JNET classification: Overall diagnostic accuracy was 58 % when compared with the JNET consensus. Accuracy by experience group was: < 300 (56 %), 300–3000 (56 %) and > 3000 (59 %).

Overall interobserver agreement for JNET classification was fair (κ = 0.34). Agreement generally improved with increasing experience: < 300 (k = 0.25), 300–3000 (k = 0.32) and > 3000 (k = 0.42).

Morphology classification: Initial interobserver agreement was poor (κ = 0.15 overall). Agreement improved with experience, but this improvement was primarily observed in the most experienced group: < 300 κ = 0.16; 300-3000 κ = 0.14; and > 3000 κ = 0.21.

After grouping the morphology, overall agreement increased to κ = 0.27, with improvements seen across all experience levels. The most significant gains were observed at the highest experience level: < 300 cases, κ = 0.23; 300-3000 κ = 0.24; and > 3000 κ = 0.37.

Conclusions In this UK survey, the diagnostic accuracy of JNET classification among endoscopists was moderate (58 %), with fair interobserver agreement (κ = 0.34). Accuracy and agreement both tended to improve with greater endoscopic experience. Morphology assessment showed only slight agreement (κ = 0.16), though grouping of the classification improved reproducibility. This suggests that reducing the category complexity enhances consistency amongst endoscopists.

These findings highlight persistent variability in the optical diagnosis of colorectal polyps with the use of JNET and morphological classification. This illustrates the need for standardized national training with focused image interpretation workshops and feedback. In addition, a grouping of morphological description may improve diagnostic consistency.

PYP158 Recurrence Rates Following Endoscopic Mucosal Resection versus Endoscopic Submucosal Dissection for Colorectal Polyps: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Authors Nishimura T[1], Khalaf K[1], Bucheeri MAGA[1], Li H[1], Yuan Y[2], Calo N[1], May G[1], Mosko J[1], Teshima C[1]

DOI 10.1055/s-0046-1821098

Aims Endoscopic Mucosal Resection (EMR) and Endoscopic Submucosal Dissection (ESD) are widely used for resecting large, laterally spreading colorectal polyps. While ESD offers higher *en bloc* resection rates, its comparative efficacy and safety relative to EMR remain uncertain, particularly in Western practice. This systematic review and meta-analysis aimed to evaluate the recurrence and adverse event rates of EMR versus ESD in adult patients with colorectal polyps ≥ 20 mm.

Methods We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) comparing EMR and ESD for non-pedunculated colorectal polyps ≥ 20 mm. MEDLINE, Embase and Cochrane CENTRAL were searched from inception to April 2025. The primary outcome was recurrence rate; secondary outcomes included total adverse events, bleeding, and perforation. Certainty of evidence was assessed using the GRADE framework (▶ **Table 1**).

Results In this meta-analysis of three randomized controlled trials including 484 patients, ESD was associated with significantly lower recurrence rates compared to EMR (OR 3.24, 95 % CI: 1.58–6.64), with high certainty of evidence. There were no significant differences between EMR and ESD in total adverse events (OR 1.14, 95 % CI: 0.78–1.66), bleeding (OR 0.97, 95 % CI: 0.53–1.76), or perforation rates (OR 1.01, 95 % CI: 0.14–7.22), though certainty for these outcomes was moderate due to heterogeneity and imprecision.

Conclusions ESD is associated with significantly lower recurrence rates compared to EMR in the treatment of large colorectal polyps. These findings support the use of ESD when recurrence risk is a primary concern, while EMR remains a feasible alternative with comparable safety.

▶ **Table 1**

Outcome	Participants (Studies)	Risk of Bias	Inconsistency	Indirectness	Imprecision	Publication Bias	Relative Effect (OR, 95 % CI)	Absolute Effect (EMR vs. ESD)	Certainty (GRADE)	Comments
Recurrence	484 (3 RCTs)	Not serious	No serious inconsistency	Not serious	Not serious	Not detected	OR 3.24 (1.58–6.64)	10.8 % vs 4.9 %	⊕⊕⊕⊕ **High**	Consistent,⊕ precise, and robust effect
Total Adverse Events	525 (3 RCTs)	Not serious	Serious	Not serious	Serious	Not detected	OR 1.14 (0.78–1.66)	31.5 % vs 29.6 %	⊕⊕⊕○ **Moderate**	Downgraded for inconsistency and imprecision
Bleeding	525 (3 RCTs)	Not serious	Serious	Not serious	Serious	Not detected	OR 0.97 (0.53–1.76)	11.3 % vs 11.8 %	⊕⊕⊕○ **Moderate**	Downgraded for inconsistency and imprecision
Perforation	525 (3 RCTs)	Not serious	No serious inconsistency	Not serious	Serious (very low events)	Not detected	OR 0.96 (0.14–6.65)	~0.36 % vs ~0.36 %	⊕⊕⊕○ **Moderate**	Downgraded for imprecision (few events, wide CI)

PYP159 Narrow Band Imaging vs. Magnifying Chromoendoscopy for the Diagnosis of Early Colorectal Cancer Invasion Depth: Systematic Review and Meta-Analysis

Authors Nishimura T[1], Khalaf K[1], Kataoka Y[2], Jun W[3], Yuan Y[4], Rizkala T[5], Li H[1], Bucheeri MAGA[1], Hayashi N[6], Calo N[1], May G[1], Teshima C[1], Mosko J[1]

DOI 10.1055/s-0046-1821099

Aims Accurate endoscopic assessment of the depth of submucosal invasion in T1 colorectal cancer is critical for determining the optimal treatment strategy. This assessment is currently performed with narrow-band imaging (NBI) and magnifying chromoendoscopy (MCE), yet the superiority of either modality in direct comparisons remains unclear. We therefore restricted our evaluation to paired, within-study direct comparative diagnostic accuracy studies in which both NBI and MCE were applied to the same lesion and compared the diagnostic performance of NBI and MCE for identifying deep submucosal invasion (T1b).

Methods We systematically searched PubMed, Embase, and Cochrane CENTRAL from inception to September 19, 2025 using MeSH/keywords for NBI, narrow-band imaging, JNET, magnifying chromoendoscopy, Kudo classification, pit pattern, deep submucosal invasion, T1 colorectal cancer, T1b. We included paired, within-study direct comparative diagnostic accuracy studies in adults in which both NBI and MCE were applied to the same lesion during the same session, 2 × 2 data for each test could be reconstructed and histology was the reference standard with T1b defined as ≥ 1,000 µm (SM2/3). Two reviewers independently screened and extracted data; risk of bias was assessed with QUADAS-2 and QUADAS-C. The primary synthesis used a Bayesian bivariate HSROC model with test type as a covariate to estimate pooled sensitivity/specificity and relative effects (ratios and differences; NBI/MCE), reported as posterior medians with 95 % credible intervals. Small-study effects were examined with Deeks' test (all $p > 0.10$).

Results Eleven studies (7 prospective, 4 retrospective; 2928 lesions) were included. Pooled performance: NBI sensitivity 0.746 (95 % CrI 0.629 to 0.834) and specificity 0.962 (0.930 to 0.981); MCE sensitivity 0.817 (0.728 to 0.890) and specificity 0.941 (0.892 to 0.967). Comparative effects (NBI vs MCE) showed no clear differences: sensitivity ratio 0.914 (95 % CrI 0.744 to 1.069; difference − 0.071, − 0.218 to 0.052) and specificity ratio 1.021 (0.982 to 1.077; difference 0.020, − 0.017 to 0.069). Heterogeneity was moderate–substantial; index-test risk of bias was common on QUADAS-C; small-study effects were not evident (Deeks $p = 0.30$).

Conclusions In paired within-study comparative analyses, NBI and MCE showed comparable diagnostic accuracy for identifying T1b, with substantial overlap of their 95 % credible intervals. At present, an NBI-first strategy with selective MCE add-on is reasonable for the initial assessment of colorectal lesions.

PYP160 Complexity of endoscopic resection for appendiceal orifice lesions suggests consideration of both surgical and endoscopic options

Authors Ayubi H[1], Judge C[1], Olaolu O[1], Noreillie MA[1], Eqbal A[1], Campion J[1], Lim A[1], Adeyeye A[1], Gulati S[1], Thrumurthy S[1], Hayee B[1], Haji A[1], Emmanuel A[1]

Institute 1 King's College Hospital, London, United Kingdom

DOI 10.1055/s-0046-1821100

Aims Large non-pedunculated colorectal polyps (LNPCP) and laterally spreading tumours (LST) > 10mm involving the appendix orifice (AO) are notoriously challenging to treat with endoscopic resection (ER). Few studies report outcomes of conventional ER to treat these lesions. The optimal therapy and expected outcomes remain unclear. We report the outcome after EMR and ESD of lesions involving the AO from a large series of ER performed at a tertiary referral centre.

Methods Patients undergoing ER at a tertiary referral centre between January 2011 and September 2023 were included. Techniques and outcomes of ER of lesions involving the AO were compared with other colorectal locations. Involvement of the AO was defined as any LNPCP or LST encroaching within 5mm of the orifice. These were classified as encroaching the AO, involving part of the circumference of the AO and involving the full circumference of the AO.

Results ER was performed for 1596 LNPCP and LSTs during the study period. 40 lesions involved the AO: 10 encroached within 5mm of the AO, 14 involved part of the circumference and 16 involved the full circumference. 25 (63 %) were resected by EMR, 8 by ESD (20 %) and 7 by Hybrid ESD (18 %). Initial successful ER was similar for lesions involving the AO and other colonic LNPCP (95.0 % *versus* 97.6 %, p = 0.27). Clinically significant perforation occurred in 3 patients with lesions involving the AO (2 with partial circumference involvement and 1 with complete circumference involvement) and was more frequent after ER of these lesions than others (7.5 % *versus* 1.2 %, p < 0.001). 2 of these patients required surgery. The incidence of post procedure bleeding was similar (p = 0.44). One patient developed appendicitis, more than 12 months after resection. Recurrent/residual adenoma at first surveillance was significantly more likely after ER of AO lesions than others (22.2 % *versus* 4.8 %, p < 0.001). Significantly more patients with lesions involving the AO ultimately required surgery for any reason than patient with other colorectal lesions (12.5 % *versus* 3.9 %, p = 0.02). This was significantly more likely for AO lesions involving the complete or partial circumference (18.8 % *versus* 14.3 % partial circumference involvement *versus* 0 % encroaching AO *versus* 3.9 % other locations, p = 0.004).

Conclusions These results demonstrate the challenging nature of ER for lesions involving the AO. Safe and effective ER without recurrence is achieved for many patients, including those with lesions involving the complete circumference, but significant complications, recurrence and surgery are more common with these lesions. Given there are relatively low risk minimal access surgical options to treat these lesions, these data will help inform detailed discussions with patients regarding the risks and benefits of ER (which differ from LNPCP elsewhere in the colon).

Colorectal Resections Revisited: Lessons and Insights

15/05/2026, 11:00–12:00 **Emerald 5**

PYP161 Impact of Prior Biopsy on Submucosal Fibrosis and Technical Difficulty during Colorectal Endoscopic Resection: A Prospective Observational Cohort Study

Authors Zhang L[1], Khalaf K[1], Mahamud O[1], Bucheeri MAGA[1], Harb M[1], Jugnundan S[1], Abu Shawish W[1], Devloo R[1], Hanna Y[1], Nishimura T[1], Li H[1], Calo N[1], May G[1], Teshima C[1], Mosko J[1]

Institute 1 St. Michael's Hospital, Toronto, Canada

DOI 10.1055/s-0046-1821101

Aims Guidelines discourage pre-resection biopsy because of concerns about inducing submucosal fibrosis, impairing mucosal lifting, and increasing technical difficulty. However, biopsies remain common in routine practice, often performed before referral, creating a need to quantify their real-world impact. To date, no single cohort has comprehensively evaluated these outcomes stratified by biopsy status.

Methods Consecutive patients undergoing endoscopic resection (ER) for LNPCPs at St. Michael's Hospital, Toronto, Canada between November 2024 and October 2025 were prospectively enrolled in an observational cohort. Lesions with a history of previously attempted endoscopic resection or prior tattooing were excluded. This study evaluates whether prior biopsy adversely affects the technical feasibility and safety of ER for advanced colorectal lesions, and examines how these effects vary according to biopsy timing. Time-to-event analysis was performed using a Cox proportional hazards model with the biopsy-to-procedure interval as the underlying time axis to identify variables associated with the hazard of intermediate/high technical difficulty, including lesion size, submucosal fibrosis, and lifting adequacy as covariates.

Results A total of 150 lesions were included (69 naïve and 81 previously biopsied). The mean biopsy-to-procedure interval was 112 ± 81 days in biopsied lesions (p < 0.001). Biopsied lesions were larger (4.41 ± 3.19 cm vs. 3.57 ± 1.69 cm; p = 0.04). Lesion location distribution was similar between groups across the colorectum (p = 0.4). Resection type differed (EMR: 81 % vs. 72 %; ESD: 19 % vs. 28 %; p = 0.2), respectively. Among EMR cases, biopsied lesions had lower en-bloc resection (4.9 % vs. 19 %; p = 0.007), higher hot piecemeal use (63 % vs. 43 %; p = 0.02), and lower cold piecemeal use (4.9 % vs. 19 %; p = 0.007). Planned hybrid EMR occurred only in biopsied lesions (4.9 %, p = 0.12). Use of adjunctive techniques was similar between groups: hot avulsion was used in 2.9 % naïve vs 2.5 % biopsied lesions (p = 0.9), CAST in 5.8 % vs 7.4 % (p = 0.8), and submucosal release in 2.9 % vs 6.2 % lesions (p = 0.5). Lifting adequacy was similar between groups (p = 0.9), good lifting was achieved in 93 % naïve vs 90 % biopsied lesions, partial lifting in 4.3 % vs 6.2 %, and no lifting in 2.9 % vs 3.7 %. Submucosal fibrosis was more common in biopsied lesions (F0: 65 % vs. 84 %; F1: 23 % vs. 12 %; F2: 11 % vs. 4 %; p = 0.03). Technical difficulty differed significantly (p = 0.002), with high-difficulty resections more frequent in biopsied lesions (26 % vs. 4 %). Technical success rates were 97 % in naïve lesions and 91 % in biopsied lesions (p = 0.2). Total procedure time was longer in biopsied lesions (105 ± 125 min vs. 74 ± 67 min; p = 0.02). Adverse events were infrequent and similar between groups: major early bleeding (0 % vs. 0 %), major delayed bleeding (0 % vs. 0 %), and deep mural injury without perforation (7.4 % vs. 4.3 %; p = 0.5), and perforation (3.7 % vs. 5.8 %; p = 0.7). Sydney DMI classification distributions were comparable (p = 0.2). Most lesions were Type 0 (69 % vs. 83 %). Length of stay did not differ significantly between groups (p = 0.3); hospitalizations of 3 or 7 days occurred only in biopsied lesions (3 days: 1/81 [1.2 %]; 7 days: 1/81 [1.2 %]), whereas no naïve lesions required admission beyond 2 days. Using the biopsy-to-procedure interval as a proxy for healing time, severe

submucosal fibrosis was associated with a higher hazard of intermediate/high technical difficulty (HR 2.41, 95 % CI 1.15–5.06; p = 0.020), supporting that biopsied lesions, especially with shorter intervals from biopsy to resection, are more fibrotic and technically more challenging to resect, while mild fibrosis showed a non-significant trend in the same direction (HR 1.62, 95 % CI 0.92–2.87; p = 0.094). Kaplan–Meier curves indicated that higher technical difficulty was clustered among procedures performed shortly after biopsy, while lesions with longer biopsy-to-procedure intervals were less likely to reach intermediate or high technical difficulty (p < 0.001).

Conclusions Biopsied lesions demonstrated significantly more fibrosis and higher technical difficulty, especially when the biopsy-to-resection interval was short. These findings reinforce current guidelines that large colorectal lesions should not be biopsied prior to referral, as biopsy adversely impacts resection feasibility without improving diagnostic or therapeutic outcomes.

PYP162 Interval-Specific Recurrence After EMR of ≥ 20 mm Colorectal Polyps: Conditional Risk After a Negative First Surveillance Colonoscopy

Authors Rangedara DE[1], Chedgy F[1], Ha SM[1], Mohammed OK[1], Tibble J[1], Austin M[1], Wong C[1], Green S[1]

Institute **1** Royal Sussex County Hospital, Brighton and Hove, United Kingdom

DOI 10.1055/s-0046-1821102

Aims Endoscopic mucosal resection (EMR) is the standard treatment for large (≥ 20 mm) non-pedunculated colorectal polyps (LNPCPs). Current guidelines (BSG/ACPGBI/PHE 2020; ESGE 2020/2022; USMSTF 2020) recommend surveillance at approximately 6, 18, and 36 months post-EMR, but these intervals are based on expert consensus rather than interval-specific recurrence evidence. The clinical value of a second surveillance colonoscopy (SC2) after a negative first surveillance colonoscopy (SC1) remains unclear. Clarifying this could inform risk-adapted surveillance strategies. We aimed to quantify recurrence rates at SC1 (3–6 months) and SC2 (12–18 months) following EMR of benign colorectal lesions ≥ 20 mm.

Methods We systematically searched Ovid MEDLINE, Embase, and the Cochrane Library (1990–2025) for studies reporting recurrence at SC1 and/or SC2 after hot EMR of benign LNPCPs ≥ 20 mm. We excluded studies without interval-specific outcomes and those involving cold EMR, serrated-only cohorts, or invasive cancer. SC1 was defined as surveillance at 3–6 months and SC2 as 12–18 months. Only lesions without recurrence at SC1 were eligible for SC2 analysis. Due to limited interval-specific data (three studies for SC1; one for SC2), formal quantitative meta-analysis was not feasible, so recurrence estimates are presented descriptively. The Sydney EMR Recurrence Tool (SERT) was synthesised narratively because only one study reported interval-specific SERT outcomes [1–5].

Results Recurrence at SC1 following hot EMR for benign LNPCPs ≥ 20 mm was consistently reported within the 3–6-month window, typically 10–20 %, giving a descriptive estimate of approximately 15 %. Among lesions recurrence-free at SC1, the conditional risk of recurrence at SC2 was low at approximately 3 %. SC2 follow-up was incomplete (~25 % of eligible patients did not undergo surveillance), but in the available multicentre dataset this low recurrence estimate appeared consistent. Most recurrences at both SC1 and SC2 (> 90 %) were managed endoscopically, with surgery required in only a small minority of cases (~5 %). Interval colorectal cancer following benign EMR was very rare (< 1 %). Across studies reporting risk factors, recurrence was more likely after piecemeal resection (particularly where ≥ 3 fragments were required) and was also associated with lesion size ≥ 40 mm, right-sided location, and tubulovillous or villous histology. High-grade dysplasia was associated with recurrence in several, but not all, multivariate analyses.

One study provided recurrence outcomes stratified by SERT. Recurrence at the first follow-up examination, typically performed at 12–18 months, was low among SERT = 0 lesions (11.6 %) and substantially higher among SERT ≥ 1 lesions (34.9–36.3 %). Late recurrence remained uncommon for SERT = 0 lesions at a median follow-up of 22 months. Approximately one-third of lesions were SERT = 0. Variability in follow-up timing and the absence of additional interval-specific datasets prevented pooling of SERT-based results.

Conclusions Most recurrence after EMR of benign ≥ 20 mm colorectal polyps is detected at the first surveillance colonoscopy. Conditional recurrence after a negative SC1 is low (~3 %) at 12–18 months, supporting further exploration of risk-adapted surveillance strategies. SERT may help identify a low-risk subgroup suitable for reduced surveillance intensity, but interval-specific evidence is currently limited to a single dataset. Prospective multicentre studies incorporating predefined conditional surveillance pathways and strict follow-up are required before guideline-recommended surveillance intervals can be safely revised.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821103

Aims Patients with ≥ 10 adenomas are considered a high-risk group, yet evidence guiding optimal surveillance intervals remains limited. This study evaluated the risk of metachronous advanced neoplasia (AN) according to the presence of advanced adenoma (AA) at index colonoscopy.

Methods In this multicenter retrospective study, patients with ≥ 10 conventional adenomas who underwent surveillance colonoscopy within 6 months to 3 years were analyzed. Individuals with colorectal cancer, inflammatory bowel disease, hereditary polyposis syndromes, inadequate bowel preparation, or technically unresectable lesions requiring surgery were excluded. The primary

outcome was the incidence of metachronous AN, compared between baseline AA and non-AA groups. Kaplan–Meier and Cox proportional hazards analyses were performed.

Results Among 447 patients, 313 (70.0 %) had baseline AA and 134 (30.0 %) did not. Metachronous AN occurred in 23.6 % of the AA group and 7.5 % of the non-AA group. The cumulative AN risk reached 7.5 % at 1 year and 44.9 % at 3 years overall, with significantly higher risk in patients with baseline AA (1-year: 9.7 % vs. 2.6 %; 3-year: 51.6 % vs. 30.2 %). In the multivariable model, baseline AA remained strongly associated with metachronous AN (HR, 3.83; 95 % CI, 1.96–7.49). Across AA subtypes, 3-year AN risk exceeded 50 %.

Conclusions This high-burden population demonstrates a substantial risk of early metachronous AN, particularly among those with baseline AA. These findings support a 1-year surveillance interval for the overall high-burden group, with even more intensive follow-up warranted for patients presenting with baseline AA.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP164 International Expert Consensus Recommendations for the Standardized Pathological and Clinical Assessment of Submucosal Invasion in Endoscopic Submucosal Dissection

Aims Endoscopic submucosal dissection (ESD) is a minimally invasive treatment for early gastrointestinalcancers. However, pathological assessment of invasive carcinoma in ESD specimens lacksstandardization. Variability in the evaluation of submucosal invasion (SMI) depth, lateral extent,resection margins, tumor budding, and related prognostic features can alter staging, prognostication,and management. In the absence of prior international standards, we convened a multinationalexpert panel to establish consensus on key pathological and clinical parameters to improveconsistency, reliability, and clinical utility of post-ESD pathology reporting [1–9].

▶ **Table 1**

Domain	Key Statement	Mean Score
Criteria for Submucosal Invasion Depth	Proper orientation and embedding of ESD specimens is essential to minimize measurement bias (tangential cuts, fragmentation, distortion).	**9.48**
Submucosal Invasion Breadth	Measuring and reporting invasion breadth supports standardized T1 cancer reporting and future research.	**6.56**
Margin Evaluation Techniques	Immediate specimen pinning on a firm surface and detailed grossing diagram are essential for orientation and artifact prevention.	**9.48**
Staining Methods	H&E remains the standard for assessing invasion depth.	**9.52**
Measurement Protocols	Parallel sectioning throughout ESD specimens preserves orientation and margin mapping accuracy.	**9.48**
Risk Assessment of Lymph Node Metastasis & Tumor Budding	Lymph-node risk assessment should integrate histologic and clinical factors (PNI, margins, depth, site).	**9.48**
Clinical Evaluation	ESD margins need distinct interpretation vs. surgery due to narrow margins and thermal artifacts; multidisciplinary review recommended.	**9.36**

Methods A modified Delphi process (five rounds) was used among 42 international experts (28 pathologists, 14endoscopists). Participants represented 15 countries across five continents. In Round 1, statementswere generated; in Rounds 2–4, panelists rated statements on a five-point Likert scale withconsensus predefined as ≥ 80 % agreement (score ≥ 4). In Round 5, consensus statements wereprioritized on a 10-point scale (▶ **Table 1**).

Results Fifty-six statements reached consensus across seven domains: SMI depth, SMI breadth, marginevaluation techniques, staining methods, measurement protocols, prognostic factors for lymph nodemetastasis (tumor budding [TB], lymphovascular invasion (LVI), and differentiation), and clinicalevaluation. Mean priority scores (10-point scale) ranged from 6.24 to 9.52; SMI breadth had thelowest mean (6.59), whereas measurement protocols had the highest (8.99).

Conclusions This international consensus provides standardized, synoptic-ready criteria for post-ESD pathologicalassessment of invasive carcinoma, including SMI depth and breadth, margin interpretation, andselective ancillary staining. By specifying measurement landmarks, artifact handling, and reportingterminology, it improves reproducibility and comparability across institutions. Incorporation intosynoptic templates and institutional QA can facilitate immediate implementation, while the inclusion ofSMI breadth offers a standardized adjunct metric for future prognostic validation and multicenterresearch.

Aims Colorectal endoscopic submucosal dissection (ESD) is an established curative technique for large superficial colorectal neoplasia, with well-described local adverse events such as perforation and delayed bleeding. However, systemic complications remain poorly characterized. In the institutional experience underlying the French ESD Colorectal Cohort (FECCO), several cases of acute kidney injury (AKI) were observed following colorectal ESD. This study aimed to determine the incidence, clinical and procedural predictors, and outcomes of AKI after colorectal ESD.

Methods All consecutive colorectal ESDs performed at Limoges University Hospital between January 2017 and December 2024 and included in the prospective FECCO cohort were retrospectively analysed. Submucosal lesions, neuroendocrine tumors, and non-neoplastic lesions were excluded. Demographic variables, comorbidities, chronic medications, lesion characteristics, procedural parameters, and peri-procedural fluid management were collected. AKI was defined and staged according to KDIGO criteria. Creatinine values were retrieved pre-procedure, 48–72 hours post-ESD in patients with clinical suspicion of complications, and at 6-month follow-up for those with AKI. Univariable testing and Firth's penalized logistic regression were used to identify independent predictors of AKI [1–23].

Results A total of 1,537 patients were included. Median age was 70 years (IQR 63–75), 57.5 % were male, and hypertension was the most common comorbidity (44.7 %). ACE-inhibitors, ARBs, and diuretics were used by 13.9 %, 18.1 %, and 15.5 % of patients, respectively. Lesions measured a median of 55 mm (IQR 45–70), with 43.1 % located in the right colon and granular-mixed LSTs representing the most common morphology (34.2 %). Median procedure time was 56 minutes (IQR 45–70); en-bloc and R0 resection rates were 96.2 % and 89.1 %. Perforation occurred in 10.7 %, delayed bleeding in 5.7 %.

Within 72 hours after ESD, 20 patients (1.3 %) developed AKI. These patients were older (74 vs 70 years, $p = 0.029$) and more frequently receiving ACE inhibitors (40 % vs 13.6 %, $p = 0.003$; OR 4.25, 95 % CI 1.71–10.5). Lesions in AKI patients were significantly larger (median 100 mm vs 55 mm, $p < 0.001$) and associated with longer procedures (181 min vs 55 min, $p < 0.001$). Perforation (35 % vs 10.4 %, $p = 0.003$) and delayed bleeding (36.3 % vs 5.4 %, $p = 0.003$) were also more common in AKI cases. Although total infused volume was higher in AKI patients, their weight- and time-adjusted infusion rate was significantly lower (0.11 vs 0.19 mL/kg/min, $p < 0.001$). Intra-procedural hypotension did not significantly differ between groups.

In the multivariable model, ACE-inhibitor therapy (OR 3.96, 95 % CI 1.40–9.36) and lesion diameter (OR 1.03 per mm, 95 % CI 1.02–1.04) remained independently associated with AKI; procedure duration was excluded due to collinearity with lesion size.

Among AKI cases, median creatinine rose from 79 µmol/L pre-ESD to 290 µmol/L post-procedure. Oliguria occurred in all but two patients; one patient (5 %) required two haemodialysis sessions. Renal biopsy was performed in three cases, all showing acute tubular necrosis. Median hospital stay was 9 days (IQR 5–15.3). All patients recovered their baseline renal function by 6 months.

Conclusions AKI after colorectal ESD is uncommon (1.3 %), yet clinically relevant due to prolonged hospitalization and occasional need for dialysis. Larger lesions and ACE-inhibitor therapy are the strongest predictors of renal injury. Preventive measures should include temporary discontinuation of ACE inhibitors, optimization of peri-procedural hydration, attention to insufflation-related abdominal pressures, and close monitoring during lengthy or complex dissections.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821106

Aims Endoscopic submucosal dissection (ESD) allows for curative resections of complex colorectal lesions which have high risk of malignancy. Although preprocedural biopsies are routinely done, their role is limited due to sampling error and the associated risk of fibrosis which may hinder dissection and compromise technical outcomes. This study aims to evaluate the association between preprocedural biopsies of colorectal lesions and the associated risk of fibrosis and its impact on ESD technical outcomes.

Methods This is a retrospective cohort study of all patients who underwent ESD for colorectal lesions at Kingston Health Sciences Center (KHSC) between October 2016-September 2025. We analyzed clinical, endoscopic, and histopathologic characteristics of lesions as well as patient outcomes. Histological diagnoses were categorized using the WHO Classification criteria for GI lesions, 5th edition. Rates of concordance and upstaging were calculated comparing the initial and final resected pathology. Univariate analysis between the presence of fibrosis and technical outcomes such as resection time, technical efficiency, en-bloc, R0, curative resections, and adverse events were used to calculate odds ratios with 95 % confidence intervals. P-value of < 0.05 was considered statistically significant.

Results This cohort study included 197 patients with lower GI lesions (colon = 102, rectal = 95) that underwent ESD at KHSC. 105/197 (53.2 %) of patients had preprocedural biopsies prior to their ESD at KHSC. The overall histologic concordance rate between tissue biopsy and ESD specimens was 34.0 % (30.9 % for colon and 37.8 % for rectal). 64.0 % (n = 64) of lesions were upstaged from initial biopsy with 45.3 % (n = 29) of those final resections being neoplastic lesions. Lesions with initial biopsies had significantly greater rates of fibrosis (41.0 % vs 19.6 %, p = 0.001). Patients with prior EMR/ESD at a different center also had higher rates of fibrosis (70.5 % vs 45.6 %, p < 0.001). Lesions with fibrosis were more likely to have less efficient procedures (mean 10.0 min/cm^2 vs

6.2 min/cm^2, p = 0.001). The presence of fibrosis was significantly associated with lower rates of en-bloc resections (91.8 % vs. 98.5 %, OR 0.18, p = 0.03), R0 resections (78.7 % vs. 94.9 %, OR 0.20, p = 0.001), and curative resections (75.4 % vs. 93.4 %, OR 0.22, p = 0.001) but no increased risk of adverse events (8.2 % vs 2.2 % p = 0.11). Subgroup analyses revealed similar trends when analyzing colon and rectal lesions separately.

Conclusions Preprocedural biopsies have poor concordance rate with post-ESD tissue histology. Biopsies may increase the risk of fibrosis which may decrease the rates of en-bloc and curative resections. Larger studies should evaluate the incremental benefit of biopsies and their potential associated risks.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP167 Underwater-ESD in the colon: results of a prospective, multicenter trial

Authors Kouladouros K[1], Ayoub M[2], Cahyadi O[2], Nagl S[3], Messmann H[4], Ebigbo A[3]

Institutes **1** Charité – Universitätsmedizin Berlin, Berlin, Germany; **2** St. Josef-Hospital, Ruhr University Bochum, Bochum, Germany; **3** University Hospital Augsburg, Augsburg, Germany; **4** Internal Medicine III – Gastroenterology, University Hospital Augsburg, Augsburg, Germany

DOI 10.1055/s-0046-1821107

Aims The benefits of endoscopic submucosal dissection (ESD) for colorectal lesions regarding curative resection and recurrence rates are well known. However, colonic ESD remains technically challenging, thus restricting its possible applications. Underwater-ESD uses the buoyancy effect of submerging the lesion under saline and the power of the water jet to open the submucosal space and has been used successfully to facilitate ESD in several regions. Nevertheless, evidence regarding its application for colonic lesions is still low.

Aim of this study is to evaluate the outcomes of underwater-ESD for colonic lesions in a prospective, multicenter setting.

Methods All consequent colonic lesions > 20mm qualifying for endoscopic resection referred to the participating centers (Charite Universitätsmedizin Berlin, Bochum University Hospital, Augsburg University Hospital) were screened for inclusion in the study. An informed consent was acquired by all participating patients. The ESD procedure was performed under saline and according to the standards of each participating center. Primary endpoints were en bloc resection and histologically complete (R0) resection rates. Secondary endpoints included duration of the procedure, adverse events and recurrence rates in the 6- and 12-months follow-up.

Results 53 consequent patients (36 male and 17 female) were included in our study. Average age was 66.8 years. 28 lesions were located in the right hemicolon, 10 in the left and 15 in the sigmoid colon. Median size of the lesions was 35mm (range: 20-115mm). 6 lesions were recurrent after previous endoscopic mucosal resection and 12 lesions were characterized as suspicious for malignancy. All lesions were successfully resected as ESD and all resections were en bloc and macroscopically complete. Internal traction was used in 18 cases. The flap technique was used in 40 cases, the pocket creation method in 12 and 1 lesion was resected with a combination of both techniques. Median duration of the ESD was 99 min. In 43 cases the ESD procedure was performed completely under saline. In the remaining 10 cases a part of the procedure (ranging between 20-50 %) had to be performed under gas insufflation because of inadequate exposure or bleeding. Intraoperative adverse events included 7 bleedings, 6 superficial injuries of the M. propria layer and 1 perforation, all of which were successfully treated endoscopically. There were no delayed bleedings or perforations. Histological examination showed an adenoma in 45 cases (25 with low-grade and 20 with high-grade intraepithelial neoplasia) and a carcinoma in 8 cases (6 pT1sm1, 1 pT1sm3 and 1 T2). A histologically complete resection was confirmed in 49 cases (92 %) and 51 resections were curative (96 %). At the time of submission of this abstract 20 patients had completed the 6-months follow-up and there were no cases of recurrence.

Conclusions Underwater-ESD is a safe and effective therapeutic option for the resection of colonic lesions, combining high rates of complete and curative resection with an improved safety profile.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP168 Impact of submucosal infiltrations depth on outcomes of colorectal ESDs: a single-center study

Authors Rodriguez-Monaco FD[1], Spuck N[2], Herter M[1], Wittich F[1], Dumoulin FL[1]

Institutes **1** Community Hospital Bonn Haus St. Elisabeth, Bonn, Germany; **2** Core Facility Biostatistik, Universität Heidelberg, Medizinische Fakultät Mannheim, mannheim, Germany

DOI 10.1055/s-0046-1821108

Aims Current ESGE guidelines consider endoscopic resection of colorectal cancer "curative" when the estimated risk of lymph node metastasis is < 3 % (Endoscopy 2022;54:591). However, established histopathologic risk factors—such as tumor grade, tumor budding, vascular invasion, resection margin status, and submucosal invasion depth > 1000 µm—do not carry equal prognostic weight. A recent meta-analysis, for example, reported a lymph node metastasis rate of only 2.6 % when submucosal invasion > 1000 µm was present as the sole risk factor (Gastroenterology 2022;163:174). In this study, we evaluated patients from a large institutional database who underwent ESD for colorectal cancer, focusing specifically on how submucosal invasion depth influenced subsequent clinical management [1, 2].

Methods Patients who underwent en bloc ESD for colorectal cancer were identified from a prospective colorectal ESD registry containing more than 800 procedures performed between 09/2012 and 09/2025. We assessed lymph node risk factors, post-ESD management decisions, and patient outcomes.

Results A total of 104 patients (median age 70.6 years; 34 % female) with 104 lesions (rectum n = 69 / colon n = 35; median size 36 mm) were included. Based on ESGE criteria, 33 lesions (32 %) were classified as very low- or low-risk for lymph node metastasis, while 71 lesions (68 %) were considered high-risk. Lesion size and location did not differ significantly between risk groups (p = 0,801 / p = 0,824). In 26 cases (38 % of high-risk lesions), submucosal invasion depth > 1000 µm was the only high-risk feature. Among these, nine patients underwent additional surgery, and none showed lymphatic metastasis. The remaining seventeen patients did not undergo surgery and remained disease-free during an average follow-up period of 25 months.

Conclusions In our cohort of 104 early colorectal cancers, the proportion of resections considered curative would increase from 32 % to 54 % if submucosal invasion depth > 1000 µm as the sole risk factor were reclassified as low-risk. Our findings suggest that this criterion alone should no longer define a high-risk resection.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Endoscopic submucosal dissection (ESD) is an established treatment for superficial colorectal tumors. However, its technical difficulty varies according to lesion location, and right-sided colonic lesions often present poor scope maneuverability, making the procedure more challenging. We previously reported that balloon-assisted endoscopy (BAE) improves scope control in retrospective analyses. This randomized study aimed to compare balloon-assisted ESD (BAESD) with conventional ESD (CESD) for technically difficult right-sided colonic lesions.

Methods This single-center prospective randomized controlled trial was conducted at Jichi Medical University Hospital. Patients with superficial right-sided colonic tumors (20–50 mm) judged to have poor maneuverability during preoperative colonoscopy were randomly assigned (1:1) to BAESD or CESD. The primary endpoint was the ESD completion rate. Secondary endpoints included procedure time, dissection speed, specimen size, en bloc resection rate, R0 resection rate, operator change, and complications. Analyses were performed on both an intention-to-treat (ITT) and per-protocol (PP) basis.

Results Thirty patients were enrolled (14 in the BAESD group and 16 in the CESD group). In the ITT analysis, the ESD completion rate was 100 % (14/14) in the BAESD group and 75 % (12/16) in the CESD group, showing a higher trend in favor of BAESD, although without statistical significance (P = 0.103). All incomplete CESD cases were successfully completed after conversion to BAESD. Procedure time (93 vs. 102 minutes), dissection speed (20.2 vs. 21.5 mm^2/min), en bloc resection rate (100 % in both groups), and R0 resection rate (93 % vs. 88 %) were comparable. One microperforation occurred in the BAESD group and was managed endoscopically; no delayed bleeding or severe complications were observed.

Conclusions Although recent technical advancements such as traction devices and injectable knives have expanded the indications for colorectal ESD, scope maneuverability based on lesion location remains a key determinant of technical difficulty. While statistical significance was not reached, the 100 % completion rate in the BAESD group and the successful completion of all CESD-interrupted cases after switching to BAESD are clinically meaningful. BAESD may facilitate complete ESD in technically difficult right-sided colonic lesions and represents a practical rescue strategy.

DOI 10.1055/s-0046-1821110

Aims Unlike rectal lesions, the reported prevalence of submucosal invasive cancer (SMIC) in large non-pedunculated colonic polyps (LNPcPs > 20 mm) is discordant. We conducted a systematic review and meta-analysis to estimate the pooled prevalence of SMIC in LNPcPs, including rates of superficial SMIC (sSMIC) and low-risk SMIC (lrSMIC), and to provide stratified prevalence estimates by colonic location (right and left colon).

Methods Multiple databases were searched through October 2025 for studies on the endoscopic resection of LNPcPs (≥ 20 mm) reporting SMIC, including cohorts from both Eastern and Western countries. Data were extracted for overall SMIC and, when available, for sSMIC (defined as submucosal invasion < 1000 µm) and lrSMIC (superficial invasion without high-risk histologic features). Pooled prevalence estimates with 95 % confidence intervals (CI) were calculated using a random-effects model. Prevalence estimates were also generated stratified by colonic location. Between-study heterogeneity was assessed using the I^2 statistic.

Results A total of 80 studies including 17,927 lesions were analyzed. Across all LNPcPs, the pooled prevalence of SMIC was 6.2 % (95 % CI 5.2–7.5 %). Among the 38 studies (n = 8,977) reporting depth of invasion, the pooled prevalence of superficial SMIC (sSMIC) was 3.7 % (95 % CI 2.6–5.2 %), while low-risk SMIC (lrSMIC), reported in 25 studies (n = 7,009), had a pooled prevalence of 2.8 % (95 % CI 1.8–4.3 %). All analyses showed substantial heterogeneity (overall SMIC I^2 = 83 %; sSMIC I^2 = 80 %; lrSMIC I^2 = 74 %).

When stratified by colonic location, SMIC prevalence was 5.1 % (95 % CI 4.0–6.5 %) in right-colon LNPcPs (12,926 lesions) and 13.5 % (95 % CI 11.7–15.6 %) in left-colon lesions (3,314 lesions). Superficial SMIC prevalence was 3.3 % (95 % CI 2.1–5.1 %) in the right colon and 6.0 % (95 % CI 4.4–8.3 %) in the left colon. The prevalence of lrSMIC was 2.3 % (95 % CI 1.3–4.1 %) in the right colon and 4.5 % (95 % CI 3.3–6.2 %) in the left colon.

Conclusions In this meta-analysis approximately 6 % of LNPcPs harbored SMIC, with variation by colonic location. The prevalence of lrSMIC was uncommon overall and approximately 2 % in the right colon. These estimates provide comprehensive benchmarks that may support the selection of appropriate resection strategies for LNPcPs, helping to balance risks and benefits and to determine the level of technical expertise required.

