % (142/142). Adequate antibiotic prophylaxis was achieved in 99 %.

The overall AE rate was 16.8 %, and overall mortality was 1.6 %. Independent predictors were age (OR 1.72 per 10 years, 95 % CI 1.09–2.72) and chronic kidney disease (CKD) (OR 3.17, 95 % CI 1.22–8.20). Sex was not associated with mortality.

Post-ERCP pancreatitis (PEP) occurred in 71 cases (5.7 %), with AGREE severity grade I-16.9 %, II-59.2 %, IIIa-9.9 %, IIIb-2.8 %, IVa-2.8 %, IVb-1.4 % and V-7 %. In the multivariable model, independent predictors of PEP were papilla regular/classic morphology (OR 1.77, 95 % CI 1.00–3.12), difficult cannulation (OR 1.86, 95 % CI 1.01–3.45) and partially covered metal stent (OR 5.33, 95 % CI 2.57–11.09). Unintentional pancreatic cannulation and NSAID prophylaxis were not independently associated with PEP. Cholangitis occurred in 51 cases (4.1 %). Severity by AGREE was grade I-6 %, II-50 %, IIIa-28 %, IIIb-2 %, IVa-2 % and V-12 %.

Independent predictors were primary sclerosing cholangitis (OR 8.54, 95 % CI 2.11–34.54), malignant stent dysfunction (OR 4.92, 95 % CI 1.73–14.02), placement of a plastic biliary stent (OR 2.01, 95 % CI 1.08–3.72) and CKD (OR 2.48, 95 % CI 1.17–5.26). Female sex showed a protective effect (OR 0.49, 95 % CI 0.27–0.90). Cholangitis in suspected malignant stent dysfunction (n = 31), occurred in 16.1 %, with a trend toward higher risk in those receiving plastic stents (37.5 % vs. 8.7 %). Bleeding occurred in 60 cases (4.8 %). Severity was AGREE I-23 %, II-18.3 %, IIIa-45 %, IV-3.3 % and V-5 %. Neither antiplatelet nor anticoagulant therapy, comorbidity burden, were associated with bleeding. In multivariable analysis, no independent predictors were identified; sphincterotomy showed only a non-significant trend (OR 1.64, p = 0.079). Cholecystitis occurred in 12 patients (1.0 %), with AGREE II-33 %, IIIa-25 %, IIIb-33 %, IVa-2 % and V-8.3 %. Biliary stent placement was independently associated with increased risk (OR 3.93, 95 % CI 1.00–15.37). Gallbladder opacification (OR 3.68) and partially covered metal stents (OR 4.41) showed strong but non-significant trends. Fully covered stents were not associated with increased risk. Post-ERCP perforation occurred in 11 patients (0.9 %): AGREE II-18 %, IIIa-27 %, IVa-9.1 %, V-45 %; intraprocedural 36 % and delayed 64 %.

Conclusions This Spanish registry demonstrates high compliance with ESGE–UEG performance measures providing robust real-world data on post-ERCP complications. Systematic follow-up enabled comprehensive AE detection, revealing clinically meaningful predictors. These findings highlight the value of national prospective registries in ERCP practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822573

Aims The optimal timing of endoscopic retrograde cholangiopancreatography (ERCP) in pancreatitis remains debated, especially in patients without cholangitis or persistent biliary obstruction. This study evaluated technical outcomes, procedural complexity, and adverse events of ERCP performed during the acute phase of pancreatitis compared with ERCP undertaken after clinical and biochemical resolution.

Methods In this retrospective real-world study, consecutive ERCPs performed for pancreatitis at two high-volume hepatopancreatobiliary centers (January 2001–July 2025) were reviewed. Among 5,983 ERCPs, 344 met inclusion criteria. Patients were categorized into: Group A (acute pancreatitis with cholangitis and/or elevated bilirubin; n = 114) and Group B (post-acute ERCP performed after resolution of abdominal pain and normalization of amylase < 3 × normal; n = 230). Demographic, imaging, procedural, and outcome variables were analyzed. Primary endpoints were biliary cannulation success, duct clearance, and ERCP-related adverse events.

Results Overall, successful biliary cannulation was achieved in 309/344 patients (89.8 %), increasing to 93.9 % when excluding the 15 patients in whom the papilla could not be reached. Cannulation success did not significantly differ between acute and post-acute ERCP (93.0 % vs 88.3 %; p = 0.114). However, procedures in the post-acute group were technically more demanding, with higher rates of precut fistulotomy (33.8 % vs 25.2 %; p = 0.040) and > 5 cannulation attempts (54.1 % vs 41.4 %; p = 0.017). Choledocholithiasis was present in 46.8 % of patients and the majority of stones were < 1.5 cm. Complete bile duct clearance was achieved in 140/154 (90.9 %) patients, with no significant difference between groups (92.7 % vs 89.9 %; p = 0.468). Periampullary diverticula were significantly more common in the post-acute group, whereas an inflamed papilla was more frequent during the acute phase. ERCP-related adverse events were uncommon overall (17/344; 4.9 %) and tended to be more frequent in the post-acute group (6.1 % vs 2.6 %; p = 0.128). Intraprocedural bleeding occurred significantly more often post-acutely (37.8 % vs 28.1 %; p = 0.047), paralleling the increased procedural complexity. Post-ERCP pancreatitis was observed only in Group B (6/230; 2.6 %), while other specific events, including perforation (0.3 %), clinically significant bleeding (0.9 %), cholecystitis (0.6 %) and sedation-related serious adverse events (0.3 %) were rare. Mortality occurred exclusively in the acute group (4/114; 3.5 %; p = 0.012) and was largely attributed to severe underlying pancreatitis rather than the procedure itself.

Conclusions In this large, long-term real-world cohort, ERCP performed during either the acute or post-acute phase of pancreatitis achieved high biliary cannulation and duct clearance rates with low overall complication rates when undertaken by experienced endoscopists. These findings suggest that procedural complexity and baseline disease severity, rather than timing alone, are the principal determinants of ERCP risk in pancreatitis-associated indications.

eP1247 Index Bile Culture as a Predictor of Infectious Complications After EUS-BD – A Single-Center Retrospective Study

Authors Male N[1], Karagyozov P[2]

Institutes 1 Acıbadem City Clinic Tokuda Hospital, Sofia, Bulgaria; 2 Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofia, Bulgaria

DOI 10.1055/s-0046-1822574

Aims EUS-guided biliary drainage (EUS-BD) is increasingly used for malignant and benign obstruction when ERCP is unsuccessful or not feasible. Due to tract creation and larger stent systems, EUS-BD represents a more invasive endoscopic intervention, potentially increasing the risk of bacteremia and the frequency of infectious complications. We aimed to evaluate the prognostic role of positive index bile cultures for predicting post-interventional infectious morbidity and infection-driven re-interventions.

Methods We performed a retrospective single-center cohort of 227 patients undergoing EUS-guided hepaticogastrostomy or other EUS-guided biliary drainage between March 2020 and March 2025 at our tertiary endoscopy center. Index bile aspirates were classified as positive or non-positive. At our center, bile microbiology sampling is routinely performed in all patients during EUS-BD interventions before stent deployment. Primary endpoints included a 30-day infectious adverse event, notably post-drainage cholangitis, graded by the Tokyo Guidelines. Secondary endpoints were the rate of infection-driven reinterventions within 6 months and mortality.

Results Positive index bile cultures obtained at the time of EUS-guided biliary drainage were found in 62 of 227 patients (27.3 %). Patients with culture-positive bile had significantly higher rates of 30-day infectious adverse events compared with non-positive cases (30.6 % vs. 8.3 %, p < 0.001), and more fre-

quent acute cholangitis recurrence within 90 days (17.7 % vs. 4.2 %, p < 0.001). A positive index bile culture also translated into increased infection-driven reintervention during 6-month follow-up (29.0 % of culture-positive vs. 5.0 % of non-positive patients, p < 0.001), typically managed by restenting through the existing stent lumen when purulent stent occlusion or clinical sepsis signs developed. Most cultured pathogens were MDR gram-negative Enterobacteriaceae. Bile microbiology taken at the index EUS-BD allowed early infection-risk recognition, directly guiding adverse events grading, antibiotic choice, and close 6-month follow-up intensity. In patients with culture-positive index bile, early infectious adverse events were significantly more frequent after hepaticogastrostomy than after other EUS-guided biliary drainage techniques (48.4 % vs. 12.9 %, p < 0.001), supporting that, in the presence of infected bile, the hepaticogastrostomy pathway is associated with greater early infectious activity, likely related to transluminal tract creation.

Conclusions In this real-world cohort, positive bile culture obtained at the index EUS-BD session was strongly associated with early infectious adverse events and a high risk of infection rebound requiring subsequent reintervention for acute cholangitis. Index biliary microbiology provides a practical assessment of infection risk, but negative cultures do not exclude severe or fatal biliary sepsis.

DOI 10.1055/s-0046-1822575

Aims Gastroparesis is a common complication in patients with diabetes mellitus (DM). During video capsule endoscopy (VCE), delayed gastric emptying may lead to incomplete examinations or require endoscopic placement of the capsule into the duodenum. GLP-1 receptor agonists (GLP-1RAs), increasingly used in the treatment of type 2 DM and obesity, are known to slow gastric motility. However, their effect on gastrointestinal transit times during VCE remains unclear. This study aimed to evaluate the association between GLP-1RA use and VCE outcomes in diabetic patients.

Methods We performed a retrospective analysis of diabetic patients who underwent VCE. Patients were categorized based on GLP-1RA therapy. Gastric transit time (GTT) and small bowel transit time (SBTT) were recorded. Prolonged GTT was defined as capsule retention in the stomach for more than 60 minutes. Glycated hemoglobin (HbA1c) and potential confounders (age, sex, hospitalization, smoking status, use of psychotropics, hypothyroidism, and inflammatory bowel disease) were collected.

Results A total of 90 patients were included (50 % male, mean age 70 ± 11 years), of whom 18 (20 %) were receiving GLP-1RA.

Prolonged GTT was more frequent among GLP-1RA users (61.1 % vs 34.7 %, p = 0.041). However, in multivariable logistic regression, this association was no longer statistically significant (OR 3.51, p = 0.061), while HbA1c was the only independent predictor of delayed gastric emptying (OR 3.24 per 1 % increase, p < 0.001).

Median GTT and SBTT did not significantly differ between GLP-1RA and non–GLP-1RA groups (GTT: 49.0 vs 33.0 minutes, p = 0.252; SBTT: 161.0 vs 203.1 minutes, p = 0.558).

Conclusions An association was observed between GLP-1RA use and prolonged GTT, although this effect did not persist after adjustment for clinical confounders, including HbA1c. Among all variables analyzed, HbA1c emerged as the only independent predictor of delayed gastric emptying. These findings suggest that prolonged GTT may be more closely related to poor glycemic control than to the use of GLP-1RA therapy itself. Optimizing glycemic control may therefore be a key strategy in reducing gastroparesis-related events during VCE in diabetic patients.

eP1249 Identification of Clinical and Endoscopic Phenotypes in Non-Variceal Upper GI Bleeding Using an Unsupervised Machine Learning Approach

Authors Chasani P[1], Fousekis F[2], Mpakogiannis K[3], Katsanos K[2], Christodoulou D[2], Mavrogenis G[4], Mitselos I[5]

Institutes **1** Friedrich-Alexander-Universität Erlangen-Nürnberg FAU, Universitätsklinikum Erlangen, Erlangen, Germany; **2** Department of Gastroenterology, University Hospital of Ioannina, Ioannina, Greece; **3** Department of Gastroenterology, Alexandra General Hospital of Athens, Athens, Greece; **4** Third Space Endoscopy Unit, Department of Gastroenterology, Mediterraneo Hospital, Athens, Greece; **5** Department of Gastroenterology, General Hospital of Ioannina G. Hatzikosta, Ioannina, Greece

DOI 10.1055/s-0046-1822576

Aims To identify distinct clinical and endoscopic phenotypes among patients presenting with non-variceal upper gastrointestinal bleeding (NVUGIB), based on age, sex, clinical presentation, and exposure to antithrombotic or NSAID therapy, using an unsupervised machine-learning clustering technique [1, 2].

Methods We performed an unsupervised clustering analysis using Partitioning Around Medoids (PAM) on a Gower distance matrix. Two-dimensional visualization of the cluster structure was obtained with t-distributed Stochastic Neighbor Embedding (t-SNE). The analysis included 405 patients ≥ 16 years old hospitalized with clinical signs of NVUGIB, without history of gastrointestinal malignancy, portal hypertension, or varices, at the General Hospital of Ioannina, Greece.

Results PAM clustering (k = 3) identified three distinct clinical and endoscopic phenotypes among these patients. Cluster 1 included only elderly female patients, most of whom were aged 80 years or older. Nearly all of these patients presented with melena. Endoscopic evaluations revealed no identifiable source of bleeding in 73 % of the cases. The remaining patients showed a mix of low-frequency lesions, such as arteriovenous malformations, Dieulafoy lesions, duodenal ulcers, esophagitis, Mallory-Weiss tears, and gastric ulcers. Despite the lack of clear focal endoscopic findings that could explain the suspected bleeding, patients in this cluster had significant exposure to direct oral anticoagulants (DOACs), along with smaller contributions from heparin, salospir, and dual antiplatelet therapy. This pattern indicates subtle mucosal bleeding caused by anticoagulants, which may result in melena without distinct endoscopic lesions. Cluster 2 included predominantly male patients across a wide age range, including the youngest individuals in the cohort. Drug exposure was limited, with most patients not receiving antiplatelet or anticoagulant therapy, although NSAID and salospir use were present. This group demonstrated the highest prevalence of gastric and duodenal ulcers, forming an "ulcer-driven" bleeding phenotype, likely reflecting underlying peptic ulcer disease rather than drug-related injury. Cluster 3 consisted of very elderly male patients, mostly aged 80 and older, who had significant exposure to DOACs and smaller contributions from heparin, salospir, and Dual Antiplatelet Therapy. Melena was

the dominant mode of presentation. Most endoscopies demonstrated no relevant bleeding-related findings, while the remainder revealed only low-frequency lesions, primarily duodenal ulcers, arteriovenous malformations, and esophagitis. This phenotype reflects bleeding presentations in elderly men receiving DOAC therapy, in whom mucosal bleeding is often subtle, diffuse, or endoscopically inapparent despite clinically evident melena.

Conclusions This analysis identified three distinct phenotypes of NVUGIB based on age, sex, and anticoagulant exposure. Elderly patients on anticoagulants often presented with melena but lacked identifiable endoscopic lesions, suggesting subtle mucosal bleeding. Conversely, patients with minimal drug exposure showed ulcer-related bleeding. These findings underscore the diversity of NVUGIB presentations. Clustering patient profiles may help endoscopists to anticipate endoscopic yield and prepare more effectively for managing potential findings, thereby optimising the endoscopic management of lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822577

Aims Proximal intestinal mucosal ablation (PIMA) is a novel metabolic endoscopic procedure under investigation for the treatment of patients with type 2 diabetes (T2D). The aim is to replicate the metabolic benefits of gastric bypass surgery by ablating up to 60 cm of abnormal post-ampullary intestinal mucosa using a through-the-scope radiofrequency vapor ablation (RFVA) catheter. Early pilot data suggests that endoscopic ablation of 10-15 cm of duodenal mucosa could eliminate the need for exogenous insulin therapy in T2D when combined with glucagon-like peptide-1 receptor agonists (GLP-1RA). By extending the length of ablation into the proximal small intestine, we hypothesised that insulin independence could be achieved in patients with insulin-requiring (IR)-T2D without the need for concomitant GLP-1RA therapy. Therefore, we aimed to evaluate the safety and feasibility of PIMA as a treatment for IR-T2D.

Methods A prospective, single-centre study evaluating PIMA using RFVA among patients with IR-T2D on daily long-acting insulin for ≥ 3 months (≤ 20 % dose alteration within the last month and total dose ≤ 0.6 units/kg) and a glycated haemoglobin (HbA1c) ≤ 8 % (NCT06655740). Patients were enrolled at Clinica Colonial, Santiago, between Sep-2024 to May-2025. After screening, patients started continuous glucose monitoring (CGM) and entered a 4-week run-in to ensure stable control. Post run-in, insulin was stopped, and PIMA was performed via an adult colonoscope (Olympus HQ190L) with the circumferential through-the-scope mesh-tip RFVA catheter under general anaesthesia. RFVA was delivered at a dose of 250-275J with double application to the post-ampullary intestinal mucosa. Post-procedure, patients followed a 14-day modified diet, continued oral glucose-lowering agents (GLA) only, and received standard lifestyle advice for T2D. Primary outcomes were the number of serious adverse events (SAEs), unanticipated adverse device effects (UADEs), and the proportion of patients free of insulin, without need for concomitant GLP-1RA, who had a HbA1c ≤ 7.5 % at 6-months. Secondary exploratory outcomes were change in body mass index (BMI), HbA1c, and time-in-range.

Results In total, 20 patients with IR-T2D (average age 50.5 years [IQR 43-52], 60 % female) underwent PIMA. The average disease duration of T2D was 4.5 years (IQR 3-7), baseline HbA1c was 7.1 % (SD 1.0), BMI was 33.0 kg/m2 (SD 5.2), average number of oral GLAs 1 (IQR 1-2), and baseline daily insulin dose 27 units (SD 9.6). PIMA was successful in all patients with an average length of treated bowel of 60 cm (IQR 60-65) and 48.3 (SD 7.7) ablations. Average procedure time was 58.3 minutes (SD 15.0), catheter time 41.5 minutes (SD 25.5), and the majority were treated at 275 J (n = 18). Follow-up enteroscopy with biopsy was normal in all patients. There were no SAEs or UADEs, and although asymptomatic sensor readings < 3.9 mmol/L occurred, no clinically significant hypoglycaemia was confirmed by symptoms or finger-stick capillary glucose. At 6-months, 100 % of patients remained off exogenous insulin (n = 19) without need for concomitant GLP-1RA, and 84.2 % (n = 16) maintained a HbA1c ≤ 7.5 %. One patient withdrew at 3-months while still off insulin with a HbA1c of 6.4 %. Three patients with worsening control had oral GLA optimised with use of sodium–glucose co-transporter 2 inhibitor (n = 2) or dipeptidyl peptidase-4 inhibitor (n = 1). Mean time in range (3.9-10.0 mmol/L) at 3- and 6-months was 91.6 % (SD 9.8) and 85.7 % (SD 13.5), respectively, with corresponding falls in HbA1c by -0.8 % (SD 1.0; p < 0.01) and -0.6 % (SD 1.0; P < 0.05). BMI reduced significantly at 3-months (-2.6 [SD1.9]; p < 0.001) and 6-months (-2.7 [SD 2.1]; p < 0.001) due to withdrawal of insulin.

Conclusions Among patients with IR-T2D, PIMA safely enabled discontinuation of insulin in all patients, with 84 % maintaining independence without additional medications alongside improved glycaemic control and weight reduction.

DOI 10.1055/s-0046-1822578

Aims Current European guidelines favor the use of endoscopic submucosal dissection (ESD) for the eradication of gastric dysplasia exceeding 1cm in size. Despite its efficacy in “uprooting” superficial gastrointestinal lesions, ESD is often time-consuming, requiring additional expertise and resources compared to endoscopic mucosal resection (EMR). The aim of this study was to investigate the efficacy, safety and speed of an EMR variation capable of providing a deeper resection plain, cap-assisted EMR (capEMR), for the endoscopic management of gastric dysplastic lesions measuring up to 2cm.

Methods Consenting adults with documented by 2 expert histopathologists gastric dysplasia (low and high-grade) were eligible for endoscopic treatment. Lesions > 2cm were treated with ESD, those < 1cm with capEMR whereas pa-

tients with lesions in between 1 and 2cm could choose either treatment. In the latter group, if treatment failure using capEMR occurred, patients could receive subsequent treatment with ESD. For the present study, data from cases with gastric dysplasia in between 1 and 2cm in size, diagnosed and treated during the period 2019-2025 were retrospectively collected and analysed. Dysplastic lesions with a diameter up to 2cm were treated using capEMR as follows: using an endoscope with a near focus of 1.5mm and the tip of a crescent-shaped snare, pre-resection marking was performed followed by submucosal injection of succinylated gelatin and indigo carmine solution. Then the crescent-shaped snare was prelooped and fixed onto the ridge of an oblique cap mounted onto the tip of the scope. The lesion was then carefully suctioned into the cap (pseudopolyp formation), tightly enclosed within the snare and resected using blended/mixed current (PulseCut Slow effect 2, 120 watts). Coagulation of visible or bleeding vessels and capEMR defect closure were applied in all cases using coagulation forceps and through-the-scope clips. Midazolam and fentanyl were used for patient sedation [1].

Apart from demographics, en bloc, R0 resection (dysplasia-free margins), recurrence and adverse event rates were calculated and recorded. Additional parameters such as total operation time (from marking until sample acquisition), resection time per lesion, number of resected lesions per endoscopy and depth of resection (deepest layer within the specimen eg muscularis mucosa or submucosa) were also determined.

Results Sixty-four patients (48 % females), mean age ± SD 62 ± 8.4years underwent capEMR for 103 lesions of which the vast majority (93/103) harbored low-grade dysplasia (10/103 high-grade dysplasia, P < 0.001) and were located in the antrum (77/103), incisura (12/103), corpus (12/103) and cardia (2/103) (P < 0.001). Median (interquartile range) size of the lesions was 1.7cm (1.3-2.1). Median (interquartile range) total operation time was 13min (6-21) for a median of 2(1-5) lesions per endoscopic session. Median resection time per lesion was 3min (2.8-4.6). En bloc resection rates were 91 % (94/103) whereas R0 resection rates were 99 %. The submucosa was present in all but three (100/103, 97 %) resection specimens. No recurrences were recorded during follow-up (9-64months). Adverse events included mild post-procedural pain in 59/64 cases, with only 23 cases requiring paracetamol analgesia, fever up to 38.1C in 7/64 cases and late onset bleeding in a single case upon resumption of rivaroxaban. The bleeding was successfully treated with additional hemoclip placement.

Conclusions Based on this study capEMR is a fast, effective and safe endoscopic treatment modality for the eradication of gastric dysplasia of moderate size. The endoscopist's expertise in capEMR, the location and histopathology of lesions (predominantly low-grade dysplasia of the antrum) and the routine application of endoscopic bleeding prophylaxis eg coagulation of vessels and clipping may have optimized outcomes. If these findings are confirmed in randomized controlled trials comparing capEMR with ESD then perhaps capEMR can be established as a less time-consuming alternative to ESD for treating gastric dysplasia up to 2cm.

eP1252 Endoscopic or Minimally invasive surgical step-up for Infected Pancreatic Necrosis? – Real world clinical practice evidence to guide treatment choice

Authors Basha J[1], Nayak G[2], Lakhtakia S[2], Nabi Z[2], Talukdar R[2], Gupta R[2], Jagtap N[2], Ramchandani M[2], Jagadeesh R[2], Marri UK[2], Rebela P[2], Rao GV[2], Reddy DN[2]

DOI 10.1055/s-0046-1822579

Aims Infected Pancreatic Necrosis (IPN) following Acute Necrotizing Pancreatitis (ANP) remains clinically challenging with associated significant morbidity and mortality despite treatment advances. One of the critical factors that decides the outcome is incorporation/adoption of appropriate treatment strategy at right time in the course of illness. Recent literature suggests similar clinical outcomes by either endoscopic or minimally invasive surgical drainage strategies.1,2 But in a real-world scenario, the applicability of either treatment strategies, including their feasibility and challenges have not been adequately addressed. We aimed to evaluate the management strategies followed in a cohort of patients of IPN – including their timing, challenges, and outcomes, when managed using standard treatment protocol.

Methods This was a prospective observational study including consecutive patients of ANP with clinical suspected IPN (fever, leukocytosis, persistent organ failure). The study was conducted at 2 tertiary care hospitals over one year (January to December 2023). All patients were managed using standard treatment protocols by multidisciplinary team including clinicians, endoscopists, interventional radiologists, intensivists, and surgeons. IPN was labelled after excluding other causes of infection and SIRS. Blood culture and sensitivity was performed in all subjects before initiating antibiotics. IPN was managed initially with empirical antibiotics and were changed later according to the sensitivity. Patients who didn't improve with appropriate antibiotics within 72 hours were considered for drainage. Assessment for EUS guided drainage with dedicated metals stents, including LAMS (Lumen Apposing Metal Stents) was attempted as a first preference. If EUS drainage was not feasible (due to either immature or distant collections), one or more percutaneous catheter drainage (PCDs) was considered, as a part of minimally invasive surgical (MIS) step-up strategy. Subsequent strategies of MIS approaches including upsizing of catheters, necrosectomy, retroperitoneal surgical approaches were considered during the treatment course if required. The outcome measures included – treatment strategy adopted, timing of intervention from onset of ANP, duration of treatment, clinical outcome, and mortality.

Results 117 patients were included during the study period (males 62 %, mean age 37.46 years). Etiologies were alcohol (38 %), idiopathic (32 %), gall stone related (18 %). 38 patients (32 %) could be managed conservatively. Of the remaining 79 (68 %) patients who required intervention, initial drainage performed was EUS guided in 30 (38 %) while 49 (62 %) underwent PCD placement as a part of MIS step up. The mean time interval between onset of ANP and intervention was 33 days in the MIS and 35 days in the EUS drainage. Early drainages (< 4 weeks) were performed in 30/79 patients (38 %), of which EUS drainage was possible in 8 patients while the majority (22) underwent MIS (10 % vs 28 %; p = 0.06). The overall clinical success rates were similar in MIS and EUS drainage. The overall mortality was 20.5 %. There was no significant difference in mortality between EUS drainage (22.2 %) and MIS (30 %).

Conclusions Minimally invasive surgical (MIS) step-up remains the primary modality both in early (< 4 weeks) and overall drainages in IPN despite efforts to consider EUS guided drainage. Adopting the specific modality of drainage is decided by the feasibility and safety rather than choice in real world clinical practice. Mortality occurs in about 20 % of patients despite standard treatment protocols and aggressive treatment strategies.

eP1253 Feasibility, safety, and efficacy profile of EUS-guided hepaticogastrostomy for benign and malignant indications: a single-center retrospective cohort study

Authors La Mantia A[1], Gallo C[1], Forti E[1], Pugliese F[1], Dioscoridi L[1], Cintolo M[1], Bonato G[1], Bravo M[1], Palermo A[1], Stegagnini M[1], Mutignani M[1]
Institute 1 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy
DOI 10.1055/s-0046-1822580

Aims Endoscopic ultrasound-guided hepaticogastrostomy (EUS-HGS) and hepaticojejunostomy (EUS-HJS) have emerged as reliable techniques for internal biliary drainage when ERCP fails or is technically unfeasible. This study aimed to evaluate the feasibility, safety, and efficacy of EUS-HGS/HJS performed at a tertiary referral center over a seven-year period, across different anatomical settings and clinical indications. Secondary objectives included evaluating the impact of tract dilation on procedural outcomes and adverse events (AEs), and exploring long-term stent performance and recurrence rates.

Methods We conducted a retrospective, single-center analysis including all consecutive patients who underwent EUS-HGS/HJS between October 2018 and August 2025. Demographic, anatomical, procedural, and outcome data were retrieved from institutional databases. Technical success was defined as successful creation of a patent biliary-enteric tract with stent placement; clinical success was defined as symptom resolution and/or ≥ 50 % bilirubin reduction within 30 days without need for additional drainage. AEs were classified according to the AGREE criteria. Statistical analyses were performed using Fisher's exact and Wilcoxon tests, with $p < 0.05$ considered significant [1–5].