DOI 10.1055/s-0046-1821111

Aims Up to 40 % of patients with gastro-esophageal reflux disease (GERD) do not respond to medical therapy. Laparoscopic fundoplication (LF) for GERD provides suboptimal outcomes and risk of long-lasting adverse events. Transoral incisionless fundoplication (TIF) may be proposed as alternative treatment for GERD. TIF and LF long-term effects have not been compared so far, to assess the real efficacy of TIF in clinical practice. We aimed at comparing the long-term outcomes of TIF and 360 ° LF or partial (anterior 90 ° to 180 ° or posterior 270 °) LF in GERD patients [1–18].

Methods A systematic search of major databases was performed up to September 2025. Studies reporting 5- to 10-year outcomes of TIF and LF in patients with confirmed GERD were included. Randomized controlled trials comparing 360 ° and partial LF were considered. Pooled proportions and 95 % confidence interval (95 % CI) of patient satisfaction, GERD recurrence and proton pump inhibitor (PPI) discontinuation outcomes were calculated by random-effects meta-analysis, performed for each outcome and technique, and compared by N-1 Chi-squared test.

Results Eight studies on TIF (involving 447 patients) and ten studies on LF (involving 954 and 948 patients undergone 360 ° LF and partial LF, respectively), relevant to selection criteria, were included in the meta-analyses. Following TIF, the 5- to 10-year pooled proportions of patient satisfaction, GERD recurrence, and PPI discontinuation were 79.69 % (95 % CI: 72.64 to 85.62), 15.33 % (95 % CI: 9.66 to 22.63), and 67.47 % (95 % CI: 60.29 to 74.09), respectively. Following 360 ° LF, the 5- to 10-year pooled proportions of patient satisfaction, GERD recurrence, and PPI discontinuation were 81.27 % (95 % CI: 77.43 to 84.71), 17.9 % (95 % CI: 12.71 to 24.12), and 68.55 % (95 % CI: 64.69 to 72.23), respectively. Following partial LF, the 5- to 10-year pooled proportions of patient satisfaction, GERD recurrence, and PPI discontinuation were 81.31 % (95 % CI: 77.3 to 84.89), 17.2 % (95 % CI: 12.08 to 23.28), and 51.25 % (95 % CI: 47.02 to 55.46 %), respectively. The pooled proportions of patient satisfaction and GERD recurrence did not significantly differ between TIF, 360 ° LF and partial LF. The pooled proportion of patients off-PPI following TIF was like 360 ° LF and significantly higher than partial LF ($p = 0.0001$), mainly compared to posterior 270 ° LF and anterior 180 ° LF ($p < 0.0001$).

Conclusions This meta-analysis reports that the 5- to 10-year patient satisfaction, GERD recurrence, and PPI discontinuation outcomes of TIF and LF are substantially comparable. Thus, TIF could offer a therapeutic option as clinically effective as LF in the long-term, without surgery-related side effects, for selected GERD patients, who refuse life-long medical therapy or surgery, are intolerant to PPI, or have some risk of persistent post-surgical side effects.

PYP172 Efficacy and safety of anti reflux mucosal ablation (ARMA) for proton pump inhibitor (PPI) – refractory gastroesophageal reflux disease(GERD) – A single center prospective study

Authors Gupta S[1], Kalla M[1], Shrimal P[1], Kalla V[1], Rai RR[1]

Institute **1** SR Kalla Hospital Jaipur, Jaipur, India

DOI 10.1055/s-0046-1821112

Aims Evaluation of the clinical efficacy and safety of Anti-Reflux Mucosal Ablation (ARMA) therapy in patients with proton pump inhibitor (PPI)-refractory gastroesophageal reflux disease (GERD).

Methods This single-center prospective study, conducted at SR Kalla Memorial Gastroenterology Hospital in Jaipur, India, included 45 patients with symptomatic GERD who were receiving daily oral PPI for at least 12 weeks. Esophagogastroduodenoscopy (EGD), pH studies, and high-resolution esophageal manometry (HREM) were performed on all screened patients. Quality of life was measured in these patients using the GERD Health-Related Quality of Life (GERD-HRQL) and the Frequency Scale for Symptoms of GERD (FSSG). ARMA was performed in a standardised fashion using Argon plasma coagulation (APC) ablation. Patients were followed up at 3 months after procedure with repeat EGD, HREM, GERD-HRQL, and FSSG assessment [1–3].

Results A total of 45 patients (57.8 % males; median age, 52.5 years) underwent ARMA. Significant improvements in patient-reported outcomes were observed at 3 months post-procedure. The mean GERD-HRQL score decreased significantly from 38.2 ± 6.8 to 12.4 ± 7.2 ($p < 0.001$). Similarly, FSSG scores dropped significantly from 22.3 ± 5.4 to 10.2 ± 6.1 ($p < 0.001$).Physiologic testing demonstrated effective control of pathological acid exposure. The mean DeMeester score improved significantly from 35.8 ± 28.6 to 8.4 ± 6.2 ($p < 0.001$). Mean AET also reduced significantly from 20.8 % to 2.8 % ($p < 0.001$). Endoscopic assessment confirmed enhancement of the anti-reflux barrier.Anatomical improvement was further supported by 68.9 % patients showing an improvement of ≥ 1 Hill's Grade.Regarding mucosal status, the proportion of no esophagitis increased from 29 (64.4 %) to 36 (80 %). The prevalence of Grade A and Grade B decreased significantly post-procedure. The safety profile of ARMA was favourable, only minor and transient adverse events were recorded, no major complications such as perforation, stenosis, or bleeding occurred. At 3-month follow-up, 88.9 % of patients had either reduced or discontinued PPI use, demonstrating reduced pharmacological dependence.

Conclusions ARMA demonstrated significant efficacy and safety for PPI-refractory GERD. The procedure substantially improved subjective scores (GERD-HRQL, FSSG) and objective markers (DeMeester score, AET, Hill's grade). A high rate of PPI reduction/cessation affirms ARMA's role as a promising minimally invasive treatment for long-term GERD management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821113

Aims Interdisciplinary collaboration between foregut surgeons and interventional endoscopists is paving the way for the future of benign GI disease. Concomitant hiatal hernia repair and transoral incisionless fundoplication (cTIF) is one such innovation that has emerged as a viable combination therapy for patients with gastroesophageal reflux disease (GERD). cTIF enables a consistent 270–300° omega-shaped valve in patients with pathological reflux and hiatal hernias (HH) > 2 cm, who would otherwise be unsuitable for TIF2.0 alone. cTIF is hypothesised to offer effective reflux control with lower morbidity than traditional Nissen fundoplication. We report one of the largest datasets outside North American on the safety and efficacy of cTIF conducted within the European TIF registry (EURO-TIF).

Methods A prospective, multi-centre registry conducted across seven European centres and registered at Cleveland Clinic London (CCL-2021-TIF). All prospectively collected data among patients undergoing cTIF for the management of gastroesophageal reflux disease (GERD) since 2021 were eligible for inclusion. Patients underwent a laparoscopic hiatal hernia repair immediately followed by same-session TIF in theatre. The primary outcomes were change in reflux-specific quality of life questionnaires (GERD-HRQL and RSI) and acid suppression use from baseline to 12-months follow-up. Secondary outcomes included procedural outcomes and adverse events according to the AGREE classification. Within-patient changes from baseline to 6- and 12-months were assessed using paired t-tests, while insufficient paired observations were analysed descriptively.

Results In total, 62 patients underwent cTIF with a mean age of 49.9 years (SD 13.9), and 38.7 % (n = 24) were female. All patients were naïve to previous mechanical therapy, were using regular anti-acid medication, and had a median Charlson Comorbidity Index of 1 (IQR 0-1). The median HH size was 3 cm (IQR 2-3; range 1-7), baseline acid exposure time (AET) was 9.1 % (IQR 7.1-14.2), and median total reflux episodes were 74.5 (IQR 56-107). Mean baseline GERD-HRQL and RSI scores were 34.8 (SD 12.4) and 14.8 (SD 9.3), respectively, and 98.3 % (n = 57) were dissatisfied with current treatment. The procedure was technically successful in all cases, with a mean procedure time of 84.3 minutes (SD 28.5; range 45-155), a median of 2 crural sutures (IQR 2), 14 plication pairs (IQR 10-14), and an inpatient stay of 2 days (IQR 1-2). Thirteen adverse events occurred; the majority AGREE grade I (n = 9). Two patients developed hospital-acquired pneumonia (AGREE II), one underwent pyloric botox injection for gastroparesis symptoms (AGREE IIIa), and one developed a suspected leak requiring salvage Nissen fundoplication three days post-cTIF (AGREE IIIb). At 6- and 12-months, follow-up completion was 63 % (34/54) and 38 % (15/45), respectively. The proportion of patients no longer requiring anti-acid therapy at 6- and 12-months was 68.6 % and 70.6 %. Over the same period, mean GERD-HRQL scores were 7.1 (SD 6.9; n = 34) and 6.8 (SD 5.1; n = 15), corresponding to mean within-patient reductions of -30.3 (SD 13.2; $p < 0.001$) and -32.8 (SD 13.5; $p < 0.001$), respectively, and mean RSI scores of 3.1 (SD 4.0; n = 17) and 4.7 (SD 4.5; n = 7). One patient required an additional procedure (anti-reflux mucosal ablation) for worsening symptoms without evidence of recurrent HH.

Conclusions We present the first European outcomes on patients undergoing cTIF demonstrating the combined procedure appears safe, feasible, and enables sustained symptom improvement and acid-acid therapy discontinuation over 12-months.

PYP174 Cryoballoon ablation following non-curative endoscopic therapy or a recurrence of Barrett-related dysplasia or esophageal adenocarcinoma in the resection scar: a case series

Authors Boer L[1, 2], Van Munster S[1], Pouw R[1], Weusten B[2, 1]
Institutes **1** UMC Utrecht, Utrecht, Netherlands; **2** St. Antonius Hospital, Nieuwegein, Netherlands
DOI 10.1055/s-0046-1821114

Aims Endoscopic resection (ER) is the recommended treatment for superficial visible lesions in patients with a Barrett esophagus (BE). Following non-curative endoscopic therapy for BE-related dysplasia or esophageal adenocarcinoma (EAC), or in case of a local recurrence at the ER scar for which additional ER is not deemed feasible, step-up treatment with esophagectomy and/or chemo/radiotherapy is typically considered. However, step-up treatment may not always be possible due to comorbidities and/or age or may be declined based on patient preference. This case series evaluates the use of endoscopic focal cryoballoon ablation (CBA) as potential alternative therapy.

Methods This retrospective case series was conducted at two Dutch tertiary referral centers. Patients with BE-related dysplasia or EAC were included if they underwent focal CBA between January 2018 and July 2025 for two indications: 1) prophylactic therapy following non-curative endoscopic treatment defined as a macroscopically incomplete ER, or an ER with vertical tumor-positive resection margins (R1v), and 2) an endoscopically visible neoplastic lesion < 1 cm from the ER scar for which additional ER was not deemed feasible. Treatment was performed using either the first- or second-generation CBA device, with an ablation dose of 10 to 12 seconds. The number of ablations and freeze–thaw cycles was determined at the discretion of the endoscopist. Outcomes were technical success, safety, endoscopic remission — defined as the absence of any endoscopically visible lesions suspected of dysplasia or cancer during endoscopic follow-up — and survival.

Results In total, 11 patients underwent focal CBA after a non-curative ER or an endoscopically visible lesion < 1cm from the resection scar. Patients had a median age of 77 years (p25-p75 68-81) at time of treatment, and the majority was male (9/11; 82 %). Reasons for not undergoing additional treatment with esophagectomy and/or chemo/radiotherapy included severe comorbidity and/or advanced age (n = 5) and patient preference (n = 6).

Seven patients (7/11; 64 %) underwent prophylactic CBA following non-curative endoscopic treatment, and four patients (4/11; 36 %) had treatment for an endoscopically visible lesion < 1cm from the ER scar. CBA was technically feasible in all cases, and no (serious) adverse events occurred.

In patients who underwent prophylactic CBA after non-curative endoscopic therapy, endoscopic remission was retained in 71 % of patients (5/7) and this sustained during a median endoscopic follow-up of 14 months (range 3-51) with median 2 endoscopies (range 1-3). Among patients with a local recurrence at the resection scar, 50 % (2/4) achieved endoscopic remission and this sustained during a median endoscopic follow-up of 7 months (range 6–8) with median 6 endoscopies (range 2-10).

Overall, 45 % of patients (5/11) died median 26 months (range 12-36) after CBA. Three of these deaths were attributable to esophageal cancer, and were all in patients who did not achieve endoscopic remission.

Conclusions In expert hands, focal CBA is feasible and safe following non-curative endoscopic therapy for BE-related dysplasia or EAC and for local recurrences in the ER scar. However, efficacy is limited, and therefore CBA should not be regarded as reliable alternative to esophagectomy and/or chemo/radiotherapy.

PYP175 Inadequate Cellularity of Wide-Area Transepithelial Sampling (WATS) in Barrett's Esophagus results of a Prospective, Multi Phase, Multi-Center Trial

Authors Stougie P[1], Van Munster S[2], Khoshiwal AM[3], Pouw R[2], Bisschops R[4], Weusten B[5, 2], Alvarez Herrero L[5], Curvers W[6], Schoon E[7], Herwaarden Y[8], Nagengast WB[9], Westerhof J[10], De Wulf D[11], Leclercq P[12], Duits L[13], Bergman J[3]

DOI 10.1055/s-0046-1821115

Aims Wide-Area Transepithelial Sampling with 3D analysis (WATS3D) is widely used as an adjunct to random forceps biopsies (RFB) during Barrett's esophagus (BE) surveillance endoscopies. In a previous randomized trial (WATS-EURO1) comparing WATS with RFB in 172 patients in 17 BE expert centers in Europe, we found that inadequate cellularity of WATS3D samples prohibited a reliable diagnosis in 13 % of cases, despite that procedures were performed by experienced BE endoscopists who were instructed on the brush technique and with in-room training on the sample preservation.

Methods The WATS-EURO2 study was initiated after the WATS-EURO1 study to study the relevance of WATS3D-positive-RFB-negative findings during follow-up and aimed to enroll 200 BE patients with low grade dysplasia, high-grade dysplasia or early cancer and 200 non-dysplastic BE patients with a follow-up of 3 years and without ablation for all WATS3D-positive-RFB-negative cases. Based on the sample inadequacy rates in the WATS-EURO1, the WATS-EURO2 was separated into three chronologically distinct phases : (1) Conventional Preservation Phase: after brush collection, a portion of the sample was applied as a dry smear on a glass slide, followed by the addition of preservation fluid for transport and processing; (2) Improved Preservation Phase: no dry smear was obtained and the entire brush sample was preserved in a transportation medium before transportation and processing; and (3) Post-training Phase: the same preservation method was used, but endoscopists received additional training instructions, video tutorial, and individual feedback on their sample adequacy. Sample adequacy was evaluated across each phase, with subgroup analyses by endoscopist. Specimens were categorized and assessed at the CDx Diagnostics laboratory, blinded to case indications and RFB outcomes. Samples were classified as inadequate if either the smear or cell block showed poor preservation or low cellularity.

Results Seven BE expert endoscopists contributed to the study. Sample adequacy did not improve in the Improved Preservation Phase compared to the Conventional Preservation Phase (126/218 cases (57.8 %) vs. 113/173 cases (65.3 %), p = 0.15). In the Post-Training Phase adequacy rates rose to 299/326 (91.7 %; p < 0.001, compared to the preceding phases; Figure 1). All 7 endoscopists significantly improved their adequacy rates with final adequacy rates between 73 % and 100 % (median: 92 %; Figure 2). Despite the overall improvement post-training, inadequate samples persisted in 0 to 27 % (median 8 %) of cases.

Conclusions Despite that all procedures were performed by BE expert endoscopists, after standard instructions and training, samples were deemed inad-

equate in a substantial number of cases. Sample adequacy improved to > 90 % after additional training instructions, video tutorial and individual feedback on sample adequacy. These findings underscore the critical role of a proper brushing technique in WATS3D sampling and the necessity of reporting inadequacy rates in WATS3D studies.

PYP176V A Novel Endoscopic Capsule Sponge Technique Supporting Early Detection and Risk Stratification in Barrett's Neoplasia

Authors Stougie P[1], Wajon D[2], Pouw R[3], Kramer GM[4], Duits L[5]
Institutes **1** Amsterdam UMC location University of Amsterdam, dept. of Gastroenterology and Hepatology, Amsterdam, Netherlands; **2** Amsterdam UMC, locatie AMC, Amsterdam, Netherlands; **3** UMC Utrecht, Utrecht, Netherlands; **4** Department of Gastroenterology and Hepatology, Amsterdam UMC, location AMC, Amsterdam, Netherlands; **5** Amsterdam UMC, locatie VUmc, Amsterdam, Netherlands
DOI 10.1055/s-0046-1821116

Problem to solve Effective surveillance of Barrett's esophagus (BE) requires representative sampling of the metaplastic epithelium to enable early detection of dysplasia or adenocarcinoma. However, the current gold standard of forceps biopsies is limited by sampling error, interobserver variability in histopathological assessment, and poor integration with emerging molecular diagnostic strategies. Although novel widefield sampling devices have shown promise for more extensive coverage of the BE segment, their clinical adoption is often restricted by patient intolerance or inadequate sampling. As a result, obtaining truly representative tissue samples remains technically challenging.

Innovation We use a transendoscopic sampling (TES) technique involving a dissolvable capsule sponge to enable comprehensive sampling during routine endoscopy. The capsule is introduced into the stomach alongside the endoscope using a biopsy forceps. Upon dissolution, it expands into a rough-textured sponge. While the endoscopist inspects and cleans the BE segment, the sponge is deployed and subsequently retrieved transorally, collecting cells from the entire BE without cross-contamination. The procedure results in visible abrasions across the entire BE segment, including targeted suspicious lesions.

Results In a prospective series of 226 TES procedures, technical success was achieved in 224/226 cases (99.1 %). 2/226 procedures failed due to severe esophageal stenosis that prevented passage of the capsule sponge. All 64 BE patients with histologically confirmed progression (high-grade dysplasia or esophageal adenocarcinoma) or endoscopically suspicious lesions underwent successful sampling. In 100 % of the successfully retrieved samples (224/224), sufficient material was collected for DNA isolation.

Conclusions Transendoscopic sampling using the capsule sponge is a safe, well-tolerated, and technically feasible procedure for widefield sampling of BE. It offers a scalable platform for integrating molecular biomarkers into routine surveillance and has the potential to complement, or even revolutionize, endoscopic surveillance in Barrett's esophagus.

DOI 10.1055/s-0046-1821117

Aims Endoscopic eradication therapy (EET) with radiofrequency ablation ± endoscopic resection, is recommended for treatment of Barrett's esophagus (BE) with dysplasia/early cancer [1]. After successful EET, guidelines recommend endoscopic follow-up (FU) of 5 years for baseline low-grade dysplasia (LGD), and 10 years for baseline high-grade dysplasia (HGD)/T1 cancer [1]. We present the long-term outcomes of our previously published, nationwide cohort of BE patients, successfully treated with EET between 2008-2018 in a centralized setting in BE expert centers (BEC) in the Netherlands [2]. Care for patients was provided according to a uniform protocol and by expert endoscopists and pathologists.

Methods All patients who underwent successful EET for BE with dysplasia/T1 cancer were included. Successful EET was defined as complete eradication of BE and of dysplasia/cancer. FU data was collected up to September 2025. Endoscopic FU was defined as time from last treatment until last FU endoscopy. Vital FU was defined as time from last treatment until recurrence, data collection of vital status, or death. The primary outcome was recurrent dysplasia or cancer. Recurrences were classified as LGD in random biopsies from a normal appearing gastroesophageal junction (GEJ), dysplasia/cancer in recurrent BE eligible for endoscopic treatment, or advanced a/o metastasized cancer ineligible for endoscopic treatment.

Results We included 1269 patients (1038 male, median age 66 yrs, median BE of C2M4) with baseline LGD in 27 %, and HGD/cancer in 73 %. Median endoscopic FU was 65 months (IQR 42-93) with a median of 5 endoscopies (IQR 3-7). FU endoscopies were already discontinued in 58 % after median 101 months (IQR 74-138), due to: guideline recommendation to stop (20 %), limited life expectancy (18 %), or death (14 %).

Recurrent LGD/HGD/cancer was detected in 91/1269 (7 %; annual risk 1.3 %) after a median of 35 months (IQR 23-55) and 3 endoscopies (IQR 2-5). Recurrence of HGD/cancer was detected in 4.2 % (annual risk 0.8 %). The total number of endoscopies to find one recurrence was 73. In total, 9/91 recurrences were diagnosed after the guideline-recommended time point at which FU can be discontinued. Overall, 84 % of recurrences was amenable for curative endoscopic re-treatment, while 16 % (1 % of the overall cohort) was detected as advanced cancer. In total, 11/1269 patients (0.9 %) had cancer-related death. In contrast, during a median vital follow-up of 101 months (IQR 80-136), 318 patients (25 %) had unrelated death.

In patients with baseline LGD, recurrent LGD/HGD/cancer was detected in 19/347 patients (5 %; annual risk 0.7 %). The majority of recurrences was amenable for curative endoscopic treatment (16/19; 84 %), consisting of recurrent LGD in a normal appearing GEJ in 5/347 (1.0 %, annual risk 0.2 %) or dysplasia/cancer in recurrent BE in 11/347 (3 %, annual risk 0.4 %). The remaining 3/19 patients developed advanced a/o metastasized cancer (1 %, annual risk 0.1 %), after a median 85 months (IQR n.a.) after treatment. The majority (17/19; 89 %) of recurrences were found during routine FU-endoscopy. The remaining 2/19 (11 %) were detected in patients presenting with symptoms, including one after endoscopic FU had been stopped.

In patients with baseline HGD/cancer, recurrent LGD/HGD/cancer was found in 72/922 patients (8 %; annual risk 1.0 %). Overall, 60/72 (83 %) had recurrence amenable for curative endoscopic treatment, consisting of recurrent LGD in a normal appearing GEJ in 13/922 (1 %, annual risk 0.2 %) or dysplasia/cancer in recurrent BE in 47/922 (5 %, annual risk 0.6 %). The remaining 12/72 patients

(17 %) had recurrence of advanced a/o metastasized cancer (1 %, annual risk 0.2 %) after a median FU of 34 months (IQR 17-90). Most (65/72; 90 %) recurrences were found during routine FU-endoscopy. In 7/72 (10 %) recurrence was detected in patients presenting with symptoms, including one after endoscopic FU had been stopped.

Conclusions Successful EET in an expert treatment setting, yields a long-term durable effect, demonstrating low recurrence risks in both baseline LGD and HGD/cancer patients, and < 1 % cancer related death after median vital FU of 101 months. The risk of developing symptomatic cancer recurrence after guideline advised cessation of FU is extremely low.

DOI 10.1055/s-0046-1821118

Aims Low-grade dysplasia (LGD) in Barrett's esophagus (BE) carries a significant risk of progression to high-grade dysplasia (HGD) or adenocarcinoma, estimated at 9–13 %/patient/year when LGD is confirmed by expert pathology [1]. Although radiofrequency ablation (RFA) is recommended by ESGE guidelines, results remain imperfect and sometimes contradictory [2]. Endoscopic mucosal resection (EMR) may offer both diagnostic and therapeutic advantages over ablative techniques. No prior study has specifically evaluated outcomes of EMR in confirmed LGD in BE. This study aimed to assess the efficacy and safety of EMR for confirmed LGD.

Methods This retrospective multicenter study (2008–2023) included patients from three tertiary centers who underwent EMR for histologically confirmed LGD. Inclusion required LGD validated by two expert pathologists and confirmed on the resection specimen. The primary endpoint was absence of progression to HGD or adenocarcinoma. Secondary endpoints included eradication and recurrence rates of LGD and intestinal metaplasia, as well as procedural morbidity. Adjunctive therapies (RFA and/or APC) were allowed at the discretion of the endoscopist.

Results Fifty-two patients (mean age 62.9 ± 10.3 years; 77 % male) were included. Median Prague classification was C1M3, with visible nodules in two cases. EMR sessions per patient ranged from 1 to 5. Adjunctive treatment was applied in 46.2 % of patients (RFA: 10; APC: 10; both: 4). Initial LGD eradication was achieved in 100 % of patients. LGD recurred in 15.4 % of cases (8 patients) after a mean of 30.5 months; seven of these patients underwent endoscopic retreatment with successful eradication, resulting in a final overall eradication rate of 98.1 % after a mean follow-up of 54 ± 22.3 months. The last patient's treatment began after the end of the study period. No progression to HGD or adenocarcinoma occurred. BE eradication was obtained in 65.4 % of patients, with recurrence in 11.8 %. Procedure-related morbidity was 1.9 % (one delayed bleeding episode), and delayed adverse events occurred in 15.4 % (9.6 % strictures, 5.8 % dysphagia), all resolving spontaneously or after endoscopic therapy.

Conclusions EMR appears to be a safe and effective treatment option for confirmed LGD in BE, achieving high initial and long-term eradication rates without malignant progression over a mean 4.5-year follow-up. These findings support EMR as a promising therapeutic and diagnostic strategy in selected patients, warranting further prospective validation.

PYP179 Real-life oncologic outcomes of endoscopic ablation for dysplastic Barrett's: data from a tertiary center

Authors Mastrorocco E[1], White M[1], Bhandari P[1]

Institute **1** Queen Alexandra Hospital, Portsmouth, United Kingdom

DOI 10.1055/s-0046-1821119

Aims The radiofrequency ablation has been shown to be very effective for the treatment of flat neoplastic lesions in Barrett's oesophagus irrespective of histology. In particular, this has been shown to be associated with less disease progression (3.6 % vs. 16.3 %, P = 0.03) when compared with sham. [1] The aim of our study was to identify the frequency of patients with invisible or completely flat neoplasia, treatment modality used and ultimate outcome of these patients.

Methods This is a retrospective analysis of a prospectively collected data of the last 250 consecutive Barrett's neoplasia patients treated at a tertiary referral center for Barrett's endotherapy in the UK. The endoscopy, histology and clinical records were analysed to identify all patients with invisible (biopsy proven neoplasia) or flat (IIb) lesions. Data was collected on lesion morphology, histology, treatment modality (ablation vs endoscopic resection) and overall outcome was collected. Patients were broadly divided into two group 1(Ablation only) vs group 2 (endoscopic resection).

Results We evaluated a total of 250 consecutive patients with Barrett's neoplasia treated in our centre. 87/250 (35 %) were found to be either flat IIb or with invisible / indistinct margins.

47/87 (54.02 %) underwent ablation without resection (group 1). 40/87 (45.97 %) underwent up-front resection (group 2). The median follow-up time was 1758 [1016; 2769] and 1185 [705;1899] days for group 1 and 2, respectively.

Pre-intervention histology demonstrated High grade dysplasia (HGD) in 23/47 (48.93 %) and 29/40 (72.50 %) patient in group 1 and group 2, respectively.

In group 2(EMR); comparison of post-resection histology with pre-resection histology revealed a disease upgrade in 29/40 (72.5 %) patients.

11/40 patients in group 2 had LGD pre-resection; 5/11(45.5 %) upgraded to HGD and 3/11(27.3 %) upgraded to carcinoma after resection.

Similarly, 29/40 patients had pre-resection histology of HGD. After resection, 11/29 (38 %) were upgraded to cancer.

Metachronous lesions developed in 8/47 (10.81 %) and 2/40 (5.0 %) in group 1 and group 2, respectively. The difference became more significant when stratified by index histology as patients with HGD on index histology developed

more metachronous lesion (21.74 %) when treated by ablation as compared to resection (6.89 %).

Conclusions RFA remains a valid treatment option of flat (IIb) lesions with indistinct margins and invisible but biopsy proven Barrett's neoplasia but the risk of metachronous neoplasia is high in patients with index histology of HGD so they require very careful follow up if ablated.

The resection cohort revealed a significant upgrade in disease stage both in LGD and HGD cohort despite having flat lesions with no nodules.

DOI 10.1055/s-0046-1821120

Aims Barrett's esophagus (BE) has been recognized as a precursor to esophageal adenocarcinoma (EAC). BE lesions are frequently treated by Endoscopic Submucosal Dissection (ESD) to allow for adequate staging and as a first step in the treatment of BE lesions. Lesions at the gastroesophageal junction (GEJ) present clinical challenges due to their diverse morphology and varying malignant potential. Our objective was to distinguish the clinicopathologic features of GEJ lesions from non-GEJ lesions for effective risk stratification and treatment planning.

Methods We retrospectively analyzed 108 patients with target lesions originating from Barrett's esophagus (87 located in the GEJ region and 21 in the non-GEJ region) who underwent ESD. We assessed their clinicopathological features and clinical outcomes. Lesions were classified according to the Siewert classification, differentiating those with a maximal mucosal base ranging from − 5 cm to + 2 cm from those situated more than + 5 cm above the GEJ. Chi-square tests were employed to assess the associations between lesion location and histology, submucosal invasion depth and morphology, as classified by the Paris classification.

Results GEJ lesions displayed a significantly different distribution of histological grades compared to non-GEJ lesions ($p < 0.001$), with high-grade dysplasia and adenocarcinoma more present at the GEJ. The depth of neoplastic submucosal invasion also varied significantly by location, with GEJ lesions showing higher rates of both superficial and deep submucosal cancer infiltration (pT1a, pT1b) ($p < 0.001$). Also morphological patterns differed substantially between groups ($p = 0.023$), with pejorative morphologies, particularly IIb and IIc components according to Paris classification, more commonly seen in GEJ lesions, while non-GEJ lesions exhibited a more varied distribution (Is-IIa according to Paris classification). Both groups showed no significant differences in ESD outcomes regarding procedural complications.

Conclusions Our analysis revealed that GEJ lesions have a distinctly more aggressive profile than non-GEJ lesions. Our preliminary data showed that GEJ lesions have a greater prevalence of pejorative morphologies, higher histological severity and deeper invasion. The significantly increased rates of high-grade dysplasia and adenocarcinoma at the GEJ strongly suggest that this region represents a biologically distinct and more vulnerable microenvironment, where neoplastic progression may accelerate or manifest at a more advanced stage. This heightened aggressiveness aligns with the unique exposure of the junctional zone to mixed gastric and esophageal refluxate, chronic inflammation, and aberrant metaplastic remodeling. Overall, these findings underscore the intrinsic worrisome nature of GEJ lesions and highlight the importance of rigorous, multimodal assessment in managing junctional lesions.

PYP181 Beyond Timing: How Clinical Scenario Drives the Effectiveness of Urgent Colonoscopy in LGIB

Authors Corradi M[1], Dioscoridi L[1], Gazzaniga G[2,3], Mutignani M[1]

Institutes **1** ASST GOM Niguarda, Digestive and interventional Endoscopy Unit, Milan, Italy; **2** Sapienza University of Rome, Rome, Italy; **3** Department of General Surgery, Surgical Speciality and Anesthesiology, Rome, Italy

DOI 10.1055/s-0046-1821121

Aims Current ESGE guidelines recommend urgent colonoscopy only in selected patients with acute lower gastrointestinal bleeding (LGIB), based mainly on bleeding severity and likelihood of finding stigmata of recent hemorrhage. However, they do not clearly differentiate recommendations according to the underlying clinical scenario. Since LGIB is a highly heterogeneous condition, we aimed to evaluate whether the diagnostic and therapeutic effectiveness of urgent colonoscopy differs among distinct patient populations.

Methods We conducted a retrospective single-centre study in a tertiary referral hospital with 24/7 endoscopic availability. All urgent colonoscopies (< 24 hours from request) performed for acute LGIB between July 2018 and August 2025 were analysed. Procedures were classified as diagnostic if the bleeding source or stigmata of recent haemorrhage were directly identified, and as therapeutic if endoscopic hemostasis was performed. Patients were stratified into three clinical cohorts: [1] colon-naïve patients, [2] post-polypectomy bleeding, and [3] post-surgical bleeding. The primary outcome was in-hospital mortality. Secondary outcomes included diagnostic yield, therapeutic yield, and rebleeding.

Results Among 415 urgent colonoscopies, 224 patients undergoing colonoscopy within 24 hours for LGIB were included: 129 colon-naïve, 52 post-polypectomy, and 43 post-surgery. Overall diagnostic and therapeutic yields were 58 % and 44 %, respectively, but showed marked differences across cohorts. Diagnostic yield was significantly lower in colon-naïve patients (40 %) compared with post-polypectomy (88 %) and post-surgical patients (77 %)($p < 0.001$). Similarly, therapeutic yield (endoscopic hemostasis) was 21 % in colon-naïve patients, versus 87 % in post-polypectomy and 63 % in post-surgical patients ($p < 0.001$).

On multivariable analysis, clinical scenario (population subgroup) was the strongest independent predictor of both diagnostic and therapeutic outcomes with odds ratio (OR) up to 24.5 for haemostasis in the post-polypectomy subgroup, and up to 6.28 in the post-surgery subgroup ($p < 0.001$), while age, sex, and quality of bowel preparation were not.

In-hospital mortality was 9.8 %. A multivariable Cox proportional hazards survival analysis was performed, adjusting for age, sex, clinical scenario, and ASA class. In this model, neither diagnostic nor therapeutic endoscopic outcomes were significantly associated with mortality, whereas ASA class emerged as the only independent predictor of mortality with hazard ratio (HR) of 2.74 and 2.81 respectively, ($p = 0.01$).

Notably, rebleeding rates were similar across the three clinical cohorts ($p = 0.5$) and between patients on or off antithrombotic therapy ($p = 0.66$), with only transfusion requirement (61 % vs 85 %, $p = 0.001$) and prolonged hospitalisation (9 vs 20 days, $p = 0.01$) showing significant associations.

Conclusions Compared with previously published data on urgent colonoscopy in acute LGIB, our cohort showed markedly higher diagnostic and therapeutic yields even in the colon-naïve subgroup, further supporting the high effectiveness of urgent colonoscopy in our setting with 24/7 endoscopic availability. However, this effectiveness was not uniform across all patients and was strongly influenced by the underlying clinical scenario. In particular, patients with post-surgical bleeding and post-polypectomy had substantially higher diagnostic and therapeutic yields than colon-naïve patients. These results highlight a critical gap in current guidelines, which do not adequately differentiate among patient subgroups, and support the need for a more tailored, scenario-based approach when selecting candidates for urgent colonoscopy in acute LGIB.

As for rebleeding events, no strong independent predictors were identified; the only observed associations — with transfusions and prolonged hospitalisation — likely reflect secondary consequences rather than causal factors [4].

Moreover, our findings indicate that short-term survival in acute LGIB is primarily driven by baseline patient comorbidity rather than by endoscopic outcomes, reinforcing the concept that patient-related factors outweigh procedural factors in determining prognosis, not only in randomised controlled trials but also in real-life clinical practice.

DOI 10.1055/s-0046-1821122

AimsPrimary: to describe the incidence of delayed complications after CR-ESD (bleeding, perforation, and post-electrocoagulation syndrome [PECS]). Secondary: to characterise their timing and clinical impact; to identify associated risk factors; and to evaluate the effect of prophylactic defect closure.

Methods This retrospective cohort study used data from a prospective national registry of CR-ESDs performed in 28 Spanish centres (January 2013-September 2025) by 40 endoscopists. Eligible patients were aged > 18 years and underwent CR-ESD or attempted ESD for colorectal neoplasia. Exclusion criteria were incomplete records, technical variants (hybrid ESD, endoscopic intermuscular dissection [EID] or per-anal endoscopic myotomy [PAEM]), aborted procedures, immediate surgery after ESD, failed ESDs, and low-volume centres.

Delayed complications were defined as clinically significant bleeding, PECS (pain/fever without intraprocedural perforation requiring > 1-day stay), or perforation confirmed radiologically occurring after completion of the procedure. Events not prolonging hospitalisation were not considered complications. Main data source was the Spanish National ESD Registry. Follow-up followed routine practice.

Univariable logistic regression assessed crude associations, and all clinically relevant variables entered multivariable model. The effect of prophylactic closure was evaluated using crude comparisons and propensity-score matching (PSM) to control for confounding. Analyses were two-sided with significance set at $p < 0,05$. Deterministic logical rules were used for imputation when values could be unequivocally deduced; otherwise, missing data were retained. No sample-size calculation was performed.

Results A total of 2.618 CR-ESDs were performed in 2.556 patients. After exclusions (179 hybrid ESDs, 28 EIDs, 38 PAEMs, 101 aborted procedures, 21 immediate surgeries, 133 incomplete records, 6 failed ESDs), 2.112 procedures were analysed. Intraprocedural perforations (267; 12,6 %) were excluded from PECS and delayed perforation analyses.

The cohort had a mean age of 67,7 years; 59 % were male; 88 % were ASA II–III; 14 % received antiplatelets and 10 % anticoagulation. Median lesion size was 39 mm and fibrosis was present in 60 %. Technical success was 95,5 %, en-bloc resection 90,3 %, and R0 resection 78,7 %. Median hospital stay was 1 day.

Overall delayed complications occurred in 258 out of 2.112 cases (12,2 %; CI95 % 10,1-13,7). PECS occurred in 7,0 % (CI95 % 5,9-8,9) and delayed bleeding in 5,6 % (CI95 % 4,7-6,7), whereas delayed perforation was rare (1,4 %; CI95 % 0,9-2,0). The median (IQR) length of hospital stay was 3 (2–4) days for any delayed complication, 3 (2–5) days for PECS, 3 (1–5) days for bleeding, and 7 (6–11) days for perforation. Median time to bleeding was 3 days and was longer in anticoagulated patients (6 vs 2 days). All PECS and bleeding cases were managed non-surgically; 48 % of delayed perforations required surgery.

Independent risk factors for overall delayed complications were anticoagulation, larger dissected area, and poor manoeuvrability. PECS was associated with larger area while left-sided location showed a protective effect. Delayed bleeding was strongly associated with anticoagulation and rectal location. Delayed perforation was linked to right-sided and flexural lesions.

Complete prophylactic closure was associated with a lower risk of overall delayed complications and bleeding in crude analyses (OR 0,6; CI95 % 0,4-0,8 vs 0,4; CI95 % 0,2-0,6). After adjustment using PSM, complete closure reduced the absolute risk of any delayed complication by 8,6 % and of delayed bleeding by 5,7 %. In anticoagulated patients, complete closure markedly reduced bleeding risk (absolute reduction ~17 %; NNT ≈ 6).

Conclusions In this large multicentre cohort, delayed complications occurred in 12,2 % of CR-ESDs, with PECS and bleeding being the most frequent, assuming a median increase of 2 days in the length of hospitalisation. Anticoagulation, lesion complexity (larger area or poor manoeuvrability), and specific anatomical locations emerged as key risk factors. Complete prophylactic closure was associated with a reduction in overall delayed complications and delayed bleeding, with a pronounced benefit in anticoagulated patients.

PYP183 Multimodal Endoscopic Management of a Refractory Rectovaginal Fistula After Neovagina Construction

Authors Manara Martins J[1], Bonilha D[1], Giovinazzo Castanho Barros L[1], Darcadia dos Reis T[1], Kreve F[1], Costa R[1], Garcia Montes C[1]
Institute 1 UNICAMP Universidade Estadual de Campinas, Campinas, Brazil
DOI 10.1055/s-0046-1821123

Abstract Text

A 47-year-old transgender woman developed a persistent rectovaginal fistula following neovagina construction. Colonoscopy identified a 5-mm fistulous tract near the dentate line. Initial management included argon plasma coagulation (APC) for edge debridement followed by OTS clip closure (Padlock clip, Aponos Medical Corp, Kingstone, New Hampshire). Due to recurrence, a second session was performed with additional debridement and placement of TTS clips. Because the fistula persisted despite both OTS and TTS clip attempts, we transitioned to endoscopic vacuum therapy (EVT). A handmade negative-pressure system was assembled using an adaptively crafted catheter wrapped in polyurethane material, enabling continuous suction within the fistulous cavity. EVT sessions were repeated with interval reassessment. After two catheter-based vacuum exchanges, the cavity demonstrated marked reduction, robust granulation tissue, progressive collapse of the fistulous tract, and ultimately complete closure. This case highlights EVT as an option rescue therapy for complex rectovaginal fistulas unresponsive to conventional endoscopic closure. A tailored, multimodal endoscopic approach can achieve complete healing while avoiding the need for more invasive surgical interventions [1–3].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Refractory gastroenteric fistulas, whether post-surgical or post-inflammatory, remain a therapeutic challenge. Autologous activated adipose-derived cells (ADSCs) injection is emerging as a minimally invasive option to promote fistula closure. The aim of this report is to describe two cases treated with ADSCs and evaluate safety and preliminary efficacy. Case 1 involved a 64-year-old female patient with a rectovaginal fistula following resection of the sigmoid and proximal rectum for perforated diverticulitis. Case 2 involved an 80-year-old male patient with a rectourethral fistula in the context of post-radiotherapy rectal ulceration for prostate adenocarcinoma. In both patients, autologous adipose tissue was harvested, processed, and injected endoscopically into the fistula tract. At 2.5-month follow-up, both patients showed complete clinical and endoscopic healing without adverse events.

PYP185 Prophylactic Closure After High (>75 %) Circumferential Colorectal Endoscopic Submucosal Dissection: Impact on Stricture Formation

Authors Aslan F[1], Ozer S[1], Aktas O[1], Saka B[1]
Institute 1 Koç University Hospital, Istanbul, Türkiye
DOI 10.1055/s-0046-1821125

Aims Extensive circumferential colorectal endoscopic submucosal dissection carries a high risk of stricture formation. While prophylactic closure reduces this risk, evidence in high circumferential resections (>75 %) remains limited. We evaluated the association between prophylactic closure and stricture formation in high circumferential colorectal ESD.

Methods Retrospective analysis 1,267 consecutive colorectal ESD from a single tertiary center was conducted. High circumferential resection (>75 % or complete circumferential) cases were identified. Primary outcome was stricture formation requiring dilatation. Secondary outcomes included perforation, delayed bleeding, and composite adverse events. Multivariable Firth logistic regression adjusted for lesion size, location (rectum vs colon), malignancy, and procedure duration.

Results 138 (10.9 %) of lesions required >75 % circumferential resection. Prophylactic closure was performed in 40/138 (29.0 %) cases using predominantly suture-based methods: OverStitch (n = 29, 72.5 %), Hemoclips (n = 7, 17.5 %), V-LOC (n = 4, 10.0 %). En bloc resection was achieved in 137/138 (99.3 %). Mean resection duration was significantly shorter in the closure group (118 vs 179 min, p < 0.05). Stricture rates increased with circumferential extent: 0/560 (<50 %), 0/569 (50-75 %), and 10/138 (7.2 %) in >75 % resections (p < 0.001 for trend). Among high circumferential cases, stricture occurred in 0/40 (0 %) with closure vs 10/98 (10.2 %) without closure (p = 0.036) After adjustment for lesion size (OR 1.019 per mm, 95 % CI 1.006-1.032, p = 0.004), rectal location (OR 7.38, 95 % CI 0.40-135), and malignancy (OR 0.62, 95 % CI 0.15-2.48), closure showed a protective trend (adjusted OR 0.061, 95 % CI 0.002-2.17, p = 0.125). Number needed to treat was 10 patients (95 % CI 5-20). Stricture risk increased significantly with lesion size quartiles: Q1 (smallest) 2.6 %, Q2 0 %, Q3 6.1 %, Q4 (largest) 20.6 % (p = 0.007). The protective effect of closure was most pronounced in the largest quartile (0/7 vs 7/27, p = 0.165). Closure was associated with significantly shorter hospital stay (median 2 vs 3 days, mean 2.7 ± 1.42 vs 3.47 ± 1.63 days, p = 0.007). No delayed bleeding occurred in either group. Perforation occurred in 1/40 (2.5 %) with closure vs 0/98 without (p = 0.29). Composite adverse events were numerically lower with closure: 1/40 (2.5 %) vs 10/98 (10.2 %), p = 0.176.

Conclusions Prophylactic closure achieved zero strictures versus 10.2 % without closure and significantly shorter hospital stay in high circumferential colorectal ESD with a number needed to treat of 10. Our findings support routine consideration of prophylactic closure for extensive circumferential colorectal ESD, particularly for large lesions. Prospective multicenter studies with standardized protocols are warranted to validate our findings.

PYP186 First-in-Human Clinical Application of a Next-Generation Robotic Gripper Enabling Traction and Closure in Colorectal ESD

Authors Kim S[1], Lee BM[2], Choi HS[2], Jeen YT[2]
Institutes 1 Korea University, Seoul, Republic of Korea; 2 Korea University Anam Hospital, Seoul, Republic of Korea
DOI 10.1055/s-0046-1821126

Endoscopy 2026; 58: S1–S1041

Aims Endoscopic submucosal dissection (ESD) poses considerable technical challenges and is frequently associated with lengthy procedure times. To improve procedural efficiency, we developed a robotic gripper capable of performing both tissue traction and defect closure. After demonstrating its utility in preclinical experiments, we carried out the first-in-human clinical trial to evaluate its feasibility and safety in colorectal ESD.

Methods From April through June 2025, we performed colorectal ESD with the robotic gripper in 23 consecutive patients at our institution. The primary outcomes assessed were total procedure time, dissection speed, and successful completion of defect closure. Secondary outcomes included the clip count needed for closure and any complications occurring after the procedure.

Results 23 patients with colorectal lesions (mean size, 43.6 ± 4.3 mm) underwent ESD using the robotic gripper. The mean procedure time was 42.8 ± 4.3 minutes, and the average dissection speed was 69.4 ± 18.1 mm^2/min. Complete closure of the mucosal defect was achieved in all cases, requiring a mean of 6.3 ± 2.8 clips per lesion. No delayed bleeding or perforation was observed.

Conclusions This first-in-human evaluation of a robotic dual-function gripper for colorectal ESD showed the device to be feasible, safe, and effective, with clear benefits in traction and closure. These promising results warrant further assessment in larger, multicenter trials.

PYP187V "Endoscopic Transcecal Appendectomy of an Appendiceal Adenoma Using SutuArt and the Pathfinder Rigidizing Overtube: A Feasibility Case"

Authors De María Pallarés P[1], Tavecchia M[1], Martin Arranz E[1], Burgos García A[1]

Institute 1 La Paz University Hospital, Madrid, Spain

DOI 10.1055/s-0046-1821127

Problem to solve Management of Lateral Spreading Tumors (LSTs) involving the appendiceal orifice is technically challenging. While Endoscopic Full-Thickness Resection (EFTR) is an option, deep appendiceal involvement sometimes necessitates appendectomy and is a technique with a significant rate of appendicitis. We present the case of a 63-year-old male with a recurrent 18x10mm homogeneous LST-G completely covering the appendiceal orifice. The patient, presenting with multiple comorbidities and a "hostile abdomen" due to prior surgeries, refused further surgical intervention. This scenario compelled us to explore a purely endoscopic transcecal appendectomy as a salvage therapy [1].

Innovation We describe a Transcecal Endoscopic Appendectomy adapting the technique recently described by Aslan et al. (2025). The primary innovation in this case is the strategic use of the ***Pathfinder*** *(Neptune Medical)* **rigidizing overtube**. Unlike previous reports, we utilized the Pathfinder to overcome marked cecal instability and to facilitate the repetitive insertion and removal of suturing needles. Additionally, we employed ***SutuArt*** *(Olympus)* for intraluminal traction of the appendix and planned muscular closure, combining standard ESD techniques with deep mesoappendix dissection to achieve a complete scarless appendectomy.

Results The lesion was initially circumscribed using ESD (DualKnife J). SutuArt was anchored to the lesion to provide traction into the colonic lumen, and two contralateral sutures were pre-placed in the muscular layer to allow an easy closure in later stages. Following cecal wall perforation, we proceeded with mesoappendix dissection using DualKnife J and IT Nano. The procedure was technically demanding due to marked scope instability (despite the rigidizing overtube) and the **unexpected appendix length (10 cm)**, which required extensive dissection. During this phase, appendicular artery bleeding occurred; **hemostasis was challenging as the abundant mesoappendix fat hindered the precise application of the Coagrasper**, though control was eventually achieved.

After complete inversion and resection of the specimen, the pre-placed muscular sutures had been accidentally cut during the resection. Consequently, mechanical closure was achieved using an *OTSC (Ovesco)* clip, confirming no air leakage. The total procedure time was 6 hours. The patient was discharged on day 4 with oral antibiotics and no complications.

Conclusions Endoscopic transcecal appendectomy is a feasible procedure for complex appendiceal lesions in patients who are unfit for or refuse surgery. The use of a rigidizing overtube (Pathfinder) is highly recommended to stabilize the cecum and manage accessories. However, this technique is extremely labor-intensive and time-consuming (6h) compared to laparoscopic surgery. Therefore, while feasible, it should be reserved for highly selected cases, acknowledging that surgical appendectomy remains the faster and likely safer standard of care.

PYP188 The resection ability of low-power pure-cut hot snare polypectomy for nonpedunculated colorectal polyps smaller than 10 mm: A single-center prospective study

Authors Mizuno R[1], Kimura H[1], Noguchi A[1], Uematsu S[1], Nishida A[1], Inatomi O[1], Iwashita T[1]

Institute 1 Shiga University of Medical Science, Otsu, Japan

DOI 10.1055/s-0046-1821128

Aims Although colorectal polyps smaller than 10 mm are usually removed by cold snare polypectomy (CSP), small polyps sometimes include high-grade dysplasia or intramucosal carcinoma, which require endoscopic resection with electrocautery including hot snare polypectomy (HSP) and endoscopic mucosal resection (EMR), because they have the potential to invade the muscularis mucosa. However, endoscopic resection with electrocautery carries a non-negligible risk of adverse events, including bleeding and perforation, due to deep thermal injury. Thus, low-power pure-cut hot snare polypectomy (LPPC-HSP) has been developed as a minimally invasive technique with low power, low voltage, and no coagulation current [1, 2]. This method uses pure-cut current and reduces the power of electrocautery, expecting less deep thermal damage compared with conventional HSP with blend or coagulation current, resulting in a lower risk of perforation and bleeding. To determine whether LPPC-HSP is appropriate for lesions such as high-grade dysplasia and intramucosal carcinoma that can extend into the muscularis mucosa, it is necessary to examine the actual resection depth of LPPC-HSP; however, its actual resection depth has not been evaluated. This study aimed to investigate the resection ability of LPPC-HSP for small colorectal polyps.

Methods This single-arm, prospective, observational study included patients who underwent LPPC-HSP for nonpedunculated colorectal polyps smaller than 10 mm. For LPPC-HSP, a 10- or 15-mm oval snare with a wire diameter of 0.30 mm (SnareMaster Plus S Olympus Medical Co.) was used without submucosal injection, and the polyps were resected with a low-power pure-cut current (Autocut; VIO300D: effect, 1 [10 W]; VIO3: effect, 0.4). The primary outcome was the rate of sufficient vertical R0 resection (SVR0) [3], defined as R0 resection that included a sufficient submucosal layer beneath the whole lesion. Based on previous studies of EMR for small colorectal polyps, which reported the R0 resection rates of EMR ranging from 62 % to 87.3 % and the containing submucosal tissue rate of 92 %, the expected rate of SVR0 was set at 70 %. With a non-inferiority margin of 10 %, the pre-defined threshold rate was set at 60 %. The secondary outcomes were the en bloc resection rate, the incidence of adverse events, and the pathological evaluation including the R0 resection rate, the proportion of specimens containing muscularis mucosae and the submucosa, and the thickness of the submucosa.

Results Finally, this study included 95 patients with 150 lesions. En bloc resection was achieved in all cases. R0 resection was achieved in 124 lesions (83 %). All specimens contained the muscularis mucosa, and the submucosa tissue was included in 132 lesions (88 %). The median maximum submucosal layer thickness was 1331 µm (IQR, 736-2044). The primary outcome, the SVR0 rate, was 115 lesions (76.7 %; 90 % confidence interval [90 % CI], 70.3–82.2 %). The lower limit of the 90 % CI exceeded the pre-defined threshold of 60 %, thereby meeting the primary endpoint. No bleeding, perforation, or other serious adverse events occurred.

Conclusions The vertical resection ability of LPPC-HSP was acceptable. LPPC-HSP may be applicable to colorectal polyps smaller than 10 mm that have potential malignancy, similar to conventional resection methods with electrocautery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821129

Aims Hybrid dissection techniques combine elements of ESD with snare resection, thus improving safety and efficiency for large or technically challenging colorectal lesions. As literature data is limited, our aim is to show the clinical outcomes of these hybrid techniques.

Methods We retrospectively analyzed 48 consecutive colorectal lesions resected using hybrid techniques. Lesion characteristics, technical outcomes, histology, procedure duration, and adverse events were recorded. Hybrid ESD was defined as circumferential incision with partial submucosal dissection followed by en-bloc snare resection; hybrid EMR involved partial dissection with piecemeal snare resection.

Results Resected lesions had a median size of 29 mm (7–70 mm). Hybrid ESD was performed in 27 cases (56.3 %), achieving en-bloc resection. Overall, complete R0 resection was obtained in 44/48 lesions (91.7 %). Histology showed high-grade dysplasia in 22 lesions (45.8 %) and adenocarcinoma in 10 lesions (20.8 %). The procedures were mostly performed under conscious sedation, median time for resection was 45 ± 22 minutes. Adverse events were seen in 8 cases (16.7 %) mainly bleedings, but also 3 cases of perforation – all managed endoscopically.

Conclusions Hybrid dissection techniques achieved high en-bloc and R0 resection rates for large colorectal lesions. These procedures are relatively quick and show a low complication rate (fully manageable by endoscopy). These findings support hybrid ESD/EMR as effective and safe for selected colorectal neoplastic lesions in clinical practice

DOI 10.1055/s-0046-1821130

Aims Underwater endoscopic mucosal resection (UEMR) is an emerging technique for the management of large, benign colonic polyps, with higher en bloc and R0 resection rates and shorter procedure time compared to conventional EMR. Its role in the management of polyps suspicious for submucosal invasion is yet to be defined. Few studies have investigated the depth of resection with UEMR, with inconsistent results when compared to conventional EMR. No studies have compared UEMR with endoscopic submucosal dissection (ESD). We aimed to compare the resection depth of UEMR and ESD for large (20-30mm) non-pedunculated colonic polyps.

Methods We performed a retrospective cohort study at a single UK tertiary referral centre from 2015 to 2024. All en bloc resections by UEMR or ESD of 20-30mm colonic polyps were included. Pedunculated or semi-pedunculated polyps, recurrent polyps and patients with inflammatory bowel disease were excluded. Histopathological samples were retrospectively reviewed, with measurement of maximum and minimum submucosal (SM) resection depths, measured from the muscularis mucosae. Primary outcome was the depth of SM in the resected specimen. Secondary outcomes included R0 resection rate, vertical margin (VM) positivity (defined as < 0.1mm) in cases of adenocarcinoma, and rates of deep mural injury (DMI).

Results 29 UEMR and 27 ESD resections were identified. Median lesion diameter was similar between the two groups (22 vs 25mm). Lesions resected by UEMR were more commonly protruding (69 % vs 26 %) and in the right colon (93 % vs 48 %), with ESD resections more commonly flat lesions in the left colon. Median maximum SM was significantly higher with UEMR (4.2 vs 1.75mm; $p < 0.001$). There was no significant difference in median minimum SM depth (0.4 vs 0.5mm). Median maximum SM depth was significantly higher with UEMR for both protruding (5.5 vs 2.25mm; $p = 0.015$) and flat lesions (2.3 vs 1.5mm; $p = 0.009$). 20/29 UEMR and 27/27 ESD specimens were pinned. Comparing pinned vs unpinned UEMR specimens, there was no significant difference in median maximum SM depth (3.5 vs 5.5mm; $p = 0.22$). There was no significant difference in R0 resection rates between UEMR and ESD (76 % vs 93 %; $p = 0.15$). One T1b adenocarcinoma was resected by UEMR, with positive VM. Three T1a adenocarcinomas were resected by ESD, all with negative VM. Three T1b adenocarcinomas were resected by ESD, 1/3 with positive VM. DMI (type III) was observed in one UEMR resection. There were no perforations in either group.

Conclusions In our study, en bloc UEMR achieves significantly greater maximum SM depth than ESD in both flat and protruding colonic polyps 20-30mm in diameter. R0 resection and complication rates were similar between techniques. Prospective comparative studies are needed to define the role of UEMR in managing colonic lesions suspicious for superficial submucosal invasion.

DOI 10.1055/s-0046-1821131

Aims Difficult extraction of common bile duct (CBD) stones remains a major determinant of ERCP safety, duration, and resource use. Although several factors have been proposed, robust real-life predictors applicable across centers are limited. This study aimed to identify simple, universally accessible radiologic and endoscopic parameters associated with difficult CBD stone extraction and to derive a practical predictive score.

Methods All ERCPs performed for confirmed choledocholithiasis between 2016 and 2024 were retrospectively reviewed. Difficult extraction was defined as incomplete duct clearance during index ERCP, the need for mechanical lithotripsy, or requirement for repeat ERCP. Predictors included pre-procedural imaging findings (CBD diameter and stone burden on US/CT/MRI) and endoscopic parameters (stone size and number at cholangiography, papillary morphology including peri-/intradiverticular papilla, and early difficult-cannulation indicators such as pancreatic duct injection).

Results Among 773 patients, 224 (29.0 %) experienced difficult extraction. Stone size ≥ 15 mm was the strongest predictor (OR 4.6), followed by stone burden ≥ 3 stones (OR 1.7) and CBD dilation ≥ 12 mm (OR 1.6). Papillary anatomic difficulty (distorted or diverticular papilla) and early pancreatic duct injection markedly increased risk (OR 3.0). The strength and consistency of these predictors aligned with international series. Based on the most robust variables, a simple D-ERCP Score (0–6 points) was developed:

- Stone ≥ 15 mm: + 2
- ≥ 3 stones: + 1
- CBD ≥ 12 mm: + 1
- Difficult-cannulation indicator: + 2

Risk of difficult extraction increased stepwise: 7 % (0–1 points), 28 % (2–3 points), and 64 % (≥ 4 points).

Conclusions Nearly one-third of CBD stone extractions were difficult. Four routinely obtainable parameters—stone size, stone burden, duct dilation, and early difficult-cannulation signs—consistently predicted technical complexity. The D-ERCP Score, derived from a large real-world cohort, provides a practical, universally applicable tool to anticipate difficult extractions, optimize procedural planning, and improve the safety and efficiency of ERCP in routine practice.

PYP192 CBD stent after ERC for CBD Stones in patients who have gall stones: “To put or not to put, that is the question”!

Authors Desai PN[1], Chintan P[1], Mayank K[1], Prajapati R[1], Patel N[1], Sethia M[1], Rajiv M[1], Nandwani S[1]

Institute **1** SIDS Hospital & Research Centre, Surat, India

DOI 10.1055/s-0046-1821132

Aims To assess the necessity to placed CBD stents after stone extraction in patients with co existent gall stones.

Methods Background:Whether CBD stents should be routinely placed following ductal clearance in patients who also have gallstones remains controversial. Our unit follows a uniform protocol of placing a 7Fr plastic double-pigtail (DPT) stent in all such patients after stone extraction. Cholecystectomy is subsequently performed either the same day, after 24 hours (most common), within one week, or later based on patient preference. Stents are removed four weeks after cholecystectomy with mandatory fluoroscopic assessment and CBD clearance. This retrospective analysis aimed to determine whether this routine stenting protocol is justified.

Methods: All patients who underwent ERC for CBD stones between 2021 and 2024 were included. Patients with CBD stones on any imaging modality and co-existent gallstones were analyzed. Standard ERC techniques—including sphincterotomy, large-balloon sphincteroplasty, and laser lithotripsy—were used for stone extraction. A 7Fr DPT stent was routinely placed post-extraction; in Type I Mirizzi’s syndrome, a 10Fr stent was used due to frequent cholangitis. Cholecystectomy timing varied per protocol. Stent removal four weeks post-surgery included fluoroscopy to assess migration, extraction of retained stents, and balloon or basket sweeps to document residual stones. The primary outcomes were spontaneous distal migration of stents and presence of stones at stent removal. Subgroup analysis examined single versus multiple CBD stones and Mirizzi’s syndrome.

Results Of 1,363 ERCs for stone disease, 1,162 patients (85.3 %) had both CBD stones and gallstones. Stents were placed in all 1,162 cases. A total of 1,044 patients (89.8 %) returned for stent removal; 118 (10.2 %) were lost to follow-up. Spontaneous stent migration occurred in 209 patients (20.1 %), while 835 (79.9 %) had retained stents. Among those with retained stents, 149 patients (17.8 %) had stones detected during removal.

Subgroup analysis (n = 835):

- Single stone at index ERC: 482 patients (57.7 %); stones at removal 39 (8.1 %).
- Multiple stones at index ERC: 274 patients (32.8 %); stones at removal 67 (24.5 %).
- Mirizzi’s syndrome: 79 patients (9.5 %); stones at removal 42 (53.1 %).

Discussion This large retrospective series demonstrates a substantial risk of residual or recurrent CBD stones after cholecystectomy in patients who initially present with CBD stones and gallstones. The likelihood varies significantly with clinical scenario: patients with a single CBD stone had the lowest risk, while those with multiple stones had nearly a quarter incidence of residual stones. The highest risk occurred in Mirizzi’s syndrome, where over half had stones at stent removal. This may be explained by surgical difficulty and frequent failure to extract deeply impacted stones, particularly in centers without routine operative cholangiography or fluoroscopic guidance.

The presence of a dilated CBD that initially allowed stone migration likely persists until after surgery; manipulation of the gallbladder during cholecystectomy can precipitate additional stones into the CBD. Routine stenting ensures unobstructed drainage, facilitates safe interval surgery, and provides an opportunity for definitive duct clearance at the time of stent removal. Double-pigtail stents are preferred due to a tendency for distal rather than proximal migration, minimizing the need for complex retrieval.

Conclusions Given the significant rate of stones detected during planned stent removal—ranging from 8 % in single-stone cases to over 50 % in Mirizzi’s syndrome—routine placement of a CBD stent following ERC appears justified in

patients with gallstones. DPT stents provide higher safety against proximal migration and high spontaneous distal migration, and systematic duct clearance at stent removal is essential to prevent post-cholecystectomy cholangitis.

PYP193 Endoscopic Management of Difficult CBD Stones in the Era of Cholangioscopy and Laser Lithotripsy—Do We Really Need Them in Every Case?

Authors Desai PN[1], Chintan P[1], Mayank K[1], Prajapati R[1], Rajiv M[1], Nandwani S[1], Sethia M[1], Patel N[1]

Institute 1 SIDS Hospital & Research Centre, Surat, India

DOI 10.1055/s-0046-1821133

Aims To analyze a large series of CBD stones with emphasis on techniques that can be used in difficult stones effectively and how often do we need to resort to cholangioscopy and laser or EHL.

Methods Background: Endoscopic retrograde cholangiopancreatography (ERCP) remains the cornerstone intervention for common bile duct (CBD) stone disease. With the advent of cholangioscopy-guided lithotripsy and laser fragmentation technologies, their increasing availability has prompted debate regarding their necessity in routine practice. This study analyses outcomes from a large series of 3000 biliary ERCPs, evaluating the true requirement for advanced modalities, with a focus on case distribution, anatomical challenges, and treatment success using standard versus advanced techniques.

Methods: A retrospective evaluation was conducted on 3000 consecutive biliary ERCP procedures. Cases were classified into stone disease (n = 2410) and other biliary indications (n = 590). Difficult stones were those, that were not amenable to simple balloon or basket extraction and required additional procedures for removal. This included the standard defined criteria of stone size more than 15mm, stone duct ratio > 1, anatomical variations and varied shape of the stones. Procedural outcomes, modalities used, and factors influencing technique selection were analysed. Data are presented as descriptive statistics, with tables included in text format.

Results Of 3000 ERCPs, 2410 (80.3 %) were performed for stone disease and 590 (19.7 %) for other biliary conditions. Among stone cases, 1868 (77.5 %) were considered easy stones, successfully managed with traditional extraction techniques. A total of 532 cases (22.1 %) were classified as difficult stones.

Summary Of Cases: Category — Number — Percentage

Total ERCP procedures — 3000 (100 %), Stone disease — 2410 (80.3 %), Other biliary disease — 590 (19.7 %), Easy stone cases — 1868 (77.5 %), Difficult stone cases — 532 (22.1 %), Non-calcified stones retrieved with balloon/basket — 118 (22.2 %), Anatomical abnormalities — 79 (14.8 %), Distal CBD narrowing — 29 (5.5 %), Impacted stones requiring cholangioscopy/laser — 10 (1.9 %)

Of the 532 difficult stones, non-calcified stones were 118 (22.2 %), all successfully extracted using balloon or basket. Anatomical abnormalities- 79 cases (14.8 %), necessitating large balloon sphincteroplasty.

Breakdown of Anatomical Abnormalities (n = 79), Duodenal deformity — 50 (63.3 %), Pouch formation above papilla — 20 (25.3 %), Papillary fibrosis — 9 (11.4 %)

Distal CBD narrowing -29 cases (5.5 %). True narrowing – 9 (31 %), 20 (69 %) involved faceted or square-shaped stones with normal distal duct calibre.

Distal CBD Narrowing Details (n = 29), True distal CBD narrowing — 9 (31 %), Faceted/square stones with normal CBD — 20 (69 %)

Mechanical lithotripsy was required in 29 cases (5.5 %), predominantly in those with distal narrowing or large, faceted stones. Only 10 cases (1.9 % of difficult stones; < 0.5 % of all ERCPs) required cholangioscopy and laser lithotripsy due to severely impacted stones where no space was available for balloon or basket manipulation.

Treatment Modalities for Difficult Cases (n = 532), Traditional balloon/basket extraction — 118 (22.2 %), Large balloon sphincteroplasty — 79 (14.8 %), Mechanical lithotripsy — 29 (5.5 %), Cholangioscopy with laser lithotripsy — 10 (1.9 %)

Conclusions This analysis demonstrates that the majority of difficult CBD stones, can be effectively managed using conventional or standard advanced endoscopic techniques such as balloon/basket extraction, large balloon sphincteroplasty, or mechanical lithotripsy. These findings support a stratified, anatomy- and stone-based approach rather than universal deployment of cholangioscopic laser systems in all ERCP units.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP194 Safety and efficacy of Electrohydraulic Lithotripsy for difficult bile duct stones in patients receiving Monitor Anesthesia Care: data from a tertiery center

Authors Panagaki A[1], Aggelopoulos G[1], Efstathiou S[2], Arahoviti DA[3], Giannakopoulos A[1], Tziatzios G[4], Androutsos N[5], Likoudi E[5], Koutsoukos G[5], Kontadaki A[5], Mikrovasisli M[5], Makridaki D[5], Themistokleous E[5], Mastrokosta E[1], Triantopoulou C[1], Paraskeva K[4]

Institutes 1 Konstantopouleio-Patision General Hospital of Nea Ionia, Athens, Greece; 2 Department of Gastroenterology, General Oncology Hospital of Kifisia Oi Agioi Anargyroi, Athens, Greece; 3 Metaxa Cancer Hospital Piraeus, Pireas, Greece; 4 Department of Gastroenterology, General Hospital of Nea Ionia "Konstantopoulio-Patision", Athens, Greece; 5 Konstantopoulio General Hospital, Nea Ionia, Greece

DOI 10.1055/s-0046-1821134

Aims Electrohydraulic lithotripsy (EHL) via cholangioscopy is a complex and prolonged endoscopic technique, compared with routine ERCP, carrying a higher risk of aspiration due to continuous water irrigation of the bile duct. It may be performed under general anesthesia with endotracheal intubation or under monitored anesthesia care (MAC). The aim of this study was to evaluate the safety and efficacy of EHL in relation to the afore-mentioned types of sedation.

Methods We retrospectively reviewed all EHL sessions performed in a single tertiary center between 01/01/2023 and 24/06/2025 by an experienced endoscopist. Patients were classified into two groups, based upon on pre-procedure anesthesiology assessment. The first group consisted of high risk patients (ASA > III, sleep apnea, BMI > 35, Mallampati IV/difficult airway) who underwent general anesthesia while the second group included patients without increased anesthetic risk who underwent MAC.

Results Over a three years, period, 80 cholangioscopies were performed, including 40 EHL sessions in 33 patients (73 %, female n = 24), with a mean age of 69 ± 21 years. General anesthesia was used in 22 % (n = 9) and MAC in 78 % (n = 31) of the cases. The mean procedure time was 66.6 min (range 40 to 129 min) and the mean f fluoroscopy time was 5.22 min (range 0.18 -12.1 min). Procedure duration did not differ significantly between the two groups (70.1 ± 15.5 min general anesthesia vs. 65.8 ± 19.5 min MAC, p = 0.59). Successful completion of ERCP was achieved in 97 % (32/33) patients, requiring a mean number of 1.3 sessions per patient (range 1 – 3). In 82 % of patients (n = 27) one EHL session was required, in 15 % (n = 5) two sessions and in 3 % (n = 1) > 3 sessions. No immediate complications (aspiration, cardiopulmonary event) occurred in patients that underwent MAC.

Conclusions Electrohydraulic lithotripsy via cholangioscopy appears to be both safe and effective when performed under MAC in a well-organized center with expertise in ERCP and Cholangioscopy. MAC represents a feasible alternative to general anesthesia for appropriately selected patients.

DOI 10.1055/s-0046-1821135

Aims Large bile duct stone removal in patients with surgically altered anatomy (SAA) is technically challenging. Although balloon-enteroscopy-assisted endoscopic retrograde cholangiopancreatography (BE-ERCP) has been widely adopted, endoscopic ultrasound-guided treatment (EUS-T) may achieve higher stone removal rates owing to improved device accessibility after anastomosis creation. This multicenter retrospective study aimed to compare the clinical outcomes of EUS-T and BE-ERCP for large bile duct stones in patients with SAA.

Methods Patients with SAA who underwent EUS-T or BE-ERCP for large bile duct stones (≥12 mm) between January 2016 and February 2025 were included. The primary outcome was the complete stone removal rate. Secondary outcomes included the number of sessions, procedure time, and adverse events. Propensity score matching was applied to adjust for baseline differences between groups (▶ **Table 1**).

▶ **Table 1**

	EUS-T (n = 21)	BE-ERCP (n = 21)	*P*-value
Age, mean (± SD), years	78.6 ± 9.1	79.0 ± 8.1	.369
Female:Male, n (%)	8:13	8:13	1.000
ASA-PS ≥ 3	1 (4.7)	2 (9.5)	.604
Etiology of surgery, n (%)			.753
Malignant	8 (38.1)	9 (42.9)	
Benign	13 (61.9)	12 (57.1)	
Surgical reconstruction, n (%)			.081
Billroth type 2	0 (0)	4 (19.0)	
Roux-en-Y	16 (76.2)	11 (52.4)	
Others	5 (23.8)	6 (28.6)	
Hepaticojejunostomy, n (%)	8 (38.1)	7 (33.3)	.747
Time from surgery to procedures, years, mean (± SD)	18.8 ± 13.5	19.4 ± 18.2	.232
Stone diameter, mean (± SD)	14.7 ± 3.2	14.4 ± 2.8	.581

▶ **Table 1**

	EUS-T (n = 21)	BE-ERCP (n = 21)	*P*-value
The number of stone, mean (± SD)	2.3 ± 2.1	2.0 ± 1.1	.172
Stone location, n (%)			.572
Common bile duct	15 (71.4)	15 (71.4)	
Lest intrahepatic duct	5 (23.8)	5 (23.8)	
Right intrahepatic duct	0 (0)	1 (4.8)	
Left and right intrahepatic duct	1 (4.8)	0 (0)	
Complete stone removal, n (%)	19 (90.5)	13 (61.9)	.030*
Complete stone removal at the first procedure time, n (%)	6 (28.6)	10 (47.6)	.204
Total number of sessions, mean (± SD)	2.1 ± 1.1	1.2 ± 0.4	< .001*
Total procedure time, mean (± SD) min	135.1 ± 94.7	92.4 ± 39.9	< .001*
Mean procedure time, mean (± SD) min	59.8 ± 27.1	78.9 ± 30.2	.593
AE, n (%)	2 (9.5)	1 (4.8)	.549

Results In total, 22 EUS-T and 87 BE-ERCP procedures were analyzed. After matching, the complete stone removal rate was significantly higher in the EUS-T group than in the BE-ERCP group (90.5% vs. 61.9%, *P* = .030), despite a greater number of sessions (2.1 vs. 1.2, *P* < .001). Mean procedure times and adverse event rates were comparable. Cumulative success significantly improved up to the third session in EUS-T (first session, 27%; third, 86) and the second in BE-ERCP (first, 46%; second, 69%). Severe adverse events occurred only in the BE-ERCP group.

Conclusions EUS-T achieved a higher complete stone removal rate than BE-ERCP without increased risk, suggesting it may be a viable first-line treatment for large bile duct stones in patients with SAA.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP196 Forward-viewing endoscopy with cap-fitting versus side-viewing duodenoscope for ERCP in Billroth II gastrectomy: a systematic review and meta-analysis

Authors de Carvalho Bertaccini Guriam G[1], Hissayassu GY[2], Santos VDC[2], Dutra LP[3]

Institutes **1** Department of Endoscopy, São Francisco Hapvida Hospital, Ribeirão Preto, São Paulo, Brazil, Ribeirao Preto, Brazil; **2** Leforte Hospital, Department of Endoscopy, São Paulo, São Paulo, Brazil, são Brazil; **3** Universidade Cidade de São Paulo, São Paulo, São Paulo, Brazil, São Paulo, São Paulo, Brazil, Brazil

DOI 10.1055/s-0046-1821136

Aims To compare the efficacy and safety of cap-fitted forward-viewing endoscopy versus side-viewing duodenoscopy for ERCP in patients with prior Billroth II gastrectomy.

Methods A systematic-review of PubMed, Scopus, Embase and Cochrane Library was performed to include randomized trials and observational studies evaluating ERCP in Billroth II anatomy comparing cap-fitted forward-viewing endoscopes with duodenoscopes. data extraction. The restricted estimation likelihood random-effects was applied to pool studies effects as risk ratios (RR).

Statistical significance was considered as $p < 0.05$. Outcomes were pooled using both patients and procedures as the units of analysis whenever data allowed [1–7].

Results Seven studies met the inclusion criteria, comprising 433 patients and 516 ERCP procedures. Across all efficacy outcomes, no statistically significant differences were identified between cap-fitted forward-viewing endoscopy and side-viewing duodenoscopy. Afferent limb intubation rates were virtually identical (RR 1.00; 95 % CI 0.97–1.04), and cannulation success likewise showed similar performance between techniques (RR 0.96; 95 % CI 0.80–1.10). Clinical success rates were also comparable (RR 1.02; 95 % CI 0.87–1.20).

Safety outcomes demonstrated comparable overall adverse event profiles between groups. However, relevant non-significant trends were consistently observed. Forward-viewing endoscopy with cap showed a trend toward higher post-ERCP pancreatitis (RR 2.23; 95 % CI 0.66–7.54). Conversely, a trend toward lower perforation rates was noted with cap use (RR 0.52; 95 % CI 0.09–3.08), in line with reports suggesting that cap-assisted techniques may provide improved visualization and safer advancement in altered anatomy. All pooled analyses exhibited minimal heterogeneity ($I^2 = 0$ %), reinforcing the consistency of results across studies.

Conclusions This is the first meta-analysis to directly compare cap-fitted forward-viewing endoscopy and side-viewing duodenoscopy for ERCP in patients with Billroth II gastrectomy. Our findings demonstrate that both techniques offer comparable overall efficacy and safety. Although no statistically significant differences were identified, consistent trends were observed: the cap-fitted approach showed a tendency toward higher rates of post-ERCP pancreatitis, whereas perforation appeared to be less frequent. These results highlight a more nuanced risk–benefit profile that may support individualized technique selection based on patient anatomy, procedural objectives, and operator expertise. The consistent directionality of these trends reinforces the need for high-quality prospective studies to clarify true risk differences and refine endoscope selection algorithms in altered anatomy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP197 Can Ultrasound Alone Guide ERCP? A Large Real-Life Analysis in Clinically Suggestive Choledocholithiasis

Authors Dendane Y[1], Azarkan A[1], Elmqaddem O[2], Koulali H[3], Kharrasse G[4], Zazour A[5], Ismaili Z[6]

Institutes **1** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Morocco, Oujda, Morocco; **2** Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Oujda, Morocco; **3** Mohammed VI University Hospital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **4** Mohammed VI University Hôpital, Hepato Gastro Enterology Unit, Oujda, Morocco, Oujda, Morocco; **5** Mohammed VI University Hospital Center, Digestive Disease Research Laboratory, Oujda, Morocco; **6** Oujda, Morocco

DOI 10.1055/s-0046-1821137

Aims In many healthcare systems, transabdominal ultrasound (US) is still the only morphologic evaluation performed before ERCP, despite its uncertain stand-alone diagnostic value. In settings where access to further imaging may delay care, determining when US alone is sufficient becomes clinically relevant. Whether US can independently justify ERCP in clinically and biochemically suggestive choledocholithiasis remains unclear. We aimed to determine the real-world accuracy of US as the sole pre-ERCP imaging tool and to identify actionable ultrasound criteria that can safely streamline the diagnostic pathway.

Methods All ERCPs performed for suspected CBD stones between 2016–2024 were retrospectively analyzed. Eligible patients had an evocative clinical presentation, a cholestatic profile, and an interpretable pre-ERCP US. US was considered positive when stones were explicitly described; CBD diameter was recorded. The reference standard was cholangiographic stone visualization, stone retrieval, or confirmed complete duct clearance. Diagnostic accuracy parameters were calculated, and CBD diameter cut-offs were evaluated.

Results Among the 1,092 ERCPs performed for suspected CBD stones during the study period, 837 procedures in 515 patients fulfilled inclusion criteria. Choledocholithiasis was confirmed in 510 patients (99.0 %). US identified stones in 74.0 %. Direct stone visualization yielded a sensitivity of 73.7 % and a positive predictive value of 99.1 %. No true negative case was observed, resulting in a specificity and negative predictive value of 0 %. In the subgroup with measurable CBD diameter (n = 421), a threshold of 8 mm achieved a sensitivity of 94.7 % and a positive predictive value of 98.7 %, clearly outperforming direct stone detection.

Conclusions In clinically and biologically suggestive choledocholithiasis, US used as the sole imaging modality consistently confirmed—but never excluded—the diagnosis. A positive US—either via direct stone detection or a CBD ≥ 8 mm—strongly supported proceeding directly to ERCP, enabling timely therapeutic management while avoiding delays linked to additional imaging. In contrast, a negative US remained unsafe and systematically required complementary imaging. These data refine the practical role of ultrasound in the diagnostic algorithm and provide robust real-life evidence relevant to everyday endoscopy practice, particularly in resource-limited settings.

DOI 10.1055/s-0046-1821138

Aims The main objective was to assess the rate of EUS choledocholithiasis confirmation in patients with clinical suspicion of CBD stones and to identify predictors for choledocholithiasis. The secondary objective was to develop and

internally validate a simplified clinical prediction score to refine risk stratification in patients with high-risk of choledocholithiasis according to the ESGE criteria [1–3].

Methods We performed a retrospective study including patients who underwent EUS for suspected choledocholithiasis between January 2023 and December 2024 in a tertiary referral center. Multivariate logistic regression was performed to identify independent predictors of retained CBD stones. A simplified score was constructed based of the final model. Internal validation of the score was performed through receiver operating characteristic (ROC) analysis. Sensitivity and specificity for candidate thresholds were obtained from ROC coordinates.

Results Of the 438 patients were evaluated for eligibility, 186 patients were included. 86 patients were diagnosed on EUS with choledocholithiasis and ERCP was performed. After ESGE criteria risk stratification, 10 patients (5.4 %) were found to have a low risk for lithiasis, 92 (49.5 %) were classified as having intermediate risk, and 84 (45.2 %) met high-risk criteria. In the latter subgroup, EUS confirmed choledocholithiasis in 45 patients (53.5 %), whereas 39 (46.4 %) had spontaneous clearance of the CBD. Multivariate analysis identified acute pancreatitis (aOR 0.075, $p < 0.001$), cholangitis (aOR 6.939, $p = 0.015$), and CBD diameter (aOR 1.220 per mm increase, $p = 0.027$) as independent predictors of retained stones. A three-component score (range − 2 to + 4 points) was developed incorporating these variables. Internal validation showed a good accuracy of the score, with an AUROC of 0.788. A threshold of ≥ 2 points provided optimal performance, with a sensitivity of 85.7 % and specificity of 59.0 %. Higher thresholds increased specificity (e.g., ≥ 3 points: 89.7 %) at the cost of reduced sensitivity.