Results A total of 73 patients had an indication for EUS-guided biliary drainage. Biliary puncture proved to be feasible in 69 cases (63 HGS, 6 HJS); in four cases, all in surgically altered anatomy, biliary puncture was unsuccessful resulting in an overall procedural feasibility of 94.5 %. The cohort included 42 males (60.9 %) with a median age of 73.9 years [67.2–80.7]; 36 patients (52.2 %) had surgically altered anatomy. Indications were malignant in 29 (42 %) and benign in 40 (58 %) cases. Technical success was achieved in 68/69 cases (98.6 %), and clinical success occurred in 66 patients (95.7 %), after a median of 2 endoscopic procedures [2-3]. Tract dilation was omitted in 20 cases (28.9 %), performed mechanically in 29 (42 %), by electrocautery in 16 (23.2 %), or by balloon in 4 (5.8 %). Dilation was more common in benign indications (82.5 % vs. 55.2 %, $p = 0.01$). Plastic stents were placed in 50 patients (72.5 %), and metal stents in 19 (27.5 %), the latter more frequent in malignant disease (55.2 % vs. 7.5 %, $p = 0.001$). Very early (inhospital) AEs occurred in 5 patients (7.2 %) — 2 bleedings, 2 bile peritonitis (1 fatal), and 1 stent migration. One early (≤ 30 days) and two late (> 30 days) AEs were also recorded (overall AE rate 13.5 %). Overall AEs occurred more frequently after tract dilatation (14.3 % VS 5 %, $p = 0.21$), among altered anatomies (87.5 % vs. 47.5 %, $p = 0.07$) and after plastic stent placement (14 % vs. 5.3 %, $p = 0.22$). HJSs were significantly more frequent among AE cases (37.5 % vs. 4.9 %, $p = 0.031$). Median hospital stay was 6 days [2.5–14]. Twenty-eight stents (40.6 %) were replaced, mainly (82.1 % for a planned second approach), and 20 (28.9 %) were removed, mostly (70 %) for proved clinical success. To date, 21 original stents are still in place. During a median follow-up of 7 months [4.9–14.4], 11 recurrences (25 %) occurred, with median time to recurrence of 8 months [3.5–16.5]. Recurrence tended to be lower among cases in which the stent was removed after resolution (18.2 % vs. 50 %, $p = 0.054$). Only one death (1.4 %) was procedure-related.

Conclusions EUS-HGS/HJS demonstrated high feasibility, safety, and efficacy across various clinical scenarios, achieving 98.6 % technical and 95.7 % clinical success rates, with acceptable AEs and recurrence rates. Although retrospective and limited in size, these results confirm the robustness of EUS-guided intrahepatic drainage as a minimally invasive approach, both in malignant and benign settings. Notably, metal stenting without tract dilation did not compromise technical and clinical success, with reduced very early AEs rates, supporting the pivotal role of the dilatation-free technique in minimizing tissue trauma and subsequent complications, therefore optimizing outcomes. Future prospective studies are needed to confirm these findings, refine technical strategies, and clarify long-term outcomes and recurrence mechanisms. Within expert centers, EUS-HGS/HJS should be regarded as a cornerstone in the management of complex biliary drainage, providing durable, fully internal, and patient-centered palliation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Therapeutic endoscopic ultrasound (EUS) has rapidly developed and become widespread in the last decade, and is currently applied to treat several challenging conditions, including drainage of peripancreatic fluid collections as a complication of acute pancreatitis, biliary drainage for malignant distal biliary obstruction, gallbladder drainage in frail patients with acute cholecystitis, and gastroenterostomy creation for malignant gastric outlet obstruction. Such an expansion has been made possible by the introduction of dedicated devices and stents, namely electrocautery-enhanced lumen-apposing metal stents (EC-LAMS). Three EC-LAMS are currently available on the market: Hot-Axios (Boston Scientific, USA), Niti-S Hot-Spaxus (Taewoong Medical, South Korea), and Hanarostent Hot Plumber Z-EUS IT (M.I. Tech, South Korea). While for the first two devices data on safety and efficacy are already available in the literature, for the latter only case reports are available to date. Our aim was therefore to assess the efficacy and safety of the Hanarostent Hot Plumber Z-EUS IT device in different therapeutic EUS indications.

Methods For this retrospective, multicenter study, all consecutive patients undergoing therapeutic EUS for different indications using the Hanarostent Hot Plumber Z-EUS IT at 11 referral centers between December 2021 and October 2025 were enrolled. The primary aim was the technical success of the procedures performed with the device, defined as successful placement of the stent through the wall of the gastrointestinal tract into the target organ or cavity. Secondary aims were safety, defined as the rate of procedure-related adverse events (AEs), and clinical success, defined differently according to the specific procedure and indication. AEs were also stratified according to timing and severity. Relevant procedure-related clinical and technical data were collected.

Results Seventy-eight patients were enrolled (mean age 69 years, 45 % female). Indications and procedures performed were as follows: 41 gallbladder (GB) drainages for acute cholecystitis; 30 pancreatic fluid collection (PFC) drainages; 4 choledochoduodenostomies for malignant biliary obstruction; 2 gastroenterostomies for malignant gastric outlet obstruction; and 2 drainages of intra-abdominal collections. The underlying condition was neoplastic in 33.3 %. Technical success was achieved in 96.2 % of cases. Among these, the clinical success rate was 100 %. The 3 cases of technical failure were due to stent misdeployment in 2 cases, and inability to get access to the target cavity in 1 case. Fifty-seven (73.1 %) procedures were performed under deep sedation or general anaesthesia, while the remaining 26.9 % were performed under conscious sedation. Fluoroscopic assistance was necessary in 43.6 % of cases. The most commonly used stent diameter was 10 mm (50 %), followed by 16 mm (32.1 %), 14 mm (12.8 %), and 12 mm (5.1 %). The 10-mm diameter stent was used in 78 % of EUS-guided GB drainage, while the 16-mm stent was mostly used for PFC drainage. The most common stent length was 20 mm (83.3 %). The access technique was free-hand in 87.2 %; proximal release was intrachannel in 93.6 %. Among GB drainages, 82.5 % were performed through duodenal access. PFC drainage was followed by endoscopic necrosectomy in 33.3 % of cases (90 % delayed). Coaxial double pigtail plastic stents were placed in 14.7 % of cases. Over a median follow-up time of 13 months, adverse events (AEs) occurred in 12.8 % of patients, all graded I to III according to the AGREE classification. Of these, 50 % occurred intraprocedurally (all misdeployments), 10 % were early (≤ 7 days), and 40 % were late. All AEs were treated conservatively or endoscopically, except one case of biliary peritonitis requiring surgery. No procedure-related deaths occurred.

Conclusions This is the first study to assess the efficacy and safety of the EC-LAMS Hanarostent Hot Plumber Z-EUS IT device. This device demonstrated high technical and clinical success in different therapeutic EUS indications, with an acceptable safety profile. Prospective studies are warranted to confirm these findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1255 EUS-guided choledocoduodenostomy vs. hepaticogastrostomy in case of concomitant gastric outlet obstruction treated by EUS-guided gastroenterostomy: a systematic review and meta-analysis

Aims Biliary and gastric outlet obstruction (GOO) are common complications in patients with pancreatic cancer, often delaying essential cancer treatments. While endoscopic ultrasound-guided gastroenterostomy (EUS-GE) has been shown to be superior to duodenal self-expandable metal stents (dSEMS) for managing GOO, the optimal strategy for biliary drainage (BD) in this setting remains unclear. Specifically, there is no consensus on whether to prefer EUS-guided choledochoduodenostomy (EUS-CDS) or EUS-guided hepaticogastrostomy (EUS-HGS). We conducted a systematic review and meta-analysis to identify the optimal biliary drainage approach in patients undergoing EUS-GE for concomitant GOO and biliary obstruction.

Methods We searched Medline, Scopus, and EMBASE up to February 2025. Studies were included if they reported outcomes of EUS-CDS or EUS-HGS in patients with biliary obstruction and concomitant GOO treated by EUS-GE. Pooled outcomes included technical and clinical success, stent dysfunction, and adverse events, analyzed using a random-effects model. Results were reported as relative risks (RRs) with 95 % confidence intervals (CIs).

Results Five studies met inclusion criteria, comprising 128 patients (female = 45.5 %; mean age range 63.0–73.0 years), with 61 undergoing EUS-CDS and 67 undergoing EUS-HGS. Four studies were conducted in Europe and one in the United States; one study was prospective. Technical success rates were similar between groups (RR 0.96, 95 % CI 0.83–1.11; $I^2 = 0$ %; EUS-CDS 94.5 % vs EUS-HGS 96.4 %), as were clinical success rates (RR 1.04, 95 % CI 0.92–1.19; $I^2 = 0$ %; EUS-CDS 96.5 % vs EUS-HGS 89.1 %). However, the risk of stent dysfunction was significantly higher in the EUS-CDS group compared to EUS-HGS (RR 4.42, 95 % CI 1.71–11.43; $I^2 = 0$ %; EUS-CDS 45.1 % vs EUS-HGS 10.9 %). The incidence of procedure-related adverse events was comparable between the two approaches (RR 1.14, 95 % CI 0.24–5.50; $I^2 = 40.8$ %; EUS-CDS 10.7 % vs EUS-HGS 16.0 %).

Conclusions This meta-analysis suggests that both EUS-CDS and EUS-HGS are similarly safe and effective for managing malignant biliary obstruction in the setting of concomitant GOO. However, EUS-CDS is associated with a more than four-fold increase in the risk of stent dysfunction, which may result in delays to critical cancer treatments.

eP1256 Impact of Direct Oral Anticoagulants on Clinical Presentation and Outcomes in Acute Upper Gastrointestinal Bleeding: A Retrospective Study

Authors Sidharthan A[1], Nishad N[2], Edward G[3], Syrine BR[4], Yi HT[1], Benjamin H[1], James H[1], Corbett G[5], Thoufeeq M[1]

Institutes **1** Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom; **2** Sheffield Teaching Hospitals NHS Foundation Trust, She, United Kingdom; **3** University of Sheffield Medical School, Sheffield, United Kingdom; **4** Regional Hospital of Kef, El Kef, Tunisia; **5** Cambridge University Hospitals NHS Trust, Department of Gastroenterology and Hepatology, Cambridge, United Kingdom

DOI 10.1055/s-0046-1822583

Aims The increasing use of direct oral anticoagulants (DOACs) has resulted in more anticoagulated patients presenting with acute upper gastrointestinal bleeding (UGIB). This study aimed to compare clinical presentation, endoscopic findings, interventions, and outcomes between DOAC users and non-anticoagulated patients presenting with acute UGIB.

Methods We conducted a retrospective review of all UGIB cases undergoing endoscopy at Sheffield Teaching Hospitals between January and December 2023. Patients were categorized into DOAC users and non-users. Data collected included demographics, presenting symptoms, endoscopic diagnoses, therapeutic interventions, length of hospital stay, and short-term mortality. Comparative analyses were performed to identify differences between the two groups.

Results A total of 649 patients were included, of whom 98 (15.1 %) were taking DOACs (Apixaban n = 52, Edoxaban n = 27, Rivaroxaban n = 19) and 551 (84.9 %) were not. DOAC users were significantly older than non-DOAC patients, with a mean age of 75.0 years (95 % CI 72.4–77.6) compared with 55.9 years (95 % CI 54.3–57.5; p < 0.001). The principal indications for DOAC therapy were atrial fibrillation (n = 69, 70.4 %) and thrombotic disease (n = 29, 29.6 %). Melena at presentation was reported in 43/98 (43.9 %) of DOAC users compared with 198/551 (35.9 %) non-DOAC patients. Common endoscopic findings in DOAC versus non-DOAC patients included oesophagitis (17/98, 17.3 % vs 84/551, 15.2 %), gastric ulcers (11/98, 11.2 % vs 40/551, 7.3 %), duodenal ulcers (5/98, 5.1 % vs 43/551, 7.8 %), and varices (4/98, 4.1 % vs 66/551, 12.0 %); however, these differences did not reach statistical significance (all p > 0.05). Therapeutic endoscopic procedures were less commonly performed in DOAC users compared with non-DOAC patients (8/98, 8.2 % vs 61/551, 11.1 %). (p = 0.48). Interventions in the DOAC group included injection therapy (n = 3), clips (n = 2), EMR for a bleeding polyp (n = 1), Bentonite haemostatic agent (n = 1), and other modalities (n = 3), whereas the non-DOAC group underwent APC (n = 2), band ligation (n = 19), injection therapy (n = 19), clips (n = 22), EMR (n = 3), heater probe (n = 5), Bentonite haemostatic agent (n = 3), and other treatments (n = 7). Length of hospital stay was significantly longer among DOAC users (6.0 vs 3.6 days; p = 0.009). One death within 10 days of admission occurred in the DOAC group.

Conclusions Patients presenting with UGIB while on DOAC therapy were older, underwent fewer therapeutic endoscopic interventions, and experienced longer hospital admissions compared with non-anticoagulated patients. Although endoscopic findings were similar, the extended hospital stay highlights the added complexity of managing anticoagulated patients. These findings emphasize the need for tailored management pathways and resource planning to optimize outcomes in this growing patient population.

eP1257 Early versus Delayed Feeding after Upper Gastrointestinal Endoscopic Therapies: An Updated Systematic Review and Meta-Analysis of Randomized Controlled Trials

Authors Alcantara GD[1], Aguila E[1]

Institute **1** St. Luke's Medical Center – Global City, Taguig, Philippines

DOI 10.1055/s-0046-1822584

Aims The timing of feeding after Upper Gastrointestinal (UGI) endoscopic therapies remains variable in the clinical setting. Delayed feeding is traditionally practiced to reduce perceived bleeding risk however may lead to unnecessary prolonged fasting, recovery and hospital stay. The most recent meta-analyses examined the timing of feeding after UGI endoscopic therapies; with one focusing on therapies done for UGI bleeding alone and the other focused on feeding after UGI endoscopic therapy in general. This meta-analysis aims to make an updated comparison of outcomes of early versus delayed feeding following UGI endoscopic procedures across variceal, non-variceal, and combined populations; including the latest randomized controlled trials available and excluding studies with no endoscopic therapy done [1–10].

Methods A systematic literature search identified 10 randomized controlled trials (RCTs) comparing early and delayed feeding after UGI endoscopic therapy (e.g. Endoscopic Variceal Ligation, Endoscopic Submucosal Dissection, Sclerotherapy, Endoscopic Injection with Adrenaline, Argon Plasma Coagulation, Thermal coagulation). Early feeding was defined as introduction of standard diet within 24 hours after an UGI endoscopic therapy, while delayed feeding was after 24 hours. Outcomes included early and delayed rebleeding, total rebleeding, mortality, and duration of hospital stay. Using a Mantel–Haenszel random-effects model, pooled risk ratios (RR) were calculated for binary outcomes and standardized mean differences (SMD) for continuous outcomes. Heterogeneity was assessed using I^2 statistic and subgroup analyses were conducted for variceal and non-variceal procedures to explore differences of outcomes amongst different patient populations.

Results Across the 10 RCTs, early feeding did not significantly increase total rebleeding compared with delayed feeding in the combined cohort (RR = 1.20; 95 % CI 0.74–1.93; p = 0.47), and showed no observed heterogeneity (I^2 = 0 %). Subgroup analyses showed no significant difference in total rebleeding for variceal (RR = 1.08; 95 % CI 0.53–2.22; p = 0.83) or non-variceal procedures (RR = 1.30; 95 % CI 0.68–2.48; p = 0.43), both with low heterogeneity. Mortality outcomes were similarly comparable between early and delayed feeding groups (RR = 0.73; 95 % CI 0.31–1.70; p = 0.47; I^2 = 0 %). Early feeding significantly reduced hospital stay (SMD = − 0.76; 95 % CI − 1.19 to − 0.32; p = 0.0006) though heterogeneity was substantial (I^2 = 88 %).

Conclusions Early feeding after UGI endoscopic therapy appears safe without increased risk of rebleeding or mortality and is associated with shorter hospitalization. These findings support reconsidering prolonged fasting protocols post-endoscopy while highlighting the need for standardized RCTs to refine optimal feeding timing.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1258 Efficacy and Safety of Ultrathin Endoscopic Submucosal Dissection for Superficial Pharyngeal Cancer

Authors Iizuka T[1], Eriko N[1], Yasuhiro O[1]
Institute **1** Tokyo Metropolitan Komagome Hospital, Bunkyo City, Japan
DOI 10.1055/s-0046-1822585

Aims Advances in endoscopic equipment and increased interest among endoscopists have led to higher detection rates of superficial pharyngeal cancer, with a concomitant rise in endoscopic treatments. Since early-stage treatment has been shown to improve overall survival, the current focus has shifted toward achieving safer therapeutic procedures. With recent improvements in image quality, ultrathin endoscopes are increasingly being utilized for therapeutic purposes. Based on our experience using ultrathin endoscopes for superficial pharyngeal cancer, we evaluated the efficacy and safety of this approach.

Methods We retrospectively analyzed 75 patients with 123 lesions who underwent endoscopic submucosal dissection (ESD) using an ultrathin endoscope for superficial pharyngeal cancer at our institution between June 2021 and October 2025. The control group consisted of 64 patients with 85 lesions treated with ESD using a standard-diameter endoscope during the same period. The ultrathin endoscope used was the GIF-1200N (Olympus), while the control group was treated using the GIF-260J or GIF-290T (Olympus). With the ultrathin endoscope, ESD was performed without the use of hemostatic forceps or a waterjet function. After tumor resection, the endoscope was exchanged for a standard one, and hemostatic forceps were used for hemostasis. Procedure time, en bloc resection rate, R0 resection rate, local injection volume, lesion size, resected specimen size, and postoperative complications were retrospectively compared between the two groups.

Results In the ultrathin and control groups, the mean age was 73 and 70 years, respectively; the proportion of male patients was 92 % vs 89 %; and the proportion with a history of prior esophageal cancer treatment was 85.3 % vs 87.5 %. Lesions were located in the hypopharynx (91 vs 53) and oropharynx (32 vs 32). The procedure time was 33.4 vs 32.8 minutes, lesion size was 15.7 vs 18.5 mm, and resected specimen size was 28.8 vs 29.6 mm. The en bloc resection rate was 99.2 % vs 100 %, while the R0 resection rate was 83.7 % vs 77.6 %. The local injection volume was significantly lower in the ultrathin group (3.2 vs 6.4 mL). Postoperative complications included pneumonia and hemorrhage (pneumonia 4 cases and hemorrhage 1 case vs pneumonia 2 cases), all of which resolved with conservative management. Significant differences were observed in lesion size and local injection volume. In seven cases (6 %), the procedure was converted from an ultrathin to a standard endoscope due to difficulty in maintaining adequate visualization.

Conclusions Although this study has limitations, including potential selection bias, ESD using an ultrathin endoscope demonstrated therapeutic efficacy and safety comparable to those of standard endoscopes. A key advantage of the ultrathin endoscope is its ability to allow early entry into the submucosal layer, facilitating dissection. However, in 6 % of cases, conversion to a standard endoscope was necessary due to impaired visualization, highlighting the need for further technical improvements.

eP1259 Endoscopic Ultrasound-Guided Trans-Gastric Radiofrequency Ablation: An Effective and Safe Alternative Treatment for Left-sided Unilateral Aldosterone-Producing Adenoma

Authors Abreu B[1, 2], Bombil L[3], Loubet A[3], Maiter D[3], Furnica RM[3], Deprez P[3]
Institutes **1** Hospital Beatriz Ângelo, Loures, Portugal; **2** Hospital das Forças Armadas – Pólo Lisboa, Lisbon, Portugal; **3** Cliniques universitaires St-Luc, Brussels, Belgium
DOI 10.1055/s-0046-1822586

Introduction: Unilateral aldosterone-producing adenoma (APA) represents a potentially curable cause of hypertension through laparoscopic adrenalectomy. However, surgical intervention may not be suitable for all patients, particularly those with significant comorbidities or a preference for less invasive management. Endoscopic ultrasound (US)-guided trans-gastric (TG) radiofrequency ablation (RFA) offers a minimally invasive alternative to treat left-sided APAs which are in closed proximity with the stomach. This new approach was successfully performed in our centre [1].

Case report: A 35-year-old woman with a history of familial adenomatous polyposis syndrome and previous total colectomy was referred for assessment of hypertension associated with severe hypokalaemia at 2.14 mmol/L. Biochemical evaluation confirmed primary aldosteronism with high plasma aldosterone (47.1ng/dL; nl < 14), suppressed renin concentration (0.8mU/L; nl > 4.0) and a high aldosterone-to-renin ratio of 58.9 (nl < 2.4). Abdominal CT-scan imaging showed bilateral adrenal nodules (left: 23 x 16 mm and right: 17 x 12 mm), both evoking benign adenomas. Adrenal vein sampling showed a clear lateralization ratio (10.0) of aldosterone secretion from the left side. As the patient expressed a clear desire for a minimally invasive curative treatment with preservation of left adrenal tissue, endoscopic US-TG-RFA was considered after informed consent. After a medical preparation with spironolactone 50 mg/day and an alpha-blocker (terazosin 2.5 mg twice daily for 2 weeks), the left adrenal nodule could be successfully ablated under light general anaesthesia, using a 10 mm STARMed needle (Taewoong Medical, Seoul, South Korea) and generator set at 30 W.

Follow-up: No immediate complication was noted after the procedure and blood pressure and heart rate remained normal. Complete clinical remission of hypertension was achieved within one week, allowing discontinuation of spironolactone. After five month, the patient's blood pressure remained consistently below 104/84 mmHg without medication, and CT scan imaging showed a reduction size of the left adrenal lesion with focal areas of necrosis but no evidence of delayed complication. Biochemical cure of APA was confirmed by normalization of potassium (3.82mmol/L), aldosterone (8.2ng/dL)

and renin serum concentrations (1.1mU/L), consistent with residual primary hyperaldosteronism.

Conclusion: Endoscopic ultrasound-guided trans-gastric RFA is an effective and safe, minimally invasive, adrenal-sparing alternative to surgery for patients with unilateral left-sided APA.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1260V Stricture prophylaxis of post-esophageal ESD with autologous adipose-derived stromal cell injection

Authors Fortes Fonseca Y[1], Nobre Moura R[2], Costa Martins B[2], Lenz L[2], Lima A[2], Mansilla Gallegos M[3], Morganti Ferreira Dias M[2], Gustavo ADP[1], Simas Lima M[2], Vaz Safatle Ribeiro A[2], Camargo Pires C[2], Maluf-Filho F[4]

DOI 10.1055/s-0046-1822587

Problem to solve Esophageal endoscopic submucosal dissection (ESD) involving > 75 % of the circumference is associated with refractory stricture in > 70–90 % of cases. Extensive circumferential resections progress to refractory strictures that are challenging to manage. This adverse event severely impairs quality of life and limits ESD indications for superficial squamous cell carcinoma. The prophylactic, topical, and oral administration of corticosteroids has partially addressed this problem. Several other prophylactic therapies have been proposed, and recently, autologous and allogenic adipose tissue-derived stromal cells (ADSC) injection has emerged from animal trials. The advantages of ADSC are their paracrine activity, promoting local immunomodulation, cell recruitment and neovascularization, their ability to differentiate into mesenchymal and non-mesenchymal lineage, and modulation of keratinocyte-fibroblast interaction, reducing excessive fibrosis development [1–8].

Innovation We report a novel prophylactic strategy using immediate injection of mechanically processed autologous adipose-derived stromal cells (ADSCs) directly into the post-ESD ulcer bed. A 71 male-patient, diagnosed with superficial esophageal squamous cell carcinoma (SCC), occupying 80 % of luminal circumference. He was referred to our center for treatment and underwent a 90 % of esophageal circumference, 8 cm-long ESD. Once ESD was finished, the plastic surgeon made a bilateral inguinal liposuction using two 10mL syringes. The content was decanted for ten minutes, and then the liquid part of the material was discarded. Afterwards, the fat was washed with fisiologic solution, transferred to 5mL syringes, coupled with a transfer connector, already coupled with and empty 5mL syringe. The material was transferred 10 times for adipose tissue progressive fractioning, until a final product was obtained. This product was then injected onto the ESD resection bed, as homogeneously as possible, through a 5Fr catheter. Oral prednisolone (30 mg/day with 8-week tapering) was also administered as an adjunct per institutional protocol.

Results Pathology revealed early squamous cell carcinoma, invading the lamina propria (pT1a – M2), without angiolymphatic or perineural invasion, with free margins. Serial endoscopies at 2, 3, 4, 5, 6, 8 and 12 weeks showed progressive healing with fibrin coverage and tissue retraction, but no luminal narrowing. At week 8, the ulcer was completely healed with only cicatricial retraction; a standard 9.8 mm gastroscope passed without resistance. The patient developed transitory dysphagia, that completely resolved six weeks afterwards, and needed diet adaptation throughout this period. In none of the endoscopies narrowing of the lumen was observed, and there was no need of endoscopic dilatation. A new endoscopy was performed twelve weeks after the procedure, revealing the same aspect described on the eighth week. The patient remains clinically well, without dysphagia or weight loss, until now, five months after the procedure.

Conclusions This first experience suggests the feasibility and promising efficacy of immediate autologous ADSC injection for preventing refractory stricture after high-risk oesophageal ESD, with rapid processing and no added adverse events. This strategy may improve extensive esophageal resections prognosis and consequently bring a new perspective for patient's quality of life. However, this is an initial pilot study, probably the pioneer of this therapy in humans, and further multicentre trials are essential to establish its role in extensive circumferential ESD.

eP1261V Successful endoscopic treatment (E-VAC) of complex anastomotic leak after total gastrectomy in elderly patient

Authors Marconato E[1], Desideri F[1], Bevilacqua N[1], De Marchi F[1], Mega A[1]

Institute **1** Gastroenterology Department, San Maurizio Hospital, Bolzano, Italy

DOI 10.1055/s-0046-1822588

Abstract Text

An 84-year-old male, previously treated with subtotal gastrectomy for gastric adenocarcinoma, presented 10 years later with Siewert type II cardial carcinoma detected on follow-up OGD. He underwent total gastrectomy with Roux-en-Y esophagojejunal mediastinal anastomosis. Postoperatively, septic shock, anastomotic leak, periesophageal collection, and pleural effusion occurred. Endoscopy confirmed leak communicating with mediastinal abscess and pleural cavity, demonstrated by methylene blue. Eight sessions of endoscopic VAC therapy were performed. During the first six, the sponge was placed intracavitary, achieving granulation and cavity reduction with clinical improvement. In the last two, it was positioned intraluminally adjacent to the leak. Endoscopic and radiological studies confirmed closure. The patient resumed oral intake and was discharged to a rehabilitation facility.

eP1262 Etiological and Endoscopic Profile of Portal Hypertension: Experience of a University Hospital Department

Authors Lazrak A[1], Essadiqi S[1], Belabbes F[1], Delsa H[1], Ben El Barhdadi I[1]

Institute 1 Cheikh Khalifa International University Hospital, Mohammed VI University of Sciences and Health, Casablanca, Morocco

DOI 10.1055/s-0046-1822589

Aims Portal hypertension is defined as an increase in pressure within the portal venous system caused by an obstruction located at the suprahepatic, intrahepatic, or infrahepatic level. In our setting, intrahepatic portal hypertension is predominant, mainly due to post-viral cirrhosis. The objective was to determine whether intrahepatic block and cirrhosis remain the predominant causes of portal hypertension, or whether other etiologies should be considered, and to highlight the key role of endoscopy in the diagnosis and management of related complications.

Methods This is a monocentric retrospective and prospective study conducted over a 36-month period, from February 2022 to February 2025. All patients presenting with portal hypertension were included and underwent clinical evaluation, as well as biological, radiological, and endoscopic assessments.

Results Among the 192 patients included, the mean age was 60.2 years (range: 15–97 years). The study population consisted of 100 men (52 %) and 92 women (48 %), with a male-to-female ratio of 1.1.Clinically, upper gastrointestinal bleeding was the initial presenting symptom in 49.8 % of cases. Physical examination revealed an abnormal liver in 46 % of patients, ascites in 25.5 %, splenomegaly in 24.7 %, collateral venous circulation in 15.3 %, jaundice in 9.3 %, and hepatic encephalopathy in 6.8 %.

Endoscopic evaluation showed that 93 % of patients had portal hypertension–related lesions. Esophageal varices were grade III in 49 %, grade II in 29 %, and grade I in 14 %. Gastro-esophageal varices (GOV) were observed in 37 %, isolated gastric varices (IGV) in 10 %, ectopic varices in 3 %, and signs of portal hypertensive gastropathy in 52 %. Red wale signs were present in 45 % of patients.

Regarding therapeutic management, 56 % of patients underwent esophageal variceal ligation, with a mean of 2.6 sessions per patient. Biological glue injection was performed in 6 % of cases, and argon plasma coagulation in 3 %. Somatostatin was administered in 13 % of patients, and 82 % were treated with beta-blockers.

Among the etiologies of intrahepatic portal hypertension, hepatic cirrhosis accounted for 65.6 % (n = 126). The underlying causes were: hepatitis C virus–related cirrhosis in 20.8 % (n = 41), hepatitis B virus–related cirrhosis in 7.3 % (n = 14), cirrhosis of indeterminate origin in 29 % (n = 15), alcoholic cirrhosis in 8.9 % (n = 17), primary biliary cholangitis in 7.8 % (n = 15), primary sclerosing cholangitis in 2 % (n = 4), and autoimmune hepatitis in 3.6 % (n = 7).Non-cirrhotic intrahepatic causes included porto-sinusoidal vascular disorders (PSVD) in 17.7 % (n = 34) and portal system compressions in 2.6 % (n = 5), due to compressive metastases, hepatic cysts, or giant hepatic hemangioma.Portal vein thrombosis etiologies included thrombophilia (1.6 %), malignant hematologic disorders (1.6 %), tumoral invasion of the portal vein trunk (1 %), and idiopathic portal cavernoma (4.1 %). Etiologies of Budd–Chiari syndrome included celiac disease in 1 % (n = 2) and hyperhomocysteinemia in 0.5 % (n = 1). The cause remained unidentified in 2.6 % of cases (n = 5)

Conclusions Cirrhosis remains the leading cause of portal hypertension in our population, although non-cirrhotic etiologies such as PSVD, portal vein thrombosis, and Budd–Chiari syndrome are also significant. The high prevalence of endoscopic lesions confirms the central role of endoscopy in both diagnosis and management of complications. A systematic etiological assessment remains essential to guide appropriate care.