Conclusions In nearly half of the patients that presented high risk for choledocholithiasis according to ESGE criteria EUS did not confirm CBD stones, suggesting that routine ERCP in this subgroup should be carefully considered. Acute pancreatitis, cholangitis, and EUS-measured CBD diameter independently predicted retained stones and enabled the development of a simple prediction score with good internal discriminative performance. Incorporating EUS into the evaluation of ESGE high-risk patients, and applying refined risk stratification tools may improve diagnostic accuracy and help avoid performing ERCP without a clear benefit.

DOI 10.1055/s-0046-1821139

Aims Cholangioscopy performed during endoscopic retrograde cholangiopancreatography (ERCP) can facilitate the management of complex biliary stones and improve the evaluation of biliary strictures. Treating biliary disease in patients with surgically-altered anatomy or an inaccessible ampulla, however, remains a particular challenge. Historically, antegrade cholangioscopy (AC) has been performed through the tract of a prior percutaneous transhepatic biliary drain (PTBD). More recently, options for AC have included cholangioscope insertion following EUS-guided hepatico-gastrostomy (HGS). The aim of this study was to review the approach and outcomes of AC in patients treated at a large specialist hepatopancreatobiliary (HPB) centre.

Methods We performed a retrospective review of all patients who underwent AC at a large HPB centre between January 2020 and October 2025. Procedures were performed either via IR-PTBD or EUS-HGS using a Spyglass cholangioscope (Boston Scientific Inc) (with Spyglass Discover used for percutaneous cases since 2021). Patient demographics, surgical anatomy, procedural indications, techniques, and clinical outcomes were analysed.

Results A total of 25 patients underwent AC (median age was 64 years, 52 % male), within an overall total of 3019 biliary endoscopic procedures/ERCPs (< 1 %). All patients were discussed in a multi-disciplinary team meeting (MDM) prior to their procedure. Indications for cholangioscopy included management of stone disease (19 patients (76 %)) and biliary stricture assessment (6 (24 %)). An antegrade approach was required in 23 patients (92 %) due to surgically-altered anatomy which precluded transpapillary access. Of these 13 (52 %) had a Roux-en-Y hepaticojejunostomy, 5 (20 %) had a Roux-en-Y gastric bypass, 2 (8 %) had a Roux-en-Y Whipple's procedure, 2 (8 %) had a total gastrectomy with Roux-en-Y reconstruction and 1 (4 %) had a Billroth II gastrectomy. In the 2 patients (8 %) without surgically-altered anatomy, one patient had had extensive head and neck surgery which precluded oesophageal intubation, and in the other patient an uncovered metal stent through the right hepatic system prevented retrograde left-sided access via ERCP. AC was performed via PTBD in 22 (88 %) patients and EUS-HGS in 3 (12 %) patients. All procedures were performed with anaesthetic support (Propofol or general anaesthesia). In those undergoing percutaneous AC, prior PTBD was inserted between 4-365 days (median 59 days) prior to AC. Extended duration of PTBD related to intervention prior to referral for consideration of AC. Patients with HGS had their fully covered metal stents changed to plastic double pigtail stents to retain access. 23 patients (92 %) had antibiotics at the time of AC, and these were continued for at least 3 days afterwards. Clinical success, defined as stone clearance or diagnosis clarification, was achieved in all patients. In 2 patients with intrahepatic stones above a previous biliary anastomosis, a biodegradable balloon-expandable stent (Unity B™, Q3-Medical) was placed to facilitate biliary patency and stone fragment passage. One patient (4 %) developed post-procedure bleeding following PTBD catheter removal requiring IR-guided embolisation and a 6-day ICU admission. There was no mortality at 30 days from the procedure. In 3 of 6 patients undergoing AC for stricture assessment, a diagnosis of malignancy was made on Spybite biopsy-directed histology.

Conclusions In this single-centre experience, AC was required in < 1 % of cases but provided a valuable tool where conventional papillary access was precluded. Biliary access, intraductal visualisation, and therapy were successful via both PTBD and EUS-HGS, and insertion of the 3.5mm (10F) cholangioscope to the required site within the biliary tree was achieved in all cases. Stone therapy with EHL for stone disease was effective, but it was observed that clearing stone fragments from the biliary tree was more challenging with an antegrade approach than with a conventional ERCP. AC appears to be safe, with the only observed complication related to prior PTBD insertion. Further advances in cholangioscope development (e.g. smaller-calibre cholangioscopes) and the expanding use of EUS-guided antegrade biliary access may broaden the role and clinical applications of AC.

DOI 10.1055/s-0046-1821140

Aims Biliary acute pancreatitis (AP) in pregnancy poses unique management challenges, and current guidelines in pancreatology, obstetrics, and surgery lack specific recommendations. This study evaluated the safety and effectiveness of cholecystectomy and endoscopic retrograde cholangiopancreatography (ERCP) performed during pregnancy.

Methods This international retrospective multicenter cohort study collected data on demographics, clinical presentation, management strategies, timing and type of cholecystectomy, procedural approaches, complications, and outcomes. Continuous variables were reported as medians with interquartile ranges, while categorical variables were presented as frequencies and percentages. Group comparisons were performed using Welch's t-test, Pearson's chi-squared test, or Fisher's exact test.

Results A total of 101 cases from 14 countries and 19 centers were included. Following mild AP during pregnancy, cholecystectomy was associated with a lower readmission rate due to recurrent AP or other gallstone-related complications compared with conservative management (0 % vs 24 %; n = 0/17 vs n = 12/49; p = 0.027). Cholecystectomy during pregnancy had a low complication rate, comparable to postpartum surgery (12 % vs 10 %; n = 2/17 vs n = 3/30; p > 0.999). Preterm birth occurred in 7.1 % (n = 1/14) of patients who underwent cholecystectomy versus 11 % (n = 5/45) without surgery. Fetal loss after surgery was observed only during the first trimester (n = 3/17 vs n = 1/49).Regarding ERCP, no significant differences were observed between the surgical and ERCP groups in rates of readmission (5 %, n = 1/21 vs 27 %, n = 4/15; p = 0.138), fetal loss (5 %, n = 1/21 vs 27 %, n = 4/15; p = 0.138), or preterm birth (6 %, n = 1/17 vs 8 %, n = 1/12; p > 0.999). Likewise, among patients who underwent ERCP versus those who did not, fetal loss (9.1 %, n = 2/22 vs 5.4 %, n = 4/74; p = 0.618) and preterm birth rates (5.9 %, n = 1/17 vs 12 %, n = 8/65; p = 0.677) did not differ significantly.

Conclusions Cholecystectomy is safe and effective in the second and third trimesters after a mild biliary pancreatitis during pregnancy, while ERCP can be safely performed in any trimester.

PYP201 Innovative Nursing Maneuvers for Difficult Colonoscopies

Authors Mazzarini R[1], Leonardi P[1]

Institute **1** Senigallia Hospital, Senigallia, Italy

DOI 10.1055/s-0046-1821141

Aims Nursing support plays a crucial role during colonoscopy, particularly when anatomical complexity impedes progression to the cecum (1). In our unit, four non-standardized maneuvers have proven effective in improving scope advancement during challenging cases. We aim to describe and propose these techniques as part of the nursing endoscopic toolbox.

Methods

1."Jockey maneuver" for sigmoid reduction

When the scope tip stalls in the ascending colon and fails to reach the cecum, the nurse applies pressures from the left iliac fossa and flank area, directing the sigmoid and discendig colon toward the umbilicus. This maneuver mobilizes and straightens redundant sigmoid loops that may be stealing propulsion force or forming a hidden loop.

2. "Cyclist maneuver" – variant of the "Jockey maneuver"

When the scope tip stalls in front of the ileocecal valve and fails to reach the cecum, the nurse applies a single, pulsating pressure from the left iliac fossa and flank area toward the umbilicus. This maneuver can provide just enough additional propulsion force to reach the cecum.

3. "Jingle maneuver" – exploratory rhythmic pressure

When scope advancement is impaired and it is unclear where support is needed, the nurse applies light, rhythmic, pulsating pressure over different areas of the abdomen. This technique helps identify hidden loops and the most effective location for abdominal pressure to assist progression.

4. Lever-based maneuver for the hepatic flexure

The nurse places their hand under the right costal margin and applies a downward and medial pressure, mimicking the action of a crowbar. This creates a mechanical leverage effect, helping to straighten the hepatic flexure and facilitate forward scope movement through the ascending colon

Results In our preliminary observational experience, these maneuvers improved cecal intubation rates, enhanced patient comfort, and reduced the need

for scope withdrawal due to looping. They are simple, reproducible, and expand the active role of trained endoscopy nurses during procedures.

Conclusions These hands-on techniques may be standardized in nursing protocols and deserve further clinical validation. Their inclusion could help optimize difficult colonoscopies and enhance the technical contribution of nursing staff in the endoscopic setting.

PYP202 Nursing clinical competence in the management of percutaneous endoscopic gastrostomy (PEG): a prospective observational study among hospital and community nurses of AUSL Piacenza

Authors Benedetti E[1], Droghi MG[2], Citterio C[3], Fava D[4], Sarti R[5], Contini A[4], Aragona G[6]

Institutes **1** Digestive Endoscopy Unit, AUSL Piacenza, Piacenza, Italy, Piacenza, Italy; **2** Health and social professions department, AUSL Piacenza, Piacenza, Italy, Piacenza, Italy; **3** Innovation, research and quality unit, AUSL Piacenza, Italy, Piacenza, Italy; **4** Health and social professions department, AUSL Piacenza, Piacenza, Italy, Piacenza, Italy, Piacenza, Italy; **5** Digestive Endoscopy Unit, AUSL Piacenza, Piacenza, Italy, Piacenza, Italy, Piacenza, Italy; **6** Gastroenterology and Digestive Endoscopy Unit, Guglielmo da Saliceto Hospital, Piacenza, Italy

DOI 10.1055/s-0046-1821142

Aims This study aimed to assess the level of clinical competence of nurses in managing percutaneous endoscopic gastrostomy (PEG) within the AUSL of Piacenza [1–8].

The objectives were to explore differences between hospital and community nurses regarding theoretical knowledge, perceived competence, and training needs, in order to identify gaps and promote the development of standardized clinical protocols.

Methods A prospective descriptive observational study was conducted in September 2025 among nurses working in hospitals, community services, and accredited private facilities of AUSL Piacenza.Data were collected using a structured questionnaire specifically developed and validated by a panel of experts. The tool included three sections: (1) general information, (2) theoretical knowledge and perceived competencies, and (3) training needs.

The survey was distributed through the REDCap platform to ensure anonymity and confidentiality. Descriptive statistics were used to analyze the data.

Results A total of 112 complete responses were analyzed.

Most participants worked in hospital settings (96.4 %) and had over 10 years of professional experience.Although nearly all respondents had managed PEG patients (96.4 %), only 27.7 % did so more than three times per month.

Knowledge levels were heterogeneous, with only 10.7 % of participants answering all theoretical questions correctly.

Perceived competence was high in site hygiene and patient positioning, but lower in emergency management and caregiver education.

Overall, 79.5 % of nurses had never received specific training on PEG management, yet 83 % expressed the need for a shared protocol and 65 % were willing to participate in future educational programs.Key findings indicate a gap between theoretical knowledge and clinical practice, particularly in emergency procedures and educational communication.

Conclusions Nursing clinical competence in PEG management within AUSL Piacenza is generally adequate but uneven across care settings.

The findings emphasize the importance of continuous professional development, interprofessional collaboration, and the adoption of standardized care pathways.

Structured and targeted training programs could enhance nurses' theoretical and practical skills, strengthen their educational role with patients and caregivers, and ultimately improve the quality, safety, and continuity of PEG care in both hospital and community contexts.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP203 Implementation of the esophageal VacStent in patient management: Case Report

Authors Bertić A[1], Ivančević I[1], Erceg J[1]

Institute **1** Sisters of Charity Hospital, Zagreb, Croatia

DOI 10.1055/s-0046-1821143

Aims This case report describes the successful use of a VacStent, a hybrid device that combines a fully covered self-expanding metal stent (SEMS) with an external polyurethane sponge cylinder connected to continuous negative-pressure therapy, in the management of an esophageal fistula that developed after surgical resection of an adenocarcinoma located in the distal esophagus and cardia. The aim is also to highlight the essential role of the endoscopy nurse in ensuring safe and effective treatment.

Methods Following surgery, the patient developed post-procedural complication, a stapler-related anastomotic esophageal stenosis, with a residual lumen of 2 mm. Subsequently, endoscopic dilatation was performed to sufficiently widen the esophageal lumen, allowing safe placement of the VacStent.The stent was placed endoscopically in the endoscopy room, under X-ray fluoroscopy. The stent was withdrawn 9 days later, following the same endoscopic protocol.The endoscopy nurse prepared all endoscopic acccesories – including the VacStent delivery system, suction catheter, and vacuum pump – ensured proper setup, and verified negative-pressure function before the procedure. During placement, the nurse assisted by handling the endoscopic accessories, adjusting suction in real time, and coordinating with the endoscopist to achieve precise positioning of the device. After deployment, the nurse continuously monitored the vacuum system, checked for signs of discomfort or complications, and collaborated with the multidisciplinary team to optimize timing based on healing progress.

Results Literature supports the VacStent's safety and efficacy: in a prospective multicenter study, 41 implants in 15 patients achieved a healing rate of 80 % with no severe device-related adverse events. [1] A systematic review of 65 patients showed 100 % technical success and 77 % clinical success.Moreover, in

a pilot study, preemptive application of the VacStent after esophagectomy demonstrated feasibility and no major complications [2].

Conclusions This report highlights the therapeutic potential of the VacStent in managing postoperative esophageal fistulas and underscores the indispensable role of the endoscopy nurse in ensuring safe, efficient, and patient-centered care in the endoscopy suite.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP204 New tool for EUS-guided tissue acquisition

Authors Boljesic S[1], Ana IR[1], Erceg J[1], Vedris M[1], Gordana M[1], Pavić T[1]

Institute 1 Sisters of Charity Hospital, Zagreb, Croatia

DOI 10.1055/s-0046-1821144

Aims Standard endoscopic ultrasound-guided biopsy procedures (FNB) for sampling gastrointestinal tract solid tumors have become routine practice, but a histological diagnosis is not always possible, and multiple needle passes are often required to obtain an adequate sample for analysis.A new motorized EUS-guided biopsy device has recently become available. Our institution was among first four centers worldwide that had the opportunity to test it.

Methods At Sestre milosrdnice University Hospital Centre, six patients have undergone biopsy with this method so far. Basic education on how to operate the device was done on-site by the manufacturer.Biopsies were obtained using a flexible, electrically powered, high-speed rotating device equipped with a 17G needle that collects samples through controlled passes across targeted lesions.Nurses play a key role in ensuring the procedure is performed safely and efficiently. Responsibilities of nurses include preparing the endoscopy room, checking the functionality of the EUS equipment, preparing the biopsy system, and maintaining sterile conditions. Before the procedure, the nurse participates in informing the patient, verifies documentation, and ensures that informed consent has been signed.During the biopsy procedures the nurse assists the physician, monitors the patients' vital signs, and ensures timely preparation and delivery of the required instruments. After the procedure, the nurse monitors the patient during recovery, observes potential immediate complications, and documents all relevant information regarding the procedure and the patients' condition.

Results In all six patients, the first and only EUS-guided tissue acquisition pass was sufficient to obtain diagnostic tissue.The only adverse event was mild bleeding in one patient, which was successfully stopped endoscopically and did not require blood transfusion.All patients underwent the procedure under anesthesia.Investing in nurses education for EUS-guided biopsy procedures increases patient safety, improves sample quality, and contributes to a more efficient diagnostic process.

Conclusions The nurse is a key link connecting the technical demands of the procedure with patient care and safety.Overall, initial experience with this new motorized EUS device was positive. Advantages include a higher likelihood of obtaining an adequate sample, which ultimately results in fewer repeated procedures, less discomfort for the patient, and lower overall diagnostic costs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP205 Green endoscopy: a new paradigm

Authors Hipolito M[1], Joana M[1], Maria JM[1]

Institute 1 Hospital Santa Isabel, Marco de Canaveses, Portugal

DOI 10.1055/s-0046-1821145

Aims Introduction: Green endoscopy refers to efforts and measures aimed at making endoscopic procedures more environmentally sustainable. ESGE-ESGENA recommends that endoscopy units assess, disclose, and audit their environmental impact. International Societies have developed practical measures including waste reduction, implementation of recycling programs, and reuse of equipment whenever possible. The goal is to create a more sustainable endoscopy unit by reducing waste and costs.

Methods Methods: We conducted a descriptive, quantitative, cross-sectional study and subsequently implemented a continuous improvement project in the digestive endoscopy unit to address this issue. In phase 1, we weighed the waste produced in the unit during 10 random shifts in January and February 2025. In phase 2, the multidisciplinary team received training on waste management, segregation, and recycling. In phase 3, waste was weighed again after the implementation of the new measures.

Results Results: In phase 1, 125 endoscopic procedures (EGD and colonoscopy) were performed in 74 patients. Group I/II waste totaled approximately 31 kg, Group III waste amounted to 104.8 kg, and Group IV waste reached 10 L. In phase 3, we observed a significant reduction in waste production and, consequently, in costs [1–6].

Conclusions Green endoscopy has the potential to revolutionize healthcare by promoting sustainability and minimizing environmental impact. The key to the future lies in adopting innovative practices, fostering education, and encouraging collaboration among healthcare professionals, patients, and the community. Engaging unit managers and educating healthcare professionals are essential to promote ecological practices and reduce costs.Reflecting to evolve: reflection is a commitment to continuous improvement.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP206 Establishment of the digestive endoscopy on-call nursing team in a tertiary hospital

Authors Torres Zamora YC[1], Hernández Ponce L[2], Gonzalez Gonzalez M[3]

Institutes 1 Complejo Hospitalario Insular, Las Palmas De Gran Canaria, Spain; 2 Registered Nurse, Las Palmas de Gran Canaria, Spain; 3 Hospital Insular, Las Palmas de Gran Canaria, Spain

DOI 10.1055/s-0046-1821146

Aims An endoscopic emergency is defined as any procedure performed to diagnose and/or treat gastrointestinal conditions that require immediate attention and/or pose a threat to the patient's life.

During routine care, urgent endoscopic procedures are performed by the unit's staff. However, emergencies outside working hours were handled by the hospital's backup staff.

Since April 2023, these procedures have been carried out by an on-call team consisting of an endoscopist, a registered nurse and a nursing assistant [1, 2].

Methods Urgent endoscopies are arranged via a call from the hospital switchboard to each member of the on-call team's corporate telephone.

The on-call duty hours are from 3 p.m. to 8 a.m. Monday to Friday, and 24 hours on Saturdays, Sundays and national holidays.

Depending on the patient's condition and haemodynamic stability, urgent digestive endoscopies can be performed in the Unit itself, the Emergency Department's resuscitation room, the Intensive Care Unit or the Surgical Area.

During on-call shifts, urgent digestive endoscopies on children can be performed at the Maternal and Child Hospital, which are always carried out in the Surgical Area.

Endoscopies performed at the Digestive Endoscopy Unit are carried out under deep sedation, guided by the endoscopist.

Upon arrival at the hospital, the nursing assistant is responsible for preparing the necessary equipment for the procedure, assisting the rest of the team during the procedure and reprocessing the endoscope and cleaning all equipment used safely and correctly. The nursing assistant's work is complete once the endoscope has been properly dried and stored.

Registered nurses are responsible for caring for patients during endoscopic procedures and performing the necessary techniques to control or resolve any emergencies. Once the patient has been transferred back to their original unit, their work is complete.

Results The presence of on-call nursing staff with the specific knowledge, training and skills required to perform urgent digestive endoscopies has significantly improved the safety, attention and quality of care provided to our patients (▶ **Table 1**).

▶ **Table 1**

YEAR	2022	2023	2024	2025 (nov)
emergency procedures performed outside working hours	600	780	906	803

There has been a significant increase in the number of emergency procedures performed outside working hours since the introduction of the on-call team, rising from 600 in 2022 to 906 in 2024. By 1 November 2025, a total of 803 emergency endoscopies had been performed.

Likewise, the complexity of therapeutic procedures performed during these urgent endoscopies has increased.

Conclusions Effective and safe care depends on the training, coordination and communication of the multidisciplinary team.

A well-trained team improves patient experience and safety.

Keeping up to date is essential for maintaining service quality.

Success lies not only in the technique, but also in the knowledge, ethics and professionalism of the people performing it.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP207 The role of nurses in the use of duodenoscopes in emergency situations: towards a specific on-call system

Authors Vidil A[1], Audiau C[2]

Institutes **1** Médipôle de Savoie, Challes-les-Eaux, France; **2** Université de Limoges, Limoges, France

DOI 10.1055/s-0046-1821147

Aims Endoscopy technical platforms are facing an increase in interventional endoscopy procedures in emergency situations, particularly ERCP, which requires the use of a duodenoscope. This specific device presents a high risk of microbiological contamination [1–7].

Operating units are encountering difficulties in managing the organization of these procedures in emergencies and are sometimes forced to refer patients to other facilities.

Indeed, the multi-skilled staff on-call are not sufficiently trained in digestive endoscopy—neither for providing technical assistance in the procedure room nor for the reprocessing of duodenoscopes.

In France, several cases of cross-contamination have been reported due to inadequate endoscope reprocessing, and our study aims to demonstrate that these emergencies should be handled by nurses specialized in endoscopy.

Their specific skills and knowledge will enable patients to access emergency techniques in complete safety.

Methods As part of research proposed by the University of Limoges, a study was conducted at the “Clinique de l’Anjou” in Angers between 2021 and 2023

A review of the literature compiled the recommendations issued by learned societies and their requirements concerning the continuity of care in digestive endoscopy.

Data collected in several European countries revealed several cases of duodenoscope contamination, highlighting the importance of duodenoscope reprocessing, particularly in the context of on-call duty.

Quantitative and qualitative studies in France assessed respectively, the evolution of the number of emergency ERCP performed and the level of practice of nurses in relation to the use of duodenoscopes.

Results These studies have shown an increase in the number of ERCP performed in emergency situations.

Technical platform managers face significant difficulties in scheduling emergency ERCP and managing duodenoscopes.

The data extracted and analyzed showed that the skill level of multi-skilled nurses was not sufficient for these on-call duties, either in terms of the technical procedures performed in the operating room or the handling of the duodenoscope.

Conclusions Following the development of interventional activities and endoscopic techniques in technical platforms, it seems important to consider reorganizing on-call nursing duties by calling on specialized staff to ensure optimal and safe care. However, parameters such as human resources and funding will need to be considered to enable this to be put into practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP208 The environmental impact of gastrointestinal endoscopy: a single-Center analysis of waste segregation

Authors Fiorona L[1], Italiano R[1], Biancheri P[1], Armellini E[1]
Institute 1 Digestive Endoscopy Unit, ASST Bergamo Est, Seriate, Italy
DOI 10.1055/s-0046-1821148

Aims Gastrointestinal endoscopy is a major contributor to the large amount of medical waste generated by the hospital activities. Simple measures like implementation of waste segregation may impact substantially on sustainability without affecting the quality of gastrointestinal endoscopic procedures.

Methods We conducted a prospective exploratory study on the amount of waste generated in the three rooms of our Endoscopy Unit from 1 September to 31 October 2025. At the end of each day of endoscopic activity, we weighed the amount of waste in each one of the segregated fractions.

Results We segregated the waste produced in our Endoscopy Unit into regulated medical waste and non-regulated medical waste, including paper, plastic and non-recyclable waste. Over the course of the study period (61 days), the Endoscopy Unit was fully active on 53 days. The overall amount of waste produced by our Endoscopy Unit was 1830 kg of regulated medical waste, 1142 kg of paper, 954 kg of plastic, and 636 kg of non-recyclable waste. Over the course of one year, this would mean approximately 10980 kg of regulated medical waste, 6852 kg of paper, 5724 kg of plastic, and 3816 kg of non-recyclable waste.

Conclusions Our small exploratory study confirms that routine gastrointestinal endoscopy activity produces very large amounts of waste. Simple measures like the implementation of a structured protocol for waste segregation lead to the efficient management of medical waste, and contribute substantially to improve the environmental sustainability of gastrointestinal endoscopy. Our preliminary data provide the basis for a larger analysis aiming to quantify the reduction in greenhouse gas emission after the adoption of the current waste segregation protocol in our Endoscopy Unit.

PYP209 Application of "Patient Safety Strategy of SERMAS 2027" in Endoscopy Unit

Authors Diaz-Rodriguez DR[1], Granados-Martin M[2]
Institutes 1 Hospital Henares, Coslada, Spain; 2 Hospital Universitario de Fuenlabrada, Madrid, Spain
DOI 10.1055/s-0046-1821149

Aims To describe the activities of endoscopy clinic that follow the Patient Safety Strategy SERMAS.

Methods Patient Safety is a global priority which requires an urgent action to reduce preventable harm, World Health Organization says in Global Patient Safety Action Plan 2021-2030 [1, 2].

The Consejería de Sanidad de la Comunidad de Madrid (Regional Office of Health in Madrid-SERMAS) has published the New Patient Safety Strategy 2027. It includes12 strategic lines to outline the actions that will be addressed by Health Care Centres and Hospital Units.

Every month around 400 endoscopies are performed in our endoscopy unit at Hospital Universitario del Henares (Madrid), both outpatients or inpatients. Concern for patient safety is growing with the aim of preventing or at least reducing adverse events related to medical procedures, therefore nursing staff have sought out the bibliography published by SERMAS to improve patient care. The document was studied by the nursing staff and a critical review was carried out to choose the activities that could be applied in the daily practice of Endoscopy unit. The document consisted of 12 strategic lines that are developed into 92 strategic objectives.

Results Of the 12 strategic lines (S.L.), 3 were selected for their relevance: S.L. 7.9 "Nursing care and procedures", S.L. 7.11 "Safe use of drugs" and S.L. 7.12 "Healthcare-associated infection".

S.L.7.9:

Strategic objective (S.O.) 7.9.1 "To enhance leadership in care", Action 7.9.1.2: "To promote the implementation of nursing care safety protocols": Protocols are drafted and updated.

S.O. 7.9.2 "To reduce variability in nursing practice through standardisation of care": preventing falls, management of infection, placement of ostomies. The existing protocols at our centre are implemented, with special attention to frailty.

S.O. 7.9.3 "Promoting safety through specific nursing interventions": the medication used during endoscopic procedure is studied to ensure its proper administration and the transfer of information.

S.O. 7.9.4: "Promoting training in care safety": The welcome document for new staff members is prepared.

S.L. 7.11 "Safe use of drugs":

S.O. 7.11.1 "Promoting culture to encourage safe use of medicines": application of 5 secure moments for medication safety and to report incidents related to medication administration.

S.L.7.12: "Healthcare-associated infection"

S.O. 7.12.1 "Preventing healthcare-associated infections in Primary care and other healthcare settings", by promoting regular training among professionals.

Conclusions Through the use of the document "New Patient Safety Strategy 2027 in SERMAS", nursing procedures in Endoscopy unit have been standardised to improve patient safety.

We recommend using the official bibliography as a basis for improving the performance of nursing staff in patient care.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP210 Standing Strong: Overcoming Ergonomic Challenges in Endoscopy Nursing

Authors Lovric V[1], Boljesic S[1]
Institute 1 Sestre milosrdnice University Hospital Center, Zagreb, Croatia
DOI 10.1055/s-0046-1821150

Aims Endoscopy nurses face continuous ergonomic challenges that stem from the physical demands of endoscopic procedures. These include prolonged standing in fixed positions, working with monitors placed at suboptimal heights, repetitive hand and wrist movements during scope handling assistance, frequent bending or twisting of the spine, and the need to lift, push, or reposition equipment. Over time, these stressors contribute to neck, shoulder,

and lower back pain, joint stiffness, reduced dexterity, fatigue, and an increased risk of long-term musculoskeletal disorders. Such strain not only affects individual well-being but may also influence procedural flow, team coordination, and overall patient safety

Methods Drawing on observations and experience in our endoscopy unit, nursing staff identified key ergonomic risk factors and implemented targeted strategies to reduce daily physical load. Adjustments included optimizing workspace layout, individualizing monitor height and distance, using adjustable stools for prolonged procedures, integrating brief stretching routines between cases, and ensuring rotation of roles to avoid repetitive strain. Staff also engaged in ongoing peer education to reinforce awareness of proper body mechanics and early recognition of overuse symptoms.

Results These collective efforts have led to noticeable improvements, including reduced discomfort, better concentration, increased energy levels, and higher job satisfaction. Importantly, procedural efficiency and patient safety have improved through smoother workflow and enhanced staff resilience.

Conclusions This work underscores the essential role of endoscopy nurses in recognizing and proactively managing ergonomic risks. It highlights that even low-cost, practical interventions can meaningfully enhance the quality of practice, protect musculoskeletal health, and strengthen patient safety. The strategies implemented in our unit may serve as a practical model for other endoscopy departments seeking to elevate professional performance and create safer, more sustainable working conditions.

PYP211V EUS-Guided Embolization of a Pancreatic Pseudoaneurysm

Authors Estrecha S[1], Martin S[1], Maynar J[1], De Pablos I[1], Yanguas Elorz E[1], Sanchez E[1], Gambra A[1], Campos A[1], Espinosa L[1], Alvarez M[1]
Institute **1** Araba University Hospital, Vitoria-Gasteiz, Spain
DOI 10.1055/s-0046-1821151

Abstract Text

Visceral artery pseudoaneurysms are rare but serious complications of chronic pancreatitis, often presenting with upper gastrointestinal bleeding (UGIB).A 68-year-old man with alcohol-related chronic pancreatitis and liver disease presented with recurrent UGIB.Initial endoscopic and radiologic studies were unremarkable.During a new episode, CT angiography showed a 20 mm lesion near the main pancreatic duct consistent with a pseudoaneurysm.Angiographic embolization failed due to non-identification of the lesion.Using a linear echoendoscope with Doppler from the distal duodenum, the pseudoaneurysm was located in the pancreatic uncinate process.EUS-guided thrombin injection (500 IU) achieved complete Doppler resolution.CT at 24 hours confirmed thrombosis, and the patient remained clinically stable.EUS-guided thrombin embolization is a safe, effective alternative when angiographic treatment is not feasible.

PYP212 Efficacy of a Plastic Stent–Based Gallbladder Flushing Technique in EUS-Guided Gallbladder Drainage for Acute Cholecystitis

Authors Kawasaki Y[1], Ushio J[1], Kato H[1], Sumi K[1], Inoue H[1]
Institute **1** Digestive Diseases Center, Showa Medical University Koto Toyosu Hospital, Tokyo, Japan
DOI 10.1055/s-0046-1821152

Aims Endoscopic ultrasound–guided gallbladder drainage (EUS-GBD) has emerged as an important alternative for high-risk surgical candidates with acute cholecystitis. While lumen-apposing metal stents (LAMS) are widely reported, their impact on subsequent cholecystectomy remains a concern. We have adopted a gallbladder flushing technique using a plastic stent during EUS-GBD. This study aimed to evaluate the technical and clinical outcomes of this approach and compare them with the transpapillary technique.

Methods We retrospectively reviewed 63 patients who underwent endoscopic treatment for acute cholecystitis at Showa Medical University Koto Toyosu Hospital between April 2023 and October 2025. Outcomes assessed included technical and clinical success, adverse events, procedure time, and postoperative surgical course.

Results A total of 63 patients were included, with a median age of 81 years (range 28–98). The transpapillary approach was performed in 43 patients, whereas 20 underwent EUS-GBD. Among the EUS-GBD procedures, technical success was achieved in 95 % (19/20), with one case requiring conversion to LAMS placement. Clinical success was obtained in all patients who underwent EUS-GBD. The median procedure time was 30 minutes (range 17–44). Two patients (10 %) developed peritonitis after the procedure, and both recovered with conservative management. In the transpapillary group, the cystic duct was successfully selected and the guidewire advanced into the gallbladder in 37 of 43 patients (93.3 %). Whenever guidewire placement was successful, endoscopic gallbladder stenting was completed without failure. No adverse events occurred in this group. The median procedure time was 38 minutes (range 18–118), which was significantly longer than that of EUS-GBD ($p = 0.004$). Importantly, seven patients from the EUS-GBD group subsequently underwent cholecystectomy, and none experienced complications attributable to the prior procedure. No difficulties related to the plastic stent or the flushing method were encountered during laparoscopic dissection, suggesting that the procedure is unlikely to interfere with subsequent surgery.

Conclusions A plastic stent–based gallbladder flushing method in EUS-GBD demonstrated excellent technical and clinical success. Although minor adverse events were observed, overall procedure time was significantly shorter than the transpapillary approach. Importantly, no difficulties were encountered during subsequent cholecystectomy. In addition, plastic stents may offer advantages in terms of medical cost compared with metallic stents. These findings suggest that this technique is a useful and feasible therapeutic option for acute cholecystitis, particularly in patients unsuitable for immediate surgery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP213 The role of contrast-enhanced endoscopic ultrasound (CH-EUS) in endoscopic ultrasound gallbladder drainage: a pilot study

Authors Sbrancia M[1], Binda C[2], Giuffrida P[3], Coluccio C[3], Fabbri S[4], Trama D[4], Liverani E[5], Jung C[5], Cucchetti A[4], Fabbri C[6]

DOI 10.1055/s-0046-1821153

Aims Acute cholecystitis (AC) in patients unfit for surgery requires prompt minimally invasive management. Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) using lumen-apposing metal stents (LAMS) has emerged as an effective alternative to percutaneous drainage, but success and safety depend on accurate assessment of gallbladder wall integrity and vascularity before stent deployment. Contrast-enhanced harmonic EUS (CH-EUS) with Sonovue allows real-time visualization of perfusion and microvascular changes, potentially improving detection of complicated AC such as gangrene or wall discontinuity. The aim of this study was to evaluate the pre-procedural utility of CH-EUS in characterizing gallbladder wall alterations in high surgical-risk patients with AC and to assess its concordance with CT imaging, diagnostic impact on procedural planning, and association with outcomes following EUS-GBD.

Methods We retrospectively analyzed a prospectively maintained database of eighteen consecutive patients with moderate-to-severe AC according to Tokyo Guidelines 2018, all considered unfit for cholecystectomy after multidisciplinary review. Prior transabdominal ultrasound and/or contrast-enhanced CT were available in all cases, and findings were compared with endosonography. CH-EUS with Sonovue was used to assess wall thickness, layer structure, perfusion behavior, intramural necrosis, and suspected wall interruption. When feasible, EUS-GBD was performed during the same session using a cautery-enhanced LAMS. Primary outcomes included characterization of enhancement patterns and their complementary value vs radiology. Secondary outcomes included technical/clinical success and adverse events of EUS-GBD.

Results Eighteen patients (67 % male, median age 78 years [range 44–91]) were included. Cardiovascular comorbidities were frequent (Charlson Comorbidity Index mean 5.5 ± 1.6), and 44.4 % were receiving anticoagulation. All cases were classified as moderate-to-severe AC. Transabdominal ultrasound was performed in 83.3 % and CT in 38.8 %, revealing gallbladder wall thickening in 77.7 % and suspected necrosis in three cases

On EUS, 100 % exhibited wall thickening > 3 mm, loss of normal stratification in 61.1 %, and a hypoechoic inflammatory pattern in 66.6 %. Gallstones or sludge were detected in 83.3 %, and common bile duct stones in 16.6 %, confirming higher sensitivity than CT for intraluminal pathology.

At CH-EUS, **7/18 patients (38.8 %) showed hypo-enhancement**, consistent with ischemia/gangrenous evolution, while **11/18 (61.2 %)** presented iso-/hyper-enhancement. Perfusion defects indicating necrosis or focal wall disruption were visualized in 22.2 %. CH-EUS confirmed or clarified radiological suspicion in cases with ambiguous CT findings, demonstrating that **TC and CH-EUS provide complementary structural and perfusion-based information** crucial for selecting the safest entry site for LAMS deployment.

Fourteen patients (77.7 %) underwent same-session EUS-GBD with 100 % technical and clinical success and only one self-limiting bleeding episode (5.5 %). No adverse reactions to Sonovue occurred.

Conclusions In high-risk AC patients, CH-EUS with Sonovue provides actionable characterization of gallbladder wall viability by detecting perfusion defects associated with ischemia or perforation. This information **complements CT rather than replacing it**, refining eligibility and guiding a safe stent trajectory for EUS-GBD. The excellent clinical success and low complication rate support routine pre-procedural contrast enhancement during EUS in fragile patients. Larger studies are needed to confirm these findings and validate perfusion-based criteria for risk stratification before gallbladder drainage.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP214 Elective Endoscopic GallBladder Treatment (EEGBT) in high surgical risk patients with benign diseases: a prospective multicentre study

Authors Covello C[1], Vargas-Madrigal J[2], Cominardi A[3], Tripodi G[1], Valerii G[4], Del Gaudio A[1], Hernandez-Castro D[2], Lisotti A[5], Molinario F[6], Barbera C[4], Aragona G[3], Larghi A[1]

Institutes **1** Agostino Gemelli University Policlinic, Rome, Italy; **2** Hospital San Juan de Dios, San José, Costa Rica; **3** Gastroenterology and Digestive Endoscopy Unit, Guglielmo da Saliceto Hospital, Piacenza, Italy; **4** Gastroenterologia ed Endoscopia – Ospedale Teramo, Teramo, Italy; **5** Gastroenterology Unit, Hospital of Imola, University of Bologna, Imola, Italy; **6** Gemelli Molise, Campobasso, Italy

DOI 10.1055/s-0046-1821154

Aims Elective endoscopic gallbladder treatment (EEGBT) may represent a minimally invasive alternative to cholecystectomy in fragile elderly patients with benign gallbladder disease who are considered at high surgical risk (HSR). Evidence in this specific setting remains scarce and largely retrospective. We conducted a multicenter prospective study to evaluate safety and long-term clinical efficacy of EEGBT using lumen-apposing metal stents (LAMSs) in a large cohort of elderly HSR patients.

Methods Prospective, multicentre study over a 4-year period, involving elderly (≥ 70 yrs) HSR patients (ASA score ≥ 3) with benign gallbladder disease in whom indication to cholecystectectomy was made. Patients first underwent EUS-guided gallbladder drainage using LAMSs, which worked as a port of entry for intracholecystic procedure(s) when needed. Primary endpoint was safety, defined by rate of intraprocedural, early (< 14 days), or late (> 14 days) adverse events (AEs) graded according AGREE classification. Secondary endpoints included: (i) long-term clinical success, defined as the absence of biliary recurrence within 24 months, in patients achieving either a full 2-years follow-up or ≥ 1 year of follow-up before death; (ii) predictors of biliary recurrence and mortality calculated by univariate and multivariate analysis.

Results A total of 95 consecutive frail elderly patients (mean age 83.9 ± 7.2 years; 80 % ASA III) with benign gallbladder disease deemed at high surgical risk for cholecystectomy underwent EEGBT. A transduodenal approach was performed in 55.8 % of procedures, and a 10 × 10 mm LAMS was used in 82.1 % of cases. Technical success was achieved in 94/95 patients (98.9 %). Median procedural time was 10 minutes (IQR 8–16), and median hospital stay was 5 days (IQR 3–8.25). Intracolecystic lithotripsy (mechanical or holmium laser) was performed after EEGBT in 10/95 patients (10.5 %), without any adverse events. Overall, EEGBT-related adverse events occurred in 21/95 patients (22.1 %). Among these, 5 patients experienced intraprocedural AEs only, 12 experienced late AEs only, and 4 patients (4.2 %) developed both an intraprocedural and a delayed AE. Severe AEs—defined as those requiring surgery or resulting in death—were observed in 2/95 patients (2.1 %). Intraprocedural AEs occurred in 5.3 % of cases (4 minor bleedings and one stent misdeployment), all successfully managed endoscopically or conservatively. Late AEs occurred in 20/95 patients (21.05 %). Among these, biliary recurrences were documented in 12 patients (12.6 %), including 10 recurrent cholecystitis and 2 choledocholithiasis (one presenting with acute pancreatitis). Most late AEs were managed with conservative or endoscopic therapy. Other delayed AEs included 5 cases of minor bleeding and 3 buried-LAMS events, one of which required cholecystectomy.

During a median follow-up of 27 months (IQR 24–37), we observed an overall mortality of 18.9 %, with one procedure-related death (1.2 %). Fifteen patients were lost to follow-up or died before completing 12 months. Among 80 patients eligible for secondary endopoints, clinical success was achieved in 68 (85 %). At univariate analysis, the transgastric approach showed a borderline association with increased biliary recurrence compared with the transduodenal route ($p = 0.050$). At multivariate analysis, LAMS removal followed by placement of a double-pigtail plastic stent was independently associated with biliary recurrence compared with leaving the LAMS indwelling ($p = 0.028$). Age was the only independent predictor of all-cause mortality ($p = 0.020$).

Conclusions In fragile elderly HSR patients with benign gallbladder disease, EEGBT provides very high technical success and favourable procedural safety. Long-term clinical success was high, and most late adverse events were manageable endoscopically or conservatively. LAMS removal emerged as the main driver of biliary recurrence, suggesting that long-term stent strategy is clinically relevant. With the aging of the population, this approach opens the possibility to treat electively an increasing number of elderly fragile patients with vulnerability and decreased physiological reserve, preventing or impairing post-procedural recovering and the return to preexisting functional level.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP215 Incidence and Risk factors for Acute Cholecystitis following ERCP with Metal stenting of malignant distal biliary obstruction (SCANSION Study): a prospective cohort study

Authors Vanella G[1,2], Soru P[3], Stasio RC[2,4], Guilabert L[5], Frigo F[4,2], Bara R[2,1], Archibugi L[2,1], Tacelli M[1,2], Zaccari P[2,1], Rossi G[2], Petrone MC[2], Marzocca G[2,1], Lauri G[2,1], Biamonte P[2], Ponz de Leon Pisani R[2], De Madaria E[5], Capurso G[1,2], Mariani A[2], Arcidiacono P[2,1]

Institutes **1** Vita-Salute San Raffaele University, Milano, Italy; **2** Pancreatobiliary Endoscopy and Endosonography Division, IRCCS San Raffaele Scientific Institute, Milan, Italy; **3** Division of Endoscopy, European Institute of Oncology, IRCCS, Milan, Italy; **4** University of Turin, Torino, Italy; **5** Dr. Balmis General University Hospital, Alicante, Spain

DOI 10.1055/s-0046-1821155

Aims Incidence and risk factors for Acute cholecystitis (AC) following ERCP with self-expandable metal stents (SEMS) for distal malignant biliary obstruction (DMBO) have been scarcely explored in retrospective studies.

Methods Between Feb-2024 and Apr-2025, all consecutive candidates to ERCP with a partially covered SEMS were enrolled in a single-centre prospective study (ClinicalTrials.gov NCT04813055). Two independent endoscopists blindly assessed morphological risk factors at EUS and ERCP. Clinical outcomes were evaluated by one independent assessor during admission and every 60 days. Multivariate logistic regression for Post-ERCP AC (PEC) was performed.

Results 130 patients with DMBO were included (median age 71 [IQR 62-77], pancreatic adenocarcinoma 84.6 %). At EUS, cystic duct (CD) was infiltrated in 16.9 % and closer than 10 mm from the neoplasia in 14.6 % of cases. At ERCP the SEMS covered the CD in 38.3 % of the procedures.

Median follow-up was 119 [54-204] days. Ten (7.7 %) patients experienced post-ERCP pancreatitis whereas twelve (9.2 %) experienced PEC, after a median time of 5.5 [5-51] days.

At multivariate logistic regression, the only independent predictor of PEC was a high-risk CD location (namely infiltrated or < 10mm from the neoplastic stenosis (OR [95 % CI] = 5.2 [1.5-18.3]

Conclusions In the context of SEMS placement for DMBO, PEC is relatively more frequent than post-ERCP pancreatitis. EUS ahead of ERCP can reliably predict this event as a high-risk CD location seems to independently predict this event.

PYP216 The placement of naso-cystic tube for lavage in Endoscopic ultrasound-guided gallbladder drainage with LAMS does not affect the outcome

Authors Stigliano S[1], Biasutto D[2], Citterio N[2], Marinaccio C[3], Di Matteo FM[4]

Institutes **1** Fondazione Policlinico Universitario Campus Bio-Medico, Roma, Italy; **2** Campus biomedico via alvaro del portillo 200, Roma, Italy; **3** Campus Bio Medico University of Rome, Selcetta, Italy; **4** Campus Bio Medico University of Rome, Rome, Italy

DOI 10.1055/s-0046-1821156

Aims Endoscopic ultrasound guided gallbladder drainage (EUS-GBD) with lumen apposing metal stent (LAMS) has become a favourite drainage option for high surgical-risk patients with acute cholecystitis and as rescue treatment for the relief of jaundice in patients with distal malignant biliary obstruction (DMBO) with high technical and clinical success.

The placement of naso-cystic drainage (NCD) to favour drainage and for lavage is not routinary recommended and there are no data on its use.

We aim to assess the role of NC tube in term of rate of length of hospitalization, rate of obstruction and unplanned readmissions and re-interventions.

Methods Single center retrospective analysis of all consecutive cases of EUS-GBD with LAMS acceding to the Therapeutic Endoscopy Unit of Fondazione Policlinico Universitario Campus Bio-Medico of Rome. Data about LAMS features and procedure were collected.

Results From January 2019 to October 2025 sixty-seven patients were enrolled (50.7 % male; 77 ± 12 years old). The 65.6 % of them underwent EUS-GBD for acute cholecystitis. In 51 % patients the trans-gastric access was performed. In 71.7 % patients a Hot-Axios LAMS was used and in the majority of procedure (79.1 %) a calibre bigger than 10 mm was used. Overall technical success was obtained in 98.5 % of procedures.

A naso-cystic tube was placed inside the LAMS in 33/67 (49.3 %) patients. Regarding the adverse events rate, in one patient distal flange misdeployment occurred. LAMS obstruction occurred in 7/67 patients (10.4 %) and need of reintervention in 11/67 (16.4 %).

There was no difference in term of drainage indication (61.7 % vs 69.6 % p 0.6), LAMS size (70.5 % vs 87.8 % p 0.13) and the placement of NCD. The rate of LAMS obstruction (6.7 % vs 15.2 % p 0.45) and reintervention (20.8 % vs 25 % p 1) was similar between th group of patients with NCD and without. The mean time of hospitalization after gallbladder drainage was not different between the two groups (11 ± 9 vs 8 ± 6 p 0.09).

Conclusions EUS-GBD is a safe technique with high technical success rate. The placement of naso-cystic drainage doesn't affect the post procedure outcome and doesn't reduce the length of hospital stay.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP217 Endoscopic ultrasound for nodal staging in patients with resectable gallbladder cancer

Authors de Jong DM[1], Van Driel LMJW[1], Lakhtakia S[2], Ramchandani M[2], Memon SF[2], Tyagi A[3], Kumaraswamy P[4], Modak S[4], Sekaran A[5], Bruno MJ[1], Reddy DN[2], Rughwani H[2]

DOI 10.1055/s-0046-1821157

Aims Lymph node (LN) involvement is a well-recognized adverse prognostic factor in gallbladder cancer (GBC), and accurate preoperative nodal staging is critical for improving treatment decisions and thereby optimizing patient management. Cross-sectional imaging has limited accuracy in LN staging. Endoscopic ultrasound (EUS) with tissue acquisition (EUS-TA) offers a minimally invasive method to sample suspicious LNs [1–4]. This study aimed to evaluate the impact of EUS for nodal staging in patients with presumed resectable GBC.

Methods In this retrospective, single-center cohort study at the Asian Institute of Gastroenterology, Hyderabad, India, consecutive patients with potentially resectable GBC who underwent preoperative EUS between January 2019 and November 2024 were included. Regional LNs were identified according to the 8th edition of the AJCC staging system as those located at the liver hilum, cystic duct, common bile duct, hepatic artery and adjacent to the gallbladder. Extraregional LN consisted of LNs located distal to the hepatoduodenal liga-

ment. EUS-TA was performed at the discretion of the endosonographer. The primary outcome was the impact of EUS on clinical decision making, measured as the percentage of patients in whom surgical exploration was precluded due to pathologically confirmed LN metastasis identified by EUS-TA. The secondary outcome was the incidence of adverse events, classified according to the AGREE classification.

Results A total of 56 patients were included (median age in years: 58.5, 51.8 % female). Preoperative cross-sectional imaging was performed in 94.6 % of patients with lymphadenopathy reported in 54.7 %. Across 59 EUS procedures, 46 LNs were identified, and EUS-TA was performed in 24 nodes from 21 patients. LN metastases were detected by EUS-TA in 10.7 % of patients, leading to the exclusion of these patients from surgical treatment. Notably, among patients who underwent surgical exploration after a median period of 18 days [IQR: 7.3 – 34.5], regional LN metastases were identified in nine of 31 patients and extraregional LN metastases in one patient. There were no complications reported related to the EUS or EUS-TA.

Conclusions Preoperative EUS significantly influenced clinical decision making in patients with presumed resectable GBC by identifying LN metastases and thereby altering patient management. Notably, multiple LN metastases were missed at preoperative screening. Future prospective studies employing standardized EUS protocols or integrating advanced imaging modalities are warranted to improve preoperative nodal staging and optimize management strategies in GBC.

Aims EUS-guided gallbladder drainage (EUS-GBD) with LAMS is increasingly used in managment of acute cholecystitis (AC) in patients unfit for surgery or with malignant distal biliary obstruction. Evidence comparing the trans-gastric (TG) and trans-duodenal (TD) routes remains limited.

Methods This international, multicenter retrospective study included all consecutive patients undergoing EUS-GBD from January 2019 to August 2025 across five tertiary centers (Italy, France, India). Standardized data collection included baseline characteristics, procedural variables, technical success (TS), clinical success (CS), adverse events (AEs; AGREE classification), recurrence, and recurrence-free survival (Kaplan–Meier). TS was defined as successful LAMS deployment; CS as resolution of the index condition without further intervention. Recurrence was defined as symptomatic or infectious relapse requiring reintervention.

Results A total of 194 patients were included (84 TG; 110 TD). Indications were acute cholecystitis in 69.6 % and malignant biliary drainage in 30.4 %. Overall TS and CS were 98.5 % and 96.9 %, respectively, with 5.9 % recurrence. TS was comparable between groups (TG 98.8 % vs TD 98.2 %; P = 0.726). However, CS was significantly lower in the TG group (92.8 % vs 100 % in TD; P = 0.0046). Procedural time was also significantly longer in TG (17 vs 10 minutes; P = 0.0073). Hospital stay did not differ (6 vs 6 days; P = 0.385). Overall AEs were similar (19.0 % vs 14.5 %; P = 0.404), but LAMS obstruction occurred significantly more frequently in TG (8.3 % vs 1.8 %; P = 0.033). Other AEs — LAMS migration (1.2 % vs 0.9 %; P = 0.866), bleeding (2.4 % vs 2.7 %; P = 0.907), and cholangitis (5.9 % vs 5.4 %; P = 0.882) —did not differ significantly. Recurrence remained similar (5.2 % vs 6.5 %; P = 0.716). Kaplan–Meier analysis confirmed no difference in recurrence-free survival between TG and TD (log-rank P = 0.986).

Conclusions EUS-GBD is highly feasible, effective, and safe across international real-world settings. The transduodenal approach demonstrated significantly higher clinical success and significantly shorter procedure time, while safety and recurrence outcomes were comparable. When anatomically possible, TD drainage may represent the preferred route.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP219 Transduodenal versus Transgastric Endoscopic Ultrasound-guided Gallbladder Drainage: a prospective comparative study

Authors Vanella G[1], Guilabert L[2], Stasio RC[3, 4], Bara R[3, 1], Frigo F[4, 3], Leone R[3], Marzocca G[3, 1], Archibugi L[3, 1], Tacelli M[1, 3], Lauri G[3, 1], Ponz de Leon Pisani R[3], Capurso G[1, 3], Arcidiacono P[3, 1]

DOI 10.1055/s-0046-1821159

Aims Endoscopic UltraSound guided-Gallbladder Drainage (EUS-GBD) is an established non-invasive approach for gallbladder drainage in elderly/comorbid patients. Technical guidelines suggest that a transduodenal versus transgastric route should be preferred due to the lower risk of stent occlusion and migration, despite the absence of any head-to-head comparison.

Methods This is a single tertiary center prospective study conducted between Jan-2021 and Mar-2025. Allconsecutive patients treated with EUS-GBD with Lumen Apposing Metal Stents (LAMS) were enrolled in a Prospective Registry

of Therapeutic EUS (PROTECT, ClinicalTrials.gov NCT04813055), with daily follow-upduring admission and every 60 days after discharge. Baseline characteristics and Technical / Clinical outcomes were compared between the transduodenal versus transgastric access.

Results A total of 57 patients were enrolled, 47 (82.5 %) and 10 receiving respectively transduodenal versus transgastric drainage. There was no difference in background characteristics between the groups. However, there were more EUS-GBD performed for biliary drainage in the transgastric (40 %) versus transduodenal (2.1 %) route, which also resulted in a higher prevalence of 8 mm LAMS use (30 % versus 2.1 %).Technical Success (100 %) was similar between groups. However, the transgastric route showed lower rate of Clinical Success (70 % versus 95.7 %, p = 0.01) and higher rate of Adverse Events (50 % versus 14.9 %,p = 0.01). In this group, all adverse events were severe/fatal according to ASGE lexicon, and included 4 clinical failures of EUS-GBD for biliary drainage (of which 2 with endoscopic finding of buried LAMS). After a median follow-up of 215 [61-404] days, there was no significant difference in the rate of recurrence of biliary events, despite the risk tended to be higher in the transgastric route (14.3 % versus 6.7, p = 0.5). Median estimated survival was shorter in the transgastric route (p = 0.0045).

Conclusions Despite the small sample size and the likely selection bias, this prospective comparison suggests that thetransgastric route for EUS-GBD is more prone to clinical failure and adverse events, such as LAMS occlusion or burial. The transuodenal route should be preferred, whenever feasible, for long-term LAMS indwell.

DOI 10.1055/s-0046-1821160

Aims A non-negligible proportion of patients suffering from acute cholecystitis develop a perforated cholecystitis characterized by the formation of an encapsulated pericholecystic collection (PC). Current guidelines do not provide a specific indication for EUS-GBD in perforated cholecystitis with an encapsulate PC. Currently, unfit patients presenting with perforated cholecystitis and encapsulated PC are generally managed via a percutaneous approach driven by safety concerns regarding EUS-GBD to avoid the theoretical risk of placing a LAMS into a perforated organ. Consequently, the presence of PC is often viewed as a relative or absolute contraindication for EUS-GBD. The aim of this retrospective study is to explore the safety of EUS-GBD in patients with acute cholecystitis complicated by an encapsulated fluid collection.

Methods This was a retrospective international study conducted in 10 tertiary centers. Acute choleystitis was defined and graded according to Tokyo criteria. Encapsulated PC was defined as collection adicent to gallbladder with clearly demarcated wall without detectable interruption at CT scan or intra-procedural echoendoscopic evaluation.The primary outcome was safety, evaluated by assessing adverse events according to the ASGE lexicon. Secondary outcomes were technical success, clinical success and the rate of PC resolution. Procedural features have also been reported. Technical success was defined as adequate LAMS placement confirmed by endoscopic and radiologic assessment, clinical success was defined as resolution of symptoms along with available objective improvements in biochemical and or radiological findings of cholecystitis within 3 days after. PC resolution was defined as the absence of the PC at the last radiological assessment performed during the available follow-up.

Results The study included 57 patients (24 females 42.1 % with a median age of 81 years IQR:73–85). Regarding the access route, 79 % of procedures were performed via the transgastric approach, while 21 % were performed via the transduodenal window. The most used LAMS diameter was 10 mm (60 %). All LAMS were deployed using the intra-channel release technique for the distal flange, and 87 % were placed using a free-hand technique. Technical success was achieved in all patients (100 %). Adverse events (AEs) occurred in 7 patients (12.3 %), classified as mild in three cases, moderate in three, and fatal in one. One AE occurred intra-procedurally, while the remaining six were classified as post-procedural. The single intra-procedural event involved the misdeployment of the LAMS distal flange and it was managed endoscopically. Post-procedural AEs included four bleeding episodes, one liver abscess and one perforation. One bleeding was secondary to cystic artery pseudoaneurysm and it required radiological embolization; the other three were treated endoscopically. The perforation was diagnosed 36 h after the procedure and was treated conservatively with antibiotics therapy. Clinical success was achieved in 52 out of 54 patients (96 %). The median length of hospital stay post-procedure was 6 days (range: 3–10). Resolution of the PC was observed in 94.4 % of patients. Among the three patients who did not achieve PC resolution, one developed a liver abscess, and two required subsequent percutaneous drainage, which successfully resolved the collection. A total of five deaths were recorded during the study period. One death was considered procedure-related secondary to the liver abscess, while the remaining four were unrelated to either the procedure or the cholecystitis

Conclusions This study suggests the feasibility to treat acute cholecystitis with encapsulate PC through LAMS placement in patients declared unfit for surgery

PYP221V Esophageal Endoscopic Muscularis Dissection with "tunnel first" approach as a palliative local therapy of a deeply Invasive Barrett's Adenocarcinoma in a Patient With Metastatic Squamous Cell Cancer

Authors Tvaradze G[1], Groth S[1], Lleshi D[1], Ewerton MM[2], Schneider PM[1], Tanabe M[3], Yamamoto K[3], Inoue H[3], Seewald S[1]

Institutes **1** GastroZentrum Hirslanden – Swiss Digestive Health Center – Klinik Hirslanden, Zürich, Switzerland; **2** medica MEDICAL LABORATORIES Dr. F. KAEPPELI AG, Zürich, Switzerland; **3** Showa University Koto Toyosu Hospital, Tokyo, Japan

DOI 10.1055/s-0046-1821161

Problem to solve In selected cases complete endoscopic removal of deep submucosal esophageal cancer is appropriate when surgery is not feasible. In order to achieve R0 resection the superficial circular muscle layer has to be dissected.

In non-surgical candidates, achieving R0 resection of deep submucosal esophageal cancer requires adequate prediction of how far the dissection must extend beyond the tumor. The problem is to determine the minimal depth that ensures complete tumor removal while still preventing perforation of the esophagus.

Innovation The innovative aspect of this case is the application of endoscopic muscularis dissection (EMD) in the esophagus, supported by a "tunnel first" evaluation approach. A submucosal tunnel was created to directly visualize the lesion in relation to the muscular layer. After creating the tunnel, the invasion area became clearly identifiable, and dissection was extended along the right and left sides to determine both the depth and the longitudinal extent of involvement. This "tunnel first" approach added a safety advantage by allowing precise assessment of how deep and how long the infiltration extended, guiding a controlled proper dissection plane to keep the risk of perforation low. Dissection is performed with the TTJ Neo knife, followed by the ClutchCutter, which enables efficient dissection and hemostasis simultaneously.

Results A 45-year-old male with metastatic esophageal squamous cell carcinoma, under systemic therapy, presented with a newly detected early Barrett's adenocarcinoma at the Z-line. Pre-procedural imaging and EUS suggested deep submucosal infiltration, but endoscopic resection was considered feasible as part of a palliative local-control strategy. The procedure began with creation of a submucosal tunnel to directly assess the tumor–muscularis infiltration. Within the tunnel, a clear muscular traction sign indicated superficial invasion into the muscle layer, prompting the decision to proceed with an endoscopic intramuscular dissection. The specimen was retrieved en bloc. A 4 × 3 cm R0 intramuscular resection was achieved without complications. Histopathology confirmed adenocarcinoma with sm2 invasion (1.1 mm), lymphatic invasion, and clear vertical and horizontal margins. No vascular or perineural invasion was present. At 6-month follow-up, endoscopy showed a completely healed, smooth scar with no residual or recurrent tumor. Biopsies were normal, and the patient remained under systemic treatment with stable local conditions.

Conclusions This case illustrates that EMD, supported by a tunnel-first evaluation, enables assessment of invasion depth and effective intramuscular dissection in a palliative case. Even when deep submucosal involvement is predicted, EMD can provide complete local removal while preserving esophageal integrity. This approach may be considered for select patients in whom local control of the tumor is clinically significant

PYP222 Circumferential ESD for long-segment verrucous carcinoma of the esophagus is a feasible option for curative treatment: a case series of two patients

Authors Giesecke C[1], Eleftherochorinou A[1], Vieth M[2], Albers D[1]

Institutes **1** Elisabeth-Krankenhaus Essen, Departement of Internal Medicine and Gastroenterology, Essen, Germany; **2** Klinikum Bayreuth, Department of Pathology, Bayreuth, Germany

DOI 10.1055/s-0046-1821162

Introduction Verrucous carcinoma of the esophagus (VCE) is a rare, slowly growing malignant subentity of squamous cell carcinoma, first described in 1967. The most common symptoms are dysphagia, chest pain, and weight loss. The tumor typically shows local invasion; lymph node positivity is rare, and organic metastasis hasn't yet been described. Typical endoscopic findings include exophytic growth of a whitish warty mass, hyperkeratotic plaques, and candidal esophagitis. Histopathological findings include squamous proliferation and a so-called church spire appearance of hyperkeratosis and parakeratosis within the thickened spinous cell layer. Diagnosis is complex and may require multiple biopsies, up to endoscopic mucosal resection (EMR). An association with alcohol, tobacco, and human papillomavirus is discussed. Since its first description, just around sixty cases have been published. The most common treatment is esophagectomy. Other treatment options, such as (repeated) piecemeal EMR, endoscopic submucosal dissection (ESD), and radiochemotherapy, are documented in only a few case reports.

Case description Thus, we present the first circumferential ESD using the double-tunneling technique in two patients with extended early VCE. A 77-year-old female patient and a 76-year-old male patient were recently diagnosed with early-stage VCE in our department. The endoscopic findings were an exophytic, cauliflower-like, warty mass measuring approximately 8 cm in length in the middle part of the esophagus (female patient) and a flat, hyperkeratotic lesion measuring approximately 10 cm in length in the middle and distal parts (male patient). Although the histology report showed only hyperkeratosis and candidal esophagitis, even in the snare resection specimens, the endoscopic image led to the decision to perform ESD in both cases. The procedure was performed using the double-tunneling technique over lengths of 9 and 12 cm, respectively, due to circumferential growth. The histology report of both resected specimens confirmed the diagnosis of mucosal VCE (female patient) and early submucosal VCE (male patient). The vertical margin was R0 in both patients. A microscopic edge-forming invasion of the upper horizontal margin on mucosal level was shown in both patients. Both patients received early post-interventional balloon dilatation of the esophagus two weeks after the procedure and corticosteroid treatment for four weeks. Clinical and endoscopic follow-up time is now two years and 15 months, respectively, without recurrence of carcinoma. Sequential balloon dilatation and temporary stent implantation due to post-procedural stenosis were required in the female patient [1–6].

Conclusion ESD is a feasible and promising curative treatment option even for patients with extended early-stage VCE. Recurrence rates should be low regarding submucosal tumor clearance (vertical R0 resection). Esophageal stenosis, as the main post-procedural complication, must be considered. Early balloon dilatation and corticosteroid treatment are effective in reducing the risk of post-procedural stenosis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A 68-year-old man with long-segment Barrett's esophagus (BE) repeatedly failed to achieve re-epithelialization after endoscopic mucosa resection (EMR) and multiple radiofrequency ablation (RFA) sessions. During follow-up, he developed intramucosa carcinoma with multiple non-visible high-grade dysplasia (HGD) in random biopsies. Circumferential salvage endoscopic submucosal dissection (ESD) for the entire BE was performed using a bipolar knife with tunnel creation and clip-band-line traction to enhance visualization. Microwave coagulation minimized bleeding, and the 459-minute procedure was completed safely despite the severe fibrosis. Stricture prevention included triamcinolone injection and Purastat polymer application, followed by high-dose proton-pump inhibition and oral viscous budesonide for 12 weeks. This multimodal approach effectively reduced stricture risk after circumferential ESD [1–4].

PYP224 Predictors of Clinical Success in the Endoscopic Management of Gastrointestinal Transmural Defects: A Multivariate Analysis of 95 Cases

Authors Lorenzo-Zúñiga V[1], Navarrete-Pérez I[1], Bustamante-Balén M[1], Alonso N[1], Garcia M[1], Satorres C[1], Soutullo-Castiñeiras C[1], García S[1], Argüello L[1], Pons V[1]

DOI 10.1055/s-0046-1821164

Aims Gastrointestinal transmural defects, especially postoperative leaks and fistulas, are associated with substantial morbidity and increasing incidence due to more complex surgery. Endoscopic therapy is the preferred minimally invasive alternative to rescue surgery, but clinical success varies widely and depends on anatomical, physiological, and technical factors. This study aimed to identify predictors of technical and clinical success in endoscopic management of gastrointestinal wall defects and to develop a prognostic nomogram for personalized decision-making.

Methods A retrospective cohort study was conducted at a tertiary referral center including all patients who underwent endoscopic treatment of postsurgical or iatrogenic gastrointestinal transmural defects from 2014 to 2024. Demographic, anatomical, and clinical variables were collected, along with defect size, location, and distance from natural orifices. Endoscopic therapies were classified as mechanical closure (clips or suturing) or coverage/drainage approaches (stents, vacuum therapy).Technical success was defined as complete closure or successful placement of the selected technique, and clinical success as definitive resolution without further intervention or surgery. Temporal trends were evaluated comparing early and recent periods, corresponding to wider adoption of drainage-based strategies. Univariate logistic regressions identified candidate predictors for inclusion in a multivariate logistic regression model, which was assessed for calibration and goodness of fit and used to generate a prognostic nomogram (▶ **Table 1**).

▶ **Table 1**

Variable	Effect direction	Odds Ratio (95 % CI)	p-value
Low anatomical location	↑ Higher success	81.2 (3.6–1834)	0.012
Distance to natural orifices (per cm)	↑ Higher success	1.13 (1.03–1.25)	0.011
Procedures performed ≥ 2022	↑ Higher success	7.16 (1.89–27.2)	0.0047
Mechanical techniques vs coverage/drainage	↓ Lower success	0.05 (0.009–0.27)	0.001
Defect size (per mm)	↓ Lower success	0.95 (0.91–0.99)	0.024
ASA III	↓ Lower success	0.26 (0.07–0.97)	0.045

Results A total of 95 procedures were performed in 83 patients, mostly postoperative defects (81.1 %) and predominantly located in the upper gastrointestinal tract (94.7 %). Technical success was 93.7 %, while clinical success reached 52.6 %. Outcomes improved over time, increasing from 45.1 % in 2014–2021 to 61.4 % in 2022–2024 with greater use of drainage and negative-pressure techniques (p = 0.149). In the multivariate analysis, lower gastrointestinal location (OR 81.2; p = 0.012), greater distance from natural orifices (OR 1.13 per cm; p = 0.011), and procedures performed from 2022 onwards (OR 7.16; p = 0.0047) independently predicted higher clinical success. Mechanical closure techniques (OR 0.05; p = 0.001), larger defect size (OR 0.95 per mm; p = 0.024), and ASA III status (OR 0.26; p = 0.045) were associated with lower success. The final model demonstrated good calibration and allowed development of a nomogram for individualized prognostic assessment.

Conclusions Endoscopic treatment of gastrointestinal transmural defects achieves high technical success but only moderate clinical success, although outcomes have improved significantly with the adoption of drainage-based and negative-pressure approaches. Clinical success is influenced by anatomical complexity, patient physiological status, and appropriate technique selection. The resulting predictive nomogram may support individualized risk stratifica-

tion and guide optimal endoscopic management of gastrointestinal leaks and fistulas.

Abstract Text

Refractory benign esophageal strictures are commonly treated with fully covered stents, but migration occurs in up to 40 % of cases. Endoscopic fixation methods have been introduced to resolve this issue. The X-Tack system, originally designed for GI defect closure, has been repurposed for stent anchoring. We report a simplified tack-only fixation approach that omits the suture component to streamline deployment. A 19-year-old patient with severe caustic-induced stricture, refractory to repeat dilations, experienced early migration of an initial stent. A second fully covered stent was placed and individually secured along the proximal stent edge using sequential helical tacks deployed through the stent mesh into healthy esophageal tissue. At 4-week follow-up, stent removal showed marked luminal improvement. This suture-less tack-only method appears feasible and reproducible.

PYP226 From Innovation to Standard Practice: A 100-Case Experience with Z-POEM in a Single Tertiary Center

Authors Mangiola F[1], Landi R[1], Perri V[1], Spada C[1], Familiari P[1]

Institute **1** Digestive Endoscopy Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

DOI 10.1055/s-0046-1821166

Aims Traditional management of Zenker's diverticulum (ZD) has relied on rigid endoscopic septotomy or open surgical approaches, both associated with higher procedural burden and complication rates, particularly in elderly or comorbid patients. Over the past two decades, flexible endoscopy has become an important minimally invasive alternative, offering flexible endoscopic septotomy (FES) as a valid therapeutic option with shorter recovery time and fewer complications. However, despite its advantages, FES remains limited by incomplete myotomy and technically challenging exposure in certain anatomies, which can lead to recurrence. Zenker's peroral endoscopic myotomy (Z-POEM) has emerged over the past decade as a minimally invasive alternative that enables a controlled submucosal tunneling approach and complete septal division. Although Z-POEM adoption has increased internationally, high-volume single-center analyses with consecutive, prospectively collected cases remain limited.This study aimed to evaluate the safety profile, efficacy and degree of procedural standardization achieved throughout our experience with the first 100 consecutive Z-POEM procedures at a tertiary referral center.

Methods We conducted a retrospective analysis of all consecutive patients undergoing Z-POEM between October 2020 and November 2025. Demographic characteristics, symptom duration, and diverticulum size were recorded. Diverticulum dimensions were extracted both from endoscopy (EGDS) and radiographic imaging (Rx). Procedural data included type of knife, use of guidewire, myotomy length, number of clips for mucosal closure, procedure duration, and in-hospital course.Clinical outcomes were assessed through symptom scores (Kothari), adverse events (AEs) graded according to ASGE lexicon, technical success, clinical success, and need for retreatment. Follow-up was performed through scheduled visits, telephone interviews, and additional endoscopy when indicated.

Results A total of 100 patients (61 % male; mean age 70.5 ± 10.4 years; BMI 24.6 ± 3.1 kg/m²) were included. Pretreatment symptoms persisted for a mean of 29 ± 39 months, and 95 % of patients were treatment-naïve, reflecting the role of our center as a primary referral site. Mean diverticulum size measured 14.7 ± 7.9 mm on EGDS and 24.9 ± 13.1 mm on Rx.All procedures were performed by three expert endoscopists using low-flow CO_2 insufflation and the TT-knife J in 98 % of cases, supporting high procedural standardization. Guidewire placement was required in only 3 % of cases, predominantly in anatomically challenging presentations. The mean myotomy length was 19.7 ± 7.2 mm, and closure was achieved with an average of 3.4 ± 0.8 clips.Technical success reached 98 %, two procedures were aborted due to the inability to obtain sufficient exposure of the diverticular septum during the tunneling. Procedures were efficient, with a mean duration of 17.9 ± 7.3 minutes and a mean hospitalization of 2.2 ± 1.5 days.During the index procedure, two mucosal perforations occurred but were immediately identified and managed endoscopically without clinical sequelae. No AEs occurred or conversions to alternative techniques were reported.At final follow-up (mean 22.2 ± 12.6 months; 23 % lost), 88 % of patients maintained sustained symptom relief (Kothari ≤ 4). The mean Kothari score showed a significant improvement, decreasing from 3.12 pre-procedure to 1.22 at the final follow-up, corresponding to a mean difference of 1.90 (95 % CI 1.36–2.44; $p < 0.05$). Retreatment was required in eight patients (8 %): repeat Z-POEM in 3 % and FES in 5 %. All reinterventions were completed endoscopically, without further complications, underscoring the manageable nature of recurrent symptoms.

Conclusions Our experience demonstrates that Z-POEM is a highly effective, safe, and reproducible technique for the management of Zenker's diverticulum. Technical success was consistently high across operators, while procedure time, resource utilization, and length of stay remained low, reflecting progressive standardization within the center. The absence of severe AEs or surgical conversions, and excellent long-term clinical response reinforce the role of Z-POEM as a first-line endoscopic therapy for ZD.

DOI 10.1055/s-0046-1821167

Aims Gastrointestinal transmural defects refer to a spectrum of conditions characterized by full-thickness rupture of the gastrointestinal wall. These defects are associated with high morbidity and mortality rates and often require prolonged hospital stays. Endoscopic vacuum therapy (EVT) has played an increasingly important role in managing these defects. The VacStent GI (Micro-Tech) is a novel device that synergistically combines the advantages of fully covered self-expanding metal stents (fcSEMS) with the principles of EVT.

Methods We prospectively analysed patients who underwent treatment for transmural oesophageal defects using VacStent between October 2023 and November 2025 at two tertiary referral centers in the United Kingdom. The primary outcome was clinical success, defined as the endoscopic and radiological evidence of defect closure. Secondary outcomes included the number of VacStent exchanges, technical success, serious adverse device effects (SADE), and time to defect closure.

Results Of the 22 patients treated (median age 66 years, IQR 58-73.5; 73 % male), 12 (55 %) had anastomotic leakage after oesophageal resection, 6 (27 %) had iatrogenic defects post gastroscopy, and 4 (14 %) had Boerhaave's syndrome. The median defect size was 9 mm (IQR 6-13.5). Clinical success was achieved in 73 % of cases, with a technical success rate of 100 %. The median time to defect closure was 11 days (IQR 5-14), requiring a median of 1 VacStent exchange (IQR 0-2). Of the 6 patients in which VacStent failed, 3 had defects within the surgical conduit, 2 had large associated cavities, and 1 was clinically unstable; thus, stent exchange was abandoned.

Conclusions Our multi-centre data demonstrates that VacStent therapy for transmural GI defects in the oesophagus is both safe and effective, with a clinical success rate of 73 %. A standardised pathway and protocol are needed to optimise management and improve outcomes for this challenging patient population. Higher quality data is needed as most of the literature consist of case series.

PYP228 Clinical Utility of the Water Pressure Method in Endoscopic Submucosal Dissection for Challenging Lesions: A Retrospective Study

Authors Tomida H[1, 2], Ikeda Y[1], Ninomiya T[2], Hiasa Y[3]

Institutes **1** Endoscopy Center, Ehime University Hospital, Toon, Japan; **2** Gastroenterology Center, Ehime Prefectural Central Hospital, Matsuyama, Japan; **3** Department of Gastroenterology and Metabology, Ehime University Graduate School of Medicine, Toon, Japan

DOI 10.1055/s-0046-1821168

Aims The water pressure method (WPM) was developed to perform endoscopic submucosal dissection (ESD) in the duodenum—a technically challenging procedure—safely and reliably. WPM is a type of underwater ESD that utilizes the endoscope's water jet function to create space beneath the mucosal flap, thereby improving visualization of the submucosal layer. Additionally, maintaining low intraluminal pressure increases the thickness of the submucosal layer compared to air insufflation, facilitating safer dissection. Its efficacy has also been reported in colorectal and pharyngeal ESD. At our institution, WPM is actively employed for ESD in the pharynx, esophagus, duodenum, and colon, particularly for lesions considered technically demanding. This study aimed to evaluate the effectiveness of WPM through a retrospective analysis of ESD cases performed at our institute [1, 2].

Methods We retrospectively analyzed cases of ESD for pharyngeal, esophageal, and colorectal lesions performed between January 2023 and October 2025. Patients were divided into two groups: conventional ESD under air insufflation (C group) and WPM-assisted ESD (W group). For pharyngeal/esophageal and colorectal lesions, patient characteristics and treatment outcomes were compared between the groups. The primary endpoint was treatment efficiency, calculated as dissection area per unit time (mm²/min), where the resected specimen area was estimated as πab (a = long axis, b = short axis). Secondary endpoints included en bloc resection rate and incidence of perioperative adverse events. Cases with incomplete procedures or missing data were excluded.

Results Pharyngeal/esophageal ESD was performed in 59 patients with 78 lesions. The C group included 52 patients (median age 72.5 years, range 49–88; 84.6 % male) with 6 pharyngeal and 54 esophageal lesions. The W group included 7 patients (median age 70 years, range 46–76; 85.7 % male) with 2 pharyngeal and 6 esophageal lesions. The W group comprised technically challenging lesions, such as lesions at the pharyngoesophageal junction, circumferential or near-circumferential cervical esophageal lesions, and lesions arising within an esophageal diverticulum lacking muscularis propria. Pharyngeal/cervical esophageal involvement was significantly more frequent in the W group (62.5 % vs. 10 %, $p < 0.01$). Treatment efficiency did not differ significantly (C group: 12.6 mm²/min; W group: 10.2 mm²/min, $p = 0.17$). En bloc resection was achieved in all cases. Perioperative adverse events included one post-procedural bleeding and one delayed perforation in the C group; none occurred in the W group. No intraoperative perforations were observed in either group. Colorectal ESD was performed in 95 patients with 102 lesions. The C group included 82 patients (median age 73 years, range 42–88; 51.2 % male) with 51 right-sided and 37 left-sided lesions. The W group included 13 patients (median age 74 years, range 55–85; 53.8 % male) with 7 right-sided and 7 left-sided lesions. Baseline characteristics were comparable between the groups. Lesion size was significantly larger in the W group (median 40.5 mm vs. 35 mm, $p = 0.01$). Treatment efficiency was significantly higher in the W group (22.1 mm²/min vs. 8.4 mm²/min, $p < 0.01$). Intraoperative perforation occurred in one case per group. Delayed perforation (4 cases, 4.5 %) and post-procedural bleeding (2 cases, 2.3 %) were observed only in the C group.

Conclusions In pharyngeal/esophageal ESD, WPM did not improve treatment efficiency but enabled the successful completion of procedures for high-risk lesions that were anticipated to be challenging with conventional ESD. In contrast, WPM significantly enhanced treatment efficiency in colorectal ESD. Perioperative adverse events were less frequent in WPM-assisted procedures for both pharyngeal/esophageal and colorectal lesions. WPM may improve both the safety and efficiency of ESD and facilitate treatment of lesions previously considered technically prohibitive.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Post-bariatric anastomotic leaks are serious complication following sleeve gastrectomy or gastric bypass procedures. Traditional management often requires surgical reintervention, but endoscopic techniques, particularly the use of self-expanding metal stents (SEMS), offer a minimally invasive alternative. This retrospective study evaluates the efficacy of endoscopic management of post-bariatric fistulas including the use of a double layer stent (Niti-S Beta Esophageal Stent), focusing on resolution rates, complications, and the number of procedures required for successful resolution [1–4].

Methods We retrospectively reviewed patients who developed an anastomotic leak following bariatric surgery between 2014 and 2023. These patients were treated endoscopically with the placement of a double layer stent (Niti-S Beta Esophageal Stent). The primary endpoint was resolution of the fistula considered achieved when the patient healed without requiring surgical reinterven-

tion. Secondary outcomes included adverse events, number of procedures required to achieve fistula resolution and late recurrence.

Results Data from 20 patients were collected (17 sleeve gastrectomy, 3 gastric bypass). Effective leak/fistula closure was obtained in 18/20 patients (90 %) who achieved resolution of the fistula without the need for subsequent surgical intervention. The mean number of procedures required for resolution was 3 while mean stent indwell time was 26.5 days.". Adverse events occurred in 3 patients: 1) stent migration, 1) esophageal perforation and 1) esophageal stenosis. All the adverse events were managed endoscopically respectively with 1) stent retrieval and double pig tail stents placement 2) closure with over the scope clip 3) mechanical esophageal dilations.

Regarding long-term outcomes, the mean follow-up duration was 39.3 months. A recurrence of the fistula occurred in 1 patient at 24 months post-treatment. The recurrence was also managed endoscopically. There were no further complications or recurrences during the follow-up period.

Conclusions Endoscopic management of post-bariatric anastomotic leaks using double layer stents (Niti-S Beta Esophageal Stent) is a safe and effective approach, with a high-resolution rate (90 %) and a reasonable complication rate (15 %) in our population. The mean follow-up of 39.3 months demonstrated long-term success, with only a single recurrence managed without surgery. The low need for additional surgical interventions and the ability to manage complications endoscopically further emphasize the value of double layer stents in the management of post-bariatric fistulas. These findings suggest that these stents could be considered as first-line treatment for anastomotic leaks after bariatric surgery, offering a non-invasive alternative with favourable long-term outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821170

Aims Although overall prevalence of benign oesophageal strictures (BOSs) is low, a rising prevalence of associated risk factors, such as increased life expectancy, gastro-oesophageal reflux disease and eosinophilic oesophagitis is predicted to contribute to an increased incidence and evolving aetiology. Endoscopic dilation (ED) currently remains the primary treatment modality. This study aimed to evaluate the current most common aetiologies for BOSs, alongside evaluating the success of ED.