Aims Esophageal diverticulum is a rare condition, that is most commonly associated with esophageal motility disorders. The epiphrenic diverticulum typically originates in the distal esophagus, 4-8cm above the cardia and develops in consequence of increased intraluminal pressure. Its estimated yearly incidence is 1:500,000. In the past a surgical treatment was used to remove the diverticulum, but it had 15 % morbidity and 3 % mortality rates. Nowadays, the endoscopic treatment does not remove the diverticular sac, but it copes with the symptoms and has nominal adverse events [1–4].

Methods We present five cases of esophageal diverticula in four patients aged 43 to 71. The procedures were performed from 2020 to 2025. All of the patients had symptoms of dysphagia, vomiting of unprocessed foods, chest pains and reduction in weight, with duration up to 2 years. The diverticula were diagnosed, either with endoscopy, or with upper gastrointestinal series with contrast. One of the patients had two epiphrenic diverticula one above the other. The median size of the diverticula was 5.19 cm (4-7cm range) in height. Three of the four patients had achalasia as a concomitant disease.

The procedures were performed with the patients placed under general anesthesia in supine position. The endoscopes used had distal attachments placed. After the localization of the diverticula, a solution of Gelofusine and Indigo carmine was introduced in the submucosal space 2 to 3 cm superiorly to the proximal end of the diverticula. Initial mucosal incisions were created. Dissections of both sides of the distal end of the diverticula were performed. From that point to two centimeters distal of the gastroesophageal junction submucosal tunnels were created. The tunneling was done with utmost care as not to damage the mucosa or the adventitia. Myotomy of the distal septum and myotomy of the muscle layer in the esophagus and up to 2cm below the gastroesophageal junction was performed. The initial incisions were closed using 3 to 5 hemostatic clips. Carbon dioxide insufflation was used during all of the procedures.

Results The diverticular peroral endoscopic myotomy (D-POEM) significantly relieved the symptoms of the patients and the quantity of the retained food and liquids in the diverticular sacs. The adverse events of the procedures were subcutaneous emphysema and retrosternal pain that faded within three days.

Conclusions D-POEM is a safe and effective procedure, that results in symptomatic improvement of the patients with epiphrenic diverticula, especially in those cases, where it is combined with achalasia.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1264 MRI-Based Anatomical Predictors of Difficult ERCP Cannulation: A Multivariable Model for Pre-Procedural Risk Stratification

Authors Kahwagi A[1], Wehbe P[1], Mohamad Ali H[2], Njeim M[3], Mahfouz E[1], Amara J[1], Honein K[1], Slim R[1], Yaghi C[1]
Institutes 1 Gastroenterology Department, Hotel Dieu de France, Beirut, Lebanon; 2 Radiology Department, Hotel Dieu de France, Beirut, Lebanon; 3 Hôtel-Dieu de France, Beirut, Lebanon
DOI 10.1055/s-0046-1822591

Aims Difficult cannulation during endoscopic retrograde cholangiopancreatography (ERCP) is a major determinant of complications, creating a clinical need for accurate pre-procedural risk stratification. This study aimed to identify MRI-based anatomical predictors of difficult ERCP cannulation, develop a predictive model for procedural difficulty, and support tailored prophylactic strategies for each level of difficulty [1, 2].

Methods A total of 121 patients who underwent contrast-enhanced MRI followed by ERCP at Hôtel-Dieu de France, Beirut, Lebanon, were included. Difficult cannulation was defined according to the criteria recommended in the ESGE Clinical Guideline on papillary cannulation and sphincterotomy techniques, requiring ≥ 1 of the following: more than five contacts with the papilla, cannulation time > 5 minutes, or more than one unintended pancreatic duct cannulation or opacification. MRI-derived parameters included distal common bile duct (CBD) diameter, choledochoduodenal (CD) angle, and periampullary diverticulum (PAD) size. Variables and patients with excessive missingness were excluded, and multiple imputation was applied. Associations between anatomical features and ERCP difficulty were evaluated using univariable and multivariable logistic regression with LASSO regularization. ROC curves were used to determine optimal cutoff values.

Results A smaller distal CBD diameter was consistently associated with higher odds of difficult ERCP and remained an independent predictor across all models (OR = 0.872; 95 % CI: 0.802–0.945; p < 0.001). A narrower CD angle was also significantly associated with difficult cannulation, mainly due to its strong association with unintended pancreatic duct cannulation or opacification (OR = 0.968; 95 % CI: 0.950–0.985; p < 0.001). PAD size was not significantly associated (p > 0.4). ROC analysis identified a CBD diameter < 5.5 mm as the optimal cutoff for predicting overall difficulty (AUC = 0.61; sensitivity 66.7 %, specificity 52.2 %). For predicting unintended pancreatic cannulations specifically, a CD angle < 32.5 ° showed high specificity (89.9 %) with an AUC of 0.65.

Conclusions MRI-derived anatomical metrics, particularly distal CBD diameter and CD angle, serve as meaningful predictors of ERCP cannulation difficulty. These results align with previous findings by Lee et al., while highlighting the potential advantage of MRI's superior soft-tissue contrast for pre-procedural risk assessment. Integrating MRI-based predictors into clinical workflows may enhance risk stratification and support more individualized prophylactic strategies ahead of ERCP.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1265 Large-balloon anchor and traction technique to access major papilla in a patient with giant hiatal hernia

Authors Mendes I[1], Vara-Luiz F[1], Palma C[1], Veloso J[1], Nunes G[1]
Institute 1 Hospital Garcia de Orta, Almada, Portugal
DOI 10.1055/s-0046-1822592

Abstract Text
The authors report the case of an 89-year-old male with several comorbidities, including an invasive periampullary adenocarcinoma and a large hiatal hernia. Due to obstructive jaundice the patient underwent ERCP with self-expandable metal stent (SEMS) placement for palliative biliary drainage. Eight months later, ERCP was repeated due to stent dysfunction and biliary drainage successfully re-established using a stent-in-stent approach to restore patency.
Ten months later the patient presented with acute cholangitis. CT imaging showed biliary stents *in situ* with dense endoluminal content and upstream biliary dilation without pneumobilia. Worsening of the hiatal hernia with complete intrathoracic gastric displacement with organo-axial volvulus was also noted. Antibiotics were started and a third ERCP was scheduled.
During the procedure, advancement of the duodenoscope was significantly hindered due to entrapment and looping within the herniated stomach. After multiple attempts, the scope could carefully progress into the duodenal bulb, but the second portion of the duodenum could not be reached. A 0.035´´ guidewire was passed into the proximal jejunum and a 20mm through-the-scope balloon was introduced over-the-wire. The balloon was inflated in the lumen of the fourth duodenal portion, anchoring the scope. Pulling the balloon catheter with moderate traction, the duodenoscope was straightened and could advance reaching the major papilla in a stable short position. Biliary cannulation was performed and cholangiography confirmed two metal stents with tumoral ingrowth and upstream biliary dilation. Abundant biliary sludge was removed using an extraction balloon and an uncovered SEMS (100x10mm) was placed in a stent-in-stent position achieving effective drainage. The patient was later discharged asymptomatic.
Altered gastrointestinal anatomy causes significant technical challenges in ERCP, requiring tailored endoscopic strategies to achieve biliary access. This case highlights the efficacy and safety of a balloon anchor and traction technique in overcoming duodenoscope advancement difficulty posed by a large hiatal hernia.

eP1266 EUS-guided radiofrequency ablation in pancreatic neoplasms, a single-center observational study

Authors de Wijkerslooth T[1], Verbeek W[2], Versleijen M[2], Westerink B[2], Van Den Berg J[2], Van Dieren J[2], Tesselaar M[2]
Institutes **1** St Antonius Hospital, Utrecht, Netherlands; **2** Netherlands Cancer Institute, Antoni van Leeuwenhoek, Amsterdam, Netherlands
DOI 10.1055/s-0046-1822593

Aims Pancreatic well-differentiated non-metastatic neuroendocrine tumors (PanNET) are rare neoplasms and often detected incidentally. Parenchyma-sparing surgery may be considered as first-line therapeutic approach; however, morbidity and the potential survival benefit must be carefully weighed. EUS-guided Radio Frequency Ablation (EUS-RFA) is a promising organ preserving endoscopic technique that can be performed in an outpatient setting and has the potential to serve as an alternative to surgery. We aimed to evaluate the safety and efficacy of pancreatic EUS-RFA.

Methods We retrospectively reviewed all consecutive patients with solid pancreatic neoplasms who were scheduled to undergo EUS-RFA between 2020 and 2023 at a single tertiary center. Indications, procedural characteristics, adverse events and clinical outcomes were recorded. Safety outcomes were analyzed for all included patients. Clinical outcomes were assessed in all patients with somatostatin receptor-positive PanNETs, who completed one year of follow-up with both EUS/MRI and ^{68}Ga-Dotatate PET-CT. Serious adverse events were defined as those classified as AGREE grade ≥ 3 (requiring surgical, endoscopic or radiological intervention). Radiological response was evaluated by MRI and categorized as complete (no residual lesion), partial (> 75 % volume reduction) or no response (< 75 % reduction) at 9 months of follow-up. Nuclear imaging complete response rate was defined as the absence of ^{68}Ga-Dotatate uptake at 1-year of follow-up.

Results A total of 23 patients were scheduled for EUS-RFA; in 2 cases the procedure was deemed not feasible due to the lesion's close proximity (< 1 mm) to the pancreatic duct or a vessel. Adverse events consisted of one (5 %) intraprocedural bleed that resolved spontaneously, and mild pancreatitis occurred in 5 patients (24 %). No serious adverse events occurred. Sixteen patients had SSTR-positive PanNETs, of whom 14 completed full follow-up. Their median age was 67 years (IQR 64-77), and 9 patients (64 %) were male. The median tumor diameter was 15 mm (IQR 11-18). Patients underwent a median of one RFA procedure (IQR 1-1) with a median of 3 ablations (IQR 3-4) per session. Radiological response was complete in 86 % (12/14), partial in 7 % (1/14) and absent in 7 % (1/14). Patients with incomplete radiological response had PanNET located in uncinate process. A total of 8 patients (57 %) demonstrated complete response on nuclear imaging.

Conclusions Pancreatic EUS-RFA demonstrated an acceptable safety profile. More than 8 out of 10 patients with SSTR-positive PanNETs achieved complete radiological response, while almost 6 out of 10 patients achieved complete response on nuclear imaging following a single EUS-RFA session. In selected patients, EUS-RFA represent a feasible therapeutic alternative to pancreatic surgery.

eP1267 Endoscopic ultrasound-guided tissue acquisition for pancreatic metastases: clinical features and diagnostic performance in a 12-year cohort

Authors Almeida R[1], Lenz L[2], Pombo A[3], Nobre R[3], Safatle-Ribeiro A[3], Martins B[3], Andrade De Paulo G[3], Matuguma S[3], Cesar C[3], Maluf-Filho F[3], Machado A[3]

DOI 10.1055/s-0046-1822594

Aims To describe the clinical characteristics, primary tumor sites, endosonographic features, and diagnostic performance of endoscopic ultrasound-guided tissue acquisition (EUS-TA) in patients with confirmed pancreatic metastases evaluated over a 12-year period in a tertiary oncology center in Brazil.

Methods Retrospective observational study including all consecutive patients with histologically or clinically confirmed pancreatic metastases who underwent EUS-guided fine-needle aspiration or biopsy between April 2013 and February 2025. Data collected from electronic medical records comprised demographics, primary tumor origin, lesion size and pancreatic location, and final histopathological/immunohistochemical diagnosis. Diagnostic accuracy was calculated using definitive histology of the pancreatic lesion or unequivocal clinical/imaging progression of known metastatic disease in other organs as the reference standard [1–4].

Results Among 433 patients who underwent 491 pancreatic EUS-TA procedures during the study period, 21 procedures (4.8 %) in 20 patients were confirmed as pancreatic metastases. Patients were predominantly female (80 %) with a median age of 65 years (IQR 60–70). Mean lesion size was 30.2 mm (range 8–76 mm; median 30 mm). Lesions were located in the pancreatic head in 47.6 %, body 33.3 %, tail 14.3 %, uncinate process 4.8 %, and neck 28.6 % (some lesions involving more than one segment).

The most frequent primary tumors were colorectal adenocarcinoma (23.8 %), breast carcinoma (23.8 %), melanoma (14.3 %), renal cell carcinoma (14.3 %), ovarian carcinoma (9.5 %), lung carcinoma (9.5 %), and thyroid carcinoma (4.8 %). EUS-TA yielded 18 true-positive diagnoses (85.7 %) and 3 false-negative results (14.3 %), with no false positives, resulting in an overall diagnostic accuracy of 85.7 % (95 % CI 64.9–95.4 %). Immunohistochemical studies were crucial for lineage confirmation in all true-positive cases.

Conclusions Pancreatic metastases are uncommon (4.8 % of all pancreatic EUS-TA procedures in a high-volume oncology center). Although the literature classically describes pancreatic metastases as predominantly originating from renal cell carcinoma and melanoma, in this 12-year Latin-American cohort colorectal and breast primaries were jointly the most frequent origins (each 23.8 %), highlighting potential regional differences in referral patterns and oncological epidemiology. Lesions are typically solitary, average 3 cm in diameter, and predominate in the pancreatic head.

In this 12-year cohort, EUS-guided tissue acquisition achieved a diagnostic accuracy of 85.7 %, driven largely by the systematic application of immunohistochemical panels that allowed precise diagnosis. Accurate distinction between primary pancreatic adenocarcinoma and metastatic disease carries major therapeutic and prognostic implications. Therefore, EUS-TA with adequate sampling and routine immunohistochemical work-up remains the cornerstone for correct diagnosis and appropriate oncological management in patients with suspected pancreatic metastases. These data reinforce the importance of maintaining a high index of suspicion for secondary pancreatic involvement in oncology patients and support EUS-TA as the diagnostic modality of choice in this setting.

eP1268V Complete closure of a duodenal fistula after a tumor resection, with X-Tack suture system

Authors Martinez Escapa V[1], Martí Romero L[1], Oviedo Bravo M[1], Pla Cortina C[1], Barbera Martinez T[1]

Institute 1 Hospital Arnau de Vilanova, València, Spain

DOI 10.1055/s-0046-1822595

Abstract Text

We present a case of a 69-year-old man with anemia and weight loss. The gastroscopy revealed a 20 mm Gastrointestinal Stromal Tumor (GIST) in the posterior duodenum, confirmed by computed tomography (CT). Resection of the third portion of the duodenum with latero-lateral anastomosis was performed. After septic shock, a CT scan showed free fluid and pneumoperitoneum, suggestive of suture failure. A radiological drainage was placed. A gastroscopy confirmed dehiscence in the staple suture line and a xtack suture was used for repairing the leak, checking the complete seal with contrast. One month later, follow-up CT and gastroscopy showed a decrease in the collection, with no extravasation or leakage, and the XTack correctly positioned. After the removal of the drainage, the patient was discharged, asymptomatic and with oral tolerance [1, 2].

eP1269 Management approaches and clinical outcomes of capsule-diagnosed small-bowel angiodysplasias in the absence of device-assisted enteroscopy: a retrospective descriptive cohort study

Authors Tsakou A[1], Lazaridis N[1], Arvanitakis K[1], Tsiamitros S[1], Germanidis G[1]

Institute 1 1st Department of Internal Medicine, Division of Gastroenterology, AHEPA University Hospital, Thessaloniki, Greece

DOI 10.1055/s-0046-1822596

Aims Gastrointestinal angiodysplasias are acquired vascular malformations of the gastrointestinal mucosa and submucosa and constitute a major cause of suspected small-bowel bleeding (SSBB) and iron-deficiency anemia (IDA). Small-bowel capsule endoscopy (SBCE) is the primary diagnostic tool. Standard management includes iron replacement therapy (IRT), transfusion support, and optimization of anticoagulation or antiplatelet therapy. Device-assisted enteroscopy (DAE), although recommended for endoscopic thermocoagulation, shows high rebleeding rates and is available only in a small number of referral centers in Greece, limiting its feasibility in routine care. Long-acting somatostatin analogues (SSA) represent an alternative therapeutic option for recurrent or refractory bleeding. The aim of this study was to evaluate the characteristics, management patterns, and 12-month clinical outcomes of patients with capsule-diagnosed small-bowel angiodysplasias in a real-world setting without readily accessible DAE [1].

Methods We conducted a retrospective descriptive cohort study including 26 patients with SBCE-confirmed small-bowel angiodysplasias. Demographic characteristics, comorbidities, medication history, indication for SBCE, duration of symptoms, prior treatments, SBCE findings, therapeutic interventions, and 12-month outcomes were recorded and analyzed descriptively.

Results The median age of the cohort was 69.5 years (IQR 63–79), and 50 % were male. IDA was the indication for SBCE in 14/26 patients, while 50 % underwent SBCE during hospitalization. Ischemic heart disease was the most common comorbidity, and 30.8 % were receiving single antiplatelet therapy. SBCE revealed active bleeding in 7/26 patients, multiple angiodysplasias in 57.7 %, and exclusive small-bowel involvement in 76.9 %. Patients with IDA were younger and predominantly outpatients. In this group, 42.9 % received IRT and 78.6 % were managed with supportive therapy. At 12-month follow-up, 28.6 % required no further treatment, while 42.9 % remained on IRT. Among patients with SSBB, 50 % received supportive therapy, 41.7 % were treated with long-acting SSA, and one required emergent transarterial embolization. At follow-up, 33.3 % required no additional therapy, 25 % remained on IRT, two patients received SSA as bridge therapy to valvular replacement, and two continued long-acting SSA long-term.

Conclusions In healthcare settings where device-assisted enteroscopy is not readily available, management of small-bowel angiodysplasias relies primarily on supportive measures, iron supplementation, transfusion support, optimization of antithrombotic therapy, and selective use of long-acting SSA. In this real-world single-center cohort, both IDA and SSBB patients demonstrated meaningful clinical improvement over 12 months, with a considerable proportion requiring no further intervention. Long-acting SSA appeared particularly beneficial in patients with recurrent bleeding and significant cardiovascular comorbidities, either as monotherapy or as bridging therapy until valvular replacement.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

for Liver and Digestive Health, Ion, United Kingdom
DOI 10.1055/s-0046-1822597

Aims Double-balloon enteroscopy (DBE) is an essential modality for diagnosing and managing small-bowel disorders, offering advantages over other investigations through direct visualisation, targeted biopsy, endotherapy and marking of lesions in need of further management. With rising small-bowel referrals and increasing case complexity, understanding real-world DBE performance is key to optimising service delivery and guiding clinical pathways. This study aimed to describe patient characteristics, procedural indications, diagnostic findings and clinical outcomes of DBE performed within a large tertiary small-bowel unit [1, 2].

Methods All DBE procedures performed at the Royal Free Unit for Endoscopy between July 2023 and October 2025 were analyzed through a prospectively maintained consecutive database. Patient demographics, indications, procedural parameters, diagnostic findings and clinical outcomes were recorded. Descriptive statistics were used to summarize the cohort.

Results Across the study period, 359 DBE procedures were performed in 262 patients. Median age was 64-years (IQR 51–72); 148 patients were women (41.2 %). The most common American Society of Anaesthesiologists (ASA) classification score was 2 (56.5 %), followed by ASA 3 (19.2 %); 80.5 % of the procedures were performed under conscious sedation with median doses of midazolam and fentanyl 5mg and 100mcg, respectively. The main indications for DBE were small-bowel bleeding/iron-deficiency anemia (49.6 %), small-bowel tumors or polyps (31.5 %), suspected or established Crohn's disease (8.4 %), stricture dilatation (5.6 %), and foreign-body retrieval (2.8 %). Over one-third of patients (34.8 %) were on anticoagulant or antiplatelet therapy; surgically altered anatomy was present in 73 patients (20.3 %). A preceding small-bowel investigation—CT/MR enterography or capsule endoscopy—had been performed in 90.6 % of cases. Most referrals originated from other centers or outpatient specialty clinics (74.4 %).

The insertion route was anterograde in 72.1 % and retrograde in 27.9 %. DBE was completed as intended in 95.8 % cases, and a clinical impression explaining the patient's presentation was achieved in 96.4 %. Small-bowel lesions were detected in 79.4 % of procedures, and therapeutic intervention was required in 60.2 %, with a high technical success rate (98.6 %). Repeat DBE was required in 19.5 % of cases. A total of 13.4 % of patients required subsequent enteroscopy via the alternative route, and among these, pan-enteroscopy was achieved in 33.3 %. Overall pan-enteroscopy was achieved in 9.2 % of all procedures. The overall complication rate was 0.8 % (3/359). Trainee involvement occurred in 92.8 % of procedures.

Conclusions This two-year cohort demonstrates that DBE is employed across a broad clinical spectrum, with small-bowel bleeding and suspected neoplastic pathology representing the leading indications. Technical success and diagnostic yield was high, and the vast majority of procedures resulted in a clear clinical impression, underscoring the role of DBE as an effective problem-solving instrument, particularly following capsule endoscopy or cross-sectional imaging. Therapeutic intervention was frequently required and was highly successful, while complication rates remained low. These findings highlight the central role of DBE within a structured, multidisciplinary small-bowel service and its substantial contribution to both diagnosis and treatment in complex small-bowel disease.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1271 Coexistence of Celiac Disease and Duodenal Crohn's Disease in an Adolescent: A Rare Case Report

Authors Saihi MA[1], Alioua SA[1], Khodji D[1], Azzoug L[1], Balamane A[1]
Institute **1** Department of Hepatology and Gastroenterology, Beni Messous Hospital, Algiers, Algeria
DOI 10.1055/s-0046-1822598

Abstract Text

Celiac disease and Crohn's disease are distinct chronic immune-mediated disorders that rarely coexist, especially with duodenal involvement. We report a 16-year-old girl with autoimmune hypothyroidism who presented with chronic epigastric pain, vomiting, weight loss, and iron deficiency anemia.

Endoscopy, histology, and imaging revealed features of both celiac disease and Crohn's disease affecting the duodenum, with additional ileo-rectal inflammation. HLA typing confirmed genetic susceptibility to celiac disease. Management included a gluten-free diet, corticosteroids, nutritional support, and planned immunosuppressive/biologic therapy, leading to clinical improvement and mucosal healing.

This case highlights the importance of considering dual pathology in atypical or refractory presentations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822599

Aims The optimal technique for superficial non-ampullary duodenal lesions (SDLs) is uncertain because potential gains in resection quality with ESD may trade off against safety. Thus, this study aimed to systematically review and synthesize the evidence comparing EMR and ESD techniques for efficacy and adverse events in this population (▶ **Table 1**).

Methods We searched MEDLINE and Embase (via Ovid) to July 14, 2025, for comparative studies. Two reviewers independently screened/extracted data assessed risk of bias and graded the level of certainty (GRADE). Random-effects models yielded risk ratios (RRs) and 95 %CIs. A prespecified subgroup analyzed studies where the EMR arm reported mean/median lesion diameter ≥ 20 mm.

▶ Table 1

Main analysis	Number of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Publication bias	Number of lesions		Effect		Certainty
								ESD	EMR	Relative (95 % CI)	Absolute (95 % CI)	
Local recurrence	14	non-RCT	not serious	not serious	not serious	serious	None detected (Egger p = .700)	1457/4644 (31.4 %)	3187/4644 (68.6 %)	RR 0.62 (0.28 to 1.39)	261 fewer per 1,000(from 494 fewer to 268 more)	⊕⊕○○Low
Surgical intervention for adverse events	17	non-RCT	not serious	not serious	not serious	not serious	None detected (Egger p = .174)	1806/5515 (32.7 %)	3709/5515 (67.3 %)	RR 9.13 (4.18 to 19.94)	1,000 more per 1,000(from 1,000 more to 1,000 more)	⊕⊕⊕⊕High
Endoscopic reintervention for adverse events	14	non-RCT	not serious	not serious	not serious	not serious	None detected (Egger p = .186)	614/1577 (38.9 %)	963/1577 (61.1 %)	RR 1.71 (1.04 to 2.82)	434 more per 1,000(from 24 more to 1,000 more)	⊕⊕⊕○Moderate

Results Twenty-four retrospective cohort studies (5,515 lesions: EMR 3,709; ESD 1,806) were included. ESD improved *en bloc* (RR 1.10, 95 % CI 1.05–1.16) and R0 resection (RR 1.15, 95 % CI 1.01–1.31); local recurrence did not differ (RR 0.62, 95 % CI 0.28–1.39). Procedural risk was higher with ESD, including intraprocedural perforation (RR 9.34, 95 % CI 6.03–14.45) and delayed perforation (RR 5.82, 95 % CI 3.09–10.96); delayed bleeding and the need for surgery or endoscopic reintervention were also increased. In the ≥ 20 mm subgroup, differences diminished and only intraprocedural perforation remained higher (RR 3.76, 95 % CI 1.04–13.58) with ESD. Certainty of evidence (GRADE) was low for efficacy (en bloc, R0) and local recurrence, high for perforations, delayed bleeding, and surgical intervention, moderate for endoscopic reintervention, and low for mortality.

Conclusions For SDLs, ESD achieves better resection quality but at greater significant procedural risks, particularly in smaller lesions. EMR is a reasonable default first-line strategy for most benign polyps, reserving ESD for lesions where *en bloc* histology would alter management and in expert centers. Clinical trials, particularly with size-stratification, are needed.

eP1273 Diagnostic Performance of Endoscopic Ultrasound for Gastric Cancer Staging: A Systematic Review and Meta-Analysis

Authors Zheng K[1], Khalaf K[1], Rizkala T[2], Alasmi Y[1], Bucheeri MAGA[1], Harb M[1], Hu M[1], Jayawardena R[1], Khan A[1], Li H[1], Na C[1], Mahamud O[1], Nishimura T[1], Slotin A[1], Youssef M[1], Yuan Y[3], May G[1], Mosko J[1], Calo N[1]
Institutes **1** St. Michael's Hospital, Toronto, Canada; **2** Humanitas Research Hospital, Milano, Italy; **3** McMaster University, Hamilton, Canada
DOI 10.1055/s-0046-1822600

Aims Accurate loco-regional staging is essential in the management of gastric cancer, guiding decisions regarding surgical resection, neoadjuvant therapy, and endoscopic interventions. Endoscopic ultrasound (EUS) is widely used for evaluating tumour depth (T stage) and regional lymph node involvement (N stage), but reported diagnostic performance varies across studies. This systematic review and meta-analysis aimed to synthesize evidence on the accuracy of EUS for staging gastric cancer.

Methods A comprehensive literature search was performed in MEDLINE, Embase and Cochrane Library until May 27, 2025. We identified primary studies reporting the diagnostic performance of conventional EUS (linear or radial) for gastric cancer staging compared with histopathology as the reference standard. We excluded studies using miniprobe or non-conventional EUS techniques, as well as patients who received neoadjuvant radiochemotherapy. Pooled sensitivity, specificity, PPV, NPV, accuracy, overstaging and understaging for T and N staging were calculated using a bivariate random-effects model. Heterogeneity was assessed with the I^2 statistic.

Results Nineteen studies comprising 2,982 patients were included for T-stage evaluation, and 15 studies comprising 1,272 patients for N-stage evaluation. Of the nine retrospective and ten prospective studies, most used a radial probe (n = 16) with only two using linear and one using both. The accuracy rate of EUS for overall T stage was 72 % with 14 % overstaging and 13 % understaging. For early gastric cancer (T1), diagnostic performance showed high specificity (0.95; 95 % CI 0.93–0.97) but modest sensitivity (0.76; 95 % CI 0.66–0.85), with an accuracy of 0.89 (95 % CI 0.86–0.92), with 24 % overstaging. T2 lesions showed lower sensitivity (0.64; 95 % CI 0.53–0.75) and specificity (0.89; 95 % CI 0.85–0.92), respectively, with 25 % overstaging and 8 % understaging. T3 disease had the highest rate of accurate T staging at 81 %, while T4 staging had the lowest at 57 %. For nodal disease, diagnostic performance was moderate with accuracy of 0.73 (95 % CI 0.67–0.78), sensitivity 0.69 (95 % CI 0.59–0.78) and specificity 0.82 (95 % CI 0.74–0.88), with overstaging and understaging of rates of 8 % and 20 %, respectively.