Methods Between January 2021 and December 2023, 1994 upper GI endoscopies (UGIEs) with endoscopic dilatation of a BOS were identified using electronic patient records across 11 UK centres. Details of procedures were then collected in a retrospective observational fashion at each site before central pooling of pseudo-anonymised data for analysis [1–5].

For both individual UGIEs with dilatation and given "sessions" of dilatations (defined as consecutive UGIEs separated by ≤ 6 months), treatment was deemed successful if the lumen was confirmed to be dilated to a diameter of ≥ 14mm (confirmed on a check procedure > 4 weeks after, and/or not requiring further dilatation to maintain diameter within a 6-month period).

Results Eight hundred and eighteen patients (328[40 %] female; mean age 64.3[SD 15.52]) were followed-up for a mean of 20.5 (range 4–62) months, from time of initial stricture diagnosis. The most common aetiology of BOS were peptic in 38 % (313/818), post-op anastomotic in 13 %(105/818), post-radiotherapy in 6 % (48/818), post-operative (non-anastomotic) in 6 % (47/818), Schatzki rings in 6 % (46/818), and eosinophilic oesophagitis in 5 % (37/818). Less common aetiologies seen included: post-endoscopic mucosal resection (EMR), post-radiofrequency ablation (RFA), post-caustic injury, webs, lichen planus, and connective tissue disease (see ▶ **Table 1**).

▶ **Table 1** Most common aetiology of benign oesophageal strictures for patients (*N* = 818).

Stricture Aetiology	Number of patients *n*	Percentage of patients *n*/*N* (%)
Peptic	313	38
Post-operative (anastomotic)	105	13
Post-radiotherapy	48	6
Post-operative (non-anastomotic)	47	6
Schatzki ring	46	6
Eosinophilic oesophagitis	37	5
Other*	222	26

*'Other' includes (in order of frequency, though all representing < 5 %) cases of: unidentifiable aetiology, post-endoscopic mucosal resection (EMR), post-radiofrequency ablation (RFA), post-caustic injury, webs, lichen planus, connective tissue disease, and miscellaneous

Successful dilatation for a single UGIE procedure with ED was achieved in 875/1994 (43.9 %) of procedures. With respect to 'sessions' of consecutive dilatations, success was achieved within three months in 44.2 % (388/878) of patients, and within six months in 60.6 % (530/878) of patents. For successful sessions, mean number of dilatations required was 2.2 (SD 2.4), and median number of weeks to successful dilatation was 15 (IQR 7–30).

Conclusions Peptic strictures remain the most common aetiology of BOS. A significant proportion of patients (39.4 %) with BOS failed to achieve success following ED. This may reflect both the inherent limitations of ED and subop-

timal adherence to guidelines, particularly regarding the recommended frequency of dilations until treatment success is achieved.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP231 Tale of two cases: ERCP in situs inversus totalis

Authors Ocepek A[1, 2], Ademović T[1], Bukovnik N[1]

Institutes 1 Maribor University Medical Centre, Maribor, Slovenia; 2 University of Maribor, Faculty of medicine, Maribor, Slovenia

DOI 10.1055/s-0046-1821171

Abstract Text

Introduction: Situs inversus totalis (SIT) is a rare congenital anomaly in which internal organs are mirrored along the sagittal plane. The incidence is 1.25-16.7/100,000 individuals, with a slight male predominance. Altered anatomy in SIT presents a challenge in performing endoscopic retrograde cholangiopancreatography (ERCP). Technical difficulty is greater due to an inverted endoscopic view, altered fluoroscopic orientation, and a different direction of common bile duct (CBD) cannulation. Most data on the performance of ERCP in SIT are based on clinical cases [1–5].

Case 1: A 78-year-old female patient with known gallstones was admitted for acute cholangitis, Tokyo grade 1. Magnetic resonance imaging (MRI) revealed choledocholithiasis, and ERCP was indicated. However, the patient's SIT and other co-morbidities (non-ischemic dilated cardiomyopathy, chronic kidney disease, chronic atrial fibrillation on anticoagulant therapy, and ascending aortic aneurysm) posed a challenge. Firstly, gastroscopy was performed to assess the anatomy of the upper gastrointestinal tract. ERCP was performed in standard settings with the patient in the left semi-prone position and the endoscopist on the right side of the table. A technique with 180˚ rotation in the stomach and shortening of the endoscope in the duodenum in the opposite direction from usual was used. With standard cannula and guide wire cannulation of the CBD was achieved and confirmed with fluoroscopy and bile aspiration. Sphincterotomy was performed using a standard papillotome and manipulation of the duodenoscope tip. Successful balloon extraction of the stone followed with no complications.

Case 2: A 93-year-old male patient with SIT was admitted with signs of acute cholangitis, Tokyo grade 2. CT on admission showed small gallbladder stones and dilatation of the CBD to 12 mm with a thickened wall. We proceeded with ERCP, which was performed in the same position as previously described, and the same 180˚ rotation in the stomach technique was used. In this case, cannulation of CBD was achieved using a standard papillotome and guide wire, and successful balloon extraction of microliths following sphincterotomy. We performed stenting using a biodegradable biliary stent, and no complications occurred.

Conclusion: SIT presents a significant anatomical challenge during endoscopic procedures. The literature provides insufficient evidence to determine the optimal approach, and currently, no standard patient or endoscopist position for ERCP in SIT is recommended. Recognizing the reversed anatomy and the experience of the endoscopist are essential for safe and effective ERCP performance.

Abstract Text

Complete bile duct disconnections after liver transplantation usually require surgical repair, but advanced endoscopic techniques can resolve selected cases. Patient retransplanted in 2024 for ischemic cholangiopathy with Roux-en-Y hepaticojejunostomy and complete ductal disconnection. A duodeno-jejunostomy access with an apposition stent and a hepaticogastrostomy to segment II with a 6-mm covered stent were performed. The first hepaticogastrostomy attempt failed, later corrected with percutaneous drainage and saline distension. ERCP confirmed patency and an anatomical variant, enabling placement of proximal and distal magnets to induce a new anastomosis. One week later, reconnection was documented. Magnetic biliary reconstruction through DYUSE avoided surgical intervention [1–3].

PYP233 Endoscopic reconstruction of complete common bile duct transection after right hepatectomy using an innovative cholangioscopy-assisted ERCP-EUS rendezvous technique

Authors Mendes I[1], Vara-Luiz F[1], Palma C[1], Veloso J[1], Fonseca C[1], Ferreira M[1], Pinto-Marques P[1], Nunes G[1]
Institute 1 Hospital Garcia de Orta, Almada, Portugal
DOI 10.1055/s-0046-1821173

Abstract Text

A 58-year-old man with chronic hepatitis B underwent right hepatectomy for a 58mm hepatocellular carcinoma. Postoperatively, persistent bilious drainage suggested a biliary leak.

ERCP revealed contrast extravasation from the proximal common bile duct (CBD) into two ill-defined collections adjacent to the surgical drain. The left intrahepatic ducts (LIHD) were not opacified, and the guidewire could only be directed toward the leak, indicating complete discontinuity. Persistent bleeding during biliary sphincterotomy prompted placement of a fully covered self-expandable metal stent (FCSEMS) for hemostasis and biliary decompression. Magnetic resonance cholangiography confirmed complete transection, showing non-dilated LIHD with no communication to the proximal CBD, which was intercepted by a perihepatic biloma.

After multidisciplinary discussion, a second ERCP with peroral cholangioscopy was proposed to guide LIHD cannulation. A 3.2mm cholangioscope (EyeMAX) was advanced to the disrupted CBD, revealing a loculated cavity containing devitalized tissue and purulent bile. Multiple attempts to pass the guidewire into the LIHD failed, as the hepatic end of the transection was not observed. A linear echoendoscope enabled EUS-guided transgastric puncture with a 19G needle, achieving LIHD cholangiogram and anterograde cannulation. Guidewire passage into the CBD was hindered by repeated coiling within the cavity. The wire was left inside, the echoendoscope withdrawn, and the duodenoscope was reintroduced at the papilla to repeat cholangioscopy. Using a biopsy forceps through the cholangioscope, the guidewire was captured, pulled into the duodenum, and recovered to the working channel in a rendezvous procedure. A cannula was advanced into the LIHD, and the wire exchanged for retrograde access. Both transection ends were dilated with an 8mm balloon, and a 120x8mm FCSEMS was deployed, restoring biliary continuity.

The patient was discharged uneventfully a few days later. Follow-up CT showed resolution of collections, and the FCSEMS was removed after four months. Final cholangiography confirmed CBD reconstruction and complete leak resolution. This case highlights the effectiveness of a combined EUS-ERCP-Cholangioscopy approach in managing major leaks with complete CBD transection, avoiding surgical reintervention.

PYP234V Temporizing Hepaticogastrostomy (EUS-HGS) to Reconnect a Strasberg E3 Bile Duct Injury (BDI) via Retrograde Cholangioperitoneoscopy Rendezvous (RCR)

Authors Moreno Marquez C[1], Lopez Torres L[1], Cobreros del Caz M[1], De La Serna Higuera C[1], Sánchez-Ocaña R[1], Perez-Miranda M[1]
Institute 1 Rio Hortega University Hospital, Valladolid, Spain
DOI 10.1055/s-0046-1821174

Abstract Text

Severe post-Chole BDI needs surgery, but morbidity is high. A frail patient with Strasberg E3 BDI underwent segment-3 EUS-HGS. Following leak control, magnetic compression anastomosis was attempted via HGS. Opposing magnets failed to couple across a wide gap. Endoscopic repair was offered to avoid surgery/permanent HGS. Cystotome/balloon access via ERCP allowed nasobiliary drain (NBD) placement into the subhepatic space. The NBD was targeted with a cystotome via HGS under fluoroscopy, coiling a wire into the subhepatic, and stabilizing it by an ultrathin scope. Parallel ERCP with cholangioscopy allowed subhepatic access and guidewire retrieval. Following this RCR, 2 plastic stents were placed by ERCP across the BDI. Uneventful recovery; patient awaits healing of reconnected duct before definitive stent removal.

Abstract Text

A 25-year-old man with polytrauma and splenic laceration underwent splenic artery (SA) embolization. He subsequently developed an infected traumatic pancreatic collection which was treated with EUS-guided drainage using a LAMS. Four weeks later , he presented with upper gastrointestinal bleeding. CT-angiography revealed distal SA irregularity; however endovascular access was not feasible . EUS identified two SA-dependent arterial branches in direct contact with the LAMS. Both were punctured transgastrically with a 22G needle and successfully embolized with coils (18S, 10/5–Tornado), allowing safe subsequent stent extraction. Post-procedure CT confirmed successful embolization and resolution of the collection. No further bleeding was documented during follow-up. This case highlights EUS-guided vascular embolization as an effective alternative when interventional radiology is not feasible [1, 2].

PYP236 Through-the-LAMS Retrograde Access ERCP (TRAE) in Patients with Native Upper GI Anastomy: A Novel Endoscopic Approach for Combined Biliary and Gastric-outlet Obstruction (CBGO)

Authors Martinez-Cuevas C[1], Fernández Prada SJ[1], Maroto-Martin C[1], De La Serna Higuera C[1], Sánchez-Ocaña R[1], Cobreros del Caz M[1], Sanjosé Crespo A[1], Hernandez Gonzalez V[2], De Benito Sanz M[1], Ruiz Rebollo L[3], Mateos Rodríguez JM[4], Rodriguez Gomez S[5], Torres Yuste R[6], Perez Fernandez R[7], Perez-Miranda M[1]

DOI 10.1055/s-0046-1821176

Problem to solve Biliary drainage in patients with CBGO (benign or malignant). Anterograde transpyloric access to the papilla for ERCP is difficult in the most common type I/II stenosis. Extrahepatic EUS-guided biliary drainage (EUS-BD) achieves suboptimal outocomes in the setting of CBGO, whereas intrahepatic EUS-BD is limited by lack of intrahepatic dilation and by ascites.

Innovation To solve this problem, we propose TRAE (Through-the-LAMS Retrograde Access ERCP). This approach adapts the concept of through-the-LAMS ERCP, currently widely used in patients with post-surgical anatomy, to patients with native anatomy and CBGO. To circumvent antegrade blockage preventing access to the papilla, EUS-guided gastroenterostomy (EUS-GE) with a lumen-apposing metal stent (LAMS) is first performed. Once EUS-GE is established, a duodenoscope or a therapeutic forward viewing upper endoscope is passed through-the-LAMS to access the papilla. We evaluated the safety and efficacy of TRAE for biliary drainage in non-surgical patients with native anatomy and CBGO [1–3].

Results A descriptive multicenter study was undertaken. Nineteen patients (71 % male; age: 69 [62-83]) from seven hospitals were retrospectively identified with 26 attempts at TRAE between 1/1/20 and 26/6/25. Definitions: index procedure (first successful attempt or definitive ERCP failure) or follow-up procedure. Technical success (TS): cannulation/intervention by ERCP. Clinical success (CS): resolution of cholangitis/jaundice. Baseline clinical data and technique modifications were recorded.

There were 26 TRAEs (19 index/6 scheduled revisions/1 failed prior to index TRAE) in 19 patients. TS/patient during index TRAE was 13/19 (68.5 %); one failed TRAE was salvaged at on a repeat attempt using double guidewire traction, following antergrade transpyloric rendezvous, with guidewire retrieval towards the EUS-GE through the LAMS. TS/procedure = 19/26 (73 %), with 6 failed TRAE salvaged by EUS-BD. Failed TRAE incidence: 5 (70 %) without papillary access, and 2 without cannulation. TS in follow-up TRAE was 6/6 (100 %). CS was obtained in 100 % of patients/procedures with TS.

Biliary stent carriers and patients with prior GOO treated with LAMS predominated (▶ **Table 1**). AE: 2 LAMS dislodgement (7.7 %), one required surgery and another underwent laparotomy despite successful salvage and died of postoperative AEs. Dual guidewire traction effectively prevented LAMS dislodgment (0/13 vs 2/13). During follow-up, 2 transpapillary stent dysfunctions (15 %), required convertion to EUS-BD.

▶ **Table 1**

CBGO Benign/Malignant	13/6 (70/30 %)
Follow-up days	197 (IQR 18-842)
Dysfunction rate	15 %
Gastroscope/Duodenoscope	16/12 (57/43 %)
Native papilla/Biliary stent	16/10 (62/38 %)
Single-session /2-Stage TRAE	9/17 (35/65 %)
Days between GE-USE/ERCP	42.5 (IQR 0-336)
Dual guidewire traction	13 (50 %)
TS/CS/AE	73/100/7.7 %

Conclusions TRAE allows biliary drainage in anatomically challenging patient with native upper GI anatomy and CBGO, it is facilitated by a therapeutic gastroscope with dual guidewire traction, and is particularly suited for nonsurgical patients requiring revisions. This novel approach appears to avoid less invasive therapeutic options

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821177

Aims Surgically altered anatomy may complicate retrograde endoscopic pancreatic duct access. Endoscopic ultrasound (EUS)-guided ring drainage has been suggested as an effective alternative for this specific population by providing simultaneous bidirectional trans-anastomotic and transmural drainage using double pigtail plastic stents. Our aim was to evaluate the technical and clinical outcomes of EUS-guided ring drainage in surgically altered anatomy and describe technical aspects of the procedure.

Methods In this retrospective international evaluation, patients from 6 referral centers with surgically altered enteral and/or pancreatic anatomy were included who had undergone EUS-guided ring drainage between 2013 and May 2025. Primary outcome was technical success, secondary outcomes were intra- and postprocedural adverse events. Technical approach and follow-up are furthermore described.

Results Overall, 58 patients (median age 58 years, IQR 50-65, 47 % female) were included in this study. Indication for endoscopic intervention was pain and/or repeated acute pancreatitis in 51 (88 %) patients. Most patients had a history of pancreatoduodenectomy (N = 43, 74 %) and failed enteroscopy-assisted endoscopic retrograde pancreatography (N = 22, 38 %). Technical success with complete ring drainage was achieved in 51 patients (88 %). Technical failures (N = 7, 12 %) were attributed to failure to manipulate the guidewire across the anastomosis (N = 6, 10 %) and wire rupture (N = 1, 1.7 %). In 3 primary technical failures (5.2 %), pancreatic duct drainage was achieved via pancreaticogastrostomy, which could be converted to ring drainage in a second procedure. All centers had a similar technical approach with use of a 19G needle for access and 6 French (Fr) cystotome insertion + - balloon dilation for tract preparation and trans-anastomotic access. All ring drainages were performed using double pigtail stents, most common stent diameters were 7 Fr (N = 25) and 8.5 Fr (N = 24). In 6 patients (8.6 %), intraprocedural complications occurred in form of bleeding (N = 2, 3.4 %), stent dislocation (N = 2, 3.4 %) and loss of wire access (N = 2, 3.4 %). Post-procedural adverse events were recorded in 19 patients (32 %), namely acute pancreatitis (N = 7, 12 %), abdominal pain (N = 5, 8.6 %), bleeding (N = 4, 6.9 %), leak/exudation (N = 2, 3.4 %), stent dislocation (N = 1, 1.7 %) and others (N = 3, 5.2 %). Clinically, complications were graded AGREE I (N = 1, 1.7 %), II (N = 13, 22 %), IIIa (N = 4, 6.9 %), and IIIb (N = 1, 1.7 %). One patient (1.7 %) underwent surgery after stent dislocation with subsequent intramural gastric hematoma. All other complications were managed conservatively with medical and/or endoscopic treatment. During a median follow-up of 284 (IQR 95-556) days, one patient (1.7 %) underwent elective surgery because of insufficient clinical success. Planned endoscopic reintervention was performed in a median interval of 104 (IQR 84-180) days in 41 cases (71 %). In 28 patients (48 %), final stent extraction was performed after a median interval of 151 (IQR 97-382) days.

Conclusions Our data suggests that EUS-guided ring drainage in surgically altered anatomy is feasible and relatively safe. By providing effective bidirectional drainage using a homogenous technical approach across centerselective conversion to surgery was clinically warranted only in one patient. . Since this procedure is often applied in highly selected cases, prospective randomized studies are unlikely to be performed, but long-term clinical data from larger samples are required to investigate optimal follow up strategies.

Abstract Text We report the case of a patient with pancreatic adenocarcinoma who underwent pancreatico-duodenectomy and later developed two malignant afferent-loop strictures causing biliary tract dilation and jaundice. An initial EUS-guided gastroenterostomy (EUS-GE) was created using a 15 × 10 mm LAMS placed between the stomach and the best visualized segment of the afferent loop, located between the strictures. Despite technical success, the patient developed cholangitis due to an unaddressed proximal stricture. The initial LAMS was secured with an X-Tack system to prevent migration. Through an endoscopic ultrasound-directed transgastric intervention (EDGI), a second 15 × 15 mm LAMS was deployed across the proximal stricture. This stepwise strategy achieved full symptom resolution and biochemical normalization. The case highlights effective combined use of EUS-GE and EDGI in post-surgical anatomy [1–3].

Abstract Text

Lumen-apposing metal stent (LAMS) misdeployment occurs in ~10 % of EUS-guided gastroenterostomies (EUS-GE). Type III misdeployments (proximal flange in peritoneum) usually require surgery.[1, 2] We report the case of a patient with malignant gastric outlet obstruction who experienced a type III misdeployment during EUS-GE. Using EUS/fluoroscopic guidance, a transgastric puncture with a 19G needle allowed guidewire advancement into the malpositioned LAMS and jejunal loop, enabling successful LAMS-in-LAMS placement. Post-procedure imaging confirmed correct lumen apposition and no leak. After resuming a solid diet the patient was discharged. To our knowledge, this is the first report of successful endoscopic rescue of a type III misdeployment, demonstrating its feasibility and potential to avoid surgery.

PYP240 Combined Endoscopic Ultrasound and Endoscopic Retrograde Cholangiopancreatography using a single endoscope

Authors Pham KDC[1], Akerkar S[2], Inderson A[3]
Institutes **1** Haukeland University Hospital / Health Bergen, Bergen, Norway; **2** Haukeland University Hospital, Bergen, Norway; **3** Department of Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands
DOI 10.1055/s-0046-1821180

Aims Endoscopic Ultrasound Retrograde Cholangiopancreatography (EURCP) is a procedure that combines EUS and ERCP during the same endoscopic session. This study aimed to evaluate the feasibility, procedural success, and safety of performing single-session endoscopic ultrasound (EUS) and endoscopic retrograde cholangiopancreatography (ERCP) using a new linear EUS echoendoscope (EG-740UT, Fujifilm, Japan). We hypothesized that the unified platform is feasible, potentially reduces procedural time, and maintains a favorable adverse-event profile compared with multiple endoscope workflows.

Methods We conducted a retrospective analysis of consecutively performed EURCP procedures at two European tertiary centers between 2024 and 2025. All procedures were performed with the new linear EUS echoendoscope in a single-session format. Extracted variables included indication, duct cannulation outcomes, need for advanced cannulation techniques, completion of intended ERCP therapy, stent placement, EUS-guided therapy, and adverse events.

Results Twenty-three patients were included. The median age was 63 years (range 31–82); 15 females; 13 patients had a malignant indication. The primary endpoint—completion of both diagnostic EUS and therapeutic ERCP without endoscope exchange—was achieved in 22 of 23 cases (95.7 %). In the single case in which the primary endpoint was not met, ERCP could not be performed with the EUS scope, and conversion to a standard duodenoscope was required. Bile duct cannulation was successful in 21 patients (91.3 %), and procedural success, defined as successful cannulation followed by completion of the intended ERCP therapy, was achieved in 20 patients (87.0 %). Pancreatic duct cannulation occurred in three cases. Adjunctive cannulation techniques were required infrequently, with the double-guidewire method and needle-knife access each used in two cases (8.7 %). Therapeutic ERCP with transpapillary stenting was performed in 17 patients (73.9 %), including 11 plastic and six fully covered metal stents. Same-session therapeutic EUS was additionally performed in eight patients, comprising hepaticogastrostomy (n = 5), gastroenterostomy (n = 2), and combined gastropancreatostomy with biliary drainage (n = 1). Cholangioscopy was performed in one case. No severe adverse events occurred. Mild post-procedural abdominal discomfort was reported in two patients (8.7 %), cholangitis in 3 patients, and no instances of post-ERCP pancreatitis, bleeding, perforation, or infection were observed.

Conclusions EURCP using the new linear EUS echoendoscope demonstrated high technical feasibility, high procedural success, and an excellent safety profile. The ability to perform both diagnostic and therapeutic interventions with a single scope may streamline workflow, reduce scope exchanges, and enhance procedural efficiency. Future multicenter studies with larger cohorts are needed to compare this approach directly with conventional dual-scope strategies.

PYP241 Clinicopathological features associated with submucosal invasive cancer (SMIC) in large non-pedunculated colorectal polyps: defining the risk in morphological subtypes

Authors Lim A[1], Ayubi H[1], Campion J[1], Judge C[1], Eqbal A[1], Olabintan O[1], Adeyeye A[1], Bhoday J[1], Gendia A[1], Thrumurthy SG[1], Hayee B[1], Gulati S[1], Haji A[1], Emmanuel A[1]
Institute **1** King's College Hospital NHS Foundation Trust, London, United Kingdom
DOI 10.1055/s-0046-1821181

Aims Large series from eastern expert centres have defined the rate of submucosal invasive cancer (SMIC) in large non-pedunculated colorectal polyps (LNPCP) according to subtype along with associated clinicopathological features. Large western studies are limited and provide conflicting results leading some authors to suggest differences in invasive potential between eastern and western patients with LNPCP. Notable differences exist between studies in reported associations between incidence of submucosal invasion and clinicopathological features which can influence therapeutic recommendations. We aimed to define the true risk of SMIC by morphological subtype and clinicopathological features of LNPCP in patients referred to our tertiary centre.

▶ **Table 1** Rates of SMIC according to group

Morphological subtype:	
Is	12.9 %
LST G H	2.8 %
LST G NM	13.4 %
LST NG FE	17.3 %
LST NG PD	51.6 %
Size:	
20-30mm	9.8 %
31-40mm	12.3 %
41-60mm	11.4 %
>60mm	12.2 %
Location:	
Right colon	5.7 %
Left colon	14.9 %
Sigmoid/rectum	15.3 %

LST G H: laterally spreading tumour, granular, homogeneous; LST G NM: laterally spreading tumour, granular, nodular mixed; LST NG FE: laterally spreading tumour, non-granular, flat elevated; LST NG PD: laterally spreading tumour, non-granular, pseudodepressed

Methods All patients with LNPCP referred for consideration of treatment by endoscopic resection at a tertiary referral centre between January 2011 and December 2024 were included. Data collected included morphological subtype of LNPCP, size, location, sex and age. The incidence of SMIC by morphological subtype was determined and significant differences in SMIC by clinicopathological features were sought.

Results 1641 LNPCP (median size 40mm, range 20-210mm) were treated by endoscopic resection. 43 % of lesions were located in the right colon, 20 % in the left colon and 37 % in the rectum. 45 % were treated using ESD whilst 57 % were resected en bloc. Laterally spreading tumours which were non-granular and had pseudodepression had the highest risk of SMIC with SMIC incidence of 51.6 % (▶ **Table 1**). The rate of target SMIC was similar across size groups from 22) to 12.2 % (p = 0.59). No association was found between SMIC and age (p = 0.35) or sex (p = 0.12). Rectal or left colonic LNPCP were associated with higher risk of SMIC (p < 0.001). In a subgroup of patients with right colonic LNPCP, the incidence of SMIC in LST G NM was 7.0 %, LST NG 14.3 % and LST NG PD 50.0 %.

Conclusions This is a large western series allowing the assessment of SMIC risk according to clinicopathological features of LNPCP. High rates of en bloc resection increase the validity of these results. The risk of SMIC is largely determined by morphological subtype with comparable results to that in eastern centres, suggesting similar tumour biology. Contrary to findings from some studies, size of LNPCP, age or sex are of limited significance. Although right colon LNPCP have a lower overall risk of SMIC, specific morphological subtypes carry a higher risk of SMIC justifying en bloc resection in these cohorts.

DOI 10.1055/s-0046-1821182

Aims Colorectal cancer (CRC) remains one of the leading causes of cancer-related morbidity and mortality worldwide. The widespread implementation of screening programs led to an increased detection of T1-CRC, defined as CCR with submucosal invasion, and accounting for approximately 40 % of cancers identified during screening colonoscopy [1]. These lesions are potentially curable through endoscopic resection (ER). ER offers a less invasive alternative to surgery, with lower morbidity and shorter hospital stays [2, 3]. According to current international guidelines [4–6], when histopathological analysis reveals high-risk features [lymphovascular invasion (LVI), poor differentiation, high-grade budding, deep submucosal invasion, positive resection margins (R1 or Rx)], surgical intervention with lymphadenectomy is recommended. However, only 10 % of patients (pts) with T1-CRC exhibit lymph node metastasis (LNM) following surgery [7–9], indicating a high percentage of overtreatment. On the other hand, the definition of a "free resection margin" (FRM) is highly variable in literature: most guidelines suggest that an R0 resection requires a distance from the nearest tumor cell to the deep resection margin of > 1 mm, some studies have perhaps indicated that a margin of 0.1 mm may suffice [10], while a large meta-analysis assessing pathological factors associated with LNM in early CCR found no increased risk associated with R1 [11].

On this basis, there is a need for a more precise strategy for oncological risk assessment (local residual, LNM, distant metastasis (M) and recurrence) following ER of early CCR in order to minimize unnecessary surgeries. This study aims to evaluate the risk of local residual cancer, LNM, M, and recurrence in pts who underwent ER for T1-CRC with a positive resection margin (R1) and without other risk factors except deep submucosal invasion.

Methods Single-center retrospective study conducted in our academic tertiary referral center evaluating pts diagnosed with T1-CRC with positive resection margin irrespective of subsequent surgery (2013-2025). Inclusion criteria were: ER of T1-CRC; R1 (FRM ≥ 0 mm); deep submucosal invasion (sm2-sm3) as the unique risk factor; at least 1 year follow-up; evaluability of the margins in case of piece-meal resection of T1 CRC (no Rx). Exclusion criteria were: hereditary CRC syndrome; inflammatory bowel disease; preoperative radio-chemotherapy; presence of synchronous CRC; diagnosis of CRC > T2 in the 5 years before; Rx margins.

FU comprehended endoscopic evaluation (at 6 and 12 months for piece-meal resections and at 12 months for en-bloc resections) and a CT scan at 12 months.

Results A total of 39 pts were included. These were divided in 2 groups: 1) R1 margin of 0 mm (17pts; 43.6 %); 2) R1 margin between 0.1 and 1 mm (22 pts; 56.4 %). At diagnosis, none of the pts had LNM, while local residual cancer was found in 2 pts of group 1 (5.13 % [95 % CI: 1.07 % – 17.72 %]) and in none of group 2. At 1 year, none of the pts developed LNM, distant metastasis, nor local recurrence.

Conclusions Our study shows that in endoscopically resected T1-CRC the risk of LNM at diagnosis is extremely low (0 pts), while local residual cancer was observed in a small percentage of pts, irrespective of the entity of R1 (no statistical difference between 0 mm-R1 and 0.1-1mm-R1). The absence of LNM, M, and recurrence at 1 year FU further strengthens the notion that close monitoring may be sufficient for these pts, avoiding overtreating surgery. To support and to refine risk assessment strategies in early-stage CRC, larger, multi-center studies are warranted.

DOI 10.1055/s-0046-1821183

Aims To determine the prevalence of submucosal invasive cancer and assess curative endoscopic resection outcomes for large low-risk LNPCPs (≥ 20 mm) located in the left colon.

Methods A prospective multicentre cohort of patients referred for ER of LNPCPs between October 2008 and February 2025 was reviewed. All centres were tertiary referral hospitals performing both endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD). The left colon was defined as rectosigmoid to the splenic flexure inclusive. The primary outcome was to determine the rate of endoscopically curable SMIC in left colon LNPCPs.

Results 867 patients with sporadic left colon LNPCPs were included (median age 68, gender male 440 (50.7 %)). 842 underwent ER, and 25 did not have ER attempted due to either suspicion of deep SMIC (n = 22) or technical reasons (n = 3). Of those that underwent ER, SMIC was present in 100/842 (11.9 %), and in those who went direct to surgery, the SMIC rate was 16/25 (64.0 %). Thus, the overall rate of SMIC was 116/867 (13.4 %). 105/116 (90.5 %) cancers had full histopathological data to assess endoscopic curability. 13/105 (12.4 %) were considered low-risk. The rate of endoscopically curable SMIC of the entire cohort analysed was 13/856 (1.5 %)

Conclusions In a large Western multicentre cohort, the rate of SMIC in left colon LNPCPs was 13.4 %. Endoscopically curable cancer was 1.5 %. A selective resection algorithm that identifies curable SMIC is required to facilitate selection between different ER modalities.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP244 Resection of pT1 Colorectal Polyps: Experience from a Tertiary Care Center

Authors Pastor P[1], Castro Reyes LM[1], Masachs M[1], Armengol J[1, 2], Abu-Suboh M[1, 2], Benages A[1, 2], Guevara Cubas JA[1], Castillo MD[1, 2], Jimenez C[1], Pigrau M[1, 2], Cespedes C[2], Formento A[1], Tabares A[1], Baiget D[1], Suárez D[1], Aguilera L[3], Espin E[1], Kraft M[1], Silva L[1], Zucchiatti A[1], Landolfi S[1], Dot J[1, 2]

Institutes **1** Vall d'Hebron University Hospital, Barcelona, Spain; **2** Vall d'Hebron University Hospital Digestive Endoscopy Service, BARCELONA, Spain; **3** Hospital Universitari Vall d'Hebron, Barcelona, Spain

DOI 10.1055/s-0046-1821184

Aims pT1 colorectal polyps represent an early stage of colorectal cancer with a variable risk of lymph node involvement and recurrence. Treatment selection—endoscopic resection (ER) versus surgery—relies on the presence of high-risk histological features. Although the Japanese Society for Cancer of the Colon and Rectum (JSCCR) criteria are widely applied, their predictive accuracy remains controversial. This study evaluated our center's experience with pT1 colorectal polyp management and analyzed the association between histological risk factors and oncological outcomes.

Methods We performed a retrospective descriptive study of 154 patients with pT1 colorectal polyps resected between 2010 and 2022. Patients were classified according to initial treatment: ER alone (n = 75), ER followed by immediate surgery (ER + S, n = 26), or primary surgery (S,n = 53). Clinical, histological, and oncologic variables were collected. Univariable logistic regression analyses were used to assess associations between histological features and lymph node metastasis.

Results Among the 154 patients, 4 developed recurrence and 12 died, none of the deaths directly attributable to the pT1 lesion. All recurrences occurred in the high-risk group. High-risk histological features were present in 72.1 % of patients (n = 111). Lymph node metastasis was identified in 12 patients, all within the surgically treated groups. Among these, 5 (41.7 %) had perineural invasion and 4 (33.3 %) had lymphovascular invasion. In the surgical subgroup, both features were independently associated with lymph node metastasis (p = 0.01)

Conclusions ER appears to be a safe and effective treatment for selected pT1 colorectal polyps, even when some high-risk features are present. PNI and LVI emerged as the strongest predictors of lymph node metastasis. These findings support an individualized approach to decision-making, prioritizing histological factors with proven prognostic relevance and potentially reducing unnecessary surgical interventions.

PYP245 Advanced multimodal rectal dissection (ESD/EID/EFTR) for malignant rectal lesions enables ultra-low organ preservation: a multicentre cohort from three ESD referral centres in Greece

Authors Tribonias G[1], Mavrogenis G[2], Zormpas P[1], Marakis I[3], Leontidis N[1], Vogli S[2], Nakou E[1], Katzakis C[3], Spinou M[1], Pikoulas A[1], Bassioukas S[3]

Institutes **1** Gastroenterology Department, Korgialeneio-Benakeio Hellenic Red Cross Hospital, Athens, Greece; **2** Third Space Endoscopy Unit, Department of Gastroenterology, Mediterraneo Hospital, Athens, Greece; **3** METROPOLITAN GENERAL, Athens, Greece

DOI 10.1055/s-0046-1821185

Aims Apart from endoscopic submucosal dissection (ESD), endoscopic intermuscular dissection (EID) and exposed full-thickness resection (EFTR) extend curative endoscopic resection to the ultra-distal rectum, but multicenter outcome data are scarce. We evaluated oncological adequacy, safety and rectal preservation of a multimodal dissection strategy for malignant rectal lesions.

Methods We analyzed a prospectively maintained database of 275 consecutive advanced endoscopic rectal resections performed in three Greek ESD referral centers (Dec-2021 to Oct-2025). All lesions classified as malignant (pT1a or more) were included. Resections were categorized as ESD or EID ± EFTR. R0 required clear lateral and vertical margins. High-risk histology was defined as pT1a lesions with, lymphovascular or perineural invasion, poor differentiation or tumor budding Bd2–3 or pT1b and PT2 lesions. Primary outcomes were en-bloc and R0 resection; secondary outcomes were adverse events (AEs), local recurrence and need for radical rectal surgery (TME). Statistical analysis was performed using R Statistical Software (v4.4.1; R Core Team 2021).

Results Among 275 rectal resections, 46 (16.7 %) malignant lesions were analyzed (ESD 30, EID ± EFTR 16). EID ± EFTR was mainly used for ultra-distal lesions (median distance from anal verge 10 vs 75 mm for ESD, p = 0.044) with higher rates of fibrosis (57 % vs 21 %) and previous neoadjuvant therapy (31 % vs 4.3 %). Pathological staging was also more advanced in the EID ± EFTR group, with a higher proportion of pT2 cancers (38 % vs 6.9 %). Despite this selection bias toward technically challenging lesions, en-bloc and R0 resection rates remained high at 96 % and 80 %, respectively, with similar R0 between ESD and EID ± EFTR (86 % vs 69 %; p > 0.2). High-risk histology was present in 31/46 (69 %). AEs occurred in 5/46 (11 %), all managed non-surgically. Radical surgery was required in 10/46 (22 %), yielding a rectal-preservation rate of 78 %. A median follow up of 14 months (IQR: 7-32) was available in 18 patients, local recurrence

occurred in 3 (17 %) with no significant differences in recurrence or survival outcomes between techniques. Full data are provided on ▶ **Table 1**.

▶ **Table 1** Baseline characteristics by type of resection

Characteristic	EID + /-EFTR N = 16	ESD N = 30	p-value
Lesion size (mm)	25 (20, 43)	39 (25, 65)	0.073
Distance from anus (mm)	10 (0, 30)	75 (5, 145)	**0.044**
Preoperative neoadjuvant treatment	4 (31 %)	1 (4.3 %)	**0.047**
Postoperative adjuvant treatment	4 (31 %)	3 (13 %)	0.2
R0	11 (69 %)	25 (86 %)	0.2
En bloc resection	16 (100 %)	27 (93 %)	0.5
Fibrosis	8 (57 %)	5 (21 %)	**0.035**
Pathological staging			**0.016**
pT1a	4 (25 %)	12 (41 %)	
pT1b	5 (31 %)	15 (52 %)	
pT2	7 (44 %)	2 (6.9 %)	
High risk histology	12 (75 %)	19 (66 %)	0.7
Complications	1 (6.3 %)	4 (14 %)	0.6
Follow up months	17 (8, 30)	14 (6, 32)	0.8
Recurrence	2 (25 %)	1 (10 %)	0.6
Surgery	3 (19 %)	7 (23 %)	> 0.9
Rectal preservation	13 (81 %)	23 (77 %)	> 0.9

Conclusions In this three-center cohort, a multimodal dissection strategy combining ESD, EID and EFTR safely extends curative intent to the ultra-distal rectum, with high R0 rates, low morbidity and > 75 % of rectal preservation despite a substantial burden of high-risk histology. Although the retrospective, observational design introduces expected selection bias between resection methods, these data remain particularly valuable given the scarcity of evidence.

PYP246 The Validation of the Predictive Performance of a Nomogram for Synchronous Lymph Node Metastasis in pT1 Colorectal Cancer after Endoscopic Resection: A Multicenter Cohort Study

Authors Yoshii H, Hotta K[1], Uozumi T[2], Kisihda Y[3], Mizuguchi Y[2], Sekiguchi M[2], Oka S[3], Saito Y[2]

Institutes **1** Division of Endoscopy, Shizuoka Cancer Center, Shizuoka, Japan; **2** Endoscopy Division, National Cancer Center Hospital, Tokyo, Japan; **3** Department of Gastroenterology, Hiroshima University Hospital, Hiroshima, Japan

DOI 10.1055/s-0046-1821186

Aims The Japan Society for Cancer of the Colon and Rectum (JSCCR) developed a nomogram predicting lymph node metastasis (LNM) in T1 colorectal cancer (CRC) through a nationwide multicenter study [1]. Although the nomogram demonstrated good predictive performance, it has not been validated exclusively in endoscopically resected T1 CRC, which represents the intended target population of the nomogram. The nomogram is expected to identify patients who require additional surgery after endoscopic resection, although its optimal cutoff value has not yet been established. This study aimed to validate the predictive performance of the nomogram for synchronous LNM in patients with endoscopically resected T1 CRC and to explore an optimal threshold for identifying patients at low risk of synchronous LNM.

Methods Patients who underwent endoscopic resection for pT1 CRC between 2018 and 2024 at multiple institutions were retrospectively reviewed. Among 1,037 endoscopically resected cases, 490 underwent additional surgery. After applying exclusion criteria, 323 cases were analyzed. Predictive performance was evaluated using the area under the receiver operating characteristic curve (AUC).

Based on data from the Japanese National Clinical Database, surgery-related mortality for colorectal cancer ranges from 0.6 % to 2.1 % [2]. Given these figures, surgery-related mortality for pT1 colorectal cancer would conservatively be expected to remain below 1 %. Consequently, in patients categorized as low risk by the nomogram, an incidence of synchronous LMN exceeding 1 %—the assumed surgical mortality rate—would be clinically unacceptable. On this basis, the cutoff value of the nomogram was set at < 1 %.

A logistic regression analysis was performed to determine a nomogram score threshold corresponding to an estimated LNM rate below 1 %. Patients were then divided into low- and high-score groups, and actual LNM rates were compared.

Results Among the 323 patients (median age, 68 years [IQR: 60–74]; 189 men and 134 women), the primary tumor locations were as follows: cecum (n = 20), ascending colon (n = 59), transverse colon (n = 29), descending colon (n = 14), sigmoid (n = 109), rectosigmoid (n = 33), rectum Ra (n = 20), and rectum Rb (n = 39). The median tumor size was 21 mm (IQR: 15–33). The median submucosal invasion depth was 2,480 µm (IQR: 1,478–4,000), and lesions were classified as < 1,000 µm (n = 36), 1,000–1,999 µm (n = 92), and ≥ 2,000 µm (n = 195). Histologic grading revealed G1 in 271, G2 in 51, and G3 in 1. Lymphovascular invasion (LVI) was negative in 154 lesions and positive in 169. Tumor budding (BD1/2/3) was observed in 264, 41, and 18 lesions, respectively.

Synchronous LNM was identified in 30 patients (9.3 %). The nomogram demonstrated good predictive performance for synchronous LNM, with an AUC of 0.772. The optimal nomogram score threshold corresponding to an expected LNM risk < 1 % was 87.3. Based on this cutoff, 12 patients were classified as low-score and 311 as high-score, with observed LNM rates of 0 % and 9.6 %, respectively.

Conclusions A nomogram-based risk classification using a threshold to maintain a synchronous LNM rate below 1 % accurately identified LNM-negative patients after endoscopic resection for pT1 CRC. However, the potential to reduce overtreatment remains limited, and further study is warranted.

Aims The risk factors for metastasis in T1 colon cancer and the criteria for additional resection following endoscopic treatment are important topics. In recent years, several reports have emerged suggesting that among risk factors, the depth of invasion shows a weak correlation with metastasis. Furthermore, there are reports indicating differences in recurrence risk and prognosis between the rectum and the colon. Therefore, we aimed to clarify the impact of tumor location on metastasis risk using a multicenter prospective registry database of colorectal T1 cancers without considering invasion depth.The risk factors for metastasis in T1 colon cancer and the criteria for additional resection following endoscopic treatment are important topics. In recent years, several reports have emerged suggesting that among risk factors, the depth of invasion shows a weak correlation with metastasis. Furthermore, there are reports indicating differences in recurrence risk and prognosis between the rectum and the colon. Therefore, we aimed to clarify the impact of tumor location on metastasis risk using a multicenter prospective registry database of colorectal T1 cancers without considering invasion depth.

Methods Patients aged 20 years or older diagnosed with colorectal pT1 cancer and resected endoscopically or surgically at 48 Japanese institutions were prospectively enrolled after obtaining consent for cohort study participation. Exclusion criteria were inflammatory bowel disease associated colorectal cancer, familial adenomatous polyposis, coexisting or past history of invasive colorectal cancer, and active cancer in other organs. The rectum was defined as the upper rectum (Ra) and the lower rectum (Rb), and the colon as all other locations. The metastasis high-risk group was defined as cases not meeting all of the following pathological criteria without considering invasion depth: 1) no lymphatic invasion (Ly0), 2) no venous invasion (V0), 3) tumor budding grade1 (BD1), and 4) well to moderate differentiated tubular adenocarcinoma (tub1 or tub2). This study compared the proportion of high-risk groups for metastasis in the rectum and colon using data at the time of registration.

Results Between May 2017 and January 2021, 1527 patients were registered, and 1479 patients were included after excluding ineligible cases. The final analyzable patients were 351 rectal cases and 1128 colon cases. Their respective backgrounds were: male 67 %/58 %, median age 68/70 years old, macroscopic type including depressed type 27 %/31 %, median tumor size 20/18 mm, and initial endoscopic treatment (including surgical local resection) 78.0 %/68.1 %. The proportion of high-risk groups for metastasis was 55.0 % in the rectal group and 40.3 % in the colonic group ($P < .001$), with an odds ratio of 1.18 (95 % confidence interval 1.42-2.30). Furthermore, when limited to cases with a lesion diameter < 10 mm, the rectal group was 78.6 % and the colonic group was 38.1 %, with an odds ratio of 5.95 (95 % confidence interval 1.56-22.72).

Conclusions When evaluating the risk of metastasis in T1 colorectal cancers without considering invasion depth, the rectum was found to be a significantly higher risk than the colon. This was particularly pronounced in cases with a diameter of less than 10 mm. A careful pre-treatment evaluation is necessary, and caution should be exercised against performing cold snare polypectomy too readily.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP249 A Novel Diagnostic Algorithm for the Detection of Submucosal Invasive Cancer in Large Colorectal Polyps: Results from a Multicentre Prospective Study

Authors Argenziano ME[1, 2], Badrulhisham F[1, 2], Sorge A[3, 4], Poortmans PJ[5, 2], Monod A[1], Montori M[6], Tornai T[1], Debels L[5, 2], Desomer L[7, 2], Tate D[1, 2]

DOI 10.1055/s-0046-1821189

Aims Accurate optical assessment of submucosal invasive cancer (SMIC) in large non-pedunculated colorectal polyps (LNPCPs) is crucial for selecting appropriate treatment. Current classification systems are complex and vary in accuracy. We developed a simple diagnostic algorithm combining gross morphological assessment (Blink impression: spontaneous bleeding, extra redness, depression, fold deformation, ulceration, chicken-skin mucosa), the presence of a ≥ 10 mm Paris 0-Is nodule and a validated simplified vascular pattern score (Colorectal Regular-Irregular Score, CRIS) [1]. This multicentre prospective study evaluated the real-time accuracy of this algorithm for SMIC detection by trained endoscopists.

Methods We conducted a prospective study across four centres (three Belgian, one Italian; August 2023–November 2025). Consecutive LNPCPs were assessed in vivo before resection. For each lesion, a structured approach was followed: (1) Blink impression, positive when ≥ 2 gross morphologic features present using high definition white light; (2) presence of a ≥ 10mm Paris 0-Is nodule; (3) CRIS as regular (R), regularly irregular (RI), or irregular (I), positive when RI or I using virtual chromoendoscopy plus up to 80x magnification. Blinded histopathologic identification of SMIC served as the reference standard. Diagnostic performance and odds ratios (OR) with 95 % confidence intervals (CI) were calculated using generalized linear mixed models.

▶ **Table 1**

	Sensitivity	Specificity	Accuracy	OR (95 % CI)	p value
Blink (≥ 2 features)	76.0 % (61.8-86.9)	69.2 % (62.0-75.7)	70.6 % (64.4-76.4)	2.3 (1.7-3.0)	**< 0.001**
CRIS (RI/I)	82.0 % (68.6-91.4)	71.6 % (64.6-77.9)	73.7 % (67.7-79.2)	11.5 (5.4-26.7)	**< 0.001**
≥ 10mm Paris 0-Is nodule	40.0 % (26.4- 54.8)	63.1 % (55.9-70.0)	58.3 % (51.8-64.6)	1.1 (0.6-2.1)	0.682
Blink or CRIS positive	84.0 % (70.8-92.8)	61.6 % (54.2-68.7)	66.4 % (59.9-72.4)	8.4 (3.9-20.3)	**< 0.001**

Results Overall, 240 LNPCPs from 240 patients were assessed by 10 endoscopists (3 experts, 7 fellows). SMIC prevalence was 20.8 % (50/240), of which 70 % (35/50) had deep SMIC. Median polyp size was 30mm (IQR 40–20); 33.8 % were rectal (▶ **Table 1**).

For SMIC detection, Blink (≥ 2 features) achieved sensitivity of 76.0 % (95 %CI 61.8–86.9), specificity of 69.2 % (62.0–75.7), and accuracy of 70.6 % (64.4–76.4), with OR 2.3 (1.7–3.0; P < 0.001). CRIS (RI/I) achieved sensitivity of 82.0 % (68.6–91.4), specificity of 71.6 % (64.6–77.9), and accuracy of 73.7 % (67.7–79.2), with OR 11.5 (5.4–26.7; P < 0.001).

The ≥ 10mm Paris 0-Is nodule showed poor diagnostic performance: sensitivity 40.0 % (26.4–54.8), specificity 63.1 % (55.9–70.0), accuracy 58.3 % (51.8–64.6), with non-significant OR 1.1 (0.6–2.1; P = 0.682) and was excluded from the final algorithm.

When either Blink or CRIS was positive, sensitivity increased to 84.0 % (70.8–92.8), specificity was 61.6 % (54.2–68.7), and accuracy 66.4 % (59.9–72.4), with OR 8.4 (3.9–20.3; P < 0.001).

Conclusions This novel, simple diagnostic algorithm, where either Blink impression or vascular pattern assessment (CRIS) was positive achieved high sensitivity for SMIC detection. For general endoscopists evaluating LNPCPs, prioritizing high sensitivity is crucial to minimize the risk of missing malignancy. A sensitivity-first approach can naturally trigger thorough photo-documentation and clear signposting for multidisciplinary review, while the accompanying modest drop in specificity may be a reasonable and clinically acceptable trade-off. In this way, the algorithm functions as a practical, easy-to-apply aid for real-time decision-making, with the potential to shorten diagnostic pathways, reduce delays, and lessen the need for repeat procedures, ultimately easing the burden on patients.

Aims Intensive surveillance instead of completion surgery is being more widely adopted after local resection of high-risk T1 colorectal cancer (T1CRC) for early detection of recurrences. However, due to limited evidence, the optimal surveillance intensity remains unknown. This study examined the preferences and attitudes of high-risk T1CRC patients and their physicians toward surveillance.

Methods We conducted a multicenter cross-sectional survey in five Dutch hospitals. Eligible patients had an histologically confirmed high-risk T1CRC treated with local organ-preserving resection after January 2018. Physicians actively involved in T1CRC management were also invited. Participants completed an Adaptive Conjoint Analysis (ACA) to evaluate the relative importance

of surveillance attributes (mortality, endoscopy, imaging, laboratory testing and incidental findings) in context of T1CRC follow-up. Participants compared pairs of hypothetical surveillance scenarios varying across these attributes and selected their preferred option. Choices revealed the relative importance of each attribute and the trade-offs they are willing to make. Furthermore, participants completed the Medical Maximizer–Minimizer Scale (MMMS), a validated tool assessing individuals' general tendency to favor more (maximizers) or less (minimizers) medical intervention across all healthcare decisions. Patients additionally completed the Cancer Worry Scale (CWS), and the EQ-5D-5L to assess cancer-related worry and quality of life.

Based on ACA results, we developed a preference simulator, a tool integrating utility scores from individual participants to predict the proportion of patients or physicians likely to favor specific surveillance strategies under varying clinical scenarios.

Results In total, 104 patients and 40 physicians participated. Patients had a mean age of 66.1 years (Standard Deviation (SD) 9.0), with balanced sex distribution (48.9 % male). Most patients had one histological high-risk feature (66 %). Adjuvant therapy was given in 57.9 %, mostly surgery (70.5 %). Median follow-up was 46 months, with 6 % recurrence (3 % local, 3 % distant).

Among patients, 55.3 % were medical maximizers (MMMS score ≥ 40) and 44.7 % minimizers (MMMS score < 40). All physicians were medical minimizers. Overall, 39.4 % of patients reported high levels of cancer worry (CWS score ≥ 20) and the mean EQ-5D-5L score was 0.90 (SD 0.13).

Mortality was the most important ACA attribute for patients and physicians (relative importance of 31.4 and 32.3, respectively), followed by endoscopy frequency (21.3 and 20.5). Imaging frequency (17.2 and 16.6), risk of incidental findings (15.3 and 19.3), and lab testing (14.8 and 11.4) had lower but non-negligible relative importance.

Our simulator enabled modelling and comparison of multiple surveillance scenarios. Two scenarios were modeled in our simulator: (1) standard surveillance according to Dutch guidelines, consisting of five endoscopies, five imaging sessions and ten laboratory tests over five years, with 3 % mortality and 20 % risk of incidental findings; and (2) reduced surveillance, consisting of three endoscopies, three imaging sessions and five laboratory tests over five years, with 6 % mortality and 15 % risk of incidental findings. Under these assumptions, 91.7 % (Standard Error (SE) = 0.7 %) of patients and 83.0 % (SE = 2.0 %) of physicians preferred the reduced surveillance strategy. A further comparison was made between (1) guideline surveillance and (2) a lower-intensity scenario, consisting of two endoscopies, two imaging sessions and five laboratory tests over five years, with 10 % mortality and 15 % risk of incidental findings. In this comparison, 84.5 % of patients (SE = 1.5 %) and 62.4 % of physicians (SE = 4.4 %) favored the reduced surveillance strategy.

Conclusions Patients and physicians were willing to accept higher mortality in exchange for reduced surveillance, despite ranking mortality as the most important attribute. Using our simulator, a modest reduction in surveillance with higher mortality risk was preferred by most patients (91.7 %) and physicians (83.0 %), with patients showing stronger preference. This highlights the importance of considering patient perspectives in T1CRC surveillance. Our simulator can help predict and incorporate these perspectives in surveillance guidelines.

PYP251 Outcomes of double-balloon enteroscopy in the management of Peutz-Jeghers syndrome small bowel polyps: a UK tertiary centre experience

Authors Butler K[1], Nandi N[1], Dhali A[2], Shiha MG[1], Sidhu R[3, 1], Sanders DS[3, 1], Tai FWD[1]

Institutes **1** Academic Unit of Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK, United Kingdom; **2** Sheffield Teaching Hospitals NHS Foundation Trust, UK, Sheffield, United Kingdom; **3** Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom

DOI 10.1055/s-0046-1821191

Aims Peutz-Jeghers syndrome (PJS) an autosomal dominant polyposis syndrome with a predisposition to hamartomatous polyps in the small bowel (SB) and emergent risk of intussusception, obstruction and intestinal surgery. The aim of this study is to examine outcomes of balloon-assisted enteroscopy (BAE) in Sheffield, UK, and published world data.

Methods In Sheffield, patients undergoing BAE for PJS polypectomy between 1st January 2010 and 31st December 2025 were included. The number and maximum size of polyps removed, BAE-related complications, and rate of small bowel resection before and after BAE were examined. Published studies worldwide reporting these outcomes were examined.

Results ▶ **Table 1** highlights the outcomes of 18 published studies which included a total of 396 patients and 1100 BAE procedures for PJS polypectomy. Locally in Sheffield, 13 patients underwent 73 double-balloon enteroscopies (DBE) (59 antegrade, 14 retrograde) between 2010 and 2025. There was a mean of 5.6 procedures per patient during an observation time of 59 months (range 3-149 months). 69 % (9/13) had a history of previous small bowel resection. A total of 179 polyps were removed with an average maximum polyp size of 20mm (range 10-60mm) and a mean of 2.5 polypectomies per procedure. The overall complication rate was 6.8 % (5/73). Four complications were related to DBE (2 episodes of pancreatitis, 1 serositis and 1 aspiration pneumonitis). One complication occurred following polypectomy (bleeding from stalk requiring endoscopic therapy and transfusion). There were no perforations. One patient (7.7 %) required elective small bowel resection due to failure to reach the polyp via DBE. During the period of follow-up, three patients died: one from metastatic adenocarcinoma of unknown primary, one after a Whipple's procedure for a pancreatic cyst and one of unknown cause (suspected to be related to a small bowel stricture and cancer) [1–3].

Conclusions Balloon-assisted enteroscopy is a safe and effective strategy for removing PJS small bowel hamartomas. Complications rates are around 6-7 %. Small bowel surgery post BAE ranges between 0–28 %. It is anticipated that BAE and polypectomy reduces small bowel surgery in patients with PJS, however outcomes of present studies are heterogenous.

DOI 10.1055/s-0046-1821192

Aims Small-bowel surveillance and therapeutic polypectomy are key components in the management of Peutz–Jeghers syndrome (PJS). We aimed to evaluate the real-world performance of double balloon enteroscopy (DBE) in patients with PJS who had undergone prior small-bowel mapping with magnetic resonance enterography (MRE) and/or computed tomography enterography (CTE), but not capsule endoscopy due to contraindications.

Methods We retrospectively reviewed consecutive PJS patients who underwent their first enteroscopy at our center between January 2022 and December 2024. All included patients had prior small-bowel mapping with MRE or CTE but were not eligible for capsule endoscopy due to known strictures, multiple prior laparotomies or previous episodes of intussusception. Data on epidemiology, imaging characteristics, enteroscopic approach, therapeutic yield, complications, and the number of procedures required for complete polyp eradication were collected. Discrepancies between imaging and enteroscopy regarding polyp number, size, and dominant location were recorded [1, 2].

Results Sixteen patients were enrolled (11 males; mean age 39 ± 13 years). The mean age at PJS diagnosis was 17 ± 7 years. A de novo mutation was identified in 9/16 (56%) who were diagnosed following an episode of intussusception or bleeding. A history of laparotomy was present in 12/16 (75%). Prior mapping identified no polyps > 15 mm in 3/16 (18.8%), 1–5 polyps in 12/16 (75%), and > 5 polyps in 1/16 (6.2%). Enteroscopy was performed via an antegrade approach in 14/16 (87.5%) and retrograde in 2/16 (12.5%); laparoscopic-assisted DBE was required in 3/16 (18.8%). At least one polyp was removed in all patients. The median number of polyps removed during the initial procedure was 2 (range 1–7), with a median largest polyp size of 40 mm (15–70 mm). Standard endoscopic mucosal resection was performed in 14/16 (87.5%), while surgical resection was required in two cases. A single post-procedural bleeding event (6.25%) was recorded. Complete eradication of all identified polyps required a median of one enteroscopy (range 1–4). Among patients requiring multiple sessions, the median interval to complete eradication was 25 months (range 3–39). Imaging underestimated polyp burden in 9/16 patients (56.3%) and polyp size in 7/16 (43.7%), while discrepancies in dominant polyp location occurred in 3/16 (18.8%).

Conclusions Double balloon enteroscopy is a highly effective and safe therapeutic modality for small-bowel polyp management in PJS, achieving complete polyp eradication with minimal complications. When Cross-sectional imaging is the sole surveillance modality the polyp burden can occasionally be underestimated, highlighting the essential role of enteroscopy for accurate assessment and comprehensive treatment planning in PJS.

PYP253 Long term outcomes post balloon assisted enteroscopy and therapy of small bowel strictures in Crohn's disease

Authors John S[1], Sheriff N[1], Willmann L[1]
Institute 1 Gold Coast University Hospital, Southport, Australia
DOI 10.1055/s-0046-1821193

Aims Balloon assisted enteroscopy and endoscopic balloon dilatation (EBD) is a safe and effective therapeutic option for management of small bowel strictures in Crohn's disease. However, evidence for long-term clinical outcomes remains limited. Our aim was to evaluate the technical success and long-term clinical efficacy of EBD in small bowel Crohn's disease.

Methods Retrospective cohort study of adult patients with small bowel Crohn's disease who underwent enteroscopy between January 2015 – January 2025 at a single tertiary hospital. Clinical and endoscopic data at index procedure and follow up data were collected from electronic medical records.

Results 68 patients underwent 168 procedures; 35 were females (51.5 %) and 33 males with a mean disease duration of 14.7 years. 92 (54.7 %) therapeutic procedures were performed for EBD. 28 (41.2 %) patients required a single EBD, and 40 (58.8 %) patients required multiple procedures with an average of 2 procedures. The mean dilation diameter achieved was 13 mm (9-16.5mm). EBD was successfully performed in 84.8 %. There were 4 cases of bleeding (4.3 %) and one anaesthetic complication (1.1 %). No bowel perforation occurred. Clinical success defined as absence of obstructive symptoms was achieved in 90.2 % of this cohort. Only 2 patients (2.2 %) patients required surgery during follow up. The mean follow up was 60 months.

Most patients (77.9 %) were receiving concurrent medical therapy for Crohn's disease. Endoscopic findings led to a change in medical therapy following a third of EBD procedures.

Conclusions Enteroscopy and endoscopic balloon dilatation is technically feasible and clinically effective for small bowel strictures in Crohn's Disease. Long term clinical outcomes, with mean follow up period of 60 months, suggest minimal surgical rates following a combination of medical therapy and EBD. Early endoscopic assessment also allows an opportunity to optimise medical therapy in a combined management approach, potentially delaying the need for surgical intervention.

PYP254 The role of double-balloon enteroscopy in iron-deficiency anemia and small-bowel bleeding: a retrospective study at the largest tertiary referral centre in the UK

Authors Athanasiadou E[1], Kalopitas G[1, 2], Maristany Bosch E[1], Dell' Unto E[1], Cossa L[1], Rimondi A[1], Murino A[1], Despott E[1]
Institutes 1 Royal Free Hospital, London, United Kingdom; 2 AHEPA Thessaloniki University General Hospital, Thessaloniki, Greece
DOI 10.1055/s-0046-1821194

Aims Small-bowel (SB) bleeding and iron-deficiency anemia (IDA) are the most frequent indications for double-balloon enteroscopy (DBE) [1]. Angioectasias are a leading cause of SB bleeding, yet factors influencing their detection remain unclear. This study assessed the diagnostic and therapeutic performance of DBE in SB bleeding/IDA and examined whether antiplatelet or anticoagulant therapy affects the likelihood of identifying angioectasias.

Methods All consecutive DBE procedures performed for SB bleeding/IDA between July 2023 and October 2025 were retrospectively reviewed from our prospectively maintained institutional database. Procedural characteristics, endoscopic findings, therapeutic interventions, route of insertion, need for opposite-route access, panenteroscopy rates, complications, and need for repeat DBE were extracted. Associations between antithrombotic therapy (antiplatelets, anticoagulants) and detection of angioectasias were evaluated using contingency analysis with odds ratios (OR) and 95 % confidence intervals (CI).

Results A total of 178 DBE procedures were performed in 107 patients (median age 67 years, IQR 57–74;39.3 % female), of whom 88.8 % had prior evaluation with cross-sectional imaging or capsule endoscopy. Procedures were performed via the anterograde (84.3 %) or retrograde (15.7 %) route;18.0 % of patients had surgically altered anatomy. Procedure completion rate was 97.2 %, and a definitive clinical impression was achieved in 97.8 %.

Angioectasias were the most common finding (49.4 %), followed by inflammation/ulceration (10.1 %), Dieulafoy lesions (8.4 %), mass/submucosal tumors (3.4 %) and SB varices (2.8 %); 18.5 % of examinations were normal. Opposite-route enteroscopy was required in 16.9 % of procedures, and panenteroscopy was achieved in 7.9 %, corresponding to 30.8 % of patients requiring both routes.

Therapeutic intervention was performed in 71.9 % of cases, with 100 % technical success and a 0.6 % complication rate. At the patient level, 27.1 % required at least one repeat DBE. Anticoagulant use was not associated with angioectasia detection (OR 0.92; 95 % CI 0.43–2.01), whereas antiplatelet therapy was significantly associated with higher odds of detecting angioectasias (OR 2.10; 95 % CI 1.10–4.01; p = 0.036).

Conclusions DBE demonstrated high diagnostic and therapeutic yields with an excellent safety profile in patients investigated for SB bleeding/IDA. Angioectasias were the predominant finding accounting for half of all cases, and were significantly more frequently detected in patients receiving antiplatelet therapy—suggesting that antiplatelets may unmask underlying vascular lesions. In contrast, anticoagulants showed no such association. Despite the complexity of this cohort—reflected by the need for opposite-route access and repeat procedures—DBE remained consistently feasible, effective, and safe. These findings reinforce DBE as a key modality for confirming and treating the causes of small-bowel bleeding.

DOI 10.1055/s-0046-1821195

Abstract Text

Background: Blue Rubber Bleb Nevus Syndrome (BRBNS) is a rare venous malformation. Endoscopic diagnosis and therapy have evolved significantly, yet evidence from Latin America remains scarce. Retrospective case series of adults

diagnosed with BRBNS and managed at a tertiary Mexican center between 2010–2025. Results: Four patients presented with multifocal gastrointestinal involvement. Small intestine was the most affected segment. All patients required endoscopic therapy: cold snare (n = 57), EMR (n = 25), detachable snare (n = 22), cyanoacrylate injection (n = 10), and APC (n = 1). There was no mortality or major adverse events. All patients met clinical response criteria during a median follow-up of 36 months. Conclusions: Multimodal approach constitutes a safe and effective strategy for the endoscopic management of BRBNS [1–12].

Abstract Text

A 49-year-old woman with PSC and UC underwent screening colonoscopy which revealed an 8 mm ileal polyp confirmed as a well-differentiated NET (grade 1). Tektrotyd and CT scans showed no metastasis. The patient refused surgical resection. A gastroduodenal FTRD was introduced into the terminal ileum over a dilated balloon and full-thickness resection was successfully achieved. Histology confirmed R0 resection of grade 1 NET. Four-month follow-up colonoscopy showed no residual malignancy. The patient is now under oncological surveillance. This is to our knowledge the first report of a successful use of FTRD in terminal ileum.

PYP257 EUS-guided Entero-Anastomosis (EUS-EA) with Lumen- Apposing Metal Stents (LAMS) for Palliation of Lower Intestinal Malignant Obstruction (LIMO) not Amenable to Enteral Stenting

Authors Aparicio JR[1], López Torres LM[2], Subtil-Iñigo JC[3], Gornals JB[4], Velasco-Guardado AJ[5], Vila JJ[6], Barrera Sánchez P[7], Soto Solis R[8], Enrile Sánchez P[2], De Benito Sanz M[2], Perez-Miranda M[9]

DOI 10.1055/s-0046-1821197

Aims Palliation of advanced LIMO not amenable to enteral stenting is clinically challenging. Feeding/decompressing tubes negatively impact QoL and limit oncological treatment, whereas surgery carries high morbidity. Preliminary data suggesting that EUS-EA with LAMS could potentially restore intestinal transit in this setting warrant confirmation. We aimed to assess the safety and efficacy of EUS-EAwith LAMS in patients with advanced LIMO not amenable to standard endoscopic treatment with enteral stents.

Methods Retrospective multicenter study at eight tertiary hospitals in consecutive LIMO patients who failed or were not deemed candidates for enteral stenting and then underwent attempted EUS-guided EA from January 2018 to August 2025. Baseline clinical, procedural and follow-up variables were pooled. A descriptive analysis andcomparison between groups was performed using χ^2 and Fisher's exact test. Odds ratios with 95 % CI were estimated to test associations.

Results Twenty-four patients were included (42 % women, age 66 [40-97] years). Colo-rectal cancer was the most common etiology (38 %); 63 % had metastatic disease and 54 %were receiving active oncological treatment. 71 % had carcinomatosis and 42 % had ascites. LIMO location was ileum (42 %), jejunum (25 %), and colon (24 %). 71 % had received previous treatment with decompressive tubes, 13 % had received stents, and 8 % had undergone surgery. 79 % of procedures were performed in a retrograde approach; 74 % with direct puncture and 95 % with a freehand technique. Prophylactic antibiotic therapy was administered in 70 % of cases, associated with a lower infection rate (6.2 % vs. 42 %;χ^2 p = 0.040), with OR –2.351 (95 % CI –4.9873 to –0.170). Axios LAMS were used in 95 % of cases and Spaxus LAMS in 5 %. LAMS diameters were 20 mm in 77 % ofcases and 15 mm in the remainder. Sedation was most commonly performed by an anesthesiologist with endotracheal intubation (50 %). Yet, in 29 % of cases,

endoscopist-led sedation was undertaken, with comparable safety outcomes. Location of LAMS anastomosis was entero-colonic (64 %), entero-enteric (23 %), and colo-colonic (14 %).Technical success was 92 %, with no differences between patients with/without ascites or carcinomatosis. Overall clinical success was 87 % (73 % complete, and 14 % partial). Oral tolerance was restored at a median of 1 day (IQR 1–2) following EUS-EA. There were 3 perforations (14 %), 4 infections (18 %), and 1 death (5 %), with no cases of aspiration, bleeding, or misdeployment. Median hospital stay was 10 days (IQR 6–26). Sixty-five percent of patients did not require additional procedures over a median 63-day follow-up (IQR 21–121). Three patients were readmitted for recurrent LIMO after a median of 64 days. Median survival was 32 days (IQR 14–80); five patients remain alive after a median of 868 days.

Conclusions EUS-EA with LAMS appears feasible and safe at expert centers in selected patients with advanced LIMO not amenable to enteral stenting, even in the presence of carcinomatosis or ascites. Early reintroduction of oral feeding and resumption of oncological treatment are possible in most cases. This novel procedure can be offered to patients with advanced LIMO when EUS-EA expertise is available.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP258 The role of double-balloon enteroscopy in patients with suspected or confirmed small-bowel neuroendocrine tumours: A retrospective study at a tertiary UK centre

Authors Athanasiadou E[1], Kalopitas G[1, 2], Maristany Bosch E[1], Dell' Unto E[1], Cossa L[1], Rimondi A[1], Toumpanakis C[1], Murino A[1], Despott E[1]

Institutes **1** Royal Free Hospital, London, United Kingdom; **2** AHEPA Thessaloniki University General Hospital, Thessaloniki, Greece

DOI 10.1055/s-0046-1821198

Aims Small-bowel neuroendocrine tumours (SB-NETs) are typically small and multifocal, often eluding detection on cross-sectional imaging, particularly when multiple and/or of diminutive size. Accurate localisation and assessment of disease extent are crucial for staging and optimal management, especially when surgery is being considered [1]. This study aimed to assess the contribution of double-balloon enteroscopy (DBE) to diagnosis, staging, lesion localisation and management-planning in patients evaluated for SB-NETs.

Methods All DBE procedures performed between July 2023 and October 2025 for suspected, or known SB-NETs were retrospectively reviewed. Data collected included: demographics, surgical anatomy, multidisciplinary team (MDT) discussion, lesion detection, multifocality, tattoo marking, alternative diagnoses and subsequent management decisions.

Results Twenty-four patients were included. Median age was 59-years; 54.1 % were women, and 29.1 % had surgically-altered gastrointestinal anatomy. Pre-procedural MDT discussion occurred in 79.1 % of cases. The retrograde route was used in 14 patients (58.3 %). DBE identified lesions suspicious for SB-NET in 18/24 patients (75 %). Multifocal disease was detected in 6/18 patients (33 %). Tattoo marking was performed in 16/18 lesions (88.9 %). DBE findings led to surgical referral and definitive management in 12/24 patients (50 %). In 3/24 patients (12.5 %), DBE identified benign or alternative pathology (lipoma, leiomyoma, primary paraganglioma) rather than NET. In patients investigated for small-bowel bleeding, DBE distinguished NET-related bleeding from unrelated sources in those with a history of SB-NET.

Conclusions DBE added significant value in the assessment and diagnosis of SB-NETs by enabling direct lesion visualisation, targeted tissue sampling, confirmation and extent of multifocality and the detection of additional lesions not identified on imaging. It further supported management by providing precise preoperative localization through tattoo marking and subsequent mapping disease extent. DBE refined diagnosis when imaging was inconclusive and avoided misclassification when benign alternative pathology was present. By informing MDT discussions and guiding surgical strategy in half of the cases, DBE served as an integral element of the SB-NET diagnostic and management pathway.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP259 Robotic Capsule Endoscopy: Simultaneous Gastric and Enteric Evaluation in Real-World Practice

Authors Mota J[1], Mascarenhas M[1], Cardoso H[1], Almeida MJ[1], Araújo C[2], Frias J[1], Martins M[1], Mendes F[1], Martins Pinto da Costa A[3], Andrade P[2], Macedo G[1]

Institutes **1** São João Universitary Hospital Center, Porto, Portugal; **2** Department of Gastroenterology, São João University Hospital, Porto, Portugal; **3** Puerta de Hierro Majadahonda University Hospital, Majadahonda, Spain

DOI 10.1055/s-0046-1821199

Aims Robotic capsule endoscopy (RCE) is an emerging technologythat combines magnetically controlled gastric navigation with conventional capsuleenteroscopy (CE), enabling a minimally invasive, comprehensive evaluation of the upperand mid-gastrointestinal tract. This study aimed to characterize the real-worldimplementation and diagnostic performance of RCE in a European tertiary referralcenter.

Methods A retrospective, single-center analysis was conducted on adultpatients (≥ 18 years) who underwent RCE between June 2023 and June 2025. Eligiblepatients had a clinical indication for small bowel CE and a concurrent requirement fordiagnostic gastroscopy or reassessment of known gastric lesions. The RCE protocolcomprised an initial robotic-guided gastric examination followed by passive transitthrough the small bowel.

Results A total of 85 patients were included (52 % female) witha median age 49 years (IQR 40-64). The most common indications were suspected orestablished inflammatory bowel disease (57 %) and iron deficiency anemia (31 %).Gastric preparation was rated at least fair in 98 % of cases, with good preparation in38 %. Median gastric transit time was 74 minutes (IQR 35-106). Relevant gastric findingswere identified in 39 cases (46 %), namely polyps (18 %) and angiectasias (8 %, includingone with active bleeding), in addition to signs of chronic gastritis. Thirteen patientsunderwent subsequent endoscopy, resulting in seven therapeutical procedures. Smallbowel findings were present in 60 patients (71 %), including P3 (active bleeding) in 3 %and P2 lesions (angiectasias, ulcers, tumors, varices) in 39 %. One clinically significantadverse event occurred: small-bowel capsule retention in a patient with multifocalneuroendocrine tumor and ileostomy.

Conclusions Robotic capsule endoscopy is afeasible and effective tool for dual-region gastrointestinal evaluation. It enables high-quality gastric visualization, facilitates early detection of clinically actionable lesions, andmaintains the diagnostic yield expected from standard small bowel CE. These findingssupport the integration of RCE into diagnostic pathways for patients requiringsimultaneous gastric and small bowel assessment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP260 Remimazolam for Colonoscopy in IBD: A Better Experience Starts Here

Authors Bezzio C[1], franchellucci G[2, 3], Ferrari C[4], Privitera G[3], Pieri G[5], Dal Buono A[3], Gabbiadini R[3], Loy L[3], Migliorisi G[3], Ferretti S[3], Masoni B[3], Panigada V[5], Hassan C[1, 2], Repici A[1, 2], Alessandro A[3]

Institutes **1** Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy; **2** Endoscopy Unit, IRCCS, Humanitas Research Hospital, Rozzano, Italy; **3** IBD Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; **4** Division of Anaesthesiology, IRCCS, Humanitas Research Hospital, Rozzano, Italy; **5** Pharmacy, IRCCS Humanitas Research Hospital, Rozzano, Italy

DOI 10.1055/s-0046-1821200

Aims Colonoscopy is central to IBD care but acceptance may be limited by anxiety and discomfort. Remimazolam, a short-acting benzodiazepine, could offer advantages over midazolam. We compared efficacy, safety, and recovery between remimazolam and midazolam in IBD patients undergoing colonoscopy.

Methods Single-center, prospective, randomized trial of IBD patients scheduled for elective colonoscopy, allocated 1:1 to remimazolam or midazolam. Primary outcome: proportion of patients reporting at least "satisfied" immediately postprocedure (binary endpoint ≥ "satisfied" vs < "satisfied"). Secondary outcomes: discharge readiness at 10 and 20 minutes (PADSS), adverse events (allergic reactions; hypotension; hypoxia defined as SpO_2 < 90 % requiring > 4 L/min O_2; respiratory depression; bradycardia < 60 bpm; nausea; vomiting; dizziness; headache; intra- vs post-procedural timing), and endoscopic performance outcomes We used a Bayesian framework. For the primary endpoint, non-inferiority of remimazolam versus midazolam was assessed with a prespecified margin of − 10 %. Posterior distributions and 95 % credible intervals (CrI) were obtained via Monte Carlo sampling

Results A total of 216 patients were initially assessed for eligibility and assigned with an approximate ratio of 1:1 to receive either midazolam or remimazolam. Of these, 16 patients were excluded from the final analysis due to the following reasons: inadequate bowel preparation (n = 6), withdrawal of informed consent before the procedure (n = 5), and technical issues preventing completion of the colonoscopy or data recording (n = 5). The final study population consisted of 200 patients, equally distributed between the two treatment groups. Baseline demographic, clinical, and disease-related characteristics were well balanced between groups. Overall satisfaction was high and remimazolam was non-inferior to midazolam (96.4 % vs 97.3 %). "Very satisfied" responses were more frequent with remimazolam (62.2 %, 95 % CrI 55.4–72.5 %) than midazolam (48.3 %, 95 % CrI 39.5–57.3 %; posterior probability of superiority 99.3 %). Discharge readiness favored remimazolam at 10 minutes (65.0 %, 95 % CrI 56.3–73.3 % vs 27.5 %, 95 % CrI 19.9–35.8 %) and 20 minutes (88.3 %, 95 % CrI 82.0–93.4 % vs 64.2 %, 95 % CrI 55.4–72.5 %). A personalized model suggested greater benefit from remimazolam among younger patients, females, and those with shorter disease duration. Adverse events were infrequent in both treatment groups and generally mild in severity. The most commonly reported event was transient hypotension, observed in 4 % of patients receiving midazolam and 2 % of those treated with remimazolam. Nausea occurred in 3 % of midazolam-treated patients and 1 % of those in the remimazolam group. No cases of hypoxemia were reported in either group. Only one patient (1 %) in the midazolam group experienced a prolonged recovery time that delayed discharge beyond 60 minutes, whereas no such delays were observed with remimazolam

Conclusions Remimazolam is a safe, effective alternative to midazolam for colonoscopy sedation in IBD, yielding higher patient satisfaction and markedly faster recovery. Personalized sedation strategies may enhance its clinical value

DOI 10.1055/s-0046-1821201

Aims Sedation is essential in gastrointestinal (GI) endoscopy to optimize patient comfort, procedural quality, and endoscopist satisfaction [1, 2]. While non-anesthesiologist-administered sedation (NAS) with propofol is well established for low-risk patients, i.e. American Society of Anesthesiologist (ASA) I–II [3], evidence regarding its use in higher-risk groups remains limited. ASA III patients present a greater likelihood of cardiopulmonary events, and current data are heterogeneous and underpowered [4, 5]. This study aimed to evaluate the safety profile of NAS with propofol in ASA III patients undergoing routine diagnostic GI endoscopy.

Methods This observational study included ASA III patients who underwent elective gastroscopy or colonoscopy under NAS with propofol, with or without adjunctive midazolam and/or fentanyl,
between 2017 and 2024. Sedation was administered by a member of the endoscopy team (endoscopist or nurse) who had completed the ESGE/ESGENA curriculum for sedation in GI endoscopy and was exclusively dedicated to sedation. The protocol dosages were as follows: propofol 0.3–0.6 mg/kg (with an additional dose of 0.3–0.4 mg/kg after 2 minutes), preceded or not by midazolam 0.02–0.03 mg/kg and/or fentanyl 0.6–1.3 µg/kg. Anesthesia-related adverse events (ARAEs) were categorized as minor, moderate, or severe based on the World Society of Intravenous Anesthesia definitions. Secondary outcomes included the identification of potential risk factors for ARAEs.

Results Among 1219 patients, 1423 procedures were analyzed (43.4 % gastroscopies; 56.6 % colonoscopies). A total of 79.2 % of patients (965/1219) were aged 65 years or older. Four sedation regimens were used: propofol alone (19.3 %), propofol + midazolam (18.7 %), propofol + fentanyl (32.1 %), and propofol + fentanyl + midazolam (29.9 %). ARAEs occurred in 5.2 % of procedures: 3.9 % minor, 0.9 % moderate, and 0.4 % severe. No cases of tracheal intubation or death were observed. Hypotension was the most frequent event (3.6 % requiring no intervention; 0.8 % requiring fluids). Desaturation was rare (0.2 % minor; one case requiring transient bag-valve ventilation). Severe ARAEs consisted only of bradycardia treated successfully with atropine. The incidence of ARAEs differed among sedation regimens (p = 0.023): the highest rate was observed with propofol + midazolam (8.6 %), while propofol + fentanyl had the lowest (3.7 %). Post-hoc analysis showed a significant difference between these

two regimens (p = 0.04, OR 2.46). Logistic regression analysis identified lower body mass index as the only independent predictor of ARAEs (p < 0.001). Exploratory analyses to investigate these findings revealed a statistically significant negative correlation between BMI and the administered per-kilogram propofol dose (r = -0.196, p < 0.001). An ANOVA test confirmed that patients in higher BMI classes (overweight and obese) received significantly lower mean per-kilogram propofol dosages compared to the normal-weight group (p < 0.001). No differences were observed in the mean per-kilogram fentanyl and midazolam dosages. Age, procedure type, and duration were not associated with adverse events. Finally, most patients were elderly, with no increase in ARAEs compared with younger patients.