Conclusions Conventional EUS provides robust diagnostic performance for T staging in patients with gastric cancer. This is particularly useful to select patients with early gastric cancer who are candidates for endoscopic or surgical

resection. However, there remains a significant risk of overstaging, which would suggest the role of EUS as a tool within a multimodal staging strategy. Performance of nodal staging is moderate, with a modest risk of missing nodal disease. These highlight the potential value of adjunctive modalities, such as miniprobe or contrast-enhanced EUS, or techniques such as EUS-guided fine-needle biopsy to enhance diagnostic yield.

DOI 10.1055/s-0046-1822601

Abstract Text

A 61-year-old woman, was found to have an incidental gastric subepithelial tumour (SET) on upper-GI endoscopy performed for anemia. EUS revealed a fusiform-shaped SET, measuring 8.2x5.7-mm, hypoechoic pattern, arising from the muscularis propria. Using a multi-band mucosectomy device, successful SET ligation was performed without resection. Deep tissue sampling was achieved via the SINK technique. Histopathology (DOG1 + ,CD117 + ,actin +) confirmed spindle-cell GIST. Serial EUS follow-up at 6-weeks, 12-months, 2 and 5 years demonstrated no residual or recurrent tumor. The Banding-SET technique combined with SINK for GISTs ≤ 10mm is feasible and safe offering an alternative therapeutic management for small SETs with malignant potential, with a low recurrence risk over 5-year follow-up (BANDING-SET study: ClinicalTrials.gov NCT03247231) [1–3].

Abstract Text

We report a case of a 50-year-old woman with a non-ampullary duodenal adenoma treated with piecemeal EMR. She was discharged two hours after the procedure but returned ten hours afterward with severe upper gastrointestinal bleeding. Endoscopy showed active bleeding in the post-EMR defect. After hemostasis with a coagrasper, a limited muscularis propria injury was revealed which was clipped. The patient developed abdominal pain, and CT scan demonstrated retroperitoneal air. Persistent pain and melena led to a repeat endoscopy, which exposed a large perforation. Because of friable edges, an over-the-scope clip (OVESCO) was deployed to grasp deeper tissue layers. Follow-up CT scan showed no leak. On day ten, a retroperitoneal collection was successfully drained. One month later the patient was asymptomatic and six-month imaging was normal.

eP1276 Successful Endoscopic Treatment of a Complete Ileorectal Anastomotic Stenosis

Authors Kreve F[1], Ribeiro MHDP[1], De lacerda clevelario A[1], Darcadia dos Reis T[2], Costa R[2], Garcia Montes C[1], Manara Martins J[1], Bonilha D[1]

Institutes **1** UNICAMP Universidade Estadual de Campinas, Campinas, Brazil; **2** Unicamp, Campinas, Brazil

DOI 10.1055/s-0046-1822603

Abstract Text

A 39-year-old woman with Lynch syndrome and a previous diagnosis of sigmoid colon adenocarcinoma underwent total laparoscopic colectomy with ileorectal anastomosis and protective ileostomy. During planning for ileostomy reversal, colonoscopy revealed a complete stenosis of the ileorectal anastomosis, which was confirmed by contrast-enhanced computed tomography using rectal contrast. Given these findings, endoscopic management using a Rendez-vous technique was proposed. A gastroscope was introduced through the ileostomy, revealing a fixed angulation approximately 30 cm from the stoma, which prevented further advancement of the scope. At this site, a bulging area corresponding to the previous anastomosis was identified. A small central incision was made at the presumed location of the anastomotic lumen using a micro-knife. A guidewire was advanced through the incision, followed by contrast injection, which delineated the pre-anastomotic ileal loop under fluoroscopic guidance. A hydrostatic balloon was then advanced over the guidewire through the newly created orifice and dilation was performed up to 15 mm. After this initial dilation, both afferent and efferent ileal limbs—consistent with a side-to-end anastomosis—could be traversed endoscopically without complications. Two weeks later, a repeat colonoscopy performed via the anal route demonstrated a patent anastomosis with an approximate diameter of 7 mm. A second

balloon dilation was performed, achieving a diameter of 18 mm. With complete resolution of the stenosis confirmed endoscopically, the patient was subsequently referred for ileostomy closure. This case illustrates the efficacy and safety of endoscopic recanalization for complete anastomotic obstructions, even in complex postoperative anatomy such as that associated with total colectomy for hereditary colorectal cancer syndromes. The combined use of the Rendez-vous approach, micro-knife incision, fluoroscopic guidance, and sequential balloon dilations allowed successful restoration of bowel continuity while avoiding surgical reintervention [1, 2].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1277 Metachronous polyps in patients with clinically significant serrated polyps: Differences between microvesicular and goblet cell-rich hyperplastic polyps: A cohort study

Authors Toyoshima O[1], Nishizawa T[2], Hata K[1]

Institutes 1 Toyoshima Endoscopy Clinic, Setagaya City, Japan; 2 International University of Health and Welfare, Narita Campus, Narita, Japan

DOI 10.1055/s-0046-1822604

Aims The occurrence and detection of metachronous colorectal tumors are important for determining appropriate intervals of surveillance colonoscopy for polyps. Clinically significant serrated polyps (CSSPs) include sessile serrated lesions (SSLs), traditional serrated adenomas, hyperplastic polyps (HPs) ≥ 10 mm, and proximal HPs of 5–9 mm. CSSPs are associated with the metachronous large, serrated polyps, which are at risk for colorectal cancer. Meanwhile, HPs are subclassified in the WHO classification into microvesicular HPs (MVHPs) and goblet cell-rich HPs (GCHPs). MVHPs and GCHPs differ in molecular biological behavior, histology, and endoscopic findings, and MVHPs have been shown to resemble SSLs. To date, no studies have compared the metachronous tumors of SSLs, MVHPs, and GCHPs among CSSPs; thus, we investigated the metachronous polyps.

Methods This study was a single-center cohort study conducted at Toyoshima Endoscopy Clinic. We obtained data from the Toyoshima Endoscopy Clinic Database. This study was approved by the institutional review board of the Yoyogi Mental Clinic (approval no. RKK227). We evaluated patients who underwent their first (index) and second (surveillance) colonoscopy at the Toyoshima Endoscopy Clinic between April 2017 and August 2024. HPs that met the CSSP criteria (i.e., ≥ 10 mm or ≥ 5 mm at proximal colon) were enrolled in this study. We assessed the effect of detection rates of SSLs, MVHPs, and GCHPs at index colonoscopy on the time to detections of metachronous SSLs, MVHPs, GCHPs, and adenomas. Hazard ratios (HRs) were calculated to adjust for age and sex using Cox proportional hazards models.

Results A total of 3174 patients (male sex, 43.6 %; mean age, 51.2 years; median surveillance period, 499 days) were enrolled. A family history of colorectal cancer was present in 7.56 % of patients. Detection rates of SSLs, MVHPs, GCHPs, and conventional adenomas were 7.69 %, 5.36 %, 0.54 %, and 56.76 %, respectively. The detection rate of SSLs at index colonoscopy was associated with the detection of metachronous SSLs (HR 6.19, odds ratio [OR] 4.51-8.50, P<0.001), MVHPs (HR 6.83, OR 4.74-9.85, P<0.001), GCHPs (HR 4.25, OR 1.73-10.46, P=0.002), and conventional adenomas (HR 1.38, OR 1.11-1.70, P=0.003). The detection rate of MVHPs at index colonoscopy was associated with metachronous SSLs (HR 5.13, OR 3.54-7.43, P<0.001), MVHPs (HR 4.56, OR 2.92-7.12, P<0.001), and conventional adenomas (HR 1.38, OR 1.10-1.75, P=0.006). The detection rate of GCHPs at index colonoscopy was associated with the detection of metachronous GCHPs (HR 19.01, OR 4.45-81.18, P<0.001).

Conclusions This cohort study investigated metachronous polyp detection in patients with CSSPs. Detection rates of index SSLs and MVHPs were associated with metachronous detection of both SSLs and MVHPs. Detection of index GCHPs was associated with metachronous detection of GCHPs. MVHPs and GCHPs were mutually exclusive in metachronous detection

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1278 Endoscopic Resection of Visible Dysplastic Lesions in Inflammatory Bowel Disease: A Retrospective Observational Cohort Study

Authors Jugnundan S[1], Khalaf K[1], Li H[1], Chis R[1], Calo N[2], May G[1], Mosko J[2], Olivera PA[1]

Institutes 1 St. Michael's Hospital, Toronto, Canada; 2 Division of Gastroenterology, St. Michael's Hospital, Toronto, Canada

DOI 10.1055/s-0046-1822605

Aims Chronic inflammation predisposes patients with inflammatory bowel disease (IBD) to colorectal cancer. Visible dysplastic lesions without optical characteristics of deeply invasive cancer should be considered for endoscopic resection (ER). However, there is a lack of evidence regarding outcomes of ER in IBD-related dysplastic lesions. This study assesses the curative effectiveness and safety of ER for dysplastic lesions in IBD patients.

Methods This was a retrospective observational cohort of IBD patients referred to the St. Michael's Hospital, Toronto, Canada between 2012 and 2025 who underwent ER for management of sporadic polyps or IBD-related dysplasia. The primary outcome was to assess curative resection in this population, defined as; complete (R0) endoscopic removal of the lesion with no adverse histologic features (poor differentiation, lymphovascular invasion, or deep submucosal invasion) and no additional indications for colectomy based on background colitis.

Results Among 60 patients with colitis-associated neoplasia, the mean age was 61 years (range 38–97), and 66.7 % were male. Most had ulcerative colitis (85.0 %; Crohn's disease 15.0 %), with a mean disease duration of 17.8 years (0–35); disease type was predominantly extensive colitis (75.0 %), with smaller proportions of left-sided colitis (10.0 %) and Crohn's colitis (15.0 %). Patients were treated with 5-ASA (58.3 %), systemic corticosteroids (5.0 %), azathioprine (6.7 %), infliximab (8.3 %), vedolizumab (1.7 %), adalimumab (1.7 %), methotrexate (1.7 %), or ustekinumab (1.7 %), (p = 0.016). Neoplasia was most commonly right-sided (43.3 %), followed by left-sided (31.7 %), rectal (13.3 %), and transverse colon lesions (11.7 %). Lesions were frequently ≥ 30 mm (43.3 % were 30–50 mm; 6.7 % > 50 mm), with 35.0 % < 20 mm and 15.0 % 20–29 mm. Morphology were 0–IIa (50.0 %), Is (11.7 %), 0–IIb (15.0 %), mixed IIa + Is (11.7 %), pedunculated Ip (5.0 %), subpedunculated Isp (3.3 %), and IIa + Ic (3.3 %); no 0–IIc or 0–III lesions and Paris classification subtype differed significantly between curative and non-curative cases (p = 0.011). Almost all lesions did not straddle a haustral fold (98.3 %) and had no surrounding active inflammation (98.3 %). EMR was selected in (81.7 %) of patients, with (13.3 %) requiring hybrid techniques and ESD (5.0 %), without significant difference by curative status (p = 0.295). Overall technical success was 90.0 % and was universal in the curative cohort (100 %, p < 0.0001). En bloc resection and R0 resection were achieved in 25.0 % and 26.7 % of all lesions, respectively. Histopathology showed tubular adenoma (28.3 %), sessile serrated lesions (20.0 %), tubulovillous adenoma (23.3 %), hyperplastic/inflammatory polyps (18.3 %), and UCassociated neoplasia (10.0 %), with a significant difference in histologic distribution between groups for curative resection (p = 0.001). By Vienna classification, 46.7 % had low-grade dysplasia, 20.0 % high-grade dysplasia, 11.7 % indefinite dysplasia, 20.0 % were negative for dysplasia, and 1.7 % had submucosal invasive carcinoma; the distribution differed between curative and non-curative resections (p = 0.024). Intra-procedural bleeding requiring endoscopic intervention oc-

curred in 15.0 % and perforation in 1.7 %, with no delayed bleeding or perforation events. Four patients (6.7 %) ultimately underwent colectomy, including 2 (3.8 %) with prior curative resections (p = 0.013), at a median of 13.5 months (range 3–16) after index polypectomy. Surveillance colonoscopy was performed in 31 patients (55.4 %), at a median of 13 months (4–108) from index resection; recurrence at the resection site was detected in 8 patients (14.3 %).

Conclusions Endoscopic resection of colitis-associated neoplasia can be performed with high technical success, curative resection rates, and recurrence outcomes that are comparable to those reported for non-IBD lesions. Our data suggest that, in experienced hands, ER does not appear to be limited by the presence of colitis itself; rather, success is driven by lesion factors such as size, morphology, and histology. Clinically, this supports treating well-demarcated, endoscopically resectable lesions in IBD using standard advanced resection strategies, reserving colectomy for patients with high-risk histology, unresectable lesions, or diffuse colitis-associated dysplasia.

eP1279 Performance of the Limoges Bleeding Score in Predicting Delayed Bleeding After Colorectal ESD: A Retrospective Study

Authors Rozera T[1], Barbaro F[1], Schepis T[1], Pecere S[1], Maresca R[2], Blasi V[1], Piccirilli G[1], Spada C[1, 3]

Institutes **1** Digestive Endoscopy Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; **2** Università Cattolica del Sacro Cuore, Roma, Italy; **3** Center for Endoscopic Research Therapeutics and Training (CERTT), UCSC, Rome, Italy

DOI 10.1055/s-0046-1822606

Aims To assess the performance of the Limoges Bleeding Score[1] (LBS) in predicting delayed bleeding after colorectal ESD. The LBS has been recently developed to stratify bleeding risk after colorectal ESD, but external validation on independent cohorts is limited [1].

Methods We retrospectively analyzed consecutive patients undergoing colorectal ESD at our tertiary referral center between November 2020 and November 2025. For each included patient, the LBS was calculated according to the original definition.

Delayed bleeding was defined as post-ESD bleeding event needing a prolongation of hospitalization, readmission, new endoscopy (or surgery or angiography), or a blood transfusion, and occurring at least 6 hours after, and within 30 days after the procedure.

We compared LBS values between patients with and without delayed bleeding using Mann-Whitney U test / t-test, and quantified the effect size, using rank-biserial correlation.

Results Three hundred twenty patients were retrospectively analyzed. Of these patients, thirty-nine were excluded due to missing data. A total of 281 colorectal ESD procedures were included. Delayed bleeding occurred in 19 (6,7 %) of cases. LBS was slightly but significantly higher in the bleeding group (median 4 [IQR 3–4.5]) vs the non-bleeding group (3 [IQR 1–4]) (p = 0.02). The effect size indicated a moderate difference between groups (rank-biserial correlation = 0.31).

Conclusions In this external validation cohort, the Limoges Bleeding Score demonstrated a good ability to assess the risk of delayed bleeding after colorectal ESD. If confirmed in larger prospective studies, LBS may support standardized risk stratification and guide intra- and post-procedural therapeutic strategies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1280V Double-Balloon Enteroscopy assisted by a magnetic balloon anchoring system: a novel triple-balloon approach

Authors Minerba P, Rossi G[1], Rosa C[1], Parzanese MI[1], Fracas E[1], Alvisi C[1]

Institute **1** Digestive Endoscopy Unit, Regional Health Care and Social Agency of Pavia, Pavia, Italy

DOI 10.1055/s-0046-1822607

Problem to solve Since its introduction in 2001, double-balloon enteroscopy has radically changed the approach to small bowel lesions, allowing endoscopic treatment and sampling without the need for a surgical approach [1, 2]. The most common indications for enteroscopy are small bowel bleeding, Crohn's Disease or tumors [2, 3]. Anyway, a complete small bowel exploration can be achieved in only less than a half cases [3], and mainly with a combined anterograde and retrograde approach, due its noticeable length and loop configuration which often hinder deeper insertion [4]. As a result, the detection rate is limited, and patients frequently undergo multiple endoscopic procedures with considerable distress.

Innovation A possible improvement could be represented by a novel magnetic balloon anchoring system which consists of a permanent magnet and a through-the scope balloon catheter filled with a water-based iron powder dispersion. This system has already been approved for use during difficult colonoscopies, where it allows loop resolution and easier cecal intubation. This setup improves stability, allows easier loop resolution through retraction and straightening and minimize scope slippage. Upon loop formation, the magnetic balloon is inserted and inflated under fluoroscopic guidance and then magnetically anchored to the abdominal wall, in conjunction with overtube and scope balloons; at this point, loop resolution through retraction and straightening can be performed. After loop resolution, the magnetic balloon is deflated and removed, and the scope advanced using standard techniques. The sequence can be repeated multiple times.

Results We successfully employed this technique with a short enteroscope (155 cm length, 3.2 mm working channel) in two cases so far. In the first one, a 69-year-old woman with recurrent gastrointestinal bleeding underwent standard anterograde double-balloon enteroscopy but loop formation prevented the reaching of the lesion. A second anterograde approach was performed with the assistance of the magnetic anchoring system, allowing deeper penetration and treatment of a 2 mm Yano-Yamamoto type 2b non-bleeding lesion of the mid-small bowel.

In the second case, after a non-diagnostic standard anterograde double-balloon anterograde enteroscopy in a 71-year-old man with chronic iron-deficiency anaemia and a 15 mm ulcerative lesion of the proximal ileum at capsule endoscopy, this triple balloon approach allowed insertion approximately 100 cm deeper than in the previous standard procedure and biopsy of the lesion.

Conclusions The magnetic ballon anchoring system might be a useful on-demand device in enteroscopy when deeper penetration is needed. It may be particularly useful in combination with a short enteroscope, which allows better manoeuvrability and stability and requires fewer medical and nursing staff. This could lead to better patient outcomes, optimization of procedure time and overall cost reduction.

The main contraindication is the presence of permanently or semi-permanently implanted active medical devices (e.g., orthopaedic implants, cardiac pacemakers or defibrillators, drug pumps, neurostimulators, cochlear implants), ferromagnetic implanted medical devices (e.g. vascular stents, aneurysm clips) or foreign bodies; a limitation is severe obesity, due to the reduction of the transabdominal magnetic field caused by a thicker subcutaneous tissue.

Our positive experiences could pave the way for a new and innovative technique for diagnosis and treatment of small bowel diseases: the "Triple Balloon Enteroscopy". Anyway, more studies are needed to assess advantages and limitations of this new procedure.

eP1281 Therapeutic impact of ERCP in Low Phospholipid-Associated Cholelithiasis (LPAC) syndrome: a retrospective single-center study

Authors ahamam M[1], Lagdali N[2], Kadiri M[3], Ajana FZ[2], Borahma M[4]

Institutes **1** CHU Souissi, Rabat, Morocco; **2** Mohammed V University, Rabat, Morocco; **3** Rabat, Morocco; **4** Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco

DOI 10.1055/s-0046-1822608

Aims Low Phospholipid-Associated Cholelithiasis (LPAC) syndrome is a rare biliary disorder related to ABCB4 gene mutations, leading to impaired biliary phospholipid secretion and recurrent intrahepatic lithiasis in young adults. While ursodeoxycholic acid (UDCA) is the standard treatment, some patients experience persistent or complicated disease requiring endoscopic management. The therapeutic contribution of endoscopic retrograde cholangiopancreatography (ERCP) in LPAC remains poorly defined. This study aimed to assess the clinical outcomes and therapeutic role of ERCP in LPAC patients.

Methods A retrospective study was conducted at Ibn Sina University Hospital, Rabat, including all patients diagnosed with LPAC who underwent ERCP between 2022 and 2025. Data regarding demographics, clinical presentation, laboratory and imaging findings, ERCP indications, interventions, complications, and outcomes were analyzed. The primary endpoint was therapeutic efficacy, defined as symptom relief and biochemical improvement.

Results Among 16 patients followed for LPAC syndrome, ERCP was performed in 9 patients. The male-to-female ratio was 0.8, with a mean age of 40.4 years (range 26–54). Prior cholecystectomy had been performed in 55.5 % (5/9) of patients, and 44.4 % (4/9) had a family history of biliary lithiasis (including jaundice, pregnancy-related cholestasis, or cholecystectomy). All patients experienced recurrence of symptoms after cholecystectomy.

Clinically, 44.4 % (4/9) presented with pancreatic-type pain, 33.3 % (3/9) with hepatic colic, and 22.2 % (2/9) with isolated cholestatic jaundice. Diagnosis was confirmed by ultrasound, which demonstrated a "comet tail" appearance in all patients. Laboratory tests showed cytolysis and cholestasis in 66.6 % (6/9) of cases.

The indications for ERCP were cholangitis in 55.5 % (5/9), recurrent pancreatitis in 11.1 % (1/9), choledocholithiasis 33.3 % (3/9) . ERCP was performed prior to starting medical therapy in 66.6 % (6/9) of patients. Endoscopic interventions included sphincterotomy in 88.8 % (8/9) ,Dilatation was performed in 22.2 % (2/9) patients

Clinical improvement was observed in 77.7 % (7/9) of patients, with normalization of laboratory tests was achieved in 44.4 % (4/9) of patients. Symptom recurrence occurred in 44.4 % (4/9) of cases; however, this mainly reflected repeated episodes in a single outpatient who required multiple additional ERCP procedures. Overall, the final outcome was favorable in 44.4 % (4/9) of patients, while intermittent hepatic colic persisted in 22.2 % (2/9). Three patients (33.3 %) were lost to follow-up.

Conclusions ERCP provides significant therapeutic benefit in LPAC patients, particularly for post-cholecystectomy recurrences and complications such as cholangitis or pancreatitis. It ensures effective biliary drainage with an acceptable safety profile. Despite occasional recurrences, ERCP should be considered an integral component of multidisciplinary LPAC management. Larger prospective studies are needed to define standardized endoscopic strategies for this rare condition.

DOI 10.1055/s-0046-1822609

Aims Accurate real-time optical characterisation of colorectal polyps during colonoscopy is essential for optimal management and colorectal cancer prevention. Reliable differentiation of histological subtypes guides treatment decisions, determines surveillance intervals, and reduces unnecessary surgical resections. Conventional optical diagnosis using chromoendoscopy or virtual imaging is limited by operator dependence, and steep learning. Current computer-aided diagnosis (CADx) systems assist endoscopists but currently limited to binary classification (neoplastic vs non-neoplastic).

Our aim is to develop a CADx algorithm capable of differentiating polyps into four clinically relevant categories with different options for treatment decisions and follow-up: hyperplastic polyps, sessile serrated lesions (SSLs), adenomas, and T1 cancers,

Methods Between May 2023 to June 2025, we assembled an image dataset comprising of 8,635 unique polyps in white light image (WLI) and / or Narrow band image (NBI) from 6 institutions across five countries (United Kingdom, Spain, Germany, Norway, and Japan). The dataset included 1,455 hyperplastic

polyps, 707 SSLs, 5,767 adenomas (low- and high-grade combined), and 706 T1 cancers. A two-stage classification framework using the ConvNext-Small convolutional neural network architecture was implemented. In stage one, a binary classifier distinguished serrated-type (hyperplastic and SSL) from adenomatous-type (adenoma and T1 cancer) lesions. In stage two, two separate binary models were trained: a *serrated model* (hyperplastic vs SSL) and a *depth model* (adenoma vs T1 cancer). Model performance was assessed using an independent test set of 231 images (11 hyperplastic, 41 SSL, 121 adenoma, and 58 T1 cancer).

Results The multiclass model achieved an overall four-class classification accuracy of 68.8 %. When grouped into serrated versus adenomatous lesions, diagnostic accuracy improved to 84.4 %, with a sensitivity of 93.9 % and specificity of 52.0 %. The *depth model* differentiating adenomas from T1 cancers achieved an accuracy of 79.8 %, and specificity of 80.6 %.

Conclusions This study demonstrates the feasibility of a four-class CADx algorithm for endoscopic differentiation of hyperplastic polyps, SSLs, adenomas, and T1 cancers, extending beyond conventional binary AI systems. This approach has the potential to support real-time therapeutic decision-making and improve patient-level risk stratification. By enabling tailored management strategies and reducing reliance on histopathology, multi-class CADx may contribute to more efficient, cost-effective, and patient-centred colorectal cancer prevention. Further validation using video-based datasets and multicentre prospective evaluation is warranted before clinical implementation.

eP1283 Outcomes of Endoscopic Dilation with and Without Steroid Injection in Benign Oesophageal Strictures: A Retrospective Observational Comparative Study

Authors Carvalho I[1], Gago T[1], Relvas L[1], Portugal M[1], Aguieiras C[1], Caldeira P[2], Peixe B[1]

Institutes **1** ULS Algarve – Hospital de Faro, Faro, Portugal; **2** University Hospital Center of Algarve, Faro, Faro, Portugal

DOI 10.1055/s-0046-1822610

Aims Benign oesophageal strictures are primarily treated with endoscopic dilation; however, they may recur or fail to respond to treatment, requiring several additional intervention. Corticosteroid injection is a possible adjunctive therapy to decrease stricture formation. However, current literature remains inconsistent on this topic, highlighting the need for further evidence [1, 2]. This study investigates the efficacy and safety of adding intralesional corticosteroid injection to dilation in patients with benign oesophageal strictures.

Methods This is a retrospective observational comparative study over the last 15 years. Patients (> 18 years of age) with benign oesophageal strictures, regardless of aetiology, treated with TTS balloon dilation with or without peri-procedural administration of 2 mg betamethasone per quadrant, were included. Exclusion criteria included achalasia, ongoing oesophageal inflammation, non-adherence to the dilation scheme, patients lost to follow-up, and patients treated with other types of dilations such as Savary-Gilliard or pneumatic dilators. The number of sessions needed to achieve sufficient dilation (SUFD), defined as dilation up to 14 mm, the total number of dilations required (ND), sustained clinical improvement (SCI) defined as sufficient dilation + absence of dysphagia at 6 months, and the periodic dilation index (PDI), defined as the number of sessions needed over the total follow-up time, were assessed. Refractoriness was defined as the inability to achieve a 14 mm diameter after five sessions, and recurrent stenosis was defined as the inability to maintain a satisfactory luminal diameter for 4 weeks after reaching the 14 mm target diameter. To assess treatment safety, all complications resulting from dilation and/or intralesional corticosteroid injections were recorded.

Results Forty-five patients with benign oesophageal strictures were identified: caustic (12), radiation (12), peptic (11), anastomotic (7), eosinophilic esophagitis (2), and oesophageal rings (1). Of these patients, 7 were treated with dilation + corticosteroid injection (4 caustic, 1 eosinophilic esophagitis, 1 peptic, and 1 radiation), and the remainder were treated with dilation alone. A significantly lower ND was required for the corticosteroid compared to the non-corticosteroid group (2.86 ± 0.69 vs. 6.76 ± 3.82, $p < 0.001$) and fewer SUFD were needed (1.14 ± 0.38 vs. 3.63 ± 2.48, $p = 0.002$). SCI was observed in 100 % of the corticosteroid group vs. 50 % in the non-corticosteroid group ($p = 0.016$). No statistically significant relationship with the incidence of complications was found, with only two major complications occurring in the non-corticosteroid group (perforation and fistulisation). Subgroup analysis by stricture type showed a trend toward better outcomes with corticosteroids (fewer ND, SUFD, no complications or refractoriness), but no statistical significance was observed in the eosinophilic, peptic, and radiation subgroups due to their small size. In caustic strictures, the use of corticosteroids was associated with significantly lower ND and SUFD ($p = 0.015$ and 0.017, respectively). All patients treated with corticosteroids achieved SCI, although without statistical significance ($p = 0.208$).

Conclusions Intralesional corticosteroid injection as an adjunct to endoscopic dilation was associated with a significant reduction in the number of dilation sessions, faster achievement of target luminal diameter, and a marked improvement in sustained clinical outcomes, without an increase in complications. These benefits were particularly pronounced in caustic strictures, likely due to their predominantly fibro-inflammatory pathophysiology, characterized by intense inflammation and fibroblast activation with excessive collagen deposition—pathways directly inhibited by intralesional corticosteroids. In contrast, peptic, anastomotic, and radiation-induced strictures are dominated by more mature, avascular fibrosis, which may explain their lower responsiveness.

Our findings support corticosteroid injection as a safe, effective, and resource-sparing adjunctive therapy in selected patients with benign oesophageal strictures. Despite the retrospective design and limited subgroup sizes, this study provides robust real-world evidence of its clinical benefit. Prospective, adequately powered studies are warranted to further clarify its role across different stricture aetiologies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1284 Impact of Trainee Involvement on Colorectal Endoscopic Submucosal Dissection Outcomes: A Prospective Study from a Western Training Center

Authors Almalki T[1], Biscay M[1], Saunier M[1], Jacques J[2], Berger A[1]

Institutes **1** Chu De Bordeaux – Haut-Lévêque, Pessac, France; **2** CHU Dupuytren 1, Limoges, France

DOI 10.1055/s-0046-1822611

Aims Colorectal endoscopic submucosal dissection (C-ESD) is a technically demanding procedure with a steep learning curve, especially in Western centers with limited access to foundational training. To fill training gaps, supervised trainee involvement has been suggested; however, there is still a dearth of data from Western institutions. This study aimed to evaluate the impact of supervised trainee involvement on C-ESD key outcomes [1–3].

Methods This prospective, single-center study with an independent observer was conducted at Bordeaux University Hospital, France, and included 96 patients undergoing C-ESD between May 2024 and June 2025. Procedures were performed by two trainees under direct supervision (sESD group, n = 67) or by an expert endoscopist (eESD group, n = 29). Before starting supervised human cases, both trainees had completed preclinical training following the European Society of Gastrointestinal Endoscopy (ESGE) ESD curriculum. The rate of en bloc resection and clinically significant adverse events were the main outcomes. R0 resection, curative resection, procedure time, and dissection speed were evaluated as secondary outcomes. Subgroup analyses examined trainee involvement levels and procedural difficulty.

Results En bloc resection was accomplished in 100 % of cases in both groups, despite the sESD group having considerably longer procedure times (75 vs. 43 minutes, $p < 0.001$) and slower dissection speeds (16 vs. 32 mm^2/min, $p = 0.003$). The rates of curative resection and R0 resection were both high (95.5 % vs. 96.6 % and 97.0 % vs. 100 %, respectively; both $p > 0.999$). Although not statistically significant ($p = 0.11$), muscle injury rates were higher in the sESD group (25.4 % vs. 10.3 %). No perforations occurred in either group. Delayed bleeding was rare (2.1 %) and equally distributed between groups. Shorter procedure times and easier cases were linked to higher trainee involvement.

Conclusions Supervised trainee involvement in C-ESD is feasible and safe within a structured training program. Incorporating hands-on mentorship models into Western endoscopy training is supported by comparable resection quality and low complication rates.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1285 Current Practices and Opinions on Video Capsule Endoscopy in Germany (2025): A Survey among Gastroenterologists

Authors Zeisler P[1], Bettinger D[1], Knothe J[1], Küllmer A[1], Thimme R[1], Schultheiß M[1]

Institute 1 Medical Center – University of Freiburg, Department of Medicine II, Freiburg im Breisgau, Germany

DOI 10.1055/s-0046-1822612

Aims Video capsule endoscopy (VCE) is an established approach for small bowel examination. In 2022, the European Society of Gastrointestinal Endoscopy (ESGE) published an updated guideline on VCE use. However, little is known about the implementation of these guidelines in daily clinical practice in Germany.

Methods Between June and August 2025 we conducted a nationwide online-based survey on the use of VCE in Germany. An online questionnaire was distributed via a web link to members of "The German Society for Gastroenterology, Digestive and Metabolic Disease" (DGVS), the "Association of Practicing Gastroenterologists" (BNG) and senior physicians working in gastroenterology departments at academic teaching hospitals in Germany. A total of 234 accessed the survey of which 171 were included in the final analysis. The survey included topics related to the performance of capsule endoscopy, the implementation of ESGE guidelines and reimbursement.

Results The most common indications for VCE were suspected small bowel bleeding (91.2 %) and iron deficiency anaemia (86.2 %). VCE was rarely used for visualisation of the colon (5.0 %). In 2024, most clinicians (48.2 %) performed 10 to 30 VCE procedures. The PillCam system (88.2 %) was by far the most common used VCE system.

99.4 % of the asked clinicians performed bowel preparation before VCE use and reported good to very good (93.7 %) mucosal visualisation in the majority of their patients. The interpretation of VCE studies was described as time-intensive with generally requiring 31 to 45 minutes per case (34.8 %). 34.2 % spent 46 to 60 minutes or longer for analysing the examination. The implementation of validated scoring systems such as the Lewis Score for Crohn's disease (9.7 %) and the Saurin classification for bleeding lesions (5.1 %) was infrequent.

51.9 % of the participants are not familiar with the ESGE guideline from 2022. In patients with suspected small bowel bleeding VCE is performed within 48 hours after onset by 63.2 % of the participants.

The reported capsule retention rate was high: 24,5 % (39/159) had at least one retention in 2024. Patency capsules were infrequently used in patients with suspected or known Crohn's disease.

Overall, participants regarded VCE as a valuable diagnostic tool; however, reimbursement was widely perceived as inadequate.

Conclusions This first nationwide study evaluated the use of VCE in Germany, revealing that VCE is a valuable and specialised diagnostic tool, with most procedures for suspected small-bowel bleeding conducted within 48 hours of bleeding onset.

Interpretation remains time-consuming and reimbursement is widely viewed as inadequate. Among specialised gastroenterologists who routinely perform VCE, knowledge of the ESGE VCE guideline is limited.

eP1286V Cardiac septal occluder device for Malignant Gastro-colonic Fistula Closure

Authors Sud S[1], Koul S[2], Khatana G[3], Sud R[2]

Institutes 1 Medanta – The Medicity [Gurugram], Gurugram, Haryana, India; 2 Medanta – The Medicity [Gurugram], Gurugram, India; 3 Medanta – The Medicity, Gurugram, Gurugram, India

DOI 10.1055/s-0046-1822613

Problem to solve To close a large(more than 3cm diameter) malignant gastro-colonic fistula in a case of advanced pancreatic malignancy with previous attempts of closure using through the scope clips and over the scope (OTSC) clips unsuccessful. Moreover, comorbidities,advanced age and metastatic disease made surgical closure options very high risk in this case

Innovation After multidisciplinary discussion, a cardiac septal occluder device was chosen, typically used by interventional cardiologist for atrial septal defect (ASD) closure, as a salvage endoscopic procedure. A 36mm ASD occluder device– the largest size commercially available was selected. To ensure accurate orientation and optimal device positioning, simultaneous dual-endoscope technique was employed. A gastroscope was introduced through the stomach, and the colonoscope was advanced up to the defect at splenic flexure. This allowed both luminal openings to be visualized simultaneously. Under bidirectional endoscopic visualization and fluoroscopic guidance, the delivery system of 36mm ASD occluder device was advanced across the fistula tract through the gastric side into the colonic lumen. The distal (colonic) disc was first deployed, followed by gentle retraction to appose it against the colonic wall. Subsequently, the proximal (gastric) disc was released ensuring complete coverage of the fistulous orifice. The device was carefully observed to secure the site with good approximation and no immediate bleeding or leak was seen. Post-procedure fluoroscopy and barium study confirmed no contrast leak across the closure site. The patient tolerated the procedure well without any immediate complications [1–2]

Results Over subsequent weeks, patient showed a marked clinical improvement with cessation of feculent vomiting, resolution of diarrhea, and gradual improvement in appetite. During 8 weeks of follow-up, patient maintained stable body weight, resumed normal oral nutrition, and remained asymptomatic. A repeat imaging at 8 weeks confirmed persistent closure of fistula with the device in situ with no evidence of leak or migration. Patient continued to receive supportive oncological care and nutritional supplementation

Conclusions This case demonstrates that endoscopic deployment of a large (36mm) atrial septal occluder device can achieve closure even in malignant gastro-colonic fistulas where conventional approaches fail. It exemplifies the expanding frontier of interventional endoscopy through creative adaptation of cardiovascular technologies for complex gastroenterology pathologies. For patients unfit for the surgery, this approach offers an effective, safe, and minimally invasive palliative solution that can restore nutrition, and further improve quality of life. Continued innovation and structure clinical evaluation will define the precise role of these devices in future gastrointestinal oncology practice

eP1287 Mapping the Causes of Rectal Bleeding: A Colonoscopy Audit by Age Group

Author Khan A[1]

Institute 1 Second floor, room #5, HEC hostel GIMS, Gambat, Gambat, Pakistan

DOI 10.1055/s-0046-1822614

Aims The goal of this study was to define the whole etiological spectrum of bleeding per rectum (PR) as detected by colonoscopy and to examine its age-related distribution. The major goal was to test the hypothesis that the fundamental causes of PR differ considerably among age groups. The purpose of this study was to investigate this issue in order to provide a strong framework for enhanced clinical evaluation, risk stratification, and age-appropriate diagnostic techniques for patients with PR [1–5].

Methods We conducted a retrospective audit of patients presenting with PR who underwent colonoscopy at our institution. A total of 752 colonoscopies performed for PR between January 2024 and mid-September 2025 were analyzed. Patients were stratified into four age groups: Children (2-16 years), Young Adults (17-40 years), Middle Age (41-60 years), and Old Age (61-85 years). All collected data were compiled and analyzed statistically using SPSS version 26 (▶ **Table 1**).

Short Forms Key (from the image): – M: Male, F: Female, R: Rectum, RS: Rectosigmoid colon, S: Sigmoid colon, D: Descending colon, T: Transverse colon, A: Ascending colon, C: Caecum, TI: Terminal ileum, TOC: Throughout the colon, SRUS: Solitary Rectal Ulcer Disease.

Results The most common etiology overall was internal hemorrhoids (n = 294, 39.1 %), with its peak prevalence in Young Adults. Colorectal cancer (n = 116, 15.4 %) was the second most frequent finding, showing a marked increase in Middle-Aged patients. Inflammatory conditions were also prominent; Ulcerative Colitis was diagnosed in 54 patients (7.2 %), primarily in Young Adults and Middle-Aged groups, while non-specific colitis accounted for 75 cases (10.0 %). A notable age-dependent shift in pathology was observed: polyps were the leading finding in Children, while diverticular disease was exclusively found in Middle-Aged and Old Age patients.

Conclusions The causes of rectal bleeding demonstrate a distinct and significant variation across age groups. These findings underscore the critical importance of age-stratified risk assessment and diagnostic evaluation for patients presenting with PR, which can lead to more targeted and effective clinical management.

eP1288 Endoscopic Ultrasound, Imaging and Biomarker Clues for Early Chronic Pancreatitis: Moving from Suspicion to Detection — A Retrospective Study from France

Authors Coseru AI[1], Faiza K[2], Floria DE[3], Simiras C[1], Mihai C[3], Nemteanu R[4], Plesa A[4], Drug VL[3]

DOI 10.1055/s-0046-1822615

Aims Recurrent acute pancreatitis (RAP) is a key turning point toward irreversible pancreatic damage. Early chronic pancreatitis (ECP) represents a potentially reversible phase, yet its recognition remains limited in European clinical practice. This study aimed to assess the prevalence of MRI-defined ECP, based on the 2019 Japanese Pancreas Society (JPS) imaging criterion, among patients with alcohol-related RAP, and to identify clinical predictors associated with structural progression [1, 2].

Methods This retrospective single-center study included consecutive adults hospitalized for alcohol-related RAP between January 2023 and December 2024 at Perpignan General Hospital, France. All patients underwent high-resolution magnetic resonance imaging (MRI) including MR cholangiopancreatography (MRCP) 4–8 weeks after discharge. The MRI-ECP positive criterion was defined as the presence of more than three dilated side branches of the main pancreatic duct, in accordance with the 2019 JPS imaging definition. Patients were categorized as MRI-ECP positive or negative. Demographic, clinical, biochemical, and imaging parameters were systematically compared between groups using non-parametric tests and multivariate logistic regression to identify independent predictors of MRI positivity.

Results Among 26 eligible patients (92 % male, mean age 51.5 ± 9.3 years), nine (34.6 %) exhibited MRI features consistent with ECP. Patients with MRI-defined ECP experienced significantly more RAP episodes (mean 3.9 vs. 2.2, p = 0.021). No significant differences were observed regarding CT severity scores, inflammatory markers, or comorbidities. In multivariate logistic regression, the number of prior RAP episodes remained the only variable associated

with ECP (OR 4.00, 95 % CI 0.79–20.3). Age showed a borderline association (p = 0.07).

Conclusions MRI-based evaluation during the inter-critical phase identified early structural pancreatic changes in over one-third of alcohol-related RAP patients. A threshold of three or more acute episodes emerged as a consistent risk marker for early chronic remodeling. To our knowledge, this is the first European study systematically applying the 2019 JPS imaging criterion to alcohol-related RAP. Routine post-discharge MRI surveillance could enable timely recognition of high-risk patients and open a preventive window against chronic progression.

eP1289 EUS shear-wave elastography for diagnosis of chronic pancreatitis in a Western population: preliminary results from the SWEG study

Authors Canalis C[1], Gaia S[2], Bruno M[2], Alessi E[3], Camurati F[2], Sacco M[2]

Institutes **1** Ospedale degli Infermi, Rivoli, Italy; **2** Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, Torino, Italy; **3** School of Medicine, University of Turin, Torino, Italy

DOI 10.1055/s-0046-1822616

Aims Chronic pancreatitis (CP) is a progressive fibro-inflammatory disease whose early diagnosis remains challenging. Conventional cross-sectional imaging often fails to detect early parenchymal and ductal changes, while endoscopic ultrasound (EUS) with Rosemont criteria (RC) is operator-dependent and may not reliably differentiate early CP from minimal pancreatic changes. Endoscopic ultrasound–based shear wave elastography (EUS-SWE) has emerged as a promising quantitative tool to assess pancreatic stiffness. [1] This prospective study evaluated the feasibility, reproducibility, and diagnostic performance of EUS-SWE for CP in a Western cohort and explored its correlation with RC and the number of EUS features.

Methods All consecutive adult patients undergoing biliopancreatic or upper GI EUS between April and September 2025 at our tertiary center were evaluated. Exclusion criteria included known or suspected pancreatic adenocarcinoma, previous pancreatic or gastric surgery, lack of informed consent, or disagreement between two expert endosonographers regarding RC classification. For each patient, demographic and clinical data were collected, RC were independently assessed by two endoscopists, and five SWE measurements were obtained in the pancreatic body. Only measurements with VsN > 50 % were considered reliable. According to RC, patients were classified as CP ("consistent" or "suggestive" RC) or non-CP ("indeterminate" or "normal" RC). Technical feasibility of EUS-SWE was assessed. Statistical analyses evaluated the association between SWE values and RC (RC class and number of RC features), while diagnostic performance was assessed via ROC analysis.

Results Of 298 screened patients, 82 were included. The mean age was 63 years, and most participants were Caucasian. Based on RC, 18 patients (22 %) were classified as CP and 64 (78 %) as non-CP. EUS-SWE proved feasible in 96.5 % of cases, with a mean acquisition time of 65 seconds. Reproducibility was acceptable, with a mean IQR/median of 21.2 % and no significant differences between CP and non-CP groups. Mean shear wave velocity (Vs) values increased progressively across RC classes: 1.88 m/s in normal pancreas, 2.13 m/s in indeterminate cases, 2.62 m/s in suggestive CP, and 2.86 m/s in consistent CP. Mean Vs was significantly higher in CP compared with non-CP (2.67 vs 1.97 m/s, p < 0.001). SWE values correlated positively with both the number of RC features (rs = 0.32, p 0.006) and RC class (rs = 0.39, p < 0.001). ROC analysis yielded an AUC of 0.74, indicating moderate diagnostic accuracy. The optimal cut-off for CP diagnosis was 2.28 m/s, with 72 % sensitivity, 75 % specificity, and a likelihood ratio of 2.89 (▶ **Table 1**).

▶ **Table 1**

	TOT (n = 82)	CP (n = 18)	
Variable		Consistent (n = 4)	Suggestive (n = 14)
EUS-SWE Vs (m/s, DS)	2,13 (0,8)	2,67 (0,81)	
		2,86 (0,87)	2,62 (0,81)
IQR/med (%, DS)	21,2 (14)	19,4 (14,7)	
		18,5 (8,4)	19,6 (16,3)

Conclusions In this prospective cohort, EUS-SWE was highly feasible, rapid, and reproducible. SWE values correlated with RC and differentiated CP from non-CP with moderate accuracy, supporting its potential as a complementary, objective tool for CP assessment. The lower diagnostic performance compared with previous Asian studies may reflect the lower prevalence of advanced CP, with a predominance of early or preclinical disease in our cohort. Larger multicenter studies are needed to validate SWE cut-offs in diverse populations, clarify potential confounders, and assess whether longitudinal SWE monitoring can predict disease progression, pancreatic insufficiency, or pancreatic cancer risk.

eP1290 Impact of Asymptomatic Duodenal Invasion on EUS-guided Biliary Drainage Dysfunction in Patients with Distal Malignant Biliary Obstruction: a Single-Center Retrospective Study

Authors Troncone E[1], Delle Monache M[1], Amendola R[1], De Cristofaro E[1], Muzzi E[1], Moscardelli A[1], Pietrobelli L[1], Monteleone G[1], Del Vecchio Blanco G[1]

Institute **1** Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy

DOI 10.1055/s-0046-1822617

Aims EUS-guided biliary drainage (BD) is highly effective in patients with distal malignant biliary obstruction (DMBO). However, the concomitant presence of duodenal invasion (DI) may negatively affect the outcome of EUS-BD. We aimed to investigate the effect of duodenal invasion on the outcomes of EUS-BD.

Methods This retrospective single-center study included patients who underwent EUS-BD for DMBO at our institution from August 2023 to October 2025. EUS-BD outcomes, the presence of DI, as well as associated symptoms and treatments performed were evaluated. Categorical variables were compared using the chi-square test [1–6].

Results During the study period, 38 patients underwent EUS-BD for DMBO (18 males, 57.9 %; median age 73, range 50-96; 15 choledochoduodenostomies, 13 gallbladder drainages, 10 hepaticogastrostomies). In 21/38 (55.3 %) a coaxial double pigtail plastic stent was placed. Twenty-six patients (26/38; 68.4 %) presented endoscopic signs of DI. Among these, 14/26 (53.8 %) were treated for gastric outlet obstruction symptoms (9 EUS-guided gastroenterostomies, 5 duodenal SEMS). The technical and clinical success rates of EUS-BD were

38/38 (100 %) and 36/38 (94.7 %), respectively. Six patients (6/36, 16.7 %; 3 choledochoduodenostomies; 3 gallbladder drainages) experienced EUS-BD dysfunction after a median of 63 days (range 21–90). Despite a trend indicating an increased risk of dysfunction in presence of DI, no significant differences were found between patients with and without DI (6/26, 23.1 % vs 0/12, 0 %, p = 0.15). However, patients with asymptomatic DI had a significantly higher dysfunction rate compared to symptomatic treated patients (5/12, 41.7 % vs 1/14, 7.1 %; p = 0.037).

Conclusions Asymptomatic DI is associated with a higher risk of EUS-BD dysfunction. If confirmed in larger cohorts, these findings suggest that specific management strategies may be needed for these patients to improve EUS-BD outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1291 Acute Pancreatitis-Related Splanchnic Venous Thrombosis Hungarian Single Center Retrospective Data Analysis

Authors Mariyappan D[1, 2], Khan S[1, 2], Mir W[1, 2], Kaushik TC[1, 2], Banfalvi ZI[2, 1], Lee J[2, 1], Bálint E[1, 2], Péter H[1, 2], Hegyi JP[2, 1]

Institutes **1** Institute of Pancreatic Diseases, Semmelweis University, Budapest, Hungary; **2** Centre for Translational Medicine, Semmelweis University, Budapest, Hungary

DOI 10.1055/s-0046-1822618

Aims Acute Pancreatitis (AP) is a common gastrointestinal disease with an incidence of 34 per 100,000 and mortality of up to 30 % in its severe form. Frequently, AP is complicated locally and systemically. Splanchnic Venous Thrombosis (SVT) is a well-known local vascular complication of AP involving the portal vein (PV), the splenic vein (SV), and the superior mesenteric vein (SMV) in combination or alone. [1]

Splanchnic vein thrombosis occurs in approximately 16.6–22.6 % of patients with acute pancreatitis. It often presents with non-specific chronic abdominal pain and can lead to significant complications due to portal hypertension. These include variceal bleeding, splenomegaly, and, in more severe cases, bowel ischemia resulting from impaired venous drainage. Early recognition and appropriate management are crucial to prevent long-term morbidity. [2]

Methods The aim is to study and analyze pancreatitis-related Splanchnic Venous Thrombosis patients' epidemiological data, anticoagulant therapy and characteristics at the Institute of Pancreatic Diseases, Semmelweis University.

Results At the Institute, we analysed 1,141 patients with AP admitted between January 2022, and February 2024. We identified 45 cases of pancreatitis-related thrombosis, and 26 cases were included for detailed analysis.

Out of 1,141 patients, 26 were diagnosed with pancreatitis-related SVT. Among these, 19 (73 %) were male and 7 (27 %) were female and 19 patients experienced moderate acute pancreatitis (AP), while 7 had severe AP. Mean age of the patient population was 48.3 years (SD 13.5), with male patients 44.7 years (SD 10.2) and female patients 58 years (SD 16.2). Average length of hospitalization was 14.5 days (SD10.4). The splenic vein (SpV) was the most affected vessel, involved in 11 patients, followed by Superior Mesenteric Vein (SMV) in 3 patients, portal vein (PV) in 2 patients and 10 patients with two or more vessel involved of SpV, SMV, and PV. In 26 patients, 24 received low molecular weight heparin (LMWH), while 2 received direct oral anticoagulants (DOAC) during hospitalization. After discharge, 7 patients continued with LMWH, and 18 received DOAC. Of the 26 patients, 17 (65 %) showed recanalization after receiving LMWH (4) and DOAC (13) therapy after discharge.

Conclusions Our data on anticoagulant therapy has a better outcome in patients with acute pancreatitis related SVT. Therefore, dynamic changes of SVT should be closely monitored, and anticoagulant therapy should be rapidly initiated to prevent the further extension of thrombosis and subsequent complications. Unfortunately, major guidelines on the management of AP are silent on this aspect. Further prospective randomised studies needed to validate the data on different anticoagulant therapies

eP1292 Dyspepsia in autoimmune atrophic gastritis: an underrecognized manifestation?

Authors Rossi RE[1], Ferraris M[2], Petronio L[2], Masoni B[2], Di Stefano L[2], Hassan C[3], Repici A[4]

Institutes **1** Gastroenterology and Endoscopy Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; **2** Gastroenterology and Endoscopy Unit, IRCCS Humanitas Research Hospital, Milan, Italy; **3** Department of Biomedical Sciences for Health, Milan, Italy; **4** Endoscopy Unit, Humanitas Clinical and Research Hospital, IRCCS, Rozzano, Italy

DOI 10.1055/s-0046-1822619

Aims The relationship between autoimmune atrophic gastritis (AIG) and dyspepsia is known, but the evidence is scarce. The aim of this study was to evaluate the prevalence of dyspepsia and its subclasses and to evaluate correlations between clinical and biochemical parameters in a cohort of patients with AIG at a tertiary referral center.

Methods All consecutive patients with histologically confirmed AIG referring to our Center from May 2022 to November 2025 were included and retrospectively analyzed. Clinical, biochemical, and histological variables were extracted from a dedicated database. Associations between dyspepsia subclasses and risk factors (i.e., smoking, Body Mass Index (BMI), gastrin, chromogranin levels) were tested using chi-square, Spearman and Mann-Whitney tests, with bootstrap-derived confidence intervals for effect sizes.

Endoscopy 2026; 58: S1–S1041

Results A total of 160 patients were included, 115 females (71,8 %) and 45 males (29,2 %) with a median age at the diagnosis of 56 years old (range 17-88 years old). Dyspeptic symptoms were reported by 55 patients (34,4 %) at diagnosis, 45 females (81,8 %) and 10 males (10,2 %) with a median age at the diagnosis of 58,4 years old (range 27-88 years old). Postprandial Distress Syndrome (PDS) was the most frequent subtype (20 %), followed by Epigastric Pain Syndrome (EPS, 9.4 %), reflux-like symptoms (8.8 %), and nausea/vomiting (6.2 %). EPS showed a significant association with elevated chromogranin levels (p = 0.007, Cramér's V = 0.435), whereas PDS was inversely correlated with BMI (ρ = –0.195, p = 0.036). No significant correlations were found between dyspeptic symptoms and gastrin, smoking or alcohol consumption. Of note, smoking emerged as a significant risk factor for body-fundus atrophy (p = 0.023). 14 patients (25,45 %) were prescribed proton pump inhibitors (PPI) by their general practitioner with total benefit in 3 cases (21,4 %), partial in 2 (14,3 %) and no benefit in the remaining 9 patients (64,3 %). 20 patients (36,4 %) were given mucosal protective agents with full benefit in 15 patients (75 %), partial benefit in 4 (20 %) and no benefit in 1 patient only (5 %). 18 patients (32,7 %) were prescribed prokinetics agents with full benefit in 9 patients (50 %), partial benefit in 5 patients (27,8 %)and no benefit in 4 patients (22 %). Helicobacter Pylori was found in 12 patients (7.5 %); once eradicated, 6 patients and 5 patients reported full/partial symptom improvement respectively, one patient only experienced no improvement.

Conclusions Dyspepsia—mainly PDS and EPS—is a frequent manifestation of AIG, our data being in line with available literature. Elevated chromogranin levels correlate with EPS, suggesting a potential link with neuroendocrine hyperplasia, while lower BMI is associated with PDS, indicating possible nutritional impairment in symptomatic patients. The management of dyspepsia in the setting of AIG is challenging. In current cohort, only few patients were prescribed PPIs with poor outcomes, and, in fact, PPI are generally discouraged in this subset of patients who are hypochlorhydric. The use of prokinetic and mucosal protective agents appear promising, but further data are warranted to better standardize their use.

DOI 10.1055/s-0046-1822620

Aims Introduction: Obesity is a chronic, highly prevalent disease. Although bariatric surgery is the most effective treatment, access remains limited to a small proportion of eligible patients. Endoscopic bariatric techniques have emerged as minimally invasive alternatives. MEGA (Endoscopic Gastric Megaplication) is a variant of POSE 2.0 that employs two G-LIX, a 33 mm G-PROX, and a reduced suture pattern (average: six) to achieve double gastric plication, aiming to improve procedural efficiency and sustainability [1–3].

Primary objective: To evaluate the technical reproducibility, clinical efficacy, and safety of the MEGA technique at 6 months in a multicenter cohort of patients with obesity.

Secondary objectives: To analyze inter-center variability in weight loss outcomes and explore correlations between technical and clinical variables.

Methods Retrospective cohort study including 54 patients with BMI > 27 and comorbidities or BMI > 30, treated with MEGA at six European centers experienced in bariatric endoscopy. Procedures were performed by local endoscopists after standardized training delivered by a single instructor. Technical (number of sutures, procedure time) and clinical variables (%TBWL, %EBWL) were collected. Comparative and correlational analyses were performed.

Results At 6 months, mean %TBWL was 14.75 ± 6.24 % and mean %EBWL was 56.17 ± 14.91 %, with no significant differences among centers (p = 0.406). A total of 81.48 % of patients achieved > 10 % TBWL (44/54). No adverse events were reported. The mean number of sutures was 6.36 ± 0.76, and the mean procedure time was 31,4 ± 11.30 minutes. No significant correlation was found between number of sutures and %TBWL (rho = 0.20; p = 0.747). A moderate, negative Pearson correlation was observed between baseline BMI and %EBWL (r = -0.542), indicating that patients with a higher baseline BMI tended to exhibit a lower percentage of excess body weight loss, likely due to greater baseline excess weight.

Conclusions MEGA proved to be an effective, safe, and reproducible endoscopic technique. Its consistent outcomes across centers support its implementation as a sustainable option for the endoscopic management of obesity. Further prospective studies with larger sample sizes are warranted to confirm these findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Polypectomy is a common endoscopic procedure with cold snare and hot snare techniques being widely used. Hot snare polypectomy involves cautery, which may increase the risk of thermal injury and related complications. Although cold snare polypectomy has a well-established safety and efficacy profile for small colonic polyps, comparative data on the clinical outcomes of these two methods for gastric polyps remains limited.

Methods A retrospective analysis was conducted on 161 consecutive gastric polypectomies for polyps under 10mm, including 41 patients that underwent cold snare polypectomy and 120 patients that underwent hot polypectomy over a period of 5 years.

Results The mean polyp size differed significantly between groups, being smaller in the cold snare group (5.20 ± 1.18 mm vs 6.34 ± 1.49 mm; p < 0.001). The average Charlson Comorbidity Index was 3, with no significant differences between the groups regarding the use of anticoagulant or antiplatelet therapy. Statistically significant differences were observed in both the location and histological type of the polyps between the two techniques (p = 0.003 ; p < 0.001).

Cold snare polypectomy was more frequently used for polyps located in the fundus and for fundic gland polyps, whereas hot snare polypectomy was more commonly utilized for polyps located in the cardia and antrum. Submucosal injection with gelofusine and adrenaline was more frequently associated with the hot snare technique (p = 0.001). Regarding clinical outcomes, intra-procedural bleeding occurred in 16.1 % of cases and was successfully managed endoscopically in all instances, mainly with clips. No cases of delayed bleeding or perforation were observed. There were no significant differences between the groups concerning complete histological resection or polyp recurrence.

Conclusions Cold snare polypectomy demonstrated comparable safety and efficacy to hot snare polypectomy in the resection of small gastric polyps, possibly representing a preferable approach to avoid thermal injury.

eP1295 Efficacy and Safety of Endoscopic Submucosal Dissection in the Treatment of Superficial Gastric Neoplasia: Interim Analysis of a Prospective Multicenter National Registry (SIED)

Authors Barbaro F[1,2], Marchitto SA[1,3], Maresca R[1,2], Schepis T[1,2], Rozera T[1,2], Blasi V[1,2], Piccirilli G[1,2], Pecere S[1,2], Spada C[1,2]

DOI 10.1055/s-0046-1822622

Aims Endoscopic Submucosal Dissection (ESD) is considered the standard treatment for early gastric neoplastic lesions according to Japanese and ESGE guidelines. However, evidence from Western populations remains limited. This study reports the interim results of a single and high-volume Western referral center from a prospective multicenter national registry endorsed by the SIED, evaluating ESD efficacy, safety, and the diagnostic accuracy of biopsies pre-ESD in a real-world Western cohort [1–4].

Methods We analyzed 105 consecutive patients who underwent gastric ESD between January 2021 and June 2025 at a tertiary referral center. Demographics, lesion characteristics, procedural outcomes, adverse events, and follow-up findings were assessed. Primary endpoints were en bloc, R0 and curative resection rates, and procedure-related adverse events. Secondary endpoints included recurrence, metachronous lesions, predictors of treatment failure, and diagnostic accuracy of biopsies pre-ESD.

Results En bloc resection were achieved in 92.4 %, R0 resection in 90.5 %, and curative resection in 85.7 % of cases, respectively. Procedure-related perforation and delayed bleeding occurred in 4.8 % of cases each. Median procedure time was 60 minutes and median hospital stay was 3 days. No local recurrence was observed during follow-up, while metachronous lesions occurred in 9.5 % of patients. Lesions located in the cardia were significantly associated with lower en bloc resection rates (p = 0.0013). Concordance between pre-ESD biopsy and final ESD histology was limited (κ = 0.24), with a biopsy sensitivity of 50 % and specificity of 96.9 % for early gastric cancer.

Conclusions In this large Western prospective cohort, ESD demonstrated high efficacy and a favorable safety profile, fully comparable to the outcomes from Asian referral centers. The absence of local recurrence confirms its oncological reliability. The high rate of biopsy underdiagnosis underscores the importance of ESD for accurate staging and definitive treatment, particularly for lesions that appear to exhibit low or intermediate dysplasia. These results support the broader adoption of ESD in Western clinical practice in the future.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

An 85-year-old patient with multiple comorbidities, including a permanent colostomy after abdominoperineal resection for rectal adenocarcinoma and MASLD-related decompensated cirrhosis on primary prophylaxis with carvedilol, presented with four transfusion-requiring episodes of peristomal bleeding over six months. CT imaging demonstrated peristomal variceal collaterals. Due to comorbidities, an endoscopic therapeutic approach was selected. Transstomal EUS enabled identification of the ectopic varices and their feeding vessel. Combined coil-and-cyanoacrylate embolization was performed using two coil sets (6 × 14 mm and 8 × 14 mm, respectively), achieving immediate flow cessation. The patient was discharged 24 hours post-procedure with stable hemoglobin and no recurrent gastrointestinal hemorrhage during follow-up.

eP1297 Reliability and validity of Linked Color Imaging (LCI) in assessing mucosal inflammation in Ulcerative Colitis

Authors John S[1], Subhaharan D[1], Kakkadasam Ramaswamy P[1], Pillai S[1], Jones M[2], Dong-Hoon Y[3]

Institutes **1** Gold Coast University Hospital, Southport, Australia; **2** Bond University, University Drive, Robina, QLD, Australia, Southport.QLD, Australia; **3** University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea

DOI 10.1055/s-0046-1822624

Aims Accurate endoscopic assessment of mucosal inflammation is critical in managing Ulcerative Colitis (UC). Mayo endoscopic score (MES) and Ulcerative

Colitis Endoscopic Index of Severity (UCEIS) have significant interobserver variability. The role of Linked Color Imaging (LCI) in assessing inflammation is uncertain. We aimed to assess the reliability of LCI in UC.

Methods A multi-centre international survey-based study was designed with 20 sets of high-definition white light (HDWLE) images or videos matched with LCI. Each set had varying severities of inflammation as determined by Nancy and Picasso histopathology scores. The MES and UCEIS were rated along with confidence level (high vs low). To assess interobserver variability, we used percentage agreement and Kappa score with 95 % confidence intervals stratified by imaging modality and scoring system. A mixed logistic regression model was constructed to assess accuracy.

Results 43 gastroenterologists from 4 centres were included. 26 (59.1 %) were experts and 11 (25.6 %) had prior LCI experience. Interobserver variability was moderate overall with percentage agreement between 62-70 % and Kappa scores between 0.48-0.56. There was no difference in interobserver variability between HDWLE and LCI. Agreement was slightly higher for UCEIS than MES (▶ **Table 1**). 73 % reported high confidence prediction with confidence decreasing with increase in histological severity. Participants rated severity accurately 66 % of the time using MES with accuracy decreasing with increase in histological severity. Accuracy was higher for participants with prior LCI experience. Results for UCEIS were inferior with accuracy at 58 % overall. There was no evidence of a difference in accuracy between the two imaging modalities irrespective of the index used for scoring.

▶ **Table 1** Interobserver variability results

Imaging modality	Mayo	UCEIS
HDWLE	Percent agreement = 62 %	Percent agreement = 69 %
	Kappa = 0.49 (0.38, 0.59) *	Kappa = 0.55 (0.41, 0.68) *
LCI	Percent agreement = 62 %	Percent agreement = 70 %
	Kappa = 0.48 (0.38, 0.58) *	Kappa = 0.56 (0.43, 0.69) *

*95 % confidence interval

Conclusions Interobserver variability remains a challenge in accurately assessing inflammation in UC despite advances in technology and validated scoring systems. Our study suggests that LCI achieves moderate interobserver agreement with accuracy of 66 % and is not superior to HDWLE.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1298 Exploring the driving forces for surgery for non-malignant colorectal polyps within a NSW hospital network

Authors Whitfield A[1, 2], Kim YS[1], Gauci J[3], Kerrison C[3, 2], Gupta S[3, 2], Cronin O[3, 2], O'sullivan T[3, 2], El-Khoury T[3], Wright D[1], Lee EYT[3, 2], Burgess N[3, 2], Bourke MJ[3, 2]

Institutes **1** Blacktown Hospital, Blacktown, Australia; **2** University of Sydney Faculty of Medicine and Health, Westmead, Australia; **3** Westmead Hospital, Westmead, Australia

DOI 10.1055/s-0046-1822625

Aims Non-malignant colorectal polyps (NMCP) are effectively managed by advanced endoscopic resection techniques, however rates of surgery remain high. We sought to understand the reasons for this.

Methods A retrospective review was performed across our network to identify all elective surgery for NMCP between January 2011 and December 2024. Colectomy for polyposis syndromes were excluded. Electronic patient records were reviewed. Results were stratified as pre-2018 and post-2018, the latter reflecting a period where involvement of a tissue resection expert (TRE) for the management of large NMCP was recommended in major societal guidelines.

Results 116 elective resections for NMCP occurred (116/1951, 5.9 % of colorectal neoplasia surgery). Mean age 67.3 years, 51 % male. Mean ASA 2.46. 49.1 % of surgery occurred in a tertiary facility (57/116). Mean length of stay was 9.12 days (Range 1.08 – 143 days, SD 14). 85.3 % were laparoscopic. Major adverse events occurred in 30.2 % of cases (35/116). Gastroenterologists accounted for 57.1 % of referrals. 85 % of cases had a preoperative biopsy. Lesion location was right colon 76.9 %, left colon 13.8 % and 10.3 % rectum. Mean lesion size was 30.5mm (Range 1.5 – 85mm, SD 18.3). Suspected cancer was the most common indication for surgery (59/116, 50.9 %), followed by appendix involvement (11/116, 9.5 %) (▶ **Table 1**). TRE were involved in just 20 % of cases but more likely in a tertiary facility (p = 0.049). After 2018 there was a significant decrease in surgery for NMCP across both tertiary and non-tertiary facilities (77/1039, 7.4 % of colorectal neoplasia surgery pre-2018 and 39/912, 4.3 % post-2018, p = 0.0035). TRE involvement improved post-2018 (15.9 % vs 27.8 p = 0.008).

▶ **Table 1** A comparison of the reasons given for surgery for non-malignant colorectal polyps pre-2018 and post-2018

Reason for Surgery	Pre 2018(%)	Post 2018(%)
Suspected Cancer	36(46.8 %)	23(59 %)
Appendiceal	4(5.2 %)	7(17.9 %)
Failed EMR – Technical reasons	5(6.5 %)	1(2.6 %)
Failed EMR – ICV	2(2.6 %)	2(5.1 %)
Failed EMR – Non Lifting	3(3.9 %)	0
Size	4(5.2 %)	1(2.6 %)
Recurrence	4(5.2 %)	1(2.6 %)
Suspected Serrated Polyposis	4(5.2 %)	1(2.6 %)
Suspected Polyposis	3(3.9 %)	0
Involving ICV – Not attempted	2(2.6 %)	1(2.6 %)
Patient Election	0	1(2.6 %)
Suspected Fibrosis	1(1.3 %)	0
Not Recorded	9(11.7 %)	1(2.6 %)
Total	77(100 %)	39(100 %)

Conclusions Surgery rates for NMCPs have fallen. Despite this, unacceptable rates of surgery for NMCP continue to occur without adequate TRE involvement. All cases with benign histology on biopsy should be discussed with a TRE prior to surgery in a multidisciplinary team format.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1300 Patient Preferences Regarding Bleeding Versus Thromboembolic Risk After DOAC Interruption for High-Risk Endoscopic Procedures: An International Survey Informing the Design of the RESUME Trial

Authors Smith Z[1], Elmunzer J[2], Forbes N[3], Ruff C[4], Scholtens D[5]
Institutes **1** Medical College of Wisconsin, Milwaukee, United States of America; **2** Atrium Health Carolinas Medical Center, Charlotte, United States of America; **3** Division of Gastroenterology and Hepatology, University of Calgary, Calgary, Canada; **4** Harvard Medical School, Boston, United States of America; **5** Northwestern University Feinberg School of Medicine, Chicago, United States of America
DOI 10.1055/s-0046-1822908

Aims Patients with atrial fibrillation (AF) undergoing high-risk endoscopic procedures face competing risks of delayed postprocedural bleeding and stroke, yet no randomized evidence guides the optimal timing of direct oral anticoagulant (DOAC) resumption. Major society guidelines have explicitly acknowledged this evidence gap, and current recommendations rely entirely on expert opinion. Although clinician equipoise regarding DOAC resumption timing has been described, patient perspectives on this clinical tradeoff have never been assessed in the endoscopy literature. Patient-reported outcome priorities frequently diverge from clinician assumptions in procedural medicine, yet this well-documented discordance remains largely unexamined in gastrointestinal endoscopy. We aimed to characterize patient awareness of evidence gaps and preferences regarding bleeding versus stroke risk to inform the design of the RESUME trial, a proposed, large multicenter randomized trial currently seeking funding in the US and Canada.

Methods We conducted a cross-sectional survey of patients with AF, distributed electronically from 19 January through 2 February, 2026 through two international patient advocacy organizations (Arrhythmia Alliance and StopAFib.org). The survey assessed awareness of existing evidence, outcome prioritization via both a forced-choice question (major bleeding versus disabling stroke) and a five-point ordinal scale, and demographic and clinical characteristics. Subgroup analyses evaluated the influence of prior stroke/TIA, prior major bleeding, age, sex, and geographic region on preferences using Wilcoxon rank-sum and Kruskal-Wallis tests.

Results 477 patients were included (92.5 % currently taking a DOAC; 50.3 % aged ≥ 75; 57 % female). Respondents resided in North America (70 %) and Europe (27.5 %). Paradoxically, 54.6 % reported confidence that clear guidance on DOAC resumption timing exists, despite the absence of randomized evidence. Patient preferences regarding bleeding versus stroke were heterogeneous and symmetrically distributed: 28.7 % feared bleeding more, 38.1 % expressed equal concern, and 33.3 % feared stroke more. Critically, outcome preferences did not differ by prior stroke or TIA ($p = 0.3$), prior major bleeding ($p = 0.72$), age, sex, or geographic region — demonstrating that this uncertainty is genuinely population-wide.

Conclusions This is the first study to characterize patient perspectives on the bleeding-versus-stroke tradeoff after DOAC interruption for high-risk endoscopy. Patient preferences are heterogeneous, symmetrically distributed, and independent of clinical history and demographics — findings that mirror the wide practice variability observed among endoscopists. Over half of patients incorrectly believe evidence-based guidance already exists, underscoring the urgency of generating definitive data. These results provide the patient-centered ethical justification for randomization in the RESUME trial and demonstrate international generalizability across North American and European populations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1301 Diagnostic performance of the immunochemical fecal occult blood test (FIT) as an interval test in Lynch Syndrome: a systematic review and meta-analysis

Authors Ausina Pous V[1], Sandra B[1], Mangas Sanjuán C[2], Sáez M[1], Jover R[3]
Institutes **1** University General Hospital Dr. Balmis, Alicante, Spain; **2** General University Hospital of Alicante, Alicante, Spain; **3** Gastroenterology, Alicante, Spain
DOI 10.1055/s-0046-1822909

Aims To describe participation rates and the diagnostic performance of FOBT for detecting adenoma, advanced adenoma (AA), and colorectal cancer (CRC) in patients with Lynch Syndrome (LS) during the interval between surveillance colonoscopies [1–5].

Methods A systematic review and meta-analysis were conducted following a literature search in PubMed, Embase, and Scopus from inception to October 2025 for articles reporting participation rates and diagnostic performance in LS patients in the interval between colonoscopies. Results were obtained for different immunochemical FOBT (iFOBT/FIT) models using cut-offs of 2, 4, and 10 µg Hb/g of stool. For each cut-off, true positives, true negatives, false positives, and false negatives were extracted to calculate sensitivity (Se), specificity (Sp), and diagnostic odds ratio (DOR) for adenoma, AA, and CRC through a diagnostic test meta-analysis. The pooled participation rate and its 95 % confidence interval (CI) were also calculated.

Results The initial search retrieved 283 studies, of which 4 were ultimately included, comprising a total of 886 LS patients (29.4 % with MLH1 mutations, 31.7 % MSH2, 24.2 % MSH6, 11.51 % PMS2, and 3.2 % EPCAM). Mean age was 51.6 (41.7–61.5) years and 56 % were women. The time from FIT to colonoscopy ranged from 7 to 77 days. The pooled participation rate was 71.8 % (95 % CI 60.5–83.1).

For adenoma, Se was 22 %, 20 %, and 22 %; Sp was 88 %, 91 %, and 92 %; and the DOR was 2.24, 2.44, and 4.51 for cut-offs of 2, 4, and 10 µg Hb/g, respectively. For advanced adenoma, Se was 78 %, 78 %, and 44 %; Sp was 87 %, 91 %, and 87 %; and the DOR was 21.82, 36.19, and 6.49 for cut-offs of 2, 4, and 10 µg Hb/g, respectively. For CRC, Se was 79 %, 79 %, and 56 %; Sp was 85 %, 90 %, and 85 %; and the DOR was 19.48, 35.31, and 6.78 for cut-offs of 2, 4, and 10 µg Hb/g, respectively.

Conclusions FIT shows excellent diagnostic performance for advanced neoplastic lesions (AA and CRC) in patients with Lynch syndrome, particularly at low cut-offs (< 4 µg Hb/g). These findings support its use as an interval tool to prioritize colonoscopies in settings of healthcare overload and to personalize surveillance periodicity (annual vs biennial) in routine clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1302 The Efficacy of a Novel Vibrating Elevator Cleaning Brush in the Reprocessing of Linear Echoendoscopes

Author Yang F[1]
Institute **1** Sheng Jing Hospital, Shenyang, China
DOI 10.1055/s-0046-1822910

Aims The elevator mechanism of linear echoendoscopes is difficult to reprocess, posing an infection risk. We developed a novel cleaning brush for this area and aimed to determine its optimal use parameters and clinical efficacy [1].

Methods The study included three phases. Phase I identified optimal parameters using ATP testing and microorganism culture on artificially contaminated echoendoscopes. In phase II, six echoendoscopes were randomized to cleaning with the novel or conventional brush for 12 months, with monthly expert image quality assessment. Phase III randomly assigned 204 clinically used linear echoendoscope to the novel or conventional brush group, followed by ATP testing and microorganism culture.

Results The optimal parameters were a vibration frequency of 500 kHz for 20 seconds. After 12 months, the mixed linear model results showed no significant differences in expert scores between groups. Furthermore, the novel brush group demonstrated significantly lower rates of overall (18.6 % vs. 36.3 %; P = 0.005) and elevator area (15.7 % vs. 30.4 %; P = 0.013) manual cleaning failure. After high-level disinfection, the microorganism contamination rate (1.0 % vs. 7.8 %; P = 0.017) and positive culture rate (8.8 % vs. 20.6 %; P = 0.018) at the elevator area were also significantly lower.

Conclusions The novel elevator cleaning brush, used at the optimal parameter of 500 kHz for 20 seconds, did not compromise imaging quality compared to conventional brush. In clinical practice, it significantly improved the manual cleaning quality of the elevator area and reduced the microorganism contamination risk after reprocessing compared to the conventional brush.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1303 Diagnostic Yield and Clinical Impact of Small-Bowel Capsule Endoscopy in Chronic Diarrhea: A Systematic Review and Meta-Analysis

Authors Lei II[1], Naresh R[2], Koulaouzidis A[3], Arasaradnam R[1]
Institutes **1** University Hospital Coventry & Warwickshire, Coventry, United Kingdom; **2** Royal Berkshire Hospital, Reading, United Kingdom; **3** University of Southern Denmark, Odense, Denmark
DOI 10.1055/s-0046-1822911

Aims Small bowel capsule endoscopy (SBCE) is established as a first-line investigation for suspected small bowel bleeding and Crohn's disease according to current ESGE guidelines. However, its diagnostic utility in patients with chronic diarrhoea remains unclear, and no systematic review has evaluated SBCE diagnostic yield in this population. We therefore aimed to estimate SBCE diagnostic yield (DY) in chronic diarrhoea and evaluate yield across clinically relevant subgroups, including patients without suspected organic disease and those investigated for suspected coeliac disease or suspected inflammatory bowel disease (IBD).

Methods A systematic review and meta-analysis were conducted in accordance with PRISMA guidelines. MEDLINE, Embase, PubMed, and the Cochrane Library were searched from 1 November 2000 to 1 November 2025. Studies reporting the diagnostic yield of SBCE in adults referred for chronic diarrhoea were included. Only English-language full-text publications were considered. Two reviewers independently performed study selection and data extraction. Random-effects meta-analysis and meta-regression were used to estimate the pooled DY and to identify factors associated with increased DY of SBCE.

Results A total of 49 studies comprising 3,977 participants were included. The pooled DY of SBCE in chronic diarrhoea including all suspected pathologies was 36 % (95 % CI 30–43 %; I^2 = 89 %). In patients with chronic diarrhoea of unknown origin, the DY was 34 % (95 % CI, 25–44 %; I^2 = 73 %). Use of prior small-bowel radiological imaging as a pre-test filter increased DY to 47 % (95 % CI 32–61 %; I^2 = 0 %). In suspected IBD, subgroup stratification by faecal calprotectin demonstrated a stepwise increase in DY with higher thresholds: 16 % (95 % CI 7–32 %; I^2 = 71 %) for < 50 µg/g, 39 % (95 % CI 28–50 %; I^2 = 90 %) for > 50 µg/g, and 46 % (95 % CI 24–69 %; I^2 = 92 %) for > 100 µg/g. Meta-regression revealed no significant moderators. Overall, SBCE led to a change in clinical management in 46 % of patients (95 % CI, 36–57 %; I^2 = 61 %).

Conclusions SBCE demonstrates a moderate DY and is associated with changes in subsequent management in one in two patients with chronic diarrhoea. These findings also support a biomarker-informed, calprotectin-guided approach to patient selection. Future prospective studies should formally evaluate the role of early capsule endoscopy within diagnostic pathways, alongside or following colonoscopic assessment, in appropriately selected patients.

DOI 10.1055/s-0046-1822912

Aims Endoscopic ultrasound guided gastrojejunostomy (EUS GJ) has recently been shown to be superior to enteral stenting and surgery for management of gastric outlet obstruction (GOO). Outcomes outside of randomised trials is limited. We aimed to assess the outcomes from EUS gastrojejunostomy for management of gastric outlet obstruction in 13 UK centres.

Methods Retrospective analysis of patients undergoing EUS GJ was conducted and information was collected including demographics, indication, sedation, pre- and post- GOOS score, stent size, technique used, technical success rate, number of days to commencing diet, length of stay, adverse events, reintervention rate, other interventions required, and survival at 30 days. Univariate analysis was performed to assess pre- and post-procedure GOOS scores and factors associated with adverse events. Multivariable analysis using age, sex, disease type, stent size and technique was performed for adverse events.

Results 293 patients were included with median age 69 years and 146 males from 13 UK centres. Pancreaticobiliary cancer was the most common indication (73.4 %, n = 215) with other indications being gastric, metastatic deposits or

chronic benign strictures. 169 (57.7 %) procedures were performed under anaesthesia and 226 ((77.1 %) used the WEST technique vs 67 (22.9 %) needle fill technique. 20x10mm was the most common stent size (91.5 %, n = 268) followed by 15x10 (7.5 %, n = 22) and 10x10 (1 %, n = 3). Technical success was achieved in 279/293 (95.2 %) with a significant improvement in GOOS score from 0 pre-procedure to 3 post procedure ($p < 0.0001$) and a median of 1 day to full diet. Overall adverse event rate was 33/293 (11.3 %) with a procedure related adverse event rate of 19/293 (6.5 %). Stent maldeployments (n = 12, 4.1 %) were rescued endoscopically in 50 % (n = 6) with 5 patients undergoing surgical intervention and one patient treated conservatively. Median length of stay post procedure was 4 days and 30-day mortality rate was 37/293 (12.6 %) with only 2/293 (0.68 %) being directly related to the procedure. Overall adverse events were associated with younger age (63 vs 69, $p < 0.001$) but not sex, stent size, technique or disease type. No independent risk factors were identified on multivariable analysis.

Conclusions EUS GJ is an effective intervention for malignant gastric outlet obstruction showing significant improvement in GOOS scores and early return to full diet. Adverse event rates are low and do not appear to have any independent risk factors. This represents the largest study of EUS GJ and shows good outcomes in high volume UK centres.

DOI 10.1055/s-0046-1822913

Aims Endoscopic ultrasound-directed transgastric ERCP (EDGE) has emerged as an important modality for biliary access in patients with altered upper gastrointestinal anatomy, but data from real-world multicentre practice remains limited. This study reports outcomes of EDGE performed in 9 tertiary centres in the UK.

Methods A retrospective analysis was conducted of consecutive EDGE procedures performed over 2024 – 2025. Data collected included demographics, indication, anaesthesia type, stent characteristics, anastomosis type, single or multiple stage, use of stent fixation, completion of the intended therapeutic outcome, subsequent fistula management and adverse events. Analysis was performed around outcomes comparing single vs multiple stage procedures.

Results One hundred and three patients (median age 59 years; 18 males) were included. The indications were common bile duct stones (n = 83), biliary mass/stricture (n = 8), papillary stenosis (n = 4), PEG insertion (n = 3), bile leak (n = 2), drainage procedure (n = 2) and other (n = 1). Sixty-one procedures were performed under general anaesthesia and 42 under conscious sedation. Technical success was achieved in 101/103 (98.1 %) procedures with anastomoses being gastro-gastrostomy (89) and enterogastrostomy (12). Axios stents sized 15 × 10 mm and 20 × 10 mm were used in 5 and 96 procedures respectively. Thirty procedures were completed as single-stage (all under general anaesthesia), while 68 with available data were two-stage with a median interval of 14 days between the stages. 31 of the two-stage procedures were performed under general anaesthesia. Stent fixation clips were used in 36 procedures including 6 two-stage cases (24 OTSC and 11 standard clips), whereas 65 procedures were performed without clip fixation (all two-stage). Overall, the intended therapeutic outcome was achieved in 96/98 (97.95 %) procedures. During single stage there were 5/30 adverse events of which 4 were stent dislodgement (3 managed endoscopically) and 1 pancreatitis. During two-stage there were 7 adverse events of which 5 were stent dislodgement (4 were clinically relevant), 1 failed cannulation and 1 pancreatitis. Fistula follow up showed 56 closed spontaneously or had no closure (35 had a barium or endoscopy), 32 were not assessed, 13 had endoscopic closure and 2 were closed at surgically.

Conclusions In this multicentre series, EDGE demonstrated a high rate of technical and clinical success with acceptable adverse event rates. Most adverse events can be managed endoscopically and no difference was seen comparing number of stages or use of sedation/anaesthesia. The findings support EDGE as an effective modality for biliary and related interventions in patients with altered anatomy. More data concerning fistula follow up is needed.

eP1307 A feature-driven synthetic image framework for interpretable diagnosis of early gastric cancer without real cancer samples: a multi-center study

Authors Yu H[1], Li J[1], Zhang X[1]

Institute **1** Renmin Hospital of Wuhan University, Wuhan, China

DOI 10.1055/s-0046-1822915

Aims This article is expected to improve detection of early gastric cancer's efficiency and accuracy , addresses the scarcity of real medical data and offering a novel solution to address diagnostic challenges for other rare lesions [1–5]

Methods 7,650 endoscopy images retrospectively collected from Renmin Hospital of Wuhan University between January 1, 2017, and September 16, 2025, and videos from 22,039 patients undergoing gastroscopy in a prospective multicenter clinical trial, were used to construct EndoPainter, a generative diagnostic system for early gastric cancer (EGC) that does not rely on real EGC images. A multimodal large language model was used to extract lesion features automatically, and a diffusion model was trained to generate EGC images from non-EGC images and feature texts. The generated images were evaluated by nine endoscopists. EndoPainter performance was tested in internal image and multicenter video test sets and compared with sole deep learning (DL) models trained on datasets of different scales and with different strategies.

Results The feature extraction model based on non-EGC images achieved an overall accuracy of 90.50 % (95 % CI: 89.40–91.49 %). The overall specificity of endoscopists in classifying generated images was 36.39 % (95 % CI: 33.57–39.30 %). In the image test set, the accuracy of EndoPainter for diagnosing EGC (90.24 %, 95 % CI: 86.84–92.84 %) was significantly higher than that of the sole DL models (82.85 %, $p = 0.002$). In the multicenter video test set, its accuracy (90.64 %, 95 % CI: 90.25–91.02 %) also significantly outperformed the DL model trained on a large-scale real-image dataset (89.08 %, $p < 0.0001$).

Conclusions EndoPainter addresses the scarcity of real medical data by generating large-scale lesion images through feature deconstruction and recombination, while integrating human diagnostic logic to achieve interpretable decision-making. The system is expected to improve diagnostic efficiency and accuracy in clinical practice, offering a novel solution to address diagnostic challenges for other rare lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1308 Use of the Self-Assembling Peptide PuraStat for the Management and Prevention of ERCP-Related Bleeding: A multicenter prospective cohort study

Authors Alali A[1, 2], Alkandari A[3], Hashim A[4], Alsuwait R[5], Bhandari P[6]
Institutes **1** Kuwait University, Kuwait, Kuwait; **2** Amiri Hospital, Kuwait City, Kuwait; **3** Jahra hospital , Kuwait, Kuwait; **4** Mubarak Al-Kabeer Hospital, Jabriya, Kuwait; **5** Jahra Hospital, Jahra, Kuwait; **6** Portsmouth Hospitals University, Portsmouth, United Kingdom
DOI 10.1055/s-0046-1822916

Aims Endoscopic retrograde cholangiopancreatography (ERCP) remains a cornerstone therapeutic intervention for pancreatobiliary disease but is associated with clinically relevant adverse events, including bleeding. Bleeding related to endoscopic sphincterotomy or peri-ampullary manipulation may be difficult to control because of anatomic constraints and the consequences of conventional heat related haemostatic methods. PuraStat is a transparent self-assembling peptide hydrogel that promotes hemostasis through the formation of a mechanical barrier and extracellular matrix scaffold leading to formation of a stable clot. It has been extensively used in the treatment of EMR and ESD related bleeds. Data specific to ERCP-related bleeding remains limited [1–4].

Methods We performed a multicenter, prospective, observational study including consecutive ERCP procedures between January 2022 and December 2025 in which PuraStat was used to treat ERCP-related bleeding (intraprocedural bleeding (IPB) or delayed bleeding) and prophylactic application for prevention of delayed bleeding after sphincterotomy. The primary outcome was immediate hemostasis, and secondary outcomes included technical success, 30-day rebleeding, and adverse events related to use of Purastat.

Results A total of 138 patients were included. PuratStat was predominantly used to treat IPB (82.6 %) but was also used for treating delayed bleeding (10.9 %) and prophylactically (6.5 %). The severity of bleeding was mild in 68.2 %, while the remainder had moderate bleeding. Technical success was achieved in all patients. PuraStat achieved immediate hemostasis in 97.7 % of patients with active bleeding. 30-day rebleeding occurred in 7 patients (5.1 %), while adverse events occurred in 5 patients (3.6 %), all of whom had post-ERCP pancreatitis, with no reported procedure-related mortality. Subgroup analysis revealed equal efficacy when PuraStat was used as a primary or secondary (rescue) therapy but significantly higher hemostasis rate (100 % vs. 92.7 %, p = 0.01) and lower 30-day rebleeding (1.1 % vs. 12.2 %, p = 0.005) when used for mild oozing bleeding compared to moderately severe bleeding, respectively.

Conclusions Our data demonstrates the technical feasibility, efficacy and safety of using Purastat in the management of sphincterotomy related bleeds.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1309 Development and validation of an automatic reporting and diagnostic system for gastric magnifying image enhanced endoscopy based on a multimodal large language model

Authors Yu H[1], Deng M[1], Li J[1]
Institute **1** Renmin Hospital of Wuhan University, Wuhan, China
DOI 10.1055/s-0046-1822917

Aims Reporting for gastric magnifying image enhanced endoscopy (M-IEE) reporting is time-consuming and skill-dependent, leading to several issues, especially in resource-limited settings or among less experienced endoscopists. Multimodal large language models (MLLMs) hold significant potential for automating M-IEE report generation [1–9].

Methods 2,037 images and 100 videos of gastric M-IEE were retrospectively collected at Renmin Hospital of Wuhan University (RHWU). The images were randomly assigned to the training and internal test sets in a 7:3 ratio. 625 images were collected from three external hospitals for external validation. Image-text pairs, annotated by experts, were used to construct the M-IEE report system (named ME-Report Angel) based on a MLLM. Six endoscopists were invited to participate in a report-writing trial based on videos with or without the assistance of ME-Report Angel. Reporting time, report quality and diagnosis performance were evaluated.

Results The use of ME-Report Angel significantly reduced reporting time (20.00s, IQR [10.00-39.75] vs. 60.00s, IQR [38.00-113.00], p < 0.001). With ME-Report Angel assistance, diagnostic accuracy (77.33 % vs. 70.33 %, p < 0.001), sensitivity (73.67 % vs. 58.00 %, p < 0.001) and negative predictive value (75.50 % vs. 66.96 %, p < 0.01) were significantly improved. Furthermore, ME-Report Angel significantly improved the completeness, correctness and quality of reports.

Conclusions ME-Report Angel is an efficient and clinically valuable reporting system. It significantly reduced the workload of endoscopists while ensuring high report quality and diagnostic performance, thereby optimizing the M-IEE examination workflow.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1310 Diagnostic Utility of Bedside Cyst Fluid Glucose for Identifying Mucinous Pancreatic Cysts: A Prospective Study

Authors Aggarwal M[1], Lakhtakia S[1], Nabi Z[1], Reddy DN[1]
Institute 1 AIG Hospitals, Hyderabad, India
DOI 10.1055/s-0046-1822918

Aims To evaluate the diagnostic accuracy of bedside cyst fluid glucose for identifying mucinous pancreatic cysts and to assess its agreement with laboratory glucose measurements.

Methods In this prospective study, consecutive patients undergoing endoscopic ultrasound-guided cyst fluid aspiration for pancreatic cystic lesions during the study period (February 2022 – January 2026) were enrolled. Cyst fluid glucose was measured at the bedside using a glucometer and compared with laboratory glucose measurements. The reference diagnosis was established using cytology, biopsy, surgical histopathology, and clinical follow-up. Receiver operating characteristic (ROC) analysis was performed to determine the diagnostic performance and optimal cutoff value of cyst fluid glucose for identifying mucinous cysts. Agreement between bedside and laboratory glucose measurements was evaluated using correlation and Bland–Altman analysis.

Results A total of 56 patients with pancreatic cystic lesions were included. Bedside cyst fluid glucose demonstrated good diagnostic accuracy for identifying mucinous cysts with an area under the ROC curve of 0.76. The optimal cutoff value was 67 mg/dL, which yielded a sensitivity of 85 % and specificity of 68 % for differentiating mucinous from non-mucinous cysts. Bedside and laboratory glucose measurements showed excellent correlation (r = 0.96). Bland–Altman analysis demonstrated good agreement between the two methods with minimal bias.

Conclusions Bedside cyst fluid glucose measurement is a rapid, inexpensive, and reliable method for distinguishing mucinous from non-mucinous pancreatic cysts. Its strong agreement with laboratory glucose measurements supports its use as a practical point-of-care diagnostic tool in the evaluation of pancreatic cystic lesions. (NCT05962723)

eP1311 Colonoscopy-Delivered Fecal Microbiota Transplantation Versus Standard Antibiotic Therapy in Recurrent Clostridioides difficile Infection: A Prospective Comparative Study

Authors Ichim C[1], Todor S[2], Boicean A[3]
Institutes 1 Sibiu, Sibiu, Romania; 2 ULBS, Sibiu, Romania; 3 Lucian Blaga University of Sibiu, sibiu, Romania
DOI 10.1055/s-0046-1822919

Aims Recurrent Clostridioides difficile infection (rCDI) remains a major clinical challenge, with recurrence rates exceeding 30 % after repeated antibiotic therapy. Fecal microbiota transplantation (FMT) has emerged as an effective microbiome-restoring therapy; however, comparative real-world data versus standard antibiotic treatment remain limited. This study aimed to evaluate the clinical efficacy and safety of colonoscopy-delivered FMT compared with guideline-recommended antibiotic therapy in patients with rCDI [1, 2].

Methods We conducted a prospective comparative study including 85 adult patients with recurrent CDI treated at a tertiary referral center between January 2022 and December 2025. rCDI was defined as ≥ 2 documented episodes following adequate antibiotic therapy. Patients received either colonoscopy-delivered FMT (n = 43) or standard antibiotic therapy (oral vancomycin or fidaxomicin; n = 42) according to clinical decision and patient preference. Donor stool was obtained from rigorously screened healthy donors and infused into the cecum or terminal ileum during colonoscopy following bowel preparation. The primary endpoint was clinical cure, defined as resolution of diarrhea without recurrence within 8 weeks. Secondary endpoints included recurrence at 6 months and treatment-related adverse events. Statistical comparisons were performed using χ^2 or Fisher's exact test.

Results Baseline characteristics were comparable between groups (mean age 64.1 ± 13.7 years, 57.6 % female). Clinical cure at 8 weeks was achieved in 39/43 patients (90.7 %) in the FMT group compared with 26/42 patients (61.9 %) in the antibiotic therapy group (p = 0.003).

At 6-month follow-up, recurrence occurred in 3 patients (7.0 %) in the FMT group versus 14 patients (33.3 %) in the control group (p < 0.001).

FMT was well tolerated, with only mild transient adverse events (abdominal discomfort or bloating) reported in 11.6 % of patients. No severe procedure-related complications were observed.

Conclusions Colonoscopy-delivered fecal microbiota transplantation demonstrated significantly higher cure rates and markedly lower recurrence compared with standard antibiotic therapy for recurrent CDI. These findings support the integration of endoscopically delivered FMT as an effective therapeutic strategy for rCDI in routine clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1312 Adjunctive Terlipressin Therapy After Endoscopic Variceal Ligation Reduces Early Rebleeding in Acute Esophageal Variceal Hemorrhage: A Prospective Comparative Cohort Study

Authors Ichim C[1], Todor S[2], Boicean A[3]
Institutes 1 Sibiu, Sibiu, Romania; 2 ULBS, Sibiu, Romania; 3 Lucian Blaga University of Sibiu, sibiu, Romania
DOI 10.1055/s-0046-1822920

Aims Acute esophageal variceal bleeding is a life-threatening complication of portal hypertension, with early rebleeding remaining a major determinant of morbidity and mortality despite successful endoscopic hemostasis. Vasoactive agents such as Terlipressin are recommended during the acute bleeding episode; however, the benefit of continuing vasoactive therapy after successful endoscopic variceal ligation (EVL) in routine clinical practice remains incompletely defined. This study aimed to evaluate the impact of adjunctive terlipressin therapy on early rebleeding following successful EVL [1].

Methods We conducted a prospective comparative cohort study including 110 consecutive adult patients with cirrhosis presenting with acute esophageal variceal bleeding who underwent successful EVL at a tertiary referral center between February 2021 and January 2026. Acute variceal bleeding was confirmed endoscopically, and hemostasis was achieved by EVL in all cases.

Following endoscopic therapy, patients received either adjunctive terlipressin therapy (2 mg every 4 hours for 72 hours; n = 50) in addition to standard care, or standard care alone without vasoactive therapy (control group; n = 60), according to treating physician decision.

Baseline demographic and clinical data were recorded, including etiology of cirrhosis, Child–Pugh class, and Model for End-Stage Liver Disease (MELD) score.

Endoscopy 2026; 58: S1–S1041

The primary endpoint was early rebleeding within 5 days after index endoscopy. Secondary endpoints included rebleeding within 6 weeks, requirement for rescue therapy, length of hospitalization, and treatment-related adverse events. Categorical variables were compared using χ^2 or Fisher's exact test, and continuous variables using Student's t-test. Statistical significance was defined as $p < 0.05$.

Results Baseline characteristics were comparable between groups (mean age 59.9 ± 11.2 years; 64 % male; mean MELD 14.6 ± 4.5; Child–Pugh B/C 72 % vs 71.7 %, p = 0.97). Early rebleeding occurred in 4/50 patients (8.0 %) receiving terlipressin compared with 14/60 (23.3 %) in the control group (p = 0.033). At 6 weeks, recurrent bleeding was observed in 7/50 (14.0 %) versus 19/60 (31.7 %), respectively (p = 0.029). Rescue therapy was required in 3/50 (6.0 %) versus 10/60 (16.7 %) (p = 0.088). Hospital stay was shorter in the terlipressin group (5.9 ± 2.1 vs 7.2 ± 2.6 days; p = 0.006). No serious terlipressin-related adverse events were recorded.

Conclusions Adjunctive terlipressin therapy following successful EVL was associated with significantly lower early and 6-week rebleeding rates compared with EVL alone, supporting continued vasoactive therapy after endoscopic hemostasis in acute esophageal variceal bleeding.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1313 The limits of optical diagnosis in advanced colorectal polyps: a systematic review and meta-analysis of the intermediate-risk optical categories of endoscopic classifications

Authors Rimondi A[1], Dell'Unto E[2], Morais R[3], Lemmers A[4], Scalvini D[5], Rovedatti L[1], Anderloni A[1], Despott E[2], Murino A[2]

Institutes **1** Gastroenterology and Digestive Endoscopy Unit, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; **2** The Royal Free Hospital and University College London Institute for Liver and Digestive Health, London, United Kingdom; **3** Unidade Local de Saúde de São João, Department of Gastrenterology, Porto, Portugal; **4** Hospital Erasme HUB, Brussels, Belgium; **5** Department of Internal Medicine and Therapeutics, University of Pavia, Pavia, Italy

DOI 10.1055/s-0046-1822921

Aims Optical Diagnosis (OD) allows a reliable distinction between adenomatous and non-adenomatous lesions [1, 2]; however it becomes less effective when differentiating low grade dysplasia (LGD), high grade dysplasia (HGD), superficial and deep submucosal invasion (s-SMIC and d-SMIC) in advanced adenomas. The ability to obtain an accurate optical endoscopic diagnosis is essential to adopt the most appropriate polyp management, particularly in those colorectal lesions which are suspicious for submucosal invasion, such as those classified as Kudo Vi/JNET 2B [3]. Such classes constitute intermediate-risk optical categories (IOC) in the most known widespread endoscopic OD classification. Due to the limited evidence in this context, we conducted a systematic review and meta-analysis.

Methods Our search was conducted in EMBASE, MEDLINE, and the Cochrane Central Register of Controlled Trials from 2010 to 26 July 2025. Only English-language publications were included. Animal studies, reviews, correspondences, expert opinions, conference abstracts, and editorials were excluded. The IOC was identified according to widely accepted classifications (e.g. JNET 2B, Kudo Vi, Hiroshima C1/C2, Sano 2). In studies using ad hoc or locally developed classification systems, the category with the highest proportion of final histological outcomes corresponding to HGD and s-SMIC was considered IOC. The primary outcomes were defined as follows: appropriate diagnosis, when the advanced adenoma corresponded to HGD or s-SMIC; overdiagnosis, when it corresponded to LGD; and underdiagnosis, when it corresponded to d-SMIC. Pooled proportions for these outcomes were calculated using random-effects models. PROSPERO database (CRD420251039043).

Results Of 1,975 studies identified, 138 underwent full-text assessment and 37 were included (29 Eastern, 8 Western). Most were retrospective academic cross-sectional studies (75.7 %), mainly involving expert endoscopists. All studies used virtual chromoendoscopy, and most used optical magnification (86.4 %). The pooled mean polyp size was 25.9 mm (95 %CI 18.0–33.1; I^2 = 99.5 %). Overall, 39 IOC from 37 studies were analysed. When an IOC was assigned at OD, HGD or s-SMIC was confirmed histologically in 51.3 % of cases (95 %CI 41.1–61.4 %; I^2 = 95.4 %). Underdiagnosis occurred in 12.9 % (95 %CI 9.8–16.7 %; I^2 = 90.0 %) and overdiagnosis in 23.0 % (95 %CI 14.8–34.0 %; I^2 = 96.9 %). Sensitivity analyses did not reduce heterogeneity. Western studies showed a lower proportion of d-SMIC within the IOC than Eastern studies (8.5 % vs 14.0 %; p = 0.02).

Conclusions High heterogeneity and overall moderate performance of OD in discriminating HGD and s-SMIC in IOC was found. This data would favour en-bloc resection when an IOC is assigned to a lesion. Reproducibility of OD in advanced adenomas in less experienced setting is uncertain. Clear indications, further real-life studies and are warranted to better ascertain the performance of OD in this setting.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1314 Visual intuition for colorectal cancer: BLINK feature recognition in observers without endoscopy experience

Authors Razooqi D[1], Debels L[2], Poortmans PJ[3], Tate D[3], Lala V[4], Argenziano ME[5], Tornai T[3]

Institutes **1** UZ Brussel, Jette, Belgium; **2** University Hospital Brussels, Brussels, Belgium; **3** Ghent University Hospital, Ghent, Belgium; **4** Ghent University Hospital, Gent, Belgium; **5** Ghent University Hospital , Ghent, Belgium

DOI 10.1055/s-0046-1822922

Aims Six reproducible gross morphological "Blink" features — spontaneous bleeding, depression, fold deformation, extra redness, ulceration, and chicken-skin mucosa — are validated markers of deep submucosal invasion (SMI) in large (≥ 20mm) non-pedunculated colorectal polyps (LNPCPs). Prior study demonstrated that brief training in these features reduced cancer miss-rates in a pre-post survey of general endoscopists [1]. However, no study has established whether LNPCPs containing cancer carry inherent visual cues recognizable by individuals without endoscopy experience. We evaluated whether the six Blink features carry sufficient visual salience to be recognized by completely naïve observers, and whether a brief introduction can prime pattern recognition before any endoscopic experience.

Methods In this prospective interventional study, 65 participants (40 non-gastroenterology trainees, 25 medical students) none with prior endoscopy training evaluated 20 LNPCP images (8 with histologically confirmed deep SMI ≥ 1000µm, 12 benign). Participants assessed the same images before and after a 2-minute educational video introducing six Blink features; image order

was randomized between phases. Primary outcome was change in cancer miss-rate (histopathology reference standard).

Results At baseline, sensitivity for cancer detection was 67.5 % (95 %CI 63.4–71.4) and specificity 46.0 % (95 %CI 42.5–49.5), with sensitivity significantly exceeding the 40 % cancer prevalence (p < 0.001). Post-intervention, sensitivity increased to 91.3 % (95 %CI 88.6–93.5), a 3.7-fold reduction in miss-rate from 32.5 % to 8.7 %. Specificity decreased to 27.6 % (95 %CI 24.5–30.9), with the false alarm rate increasing from 54.0 % to 72.4 %. Notably, the sensitivity gain was not solely due to increased cancer-calling; participants also demonstrated improved ability to discriminate cancer from benign polyps (p = 0.025).

Conclusions Medically trained individuals without endoscopy experience demonstrate an inherent ability to detect cancer within LNPCPs at rates exceeding chance. A 2-minute introduction to the six Blink features significantly enhances this capacity, achieving sensitivity (91.3 %) comparable to that of general endoscopists (94.3 %) reported in a prior study [1]. These findings suggest that structured visual training can improve cancer detection at any stage of medical education — potentially before trainees ever perform endoscopy.

DOI 10.1055/s-0046-1822923

Aims The electrocautery-enhanced Hot Axios stent (Boston Scientific) is licensed for EUS choledochoduodenostomy (EUS CDD) and is recognised as an effective modality in biliary drainage in distal malignant biliary obstruction (DMBO). The 6mm x 8mm (6mm) and 8mm x 8mm (8mm) diameter stents are most commonly used for this purpose. On 20th December 2025, an urgent recall of the 6mm and 8mm Hot Axios stents was issued due to reports of stent deployment and expansion issues, creating an urgent need for an evidence-based effective alternative.

This study presents the first direct comparison of the 10mm x 10mm (10mm) Hot Axios stents with the 6mm and 8mm (6/8mm) Hot Axios stents in EUS CDD for DMBO.

Methods A retrospective review was conducted of EUS CDD for DMBO performed in 3 UK tertiary pancreas units from May 2024 to December 2025 using Hot Axios stents. One centre exclusively used 10mm Hot Axios stents for EUS CDD, while the other centres used 6mm and 8mm stents. Technical success, clinical success and adverse event rates were analysed. Technical success was defined as successful Hot Axios stent deployment for EUS CDD. Clinical success was defined as a 50 % drop in bilirubin in 2 weeks post EUS CDD.

Results 76 patients underwent EUS CDD for DMBO (10 mm group n = 28; 6/8 mm group n = 46). Procedural technique differed significantly between groups; most procedures in the 10 mm group were performed freehand with a guidewire preloaded (27/28), whilst in the 6/8mm group, 38/46 were performed freehand. Coaxial plastic stents were inserted through 24/25 successfully deployed 10 mm stents, versus 6/41 in the 6/8 mm group (p < 0.05).

When comparing the 10mm and 6/8mm groups, there was no statistically significant difference in median target duct size on EUS (18.0mm vs 17.5mm, p = 0.06).

Technical success (89.3 % (25/28) vs 89.1 % (41/46), p = 1.00), post-procedural adverse events (10.7 % (3/28) vs 10.9 % (5/46), p = 1.00) and 30-day mortality (10.7 % (3/28) vs 8.7 % (4/46), p = 1.00) were comparable between the 2 groups. After exclusion of technically unsuccessful cases, biliary re-intervention rates were similar (4.0 % (1/25) vs 2.4 % (1/41), p = 1.00). Following further exclusion of cases without follow-up biochemistry, clinical success did not differ significantly between groups (91.3 % (21/23) vs 97.1 % (34/35), p = 0.56).

Conclusions The 10mm × 10mm Hot Axios stent demonstrates comparable efficacy and safety to 6mm x 8mm and 8mm x 8mm stents for EUS CDD in DMBO and represents a viable alternative following the recall of smaller diameter devices.

DOI 10.1055/s-0046-1822924

Aims Superficial non-ampullary duodenal epithelial tumours (SNADETs) are pre-malignant lesions for which the optimal endoscopic management remains uncertain. This study aims to systematically compare the efficacy and safety of different endoscopic mucosal resection techniques, namely conventional (C-EMR), underwater (U-EMR), and cold-snare (CS-EMR), through a network meta-analysis.

Methods A systematic search of MEDLINE, Scopus and Web of Science databases was performed. Randomised controlled trials and comparative observational studies including adults with SNADETs treated with aforementioned techniques were eligible. Risk of bias was assessed and random-effects network meta-analysis models were used to compare outcomes across techniques.

Results Twenty studies were included, most of which were retrospective observational studies with serious risk of bias. Compared with C-EMR, U-EMR was associated with numerically higher en bloc resection (RR 1.04, 95 % CI 0.95–1.14), higher complete resection (RR 1.04, 95 % CI 0.87–1.25), and lower recurrence (RR 0.53, 95 % CI 0.22–1.29), although none reached statistical significance. CS-EMR was associated with significantly lower intraprocedural bleeding (RR 0.23, 95 % CI 0.06–0.89) and delayed bleeding (RR 0.17, 95 % CI 0.07–0.43) than C-EMR. Post-procedural perforation was numerically lower with both U-EMR (RR 0.71, 95 % CI 0.20–2.53) and CS-EMR (RR 0.48, 95 % CI 0.09–2.66). P-score ranking favored U-EMR for en bloc and complete resection and recurrence, whereas CS-EMR ranked highest for bleeding outcomes

Conclusions The choice of resection techniques for SNADETs should be individualized: U-EMR may offer favorable efficacy outcomes, whereas CS-EMR appears to provide superior bleeding safety. However, the available evidence is largely observational, and prospective comparative studies are needed to confirm these findings.

DOI 10.1055/s-0046-1822926

Aims Endoscopic examination is essential for the identification and diagnosis of ampullary adenoma. However, performance varies significantly due to operator experience and non-specific lesion features. This study aimed to develop an artificial intelligence (AI) model to improve the diagnostic accuracy of ampullary adenoma [1–12].

Methods To ensure the diagnostic system's usability, we developed two Swin Transformer-based models: one for identifying qualified papillae and another for diagnosing ampullary adenoma. A total of 2096 cases (34096 images), comprising 200 adenoma and 1896 non-adenoma cases, were used to develop and validate the models. External validation was performed on an independent multicentric dataset of 72 adenoma and 430 non-adenoma cases. Model performance was evaluated using five-fold cross-validation, random-seed allocation, subgroup analyses, and human-machine competition. Interpretability was visualized via gradient-weighted class activation mapping (Grad-CAM). Finally, we prospectively enrolled 126 patients with suspected ampullary lesions on esophagogastroduodenoscopy (EGD) from January to June 2024. AI-assisted EGD examination was performed prior to endoscopic ultrasonography or duodenoscopy to evaluate the adjunctive value of AI in improving the diagnostic accuracy of EGD for ampullary adenoma.

Results The qualified papilla identification model achieved an AUC of 0.994. The diagnostic model showed outstanding diagnostic accuracy with AUCs of 0.998 on the internal testing dataset and 0.972–0.996 on external testing datasets. Consistent high performance was maintained across all subgroups stratified by gender (AUC: 0.997–0.998), age (AUC: 0.996–0.999), and endoscopic equipment (AUC: 0.994–0.999). The AI model significantly outperformed endoscopists in diagnostic capability (accuracy: 0.970 vs 0.810–0.920). Notably, in the prospective validation dataset, the accuracy of AI on EGD images was comparable to that of endoscopists on oblique/side-viewing endoscopic images in identifying ampullary adenomas (0.913 vs 0.873, p = 0.308).

Conclusions This Swin Transformer–based AI system achieved superior real-time diagnostic capability for ampullary adenoma across multiple endoscopic modalities, significantly outperforming endoscopists and particularly enhancing diagnostic accuracy under EGD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822927

Aims The polyp trap, designed for single use, is one of the many disposable items generated in an endoscopy unit. No studies have evaluated the safety or impact of its reuse. The aim of this study was to evaluate whether the reuse of polyp traps during colonoscopy is safe and efficient. Our hypothesis was that reusing polyp traps is non-inferior to discarding them with respect to infectious complications, while also assessing potential benefits in cost and environmental impact.

Methods We conducted a prospective, multicenter, observational non-inferiority study including patients undergoing colonoscopy with polyp trap use between February 2025 and March 2026. Patients were assigned to the Discard Group (DG) or a Reuse Group (RG) according to the usual practice of each

participating Center. Data collection included demographics, adverse events (infections, fever, delayed bleeding, perforation), pathology findings, and the number and types of polyp traps used. The primary endpoint was the rate of post-procedure related infection, with a non-inferiority margin (δ) of 0.4 %. Secondary outcomes included discordance between endoscopic and pathology findings, device consumption, associated costs, and CO_2-equivalent emissions.

Results A total of 3194 patients were included (1697 in DG; 1497 in RG), 57.2 % male, with a mean age of 64 ± 11 years and no baseline differences between groups. Delayed bleeding occurred in 62 patients (2 %) and perforation in 3 (< 0.001 %), with no differences between groups. No confirmed post-colonoscopy related infections were identified. Self-limited fever or other potentially infectious events (such as diarrhea, gastroenteritis or viral symptoms) occurred respectively in 14 (0.8 %) and 35 (2.1 %) patients in DG, and 12 (0.8 %) and 20 (1.3 %) in RG (RR 1.03, 95 %CI 0.48-2.22, p = 0.94; and RR 1.54, 95 %CI 0.90-2.66, p = 0.12). None of these events were attributed to polyp trap reuse.

Pathological/endoscopic discordance occurred in 17/1373 (0.01 %) samples in DG and 19/1338 (0.01 %) in RG (OR 0.87, 95 %CI 0.46-1.67, p = 0.81), mostly reflecting non-detection of a polyp; no clinically relevant discrepancies were observed.

Device use and environmental impact differed markedly between groups. DG used 1729 traps, corresponding to a cost of 3244€/1000 patients and 314.78 kg CO_2eq/1000 patients, whereas RG used 96 traps, corresponding to 519 €/1,000 patients and 24.26 kg CO_2eq/1000 patients, representing an 84 % cost reduction and a 70 % decrease in CO_2eq emissions.

Conclusions Reuse of polyp traps during colonoscopy was shown to be safe and non-inferior to discarding them, with no increase in infectious or other adverse events. The strategy resulted in substantial reductions in device consumption, cost, and CO_2-equivalent emissions. These findings have potential implications for broader waste-reduction strategies in endoscopy units.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1320 Optical diagnosis with resect and discard for diminutive colorectal polyps: is quality maintained in practice?

Authors Saeidi R[1], Ahmad A[2, 1], Matthews T[1], Saunders BP[2, 1]
Institutes **1** Wolfson Unit for Endoscopy, St Mark's The National Bowel Hospital, London, United Kingdom; **2** Imperial College London, London, United Kingdom
DOI 10.1055/s-0046-1822928

Aims A resect-and-discard (R&D) strategy for diminutive colorectal polyps has now been implemented in the English Bowel cancer screening programme (BCSP) with significant reductions in histopathology costs. This study aimed to evaluate the accuracy and quality of high-confidence (HC) optical diagnoses (OD) of diminutive colorectal polyps performed by accredited endoscopists.

Methods This prospective, single-centre study analysed photodocumentation from nine JAG-accredited endoscopists trained in optical diagnosis and the resect-and-discard process. Between 1st October and 17th November 2025, all diminutive polyps (≤ 5 mm) assessed with high-confidence optical diagnosis and managed with R&D as per NHS BCSP guidance were included. Recorded white-light & NBI polyp image pairs were independently reviewed by two experts for polyp size, Paris classification, confidence level, and photo quality (3C criteria) [1]. Discrepancies were resolved by consensus, and interobserver agreement was assessed using Cohen's kappa. Sensitivity analyses were based on consensus HC optical-diagnosis by the experts. All analyses were performed in Stata 18.5.

Results A total of 316 diminutive polyps were identified by nine accredited endoscopists; 276 (87 %) were managed with high-confidence optical diagnosis using an R&D strategy, while 40 (13 %) were sent for histology. Of the 276, 232 (84 %) were adenomas and 44 (16 %) serrated. Of the 40 polyps sent for histological assessment, 37 (92.5 %) were due to low-confidence OD, 2 (5 %) were classified as JNET 2B, and 1 (2.5 %) was due to suspected polyp recurrence. Agreement on OD between the expert panel and the original endoscopists was 81 % (223/276) for high-confidence optical diagnosis and 87 % (241/276) overall when diagnoses of any confidence by the expert panel were considered. In 13 % (37/276) of cases, the expert panel considered a low-confidence classification more appropriate.

High-confidence diagnoses by the endoscopists showed a sensitivity of 99 % (187/188; 95 % CI 97–99 %) for adenomas and 70 % (36/51; 95 % CI 56–82 %) for serrated polyps, compared with the expert panel. In cases of low-confidence OD (37/316, 12 %) where polyps were sent for histological assessment, agreement between histology and the endoscopist diagnosis was 54 % (20/37). Photodocumentation was adequate in 273/276 (99 %) of discarded polyps, with a mean 3C score of 5.88.

Conclusions Prospective expert review of photodocumented OD at a single bowel cancer screening centre showed high agreement, supporting the effectiveness and reproducibility of OD with a resect-and-discard policy in routine screening practice. Low-confidence OD were incorrect in around half of cases, reinforcing the importance of confidence thresholds. Overall, high-confidence OD accuracy was high, and photodocumentation was excellent. Adenomas were diagnosed more accurately than serrated polyps. Multicentre studies are required to further validate these findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1321 AI-associated deskilling or learning? Results from 114 colonoscopists in NAIAD, a UK nationwide real-world study of CADe in colonoscopy

Authors Olabintan O[1, 2], Arimoro O[3], Marynina A[4], Campion J[4], George R[4], Gulati S[1], Emmanuel A[4], Haji A[1], Hayee B[4]
Institutes **1** King's Institute of Therapeutic Endoscopy, King's College Hospital NHS Foundation Trust, London, United Kingdom; **2** King's College Hospital NHS Foundation Trust, London, United Kingdom; **3** University of Calgary, Calgary, Canada; **4** King's College Hospital, London, United Kingdom
DOI 10.1055/s-0046-1822929

Aims Computer-aided detection (CADe) improves adenoma detection rate (ADR) in randomised and most pragmatic real-world trials, but recent concerns have been cited regarding potential deskilling of endoscopists. Conversely, AI is hypothesised to induce behavioural learning. Traditional RCT designs and ADR-based endpoints may not fully capture human–AI interaction.

We sought to evaluate whether CADe use is associated with persistent change in endoscopist's performance following withdrawal, we analysed the effect of CADe use followed by planned withdrawal in a large, real-world national cohort study (NAIAD – interim headline results were presented at ESGE Days 2025).

Methods NAIAD is a nationwide, multicentre study of 114 colonoscopists undergoing sequential assessment across three 3-month phases: baseline (Phase 1), CADe-assisted (Phase 2), and post-withdrawal (Phase 3). ADR was analysed at the individual endoscopist level. Persistent improvement was defined as Phase 3 ADR > Phase 1 ADR. Paired comparisons were performed across phases [1–3].

Results Mean ADR increased modestly from Phase 1 to Phase 2 (30.2 % ± 16.7 vs 33.8 % ± 18.5).Following CADe withdrawal, ADR decreased from Phase 2 to Phase 3 (33.8 % ± 18.5 vs 27.4 % ± 19.4). Overall, ADR in Phase 3 was not significantly different from baseline (30.2 % vs 27.3 %; p = 0.25). However, 41/108 endoscopists (38.0 % demonstrated persistent improvement (Phase 3 > Phase 1). ADR persistence was observed in both low (ADR < 25 %; 66 %) and high (ADR > 25 %; 23 %), baseline detectors indicating heterogeneous responses to CADe.

Conclusions In this large, real-world study, CADe was associated with sustained improvement in ADR in over one-third of endoscopists, suggesting some learning effect rather than universal deskilling.

These findings highlight limitations of conventional RCT frameworks, ADR as sole endpoints and regression to the mean in evaluating AI when linked to human performance. CADe may not only augment detection but also induce operator-level behavioural change, with variable adoption across individuals. AI may not simply replace human skill; it may reshape it.

eP1322 Breath Volatile Organic Compounds as a Non-Invasive Tool for Colorectal Cancer Screening and Prevention

Authors Martinelli E[1], Nisi MR[2], Deluca M[1], Di Gilio A[2], Palmisani J[2], Pizzillo V[2], Mazzola MC[2], De Gennaro G[2]
Institutes **1** Giovanni Paolo II / I.R.C.C.S. Cancer Institute, Bari, Italy; **2** University of Bari Aldo Moro, Bari, Italy
DOI 10.1055/s-0046-1822930

Aims Colorectal cancer (CRC) is recognised as one of the leading causes of cancer-related mortality worldwide [1]. Limitations of CRC screening programmes [2] have driven increasing interest in non-invasive complementary approaches, such as the chemical characterisation of volatile organic compounds (VOCs) in human breath [3]. This prospective study aimed to identify CRC-related VOCs fingerprint in human breath and to investigate the potential of breath analysis for the early detection of CRC and precancerous lesions in FIT-positive subjects, in order to discriminate subjects who really need colonoscopy.

Methods A total of 37 FIT-positive participants were enrolled from July to December 2025 by the Digestive Endoscopy Unit of the Clinical Cancer Centre "Giovanni Paolo II", in Bari. Breath samples were collected from them before undergoing colonoscopy. Volunteer enrolment fulfilled predefined inclusion criteria following Ethics Committee approval (Prot. 7862 del 27/11/2024). End-tidal breath samples were collected using the automated sampler Mistral (*Predict SpA*), which allows to collect 750 ml of exhaled air from patients and ambient air directly into two-bed adsorbent cartridges (Biomonitoring steel tubes, *Markes International*); after, these cartridges were analysed by thermal desorption gas chromatography – mass spectrometry (TD-GC/MS). Following colonoscopy were performed in our centre to classify enrolled patients into three groups: 17 patients diagnosed with CRC, 14 healthy controls (HC) and 6 subjects with precancerous lesions (adenomas).

Results A total of 138 VOCs was detected across the 37 samples. A patient × VOC matrix, containing the normalized relative abundances associated with each identified compound for each subject, was constructed and processed using univariate statistical analysis (nonparametric Mann-Whitney U Test) to compare the groups of healthy subjects and those affected by colorectal cancer and identify the VOCs most associated with the disease state. After the applying of Bonferroni correction and a comparison with ambient air samples to exclude any exogenous contamination, the 20 most significant VOCs were selected. Principal Component Analysis (PCA) showed improved separation between CRC-positive subjects and HC after VOCs reduction, while supervised machine learning using a Support Vector Machine with Radial Basis Function Kernel (SVM-RBF) achieved the highest diagnostic performance, with an accuracy of 84.3 %, sensitivity of 90.0 %, and an area under the ROC curve of 0.958. The six VOCs' profiles of subjects with adenomas, not included in the model building phase, were used to test the model afterward. Only the patient with three polyps was classified as "positive", suggesting that VOCs' profile could reflect the preneoplastic lesions burden.

Conclusions This study suggests that multiple VOCs contribute to the model decision. The data presented here are preliminary and require further validation especially about polyps' classification, but the observed performances fall within the ranges reported in literature.

Aims Bowel preparation quality is a key determinant of colonoscopy effectiveness; however, the incremental benefit of excellent bowel cleansing compared with adequate preparation remains debated. To date, no meta-analysis has specifically evaluated adenoma detection rate (ADR) within the adequate or excellent Boston Bowel Preparation Scale (BBPS) range. We conducted a systematic review and meta-analysis comparing ADR between excellent bowel preparation (BBPS 8–9) and adequate preparation (BBPS 6–7).

Methods A systematic literature search identified studies reporting ADR according to BBPS categories. Studies directly comparing BBPS 6–7 versus 8–9 were included. When BBPS subgroup data were not fully reported, corresponding authors were contacted, and provided additional unpublished BBPS-specific ADR data. The primary outcome was ADR. Pooled relative risks (RRs) with 95 % confidence intervals (CIs) were calculated using a random-effects model. Heterogeneity was assessed using the I^2 statistic.

Results Seven studies published between 2019 and 2025 were included, comprising 21,688 colonoscopies (10,406 with BBPS 6–7 and 11,282 with BBPS 8–9). Excellent bowel preparation was associated with a statistically significant increase in ADR compared with adequate preparation (pooled RR 1.10; 95 % CI 1.01–1.21). Substantial heterogeneity was observed across studies ($I^2 = 82.9\%$; $p < 0.001$), although most individual study estimates favored BBPS 8–9.

Conclusions This first meta-analysis evaluating ADR differences demonstrates that excellent bowel cleansing (BBPS 8–9) is associated with a significant improvement in ADR compared with BBPS 6–7. Achieving excellent bowel preparation may therefore be considered when aiming to optimize colonoscopy outcomes

eP1324 A Smartphone-Based Automated Image Measurement System (AIMS) for Standardized and Objective Assessment of Endoscopic Resection Specimens: A Prospective Validation Study

Authors Zhou J[1], Yuan Y[1]
Institute 1 Chinese PLA hospital, Beijing, China
DOI 10.1055/s-0046-1822932

Aims Precise measurement of ex vivo endoscopic specimens is crucial for quality assessment but suffers from optical distortion and subjectivity. This study aimed to prospectively validate a novel smartphone-based Automated Image Measurement System (AIMS) for objective and standardized specimen quantification [1–20].

Methods A total of 127 consecutive fresh gastrointestinal specimens obtained via endoscopic submucosal dissection (ESD) were included. Specimens were fixed on a standardized foam pad and photographed using a smartphone. The AIMS workflow automatically performed perspective correction, illumination normalization, and tissue segmentation to calculate dimensions. Results were compared against the gold-standard manual ruler measurements using Bland-Altman analysis, intraclass correlation coefficients (ICC), and Pearson's correlation.

Results AIMS demonstrated a minor systematic bias (+ 1.50 mm for length, + 1.17 mm for width) compared to the manual method. However, it exhibited excellent statistical agreement with manual measurements, yielding ICC values > 0.99 for both length and width. Pearson correlation coefficients exceeded 0.98 (r = 0.9847 for length, r = 0.9871 for width).

Conclusions The AIMS application provides a highly accurate, automated, and reproducible solution for the digital measurement of endoscopic specimens, effectively eliminating traditional optical distortions. This accessible mobile tool enhances standardized documentation and precise size-based risk stratification, significantly improving pathological assessment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1822933

Aims Colorectal cancer is a significant global health concern, and colonoscopy is crucial for identifying, classifying and removing precancerous polyps. However, its effectiveness highly depends on endoscopists' skills. Although artificial intelligence (AI) shows potential application, current research has limitations on small datasets and lack of real-world validation. Our study aims to develop a more sufficient system for polyp classification based on a more solid dataset to solve it.

Methods A real-time automatic colorectal polyp risk classification system was developed based on multi-center datasets, including 73,504 images used for the Polyp Detection Model development and 5,889 images for the Polyp Classification Model. It was prospectively validated through external image validation, real-time video validation, and a human-AI competition.

Results The real-time automatic system developed in the study achieved an accuracy of 91.0 % for polyp detection, a precision of 86.6 % and a recall rate of 89.4 %. For risk classification for polyps, the system achieved a recall rate of 90.4 % in external validation, and a precision of 95.3 % in video validation. The F1-score was 0.846 and 0.820 in external validation and video validation, respectively. The classification performance for real-time video was observed to be affected by factors such as distance and light reflection. In the human-AI

Endoscopy 2026; 58: S1–S1041

competition, the system's polyp classification accuracy was significantly higher than that of novice endoscopists and comparable to experts.

Conclusions The study successfully developed and validated a real-time polyp risk classification system, demonstrating its potential for clinical auxiliary diagnosis, especially in enhancing the diagnostic capabilities of novice endoscopists.

DOI 10.1055/s-0046-1822934

Aims Adequate bowel cleansing is essential for a high-quality colonoscopy and directly impacts key quality indicators and clinical outcomes. A very low volume preparation based on 1L polyethylene glycol plus ascorbate (1L PEG + ASC) has been recently introduced. Nevertheless, the efficacy and safety of 1L PEG + ASC as compared to that of 2L PEG + ASC in elderly outpatients is still unclear.

Methods This single-blinded, non-inferiority study randomized over-65 years old outpatients undergoing colonoscopy to receive split-dose 1L PEG + ASC or 2L PEG + ASC. The primary endpoint was the overall cleansing success (CS). Secondary endpoints were overall excellent cleansing (EC), adequate cleansing of the right colon, cecal intubation rate (CIR), adenoma detection rate (ADR), patient compliance, and safety.

Results Overall, 285 patients (mean age 73.6 ± 6.3 years) were randomized to 1L PEG + ASC (N = 139) or 2L PEG + ASC (N = 146).

The total Boston-Bowel-Preparation-Scale (BBPS) score was significantly higher in the 1L compared with the 2L PEG + ASC group (7.66 vs 7.08; mean difference 0.58, 95 % CI 0.17–0.98; P = 0.005).

The 1L PEG + ASC showed higher CS (94.2 % vs 81.5 %; OR 3.69, 95 % CI 1.58–8.63; P = 0.001) and EC rate (36.2 % vs 24.7 %; OR 1.74, 95 % CI 1.05–2.89; P = 0.034) as compared to the 2L PEG + ASC preparation. The cecal intubation rate was similar between the 1L and 2L PEG + ASC arms (95.7 % vs 91.1 %; OR 2.15, 95 % CI 0.79–5.86; P = 0.125).

ADR was significantly higher in the 1L PEG + ASC group compared with the 2L PEG + ASC group (30.9 % vs 19.9 %; OR 1.80, 95 % CI 1.04–3.12; P = 0.033), while the colorectal cancer detection rate was similar between groups (1.4 % vs 1.4 %; OR 1.06, 95 % CI 0.15–7.69; P = 0.955). Tolerability and incidence of adverse events were comparable between preparations.

Conclusions In elderly outpatients undergoing colonoscopy, 1L PEG + ASC was non-inferior and statistically superior to 2L PEG + ASC in achieving overall CS and EC, with a higher observed ADR, and comparable tolerability and safety. Further adequately powered studies are warranted to confirm the impact of 1L PEG + ASC preparation on lesion detection rates.

eP1327 Pulsed Field Ablation for Complex Colorectal Polyps (PULSAR): Prospective Target-Trial Emulation Demonstrating Safety, Efficiency, and Early Efficacy Compared with Endoscopic Resection

Authors Adeyeye A[1], Emmanuel A[1], Hayee B[1], Haji A[2]

Institutes **1** King's College Hospital, London, United Kingdom; **2** King's Institute of Therapeutic Endoscopy, King's College Hospital NHS Foundation Trust, London, United Kingdom

DOI 10.1055/s-0046-1822935

Aims Pulsed field ablation (PFA) is a non-thermal bioelectric modality based on irreversible electroporation, offering the potential to simplify treatment of colorectal neoplasia while reducing thermal injury and procedural risk. Preclinical studies [1] have demonstrated favourable safety and efficiency profiles; however, comparative human data are lacking. This study presents early prospective results from a target-trial emulation comparing PFA with endoscopic resection (ER) for complex colorectal polyps.

Methods A prospective cohort of the first 10 consecutive patients undergoing PFA (12 lesions; treatment-naïve and recurrent) was propensity-matched to 20 ER patients (2:1 nearest neighbour, caliper 0.2). Covariates included demographics, comorbidities, lesion characteristics, and prior treatment history. Balance was confirmed using standardised mean differences (SMD < 0.10), with sensitivity analysis performed using inverse probability of treatment weighting (IPTW).

Primary outcomes were safety (adverse events), procedural efficiency (procedure time, hospital admission), and treatment response. PFA response was assessed at 12 weeks, while ER complete response (CR) was assessed at 6 months. Patient-reported outcomes were evaluated using the SF-12 questionnaire.

Results Post-matching, all covariates were well balanced (SMD < 0.10). The PFA cohort included 10 patients (mean age 68.9 ± 12.8 years; 50 % female; ECOG 0–1) with 12 lesions (median size 16.5 mm, IQR 10–30; mean 20.7 ± 13.3 mm), 50 % ≤ 15 mm. Lesions were predominantly rectal (58 %), with high-grade dysplasia present in 25 %.

Median PFA application time was 11.5 minutes (IQR 5–25), compared to ER(ESD&uEMR) knife time of 74 minutes (range 45–110). No adverse events occurred in the PFA group, whereas one ER patient (5 %) required endoscopic haemostasis (risk difference − 0.05). No serious adverse events were observed in either group. Hospital admission occurred in 0 % of PFA versus 5 % of ER patients.

PFA achieved an overall response rate of 66.7 % (8/12 lesions) at 12 weeks, including CR in 58 % (7/12). Notably, 100 % CR was observed in lesions ≤ 15 mm (p = 0.016). ER achieved a CR rate of 95.8 % at 6 months. Residual disease following PFA was associated with larger lesions and incomplete electroporation coverage in early cases; all were successfully treated with en bloc ER, with no recurrence at 6 months.

Quality of life remained stable following PFA, whereas 20 % of ER patients reported transient decline at 3 months. IPTW analysis confirmed the robustness of these findings. No early recurrence was observed among PFA responders at 6 months.

Conclusions PFA demonstrates excellent safety & substantial efficiency over ER, with encouraging early efficacy, particularly in lesions ≤ 15 mm. It represents a promising non-thermal alternative for colorectal polyp management and warrants further evaluation to confirm these findings.

Conflicts of Interest This work is part of the PhD thesis of Mr Adeyeye which is funded by a grant by Mirai Medical Mr Haji is an advisor to Mirai Medical on Endoscopic Electroporation

DOI 10.1055/s-0046-1822937

Aims Molecular tools to predict prognosis and chemotherapy response in pancreatic ductal adenocarcinoma (PDAC) are limited. Transcriptomic profiling identifies classical and basal-like subtypes, with different prognosis and chemosensitivity, but data from EUS-FNA samples remain scarce. We aimed to characterize transcriptomic subtypes and biomarker expression in EUS-FNA baseline samples, assessing associations with prognosis and chemotherapy response, and in EUS-based tumor re-sampling after first-line therapy to evaluate evolution after treatment (PACEUT trial).

Methods 240 PDAC patients undergoing diagnostic EUS were prospectively enrolled, and FNA samples underwent RNA sequencing. PURIST was applied to classify subtypes. Outcomes included overall survival (OS) and progression-free survival (PFS), adjusted for age and stage. A subgroup of 25 patients underwent paired tumor sampling before and after chemotherapy.

Results RNA-seq succeeded in 239/240 basaline samples (99.6 %). Among those, 16 (6.7 %) were basal-like and 223 (93.3 %) classical. Basal-like patients had shorter OS (11 vs 15 months; p = 0.04) and were significantly older (72.3 vs 66.9; p = 0.02). Purist score associated with increased mortality risk (HR 1.08; 95 %CI 1.01-1.15; p = 0.02), in particular for patient receiving FOLFIRINOX (HR 1,23;95 %CI 1,07-1,41;p = 0,003). In the 25 PACEUT samples (RNA-seq success rate 100 %), 4 % were basal-like before chemotherapy, 8 % afterwards. Purist score increased in 8 (32 %) patients (towards a more basal-profile), remained stable in 9 (36 %) patients, and decreased in 8 (32 %) patients (towards a more classical-profile). Increased Purist score after chemotherapy associated with increased mortality risk (HR 4.48; 95 %CI 1.45-13.0; p = 0.0097).

Conclusions Transcriptome profiling of EUS-FNA samples enables prognostic stratification in PDAC both at diagnosis and after first line chemotherapy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP1330 Surgical Versus Conservative Management of Iatrogenic Colonic Perforation: A Systematic Review and Meta-Analysis

Authors Lopez MI[1], Torres Aray RA[2], Akbari Z[3], Diaz Hermosilla C[4], Vintimilla B[5], Cabrera R[6], Pimenta Peres G[7]

Institutes **1** CES University, Medellín, Colombia; **2** Facultad De Medicina (UBA), Buenos Aires, Argentina; **3** Kabul University of Medical Sciences "Abu Ali Ibn Sina", Kabol, Afghanistan; **4** University of La Frontera, Temuco, Chile; **5** University of Guayaquil (UG), Guayaquil, Ecuador; **6** Universidad Libre Cali – Valle Del Lili Campus, Cali, Colombia; **7** Universidade Federal de Mato Grosso, Cuiabá, Brazil

DOI 10.1055/s-0046-1822938

Aims To compare clinical outcomes of surgical versus non-operative management in adult patients with iatrogenic colonic perforation (ICP), focusing on hospital length of stay, overall complications, and in-hospital mortality [1–3].

Methods A systematic search of PubMed, Embase, and Scopus was conducted according to PRISMA guidelines. Observational studies directly comparing surgical and non-surgical management of adult ICP were included. Primary outcome was hospital length of stay (LOS). Secondary outcomes included overall complications and in-hospital mortality. Pooled risk ratios (RR) and mean differences (MD) were calculated using random-effects models. Sensitivity analyses were performed using Peto and GLMM methods to account for sparse data. Heterogeneity was assessed using the I^2 statistic.

Results Nine observational studies including 603 patients met inclusion criteria, of whom 335 (55.6 %) were managed non-surgically and 268 (44.4 %) surgically. Non-surgical management was associated with significantly lower in-hospital mortality compared with surgery (RR 0.24, 95 % CI 0.08–0.75; p = 0.014; I^2 = 0 %). Non-operative treatment also resulted in shorter LOS (MD − 8.02 days, 95 % CI − 12.48 to − 3.56; p = 0.0046; I^2 = 64.3 %). Overall complications showed a nonsignificant trend favoring non-surgical management (RR 0.35, 95 % CI 0.12–1.01; p = 0.053; I^2 = 46.5 %). Sensitivity analyses confirmed the robustness of mortality findings.

Conclusions In selected patients with iatrogenic colonic perforation, non-surgical management is associated with lower in-hospital mortality and shorter hospitalization compared with immediate surgical intervention. These findings support a selective, physiology- and contamination-based approach rather than routine operative management. Prospective studies are needed to refine patient selection criteria and establish standardized treatment algorithms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims To assess the incidence, timing, and clinical impact of infections occurring within 30 days following endoscopic retrograde cholangiopancreatography (ERCP), endoscopic ultrasound (EUS), and gastrointestinal polypectomies, including endoscopic submucosal dissection (ESD), endoscopic mucosal resection (EMR), and hot-snare/cold-snare resections in both the upper and lower gastrointestinal tracts.

Methods We conducted a prospective observational cohort study (March 2025 – March 2026) in a tertiary care endoscopy center in Bucharest, Romania. Adult patients without active clinical infections, and without any interventional endoscopic procedure within the previous 30 days were included, undergoing ERCP, EUS, or gastrointestinal polypectomies. Patients were actively followed at 24 hours, 48 hours, 72 hours, 7 days, 14 days, and 30 days. Infectious complications were classified as early (≤ 7 days) or delayed (> 7-30 days). Clinical impact was assessed by rehospitalization, sepsis, and 30-day mortality.

Results A total of 278 patients were included, of whom 262 had complete follow-up (114 patients were in the ERCP group, 77 in the EUS group, and 71 in the polypectomy group). Mean age was 64.6 ± 11.5 years. Rehospitalization rates were 20.2 % (23/114) for ERCP, 15.6 % (12/77) for EUS, and 5.6 % (4/71) for polypectomy group (p = 0.025). Thirty-day mortality rate was 3.1 % (8/262), with 5.3 % (6/114) occurring in the ERCP group and 2.6 % (2/77) occurring in EUS group, with no significant differences between groups (p = 0.124).

The overall infection rate was 9.5 % (25/262), significantly higher after ERCP (20.2 %; 23/114) compared to EUS (2.6 %; 2/77) and absent after polypectomy (p < 0.001). The main infection site was cholangitis 80 % (20/25), followed by pancreatic infections 8 % (2/25). Sepsis was exclusively in the ERCP group, occurring in 7.9 % of cases (9/114; p = 0.002), predominantly associated with cholangitis 88.9 % (8/9), with one case following intra-abdominal infection following ERCP-associated perforation. Nearly half of infections (48 %; 12/25), had a delayed onset beyond 7 days.

Conclusions ERCP was associated with the highest infection rates and accounted for all cases of sepsis. These findings challenge current post-endoscopic surveillance strategies, as a substantial proportion of clinically relevant infections occur beyond 7 days and may complicate short- and long-term patient outcome.

DOI 10.1055/s-0046-1822940

Aims Circumferential esophageal endoscopic submucosal dissection (ESD) frequently results in severe post-procedural strictures due to fibrotic extracellular matrix remodeling. Platelet-rich plasma (PRP) contains growth factors that may influence tissue repair and scar organization. This study evaluated the impact of leukocyte-poor PRP on stenosis development, inflammation, fibrosis, and collagen remodeling in a porcine model of circumferential esophageal ESD.

Methods Twelve pigs underwent standardized 5-cm circumferential esophageal ESD and were either administered autologous Leucocyte Poor-PRP (LP-PRP) after ESD (n = 7) or no additional treatment (controls, n = 5). Procedural characteristics were recorded to ensure comparability between groups. At day-14 follow-up, lumen patency and inflammatory endoscopic features were assessed using endoscopy and fluoroscopic contrast studies. Endoscopic videos and fluoroscopic examinations were retrospectively reviewed by an independent adjudication committee of four expert endoscopists blinded to treatment allocation to assess ESD scar characteristics. When stenosis was identified, endoscopic hydrostatic balloon dilation to 12 mm was performed according to protocol. At day 28, the esophagus was retrieved for pathological examination with macroscopic and histological analysis. Inflammation and fibrosis were scored using standardized scales. Collagen composition was assessed using multiphoton second harmonic generation microscopy together with Masson trichrome (collagen I) and Gordon–Sweet staining (collagen III). Histological and multiphoton analyses were performed blinded to treatment allocation. The collagen I/III ratio was used as a marker of extracellular matrix remodeling.

Results Procedural characteristics were comparable between groups. At day-14, esophageal stenosis was present in 100 % of subjects on both endoscopic and fluoroscopic assessment, requiring hydrostatic balloon dilation. Blinded adjudication confirmed severe luminal narrowing in all subjects and showed lower endoscopic inflammation scores in LP-PRP-treated animals (1.14 ± 0.80 vs 2.30 ± 0.84). At day 28, macroscopic examination confirmed circumferential scar formation and luminal narrowing at the ESD site in all subjects. Histological analysis showed numerically higher inflammation scores in the PRP group (5.57 ± 2.30 vs 3.80 ± 0.45), whereas fibrosis scores were identical between groups. Absolute collagen I and III deposition did not differ significantly. However, the submucosal collagen I/III ratio was significantly lower in PRP-treated animals (1.14 ± 0.11 vs 1.64 ± 0.43; p = 0.0095), indicating a shift toward a less fibrotic extracellular matrix remodeling pattern.

Conclusions In this experimental animal model of circumferential esophageal ESD, leukocyte-poor PRP did not prevent luminal narrowing but significantly modified collagen remodeling, resulting in a lower collagen I/III ratio in the stenotic submucosa. These findings suggest that PRP may influence scar architecture during esophageal wound healing.

eP1333 AI-assisted Surveillance to Improve Endoscopic Follow-up Adherence in Patients with Precancerous Gastric Conditions: A Randomized Controlled Trial

Authors Yu H[1], Li J[1], Deng M[1]

Institute 1 Renmin Hospital of Wuhan University, Wuhan, China
DOI 10.1055/s-0046-1822941

Aims Endoscopic surveillance for gastric precancerous conditions is essential but poorly adhered to in practice. Here we updated our previously developed artificial intelligence system (called ENDOANGEL-AS), which accurately identified high-risk patients and assigned standardized surveillance intervals, and validate its performance in improving follow-up adherence.

Methods The training set was expanded to include all gastroscopy patients at Renmin Hospital of Wuhan University (RHWU) from January 1, 2017 to October 31, 2019. The randomized controlled trial enrolled consecutive patients undergoing esophagogastroduodenoscopy with pathologically confirmed gastric precancerous conditions (atrophic gastritis and intestinal metaplasia) at RHWU from November 1, 2019 to October 14, 2022. Patients were randomly assigned (1:1) to the ENDOANGEL-AS-assisted group (artificial intelligence reminders

via messages and phone calls) or the control group (no extra reminders). The primary outcome was the follow-up rate of enrolled patients [1–14].

Results 324 patients with precancerous gastric conditions [mean (SD) age 56.41 (10.55) years, 165 (50.93 %) female] were randomly assigned and analyzed, with 162 patients in each group. The overall follow-up rate was significantly higher in the ENDOANGEL-AS-assisted group than in the control group (24.69 % vs 13.58 %; RR 1.818 [95 % CI 1.134-2.916]; p = 0.011). ENDOANGEL-AS assistance significantly improved the timely follow-up rate compared with usual care (16.67 % vs 7.41 %; RR 2.250 [95 % CI 1.181–4.285]; p = 0.010). Subgroup analyses showed a consistent benefit of ENDOANGEL-AS in patients with intestinal metaplasia and those aged ≥ 55 years.

Conclusions ENDOANGEL-AS improves the endoscopy follow-up rate for patients with gastric precancer and plays a role in automatic surveillance management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.