Conclusions NAS with propofol appears safe in ASA III patients undergoing elective GI endoscopy when performed by trained personnel following standardized protocols. The overall incidence of ARAEs was low, and severe events were rare and manageable, even in elderly patients. Sedation regimen and BMI significantly influenced adverse event risk, suggesting the importance of tailored drug dosing. These findings support expanding NAS with propofol to higher-risk patients within structured, guideline-based pathways. This strategy may reduce the need for anesthesiologist involvement, improve resource utilization, and potentially lower procedural costs. The results further underline the need for prospective, multicenter studies to refine risk stratification and optimize sedation protocols.

PYP262 Toward a new safe standard of deep sedation for diagnostic EUS across all ASA risk categories

Authors Gabbani T[1], Zadro V[1], Indulti F[1], Bonura GF[1], Gualandi N[1], Frassanito G[1], Bertoncini G[1], Deiana S[1], Soriani P[1], Triantafyllou K[2], Manno M[1]

Institutes 1 Gastroenterology and Digestive Endoscopy Unit, AUSL Modena, Modena, Italy; 2 Medical School, National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece

DOI 10.1055/s-0046-1821202

Aims Endoscopic ultrasound (EUS) is a second-level endoscopic procedure with substantially greater procedural complexity than standard diagnostic endoscopy, typically requiring deeper and longer sedation. However, an optimal sedation strategy in this setting has not yet been established. This study evaluated the safety of non-anesthesiologist-administered propofol sedation (NAPS) for diagnostic EUS across ASA risk classes, focusing on sedation-related adverse events (AEs).

Methods All consecutive diagnostic EUS procedures performed between January 2021 and May 2024 were included. Sedation involved balanced deep sedation using fentanyl, midazolam, and propofol administered by trained endoscopy nurses in accordance with ESGE/ESGENA guidelines. AEs were classified according to World Society of Intravenous Anesthesia definitions.

Results A total of 1134 diagnostic EUS procedures performed under NAPS were analyzed. The majority were biliopancreatic (73.0 %), followed by esophagogastroduodenal (21.2 %) and rectal EUS (5.8 %). Tissue sampling via FNB/FNA was performed in 21.3 % of cases, with a diagnostic accuracy of 93 %. Median dosages were 260 mg propofol, 70 µg fentanyl, and 1.6 mg midazolam, with a median procedure time of 34 minutes (range 10–132). Sedation-related AEs occurred in 95 cases (8.4 %): 31 (2.7 %) mild, 58 (5.1 %) moderate, and 6 (0.5 %) severe. All AEs were managed by endoscopy staff without the need for anesthesiologist assistance. Moderate AEs included hypotension requiring fluids (1.5 %), bradycardia < 60 bpm (3.4 %), and desaturation > 30 seconds (0.3 %). Severe AEs included bradycardia < 40 bpm treated with atropine (0.4 %) and severe desaturation requiring assisted ventilation (0.2 %). No AEs had clinically relevant consequences; only two procedures were discontinued, and no patient required hospitalization or extended care [1–3].

Multivariate analysis demonstrated that age (OR 1.14; p < 0.001) and ASA class (OR 7.17; p < 0.001) were the only independent predictors of AE risk. ASA III status was associated with a 1.47-fold higher relative risk compared with ASA I–II. BMI, number of comorbidities, Charlson Comorbidity Index (CCI), drug dosages, and procedure timewere not associated with AEs risk. ASA III patients accounted for 359 procedures (31.8 %) and, among them, adverse events comprised 41 % (39/95) of all AEs, with the majority (24/39, 61.5 %) occurring in patients older than 65 years. The distribution of AEs severity in ASA III patients, was as follows: mild in 2.5 % (9/359), moderate in 7.5 % (27/359), and severe in 0.8 % (3/359)

Risk stratification based on the combination of age and ASA status identified three categories with progressively increasing AEs incidence: low (ASA I–II and < 65 years), intermediate (ASA I–II and > 65 years or ASA III and < 65 years), and high risk (ASA III and > 65 years). This model showed a significant correlation with AEs occurrence (p = 0.029), with a stepwise increase in AEs rates across groups—5.6 %, 9.2 %, and 12.3 %, respectively.

Conclusions NAPS demonstrated a favorable safety profile across all ASA classes, with low rates of clinically relevant AEs. The highest AEs risk was observed in ASA III patients older than 65 years. Although these events were predominantly minor to moderate in severity, more caution could be take in this subgroup of patients.

PYP263 Virtual Reality for Pain and Anxiety Relief During Unsedated Colonoscopy: A Randomized Controlled Trial

Authors Zouaki I[1], Ait Errami A[2], Nacir O[3], Fatima Ezzahra L[2], Krati K[2]
Institutes 1 UHC MED VI, Marrakesh, Morocco; 2 CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco; 3 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1821203

Aims We conducted a randomized controlled trial including adults ≥ 18 years scheduled for outpatient, unsedated colonoscopy at the Endoscopy Unit of the Mohammed VI University Hospital, Marrakech. Patients with prior colorectal surgery, cognitive or sensory impairment, epilepsy, psychiatric disorders, or significant pre-procedural pain were excluded. Sixty patients were randomized (1:1) to receive either VR distraction plus routine care or routine care alone. Outcomes included procedural anxiety, pain, comfort, satisfaction, willingness to undergo future colonoscopies, and procedural characteristics. Validated scales were used for all patient-reported outcomes.

Methods We performed a randomized trial of 60 adults undergoing unsedated colonoscopy, assigned to VR or control.Eligible patients were ≥ 18 years; major sensory, cognitive, surgical, or psychiatric contraindications were excluded.Anxiety, pain, comfort, satisfaction, and willingness to return were assessed using validated scales.Procedural metrics, including caecal intubation time, were recorded and compared between groups.

Results VR significantly improved multiple procedural metrics. Time to caecal intubation was reduced by 4.29 minutes in the VR group. Anxiety decreased more markedly with VR compared with controls (17.4→15.8 vs. 17.3→16.2). Pain was significantly lower with VR (mean 4.53 vs. 5.83), accompanied by a shift toward higher comfort ratings. Patient satisfaction was substantially higher with VR (74 % vs. 54 %), and the Net Promoter Score improved (–0.33 vs. –16.66). Willingness to return for future colonoscopy was also greater in the VR arm. Endoscopists reported high acceptability (mean score 8.3/10) and noted reduced procedural stress with minimal implementation difficulty.

Conclusions VR significantly enhanced patient comfort, reduced pain and anxiety, and improved procedural efficiency and satisfaction during unsedated colonoscopy. Given its low cost, ease of implementation, and favorable user acceptance, VR represents a promising adjunct for routine use in endoscopy units as a non-pharmacological pain-relief and anxiolysis strategy.

DOI 10.1055/s-0046-1821204

Aims The additional safety effect of capnography monitoring during non-advanced endoscopic procedures has not been adequately examined. We aimed to evaluate the effectiveness of capnography monitoring, alongside standard monitoring, in reducing sedation-related hypoxemia.

Methods A systematic review across MEDLINE and Cochrane Central Register for all types of trials evaluating the efficacy of capnography monitoring in addition to standard monitoring in reducing the incidence of SRAE was conducted for studies published between 01.01.2019 and 31.07.2025. The primary outcome was the risk of sedation-related hypoxemia. The pooled results for the study outcomes were presented as Risk Ratios (RR) with the 95 % confidence intervals (CIs). We also performed sensitivity analyses by the severity of oxygen desaturation (mild and severe), low and high-risk procedures, and type of sedation (propofol vs. non-propofol vs. mixed regimens). We assessed the quality of evidence using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

Results Two RCTs, four service evaluation studies, and one cohort study were included. Compared to standard monitoring, addition of capnography significantly reduced the risk of oxygen desaturation [RR 0.61, 95 % CI (0.46-0.82; I^2 = 74 %)], with this effect being significant both for RCTs [RR 0.57, 95 % CI (0.35-0.93); I^2 = 70 %] and non-RCT studies [RR 0.64, 95 % CI (0.43-0.96; I^2 = 80 %], respectively; there was very low confidence in estimates. Capnography use led to a significantly lower incidence of both mild and severe hypoxemia [RR 0.74, 95 % CI (0.63-0.85); I2 = 61 % and RR 0.54, 95 % CI (0.40-0.73); I2 = 44 %, respectively]. Notably, the positive impact of capnography was also significant for low and high-risk procedures in terms of mild [RR 0.75, 95 % CI (0.60-0.93); I^2 = 69 % and RR 0.72, 95 % CI (0.57-0.89); I^2 = 55 %, respectively] and severe oxygen desaturation [RR 0.75, 95 % CI (0.60-0.93); I^2 = 69 % and RR 0.72, 95 % CI (0.57-0.89); I^2 = 54 %, respectively]. In terms of sedation type, the use of capnography was associated with a reduced risk ratio of oxygen desaturation overall; however, statistical significance was only noted in studies analyzing propofol [RR 0.59, 95 % CI 0.46-0.76; I^2 = 54 %].

Conclusions Addition of capnography to standard monitoring decreased the incidence of both mild and severe hypoxemia during sedation for gastrointestinal procedures, regardless of procedural risk.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP265 Addition of bispectral index (bis) monitoring to standard monitoring significantly reduces total propofol dose: a systematic review and a pooled analysis

DOI 10.1055/s-0046-1821205

Aims Bispectral Index Monitoring (BIS) is an objective measure of brain activity. It assists clinicians in the precise titration of anesthetic drugs, leading to reduced use of hypnotic medications and improved recovery times. We aimed to evaluate the effect of Bispectral Index (BIS) monitoring in addition to standard monitoring on the dose of propofol used.

Methods We performed a systematic review across MEDLINE and Cochrane Central Register for all types of trials from 01/01/2019 until 31/12/2024, evaluating the effect of Bispectral Index (BIS) monitoring in addition to standard monitoring on propofol dose. The primary outcome was the total propofol dose. We performed pairwise analyses and we present the effect size on study outcomes as Mean Difference (MD) with 95 % confidence interval (CI). The certainty of evidence was assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

Results Three RCTs and two cohort studies with 947 subjects were included. Compared to standard monitoring, the addition of BIS significantly reduced the total propofol used in each procedure [MD -0.25 95 % CI (-0.25, -0.47), I^2 = 61 %]. Contrariwise, use of BIS did not have a similar effect on mean propofol dose [MD -0.41 95 % CI (-0.41, -1.37), I^2 = 61 %]; the certainty of evidence was very low.

Conclusions Addition of BIS to standard monitoring during sedated GI endoscopy significantly reduces the total propofol dose.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP266 Impact of unsedated diagnostic endoscopy on endoscopy performance: a systematic review and pooled results analysis

DOI 10.1055/s-0046-1821206

Aims Unsedated diagnostic endoscopy safety and ability for immediate patient discharge should be judged in light of the adequate performance of the examination and patients' preferences. The study aimed to evaluate the impact of unsedated diagnostic endoscopy on performance measures

Methods We performed a systematic review across MEDLINE and Cochrane Central Register for all types of trials assessing the effect of unsedated endoscopy on endoscopy performance from 2014 to 2025. Diagnostic colonoscopy quality measures (Adenoma Detection Rate – ADR, cecal Intubation Rate – CIR) and diagnostic ultrathin or transnasal gastroscopy completion rates, as well as patient-reported discomfort rates, comprised our outcomes. We conducted pairwise meta-analyses to present effect sizes for study outcomes, represented as either Odds Ratios (OR) or Mean Differences (MD), along with 95 % confidence intervals (CI). The certainty of evidence was assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

Results Eight studies (six retrospective cohort, one RCT, and one cross-sectional) with 60383 patients (53633 sedated, 6750 unsedated) examining the efficacy of unsedated versus sedated diagnostic colonoscopy were included. Compared to colonoscopy under sedation, unsedated colonoscopy resulted in similar ADR [OR 0.97, 95 % CI (0.84-1.13), I^2 = 71 %] as well as CIR [OR 1.65, 95 % CI (0.45-6.01), I^2 = 91 %]; there was low confidence in estimates. Notably, colonoscopy without sedation was not associated with an increased level of patients' discomfort. [MD = 0.45; 95 % CI (0.11-1.83); I^2 = 100 %] compared to sedated procedures. The certainty of evidence was very low. Three RCTs with 703 patients (354 sedated, 349 unsedated) evaluated unsedated versus sedated diagnostic gastroscopy. Their pooled results showed a marginally higher procedure completion rate with the use of unsedated gastroscopy [OR 95 % CI 0.98, (0.96-1.00), p = 0.70; I^2 = 100 %] but significantly lower distress rates [MD -1.01, 95 % CI (-1.60 – -0.42), I^2 = 0 %]. The certainty of evidence was very low.

Conclusions Recent evidence indicates that unsedated diagnostic endoscopy is feasible and efficacious in willing patients compared to standard endoscopy under sedation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP267 Deep sedations and wrong indications: The burden of inappropriate EGDs

Authors Silva G[1], Gomes R[1], Soares C[1], Domingues Â[1], Carvalho AC[1], Pires F[1], Martins D[1], Sousa P[1], Araújo R[1], Cancela E[1], Ministro P[1], Castanheira A[1], Silva A[1], Cardoso R[1]

Institute 1 Hospital São Teotónio, Viseu, Portugal
DOI 10.1055/s-0046-1821207

Aims To analyze the burden associated with performing inappropriate esophagogastroduodenoscopies (EGDs) in a tertiary endoscopy unit. We also sought to determine whether the clinical appropriateness of EGDs is associated with the use of sedation, thus also testing the hypothesis that prescribers assign EGDs requests of low clinical value with deep sedation, since these have longer waiting periods.

Methods Retrospective observational study, conducted at a single center, including all consecutive requests for elective diagnostic EGD over a 3-month period (N = 314), excluding EGDs performed for therapeutic purposes or in an emergency setting. The appropriateness of the indication was assessed according to ASGE/ESGE criteria. Patient demographics, source of request (outpatients vs. inpatients) and type of sedation were recorded. The type of sedation was classified as no sedation, conscious sedation (benzodiazepines administered by the gastroenterologist), or deep sedation (performed by an anesthesiologist). Statistical analysis included descriptive statistics, chi-square tests and estimation of effect measures with 95 % confidence intervals (CI). Significance threshold was $p < 0.05$ [1, 2].

Results The average age of patients was 57.7 years, and 54.5 % were women. Most requests originated from outpatient clinics (90.8 %). Regarding sedation, 39.2 % of the EGDs were performed without sedation, 32.8 % with conscious sedation, and 29 % with deep sedation. In total, 63.7 % of requests were considered appropriate and 36.3 % inappropriate.

A decrease in the appropriateness rate was observed as the level of sedation increased. The appropriateness rate was highest in exams without sedation (71.7 %), decreased in exams with conscious sedation (68.0 %), and fell sharply in exams performed under deep sedation, where less than half (48.4 %) were in accordance with the indications ($p < 0.001$). Inappropriate requests were significantly more likely to be scheduled under deep sedation (RR = 1.87; 95 % CI 1.33–2.63), $p < 0.001$.

If triage were implemented, 34 additional slots would be gained in non-sedated EGD shifts, 33 in mild sedation shifts, and 47 in deep sedation shifts, repre-

senting a direct recovery of 114 EGD slots in one trimester (456 annualized), which could be reallocated to patients with appropriate indications.
Economic costs were calculated using the unit costs reported by Areia et al. (60€ per EGD without deep sedation and 137€ with deep sedation), and we estimate that at least 10,459€ was spent on unnecessary EGDs (~41,836€ per year, assuming a stable rate).
Environmental costs were considered using the values of Elli et al. (5.43 kg of CO_2 per EGD), and we concluded that our cohort emitted at least 619 kg of CO_2 in unnecessary EGDs (about 2,476 kg of CO_2 per year, equivalent to the consumption of 1,000 liters of gasoline).
Conclusions This 3-month cohort demonstrated that more than one-third of elective EGDs are inappropriate and confirmed that as the level of sedation increases, so do inappropriate requests. This burden translates into a substantial waste of resources with loss of procedural capacity (>450 slots/year), direct economic costs (>40,000€/year), and a major environmental impact (>2,400 kg CO_2/year). These results underscore the urgent need to implement effective triage strategies to optimize resource allocation, reduce costs, and mitigate the environmental impact associated with unnecessary procedures.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP268 Use of an Abdominal Compression Device During Colonoscopy Significantly Shortens Cecal Intubation Time Compared With Conventional Technique

Authors Aouroud H[1], Aouroud M[1], NACIR O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1821208

Aims Loop formation remains one of the main factors prolonging colonoscopy, often necessitating manual abdominal pressure or patient repositioning. Abdominal compression devices (ACDs) such as elastic binders or adjustable belts provide continuous counter-pressure, potentially preventing loop formation and facilitating cecal intubation.This prospective study aimed to evaluate the impact of ACD use on cecal intubation time and procedural performance during colonoscopy in a Moroccan tertiary centre.
Methods A prospective comparative trial was conducted in our Hepato-Gastroenterology Department, from January 2023 to October 2025.A total of 220 consecutive adult patients undergoing diagnostic or screening colonoscopy were enrolled and randomly assigned to either:
ACD group (n = 110) – colonoscopy performed using an adjustable abdominal compression belt,
Control group (n = 110) – conventional colonoscopy without compression.
Endpoints included:

1. Primary: mean cecal intubation time (CIT) in minutes.
2. Secondary: need for manual pressure, patient position change, and procedure-related discomfort or adverse events.All procedures were performed by experienced endoscopists under conscious sedation. Statistical analysis was carried out using SPSS 26.0; $p<0.05$ was considered significant.

Results Mean age was 55 ± 12 years; 58 % were female.Cecal intubation was achieved in 98.2 % overall.
Mean CIT: significantly shorter with ACD (5.9 ± 1.8 min) compared with control (7.8 ± 2.3 min; $p<0.001$).
Manual abdominal pressure: required in 13.6 % of ACD cases vs 47.2 % of controls ($p<0.001$).
Position change: needed in 16.3 % with ACD vs 40.9 % without ($p=0.002$).
Total procedure time: 11.2 ± 3.9 min (ACD) vs 13.7 ± 4.4 min (control; $p=0.01$).
No adverse events or device-related complications were recorded, and patient tolerance scores were higher in the ACD group ($p=0.04^*$).
Conclusions In this single-centre prospective study, the use of an abdominal compression device during colonoscopy significantly reduced cecal intubation and total procedure times, while minimising the need for manual pressure and patient repositioning, without compromising safety or comfort.These findings support the routine use of ACDs as a simple, non-invasive, and cost-effective adjunct to improve procedural efficiency, particularly in patients with redundant or difficult colons.

PYP269 Improving pain and discomfort during colonoscopy using music and task distraction: results from a three-arm observational study

Authors Aouroud H[1], Aouroud M[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1821209

Aims Fear of pain and discomfort remains one of the leading barriers to colonoscopy attendance, contributing to delayed diagnosis and reduced colorectal cancer detection rates. While sedation and advanced endoscopic systems can enhance patient comfort, these resources are not universally available—particularly in low- and middle-income settings. Low-cost, non-pharmacological interventions such as music and cognitive distraction may offer a practical alternative to improve patient experience.
Aim To assess the impact of music and smartphone-based task distraction on physiological markers of pain and patient-reported comfort during colonoscopy in a Moroccan tertiary centre.
Methods A prospective three-arm observational study was conducted at CHU Mohammed VI Marrakech between January and October 2024.Consecutive adult patients undergoing elective colonoscopy were enrolled and allocated to one of three groups:
Arm A: standard colonoscopy; Arm B: colonoscopy with music; Arm C: colonoscopy with smartphone task distraction
Real-time heart rate and respiratory rate were recorded using a wearable monitor. Patient satisfaction, perceived discomfort, sedation use, and procedural difficulty were documented. Data were analysed using ANOVA and generalized estimating equations.
Results A total of 96 patients were included in the interim analysis (32 per arm; 49 % female; mean age 49.2 years). Baseline demographic and clinical characteristics were comparable across all three groups.

1. Heart rate (mean HR)Real-time mean heart rate differed between groups:, Arm A – Standard colonoscopy: 85.7 bpm (SD 22.9), Arm B – Music: 79.4 bpm (SD 20.1), Arm C – Smartphone task distraction: 76.1 bpm (SD 19.4)ANOVA showed a significant difference between groups (p = 0.03), with the lowest HR observed in Arm C.
2. Respiratory rate (mean RR)Mean respiratory rate followed a similar pattern: Arm A: 13.9/min (SD 6.0); Arm B: 13.1/min (SD 5.4); Arm C: 12.8/min (SD 5.7)Group comparison reached significance (p = 0.04).
3. Patient comfortPatient-reported pain and discomfort scores (0–10 scale) were lower in the intervention arms:Pain: Arm A 5.6 vs Arm B 4.1 vs Arm C 3.7, Discomfort: Arm A 6.2 vs Arm B 4.5 vs Arm C 3.9, Overall p < 0.01.
4. SatisfactionA large majority of patients in intervention groups reported high satisfaction: Arm A: 63 %, Arm B: 91 %, Arm C: 94 %Almost all patients in Arms B and C stated they would choose the same method again.

Endoscopy 2026; 58: S1–S1041

5. Sedation and procedural difficultySedation rates were similar across groups (25–30 %, p = NS).Endoscopist-rated procedural difficulty did not differ significantly between arms.
6. Safety

No intervention-related adverse events were recorded. Completion rates (cecal intubation) were high across all groups (> 95 %).

Conclusions In this Moroccan monocentric cohort, music and smartphone task distraction significantly improved objective and subjective measures of comfort during colonoscopy. These simple, low-cost interventions offer a practical strategy to enhance patient experience, increase acceptance of colonoscopy, and potentially improve adherence to colorectal cancer screening programmes.Final results from the ongoing larger cohort will help refine implementation strategies in routine endoscopy practice.

DOI 10.1055/s-0046-1821210

Aims Gastric twist after sleeve gastrectomy is an increasingly recognized cause of obstructive symptoms and dysphagia. Endoscopic dilation (ED) has been traditionally used, while lumen-apposing metal stents (LAMS) and fully covered self-expandable metal stents (FC-SEMS) have emerged as alternative options. This study compared the efficacy and safety of LAMS, FC-SEMS, and ED for the treatment of post-sleeve gastric twist.

Methods Single-center retrospective cohort including all consecutive patients with symptomatic gastric twist after sleeve gastrectomy treated with LAMS (16 × 30 mm), FC-SEMS (22 mm × 110 mm), or pneumatic dilation between January 2012 and August 2025. Technical success (TS) was defined as completion of the planned procedure. Clinical success (CS) was defined as improvement of ≥ 1 level in the Mellow–Pinkas Dysphagia Score. Recurrence was defined as dysphagia score 3–4 and/or inability to maintain a satisfactory luminal caliber within 4 weeks after CS. Adverse events (AEs) were classified according to AGREE, and recurrence-free survival (RFS) was assessed by Kaplan–Meier analysis. Group comparisons were performed using Kruskal–Wallis and χ^2/Fisher's exact tests.

Results Overall, 151 patients were included (LAMS 97; ED 31; FC-SEMS 23). Baseline characteristics showed some differences in age, BMI, smoking, prior complications, and dysphagia severity across groups. TS was achieved in all patients (LAMS 96.9 % with three immediate FC-SEMS crossovers, ED 100 %, FC-SEMS 100 %). CS was comparable (79.8 % LAMS, 90.3 % ED, 82.6 % FC-SEMS; P = 0.4091). Among patients with CS, recurrence occurred in 16.0 % after LAMS, 39.3 % after ED, and 31.6 % after FC-SEMS (P = 0.0324). RFS did not differ significantly by treatment at Kaplan–Meier analysis (log-rank P = 0.1490). LAMS required fewer procedures (median 1 vs 2 with ED; P < 0.000001) and shorter hospital stay (0 vs 2 days; P < 0.000001). AEs were numerically lower with LAMS (13.4 % vs 25.8 % ED vs 30.4 % FC-SEMS; P = 0.0849), predominantly late migrations.

Conclusions In post-sleeve gastric twist, LAMS achieved comparable clinical success with fewer procedures, shorter hospitalization, and a lower crude recurrence and AE rate compared with ED and FC-SEMS, supporting its role as an attractive first-line endoscopic option.

PYP271 Economic evaluation of proximal intestinal mucosal ablation in insulin-requiring type 2 diabetes: cost-effectiveness and price threshold analysis from a UK NHS perspective with comparison to semaglutide

Authors Norton B[1, 2], Telese A[2, 1], Marin P[3], Hoebel P[3], Vignolo P[3, 4], Johnson G[5, 2], Rodriguez Grunert L[3], Shaheen N[6], Haidry R[2]

DOI 10.1055/s-0046-1821211

Aims Proximal Intestinal Mucosal Ablation (PIMA) is an emerging endoscopic therapy for type 2 diabetes that may improve glycaemia and enable discontinuation of exogenous insulin use. Given the burden and adverse effects of long-term insulin therapy, reducing or eliminating its use could yield meaningful economic benefits. We aimed to develop a cost-effectiveness model, from a UK National Health Service (NHS) perspective, to evaluate PIMA compared with standard-of-care (SoC; continued insulin therapy), as well as its cost impact relative to escalation to the glucagon-like peptide-1 receptor agonist (GLP-1RA) Semaglutide.

Methods A Markov model compared PIMA to SoC and GLP-1RA escalation over 2- and 5-year horizons. Three health states (OFF-insulin, ON-insulin, death) were modelled using 6-month cycles and 3 % annual discounting. PIMA was assumed to achieve complete insulin discontinuation, followed by time-varying relapse back to insulin based on current data. Relapse was estimated as a gradual increment from 0-45 % (sensitivity analysis up to 68 %) over 5-years with increases in oral medication by 50 %. GLP-1RA therapy was modelled using UK acquisition costs (£294/month) and real-world discontinuation and insulin-reduction effects. Outcomes included costs, QALYs, incremental costs, incremental QALYs, and incremental cost-effectiveness ratios (ICERs). Uncertainty was evaluated using one-way, scenario, and probabilistic sensitivity analyses (PSA), varying PIMA price, relapse probability, escalation rates, and utilities, with a £30,000/QALY willingness-to-pay (WTP) threshold.

Results Over 2 years, PIMA yielded QALY gains of 0.16-0.19 at incremental costs of £3,500-3,700, producing ICERs of £18,000-23,500/QALY at the base-case device cost (£8,000), within the National Institute for Health and Care

Excellence (NICE) £20,000–30,000/QALY threshold. Over 5 years, QALY gains were smaller (0.10-0.12) and incremental costs remained substantial (£4,700-5,100), resulting in ICERs of £41,700-49,000/QALY. PSA generated a mean ICER of £31,018/QALY, with 60–65 % probability of cost-effectiveness at £30,000/QALY. Under favourable assumptions, ICERs ranged from £18,700-32,800/QALY and under unfavourable assumptions, £23,400-50,300/QALY. At base cost, ICER was most sensitive to device cost, followed by relapse reduction and escalation to oral medication. PIMA was consistently dominant relative to Semaglutide, which incurred higher costs and generated lower QALYs across all scenarios. Across all device price modelled (£5,000-15,000), PIMA remained cost-saving compared with Semaglutide, which remained consistent when modelling drug cost variation (± 30 %).

Conclusions PIMA is likely cost-effective over a 2-year horizon as an endoscopic treatment for insulin-requiring type 2 diabetes and demonstrates marginal cost-effectiveness over 5 years at current pricing. PIMA is consistently cost-saving compared with Semaglutide, supporting its potential as a lower-cost alternative treatment.

PYP272 Comparison Between Gastric Fundus Endoscopic Ablation and BioEnterics Intragastric Balloon in Obesity Management: preliminary results from a pilot study

Authors Dioscoridi L[1], Girardi V[2], Salerno A[3], Mutignani M[4]
Institutes **1** ASST Great Metropolitan Niguarda, Milano, Italy; **2** Niguarda, Milan, Italy; **3** Istituto Nazionale per la Cura dell'Obesità, Clinica Galeazzi, GSD, Milan, Milan, Italy; **4** Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy., Milan, Italy
DOI 10.1055/s-0046-1821212

Aims Minimally invasive endoscopic therapies have emerged as alternatives to bariatric surgery for patients with obesity. Among these, gastric fundus endoscopic ablation (GFEA) — a technique aimed at reducing gastric accommodation and decreasing ghrelin secretion — and the BioEnterics Intragastric Balloon (BIB) — which induces early satiety through intragastric volume displacement — represent two distinct approaches. Comparative evidence, however, are not available.

Methods After reviewing the available literature on mechanisms, efficacy, and safety of GFEA and BIB in obesity treatment, including pilot trials, observational series, and meta-analyses of intragastric balloon (IGB) therapy, we designed a prospective randomized study on comparison between the two techniques. Primary outcomes was total body weight loss (TBWL); secondary outcomes were tolerability and rates of complications [1, 2].

Results 10 obese patients (mean BMI ~40 kg/m²) were included and equally randomized in GFEA using hybrid argon-plasma ablation of the fundus and placement of air-inflated BIB. At 6 months, mean TBWL ranged from 8 to 10 % in GFEA group and from 10 to 12 % TBWL in ballon group (p > 0,1).

No serious adverse events occurred in both groups. In GFEA group, intense postprocedural abdominal pain was experienced in one patient while in BIB group one patient needed early removal due to intolerance at day one .

No gastric ulceration or perforation were reported in both group.

Conclusions Gastric fundus endoscopic ablation and the BioEnterics Intragastric Balloon are both effective and with low rate of adverse events. While BIB offers more established short-term outcomes, GFEA appears promising for more durable physiological modulation through reduction of ghrelin secretion and fundic capacity; however, evidence remains preliminary.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP273 The Hidden Burden of International Gastric Balloon Tourism: A Five-Year Analysis of Removal Procedures Performed at Homerton University Hospital an NHS Bariatric Centre in London, UK

Authors Buckley A[1], El Menabawey T[2, 3], Ewing I[3], Shidrawi R[3], Hwang S[3]
Institutes **1** Homerton Healthcare NHS Foundation Trust, London Fields, United Kingdom; **2** University College Hospital, London, United Kingdom; **3** Homerton Healthcare NHS Foundation Trust, London, United Kingdom
DOI 10.1055/s-0046-1821213

Aims Gastric balloons are used as a minimally invasive treatment for obesity in patients who have not achieved adequate weight loss through lifestyle modification and who may not be suitable for bariatric surgery. Randomised controlled trials and meta-analyses show that fluid-filled intragastric balloons achieve mean total body weight loss of 10–15 % at 6–8 months, compared to 3–4 % with lifestyle intervention alone [1, 2]. The aim of this study was to evaluate outcomes, technical success, complications, and healthcare utilisation (including financial impact) associated with gastric balloon removal in a UK NHS bariatric centre, with a particular focus on devices inserted overseas through medical tourism.

Methods A five-year retrospective review was undertaken of all gastric balloon removal procedures between October 2020 and October 2025. Data were collected from endoscopy reporting software for all patients undergoing oesophagogastroduodenoscopy (OGD) for balloon removal using a dedicated endoscopic gastric balloon removal kit. Electronic patient records provided additional information including presenting symptoms, number of OGD attempts, procedural challenges, complications, cross-sectional imaging, length of hospital stay, balloon insertion origin, and weight-loss reporting.

To estimate the financial burden to the NHS, we used publicly available NHS reference-cost benchmarks to approximate the mean healthcare cost per emergency admission for gastric balloon removal, incorporating inpatient stay, cross-sectional imaging, anaesthetic support, and therapeutic endoscopy.

Results A total of 51 OGD balloon removal attempts were performed for 48 patients. Presenting symptoms included abdominal pain, nausea, vomiting, and reflux. One patient presented with acute pancreatitis, believed to be secondary to the gastric balloon.

Most patients (n = 46) required a single procedure, while two required two attempts: one due to intolerance of sedation (later removed under general anaesthesia), and another in whom balloon deflation was achieved initially but retrieval required a second OGD. Successful removal was achieved in 98 % of cases, with one patient awaiting removal under GA.

Technical challenges included one overinflated balloon that ruptured during extraction and one case requiring an overtube to facilitate removal of friable debris. Cross-sectional imaging was performed in 23 patients (48 %), including four at external centres. Median length of hospital stay was 2 days (range 1–10).

Weight-loss data were inconsistently documented: 10 patients reported weight loss, 17 reported none, and information was unavailable for 21.

Balloon insertion occurred predominantly outside the UK: 31 from Turkey, 2 from Brazil, 1 from Albania, 1 from the Czech Republic; 9 were inserted in the UK (mostly private providers), and 4 had undocumented origin. Documentation regarding planned removal was poor: 8 patients had confirmed dates, 3 had general timeframes, 3 had no documented plan, and 31 had no recorded information.

Cost analysis: Using current NHS reference-cost benchmarks [5], the estimated mean cost per emergency admission for gastric balloon removal was £3,040, with a plausible range of £1,800–£5,500 depending on duration of admission, imaging requirements, anaesthetic input, and procedural complexity. The largest contributors were inpatient stay, cross-sectional imaging, and thera-

peutic endoscopy. The total projected cost to the hospital over the 5-year period was approximately £158,100.

Conclusions This five-year review demonstrates that endoscopic gastric balloon removal can be performed safely and with high technical success. However, most balloons were inserted privately and internationally, with no follow-up and removal planning. The frequent need for admission, imaging, and specialist endoscopy creates a significant unplanned financial burden on NHS services.

With the increasing availability of effective pharmacological weight-loss therapies such as GLP-1 agonists [2, 3] and newer endoscopic bariatric techniques such as endoscopic sleeve gastroplasty [4], gastric balloons may become less favoured. Establishing clearer follow-up pathways, improving patient education, and addressing risks associated with international health tourism may help reduce unnecessary NHS resource utilisation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP274 Long-term outcomes of transoral outlet reduction (TORe) for dumping syndrome and weight regain after Roux-en-Y gastric bypass

Authors Birzle L[1], Gölder SK[2], Ebigbo A[1, 3], Messmann H[4], Nagl S[1]

Institutes **1** University Hospital Augsburg, Augsburg, Germany; **2** Ostalb-Klinikum Aalen, Aalen, Germany; **3** St. Josef-Hospital, Ruhr-University Bochum, Bochum, Germany; **4** Internal Medicine III – Gastroenterology, University Hospital Augsburg, Augsburg, Germany

DOI 10.1055/s-0046-1821214

Aims Weight regain and dumping syndrome are known to be associated with widening of the gastro-jejunal anastomosis after Roux-en-Y gastric bypass. In this study, we aim to evaluate the efficacy of endoscopic outlet reduction in achieving weight loss and in alleviating symptoms of dumping syndrome

Methods We conducted a retrospective analysis of a total of 45 cases of TORe after prior Roux-en-Y gastric bypass surgery.

Between May 2018 and July 2025, we performed TORe in 45 patients (8 male, 37 female; average age 48 years) at the endoscopy unit of the University Hospital in Augsburg.

All patients had previously undergone laparoscopic Roux-en-Y gastric bypass surgery before the TORe procedure. In 17 cases, a laparoscopic sleeve gastrectomy had been performed prior to the gastric bypass.

Endoscopic outlet reduction was performed using the Boston Scientific OverStitch NXT in 37 cases and the ovesco BARS system in 8 cases.

The primary endpoint of the study was the degree of weight loss after TORe, quantified as percentage total body weight loss (%TBWL). The secondary endpoint was the improvement in dumping symptoms, quantified by the reduction in the Sigstad score.

Results In 21 patients, TORe was performed for weight regain after bariatric surgery. In 12 cases, endoscopic outlet reduction was carried out due to postoperative dumping syndrome and in 17 cases, both weight regain and dumping syndrome were present.

Prior to TORe the average BMI was 37,7 kg/m2 and the average Sigstad's score was 13,5.

Two patients were lost to follow-up and were therefore excluded from the statistical analysis.

A statistically significant reduction in BMI was demonstrated at the first follow-up at 3–6 months (mean BMI 37,69 kg/m2; 35,29 kg/m2, $p < 0,005$). A significant reduction in BMI was also observed at the second follow-up at 12-months (mean BMI 37,69 kg/m2; 33,97kg/m2, $p < 0,005$). The %TBWL was 6,8 % within 6 months and 6,7 % at 12 months.

In addition, a significant decrease in the Sigstad's score was observed at the initial follow-up within the first six months (mean 13,2; 7,8, $p < 0,05$) as well as at the 12-month follow-up (mean 13,2; 6,1; $p < 0,005$).

In 38 % (18 cases), re-interventions were performed due to recurrent symptom exacerbation or weight regain. In 6 cases, argon plasma coagulation (APC) was used to reduce the outlet. In 10 cases, the anastomosis was re-tightened using the OverStitch NXT. In 2 cases, the anastomosis was reduced using the ovesco BARS system.

In cases where APC therapy was used, multiple treatment sessions (min. 2, max.6 sessions) were performed at intervals of 6–8 weeks to achieve outlet reduction.

Conclusions Endoscopic outlet reduction is an effective intervention for achieving both a reduction of dumping syndrome and clinically relevant weight loss in patients after Roux-en-Y gastric bypass surgery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP275 Endoscopic septotomy with argon plasma coagulation (ES-APC) for the management of refractory late and chronic post-bariatric surgery fistulas and leaks: results from a prospective series

Authors Dell'Anna G[1, 2, 3, 4], Mandarino FV[2, 5], Fanizza J[6], Fasulo E[3], Rotkopf H[4], Tuszynski T[4], Dumont JL[4], Facciorusso A[7], Dell'anna A[8], Fuccio L[9], Zito FP[10], Galasso G[11], D'alessandro A[11], Dagher I[12], Tranchart H[13], Poghosyan T[14], Arienzo R[15], Pacini F[15], D'alessandro A[16], Annese V[17], Danese S[18], Donatelli G[4]

DOI 10.1055/s-0046-1821215

Aims Refractory late and chronic leaks or fistulas after sleeve gastrectomy (SG) and Roux-en-Y gastric bypass (RYGB) represent one of the most challenging post-bariatric complications. Endoscopic septotomy with argon plasma coagulation (ES-APC) facilitates internal drainage by incising the septum separating the perigastric cavity or fistulous tract from the gastric lumen. This study eval-

uated its efficacy and safety in a prospective cohort from a tertiary referral center.

Methods Consecutive adults with refractory late or chronic post-bariatric leaks or fistulas treated with ES-APC between September 2019 and August 2025 were included. ES-APC consisted of stepwise ablation of the septum until complete luminal communication was achieved, followed by placement of a through-the-scope metallic clip at the base to promote localized ischemia and reduce bleeding or perforation risk.

Results A total of 64 patients were treated (76.6 % female; mean age 40.8 ± 11.2 years; BMI 32.2 ± 7.7 kg/m²). Most complications occurred after SG (95.3 %). At presentation, 48.4 % had leaks, 48.4 % fistulas, and 46.9 % had an associated gastrocutaneous fistula (GCF). According to Rosenthal, 25 % were late and 75 % chronic. Patients had undergone a median of 4 prior treatments (IQR 3–5), with a median pretreatment duration of 106 days (IQR 79–138). Median number of ES-APC sessions was 1 (IQR 1–2), with a median procedural time of 15 min (IQR 12–22). Technical success was 100 %. Clinical success (CS) was achieved in 93.7 % (60/64), with only one recurrence (1.7 %) during a median follow-up of 44 months (IQR 29–67). CS was significantly lower in patients with GCF (86.7 % vs 100 %, p = 0.04). No major adverse events occurred.

Conclusions ES-APC is a safe, standardized, and highly effective minimally invasive therapy for refractory late and chronic post-bariatric leaks and fistulas, providing durable closure while significantly reducing the need for surgery.

PYP276 Endoscopic Closure of Sleeve Gastrectomy Leaks Using the X-Tack System: A Single-Center Experience

Authors Kranidiotis G[1], Tsoukalas N[1], Ellina M[1], Emmanouilidou G[1], Martinos N[1], Ziogas D[1], Rodias M[1], Vasileiadis K[1], Sgouros S[1], Stefanidis G[1]
Institute 1 Athens Naval Hospital, Athens, Greece
DOI 10.1055/s-0046-1821216

Aims Leaks following sleeve gastrectomy represent a potentially life-threatening complication associated with significant morbidity. Endoscopic management is continuously evolving, with the X-Tack system (Endoscopic Helix Tacking System, Boston Scientific) emerging as a novel through-the-scope suturing approach for defect closure. The aim of this study is to present the first Greek case series of endoscopic management of post-sleeve gastrectomy leaks using X-Tack as the sole therapeutic modality, and to evaluate its effectiveness, recovery time, and success rate [1, 2].

Methods This study included patients from a single center who underwent sleeve gastrectomy for morbid obesity and developed a postoperative leak between April 2024 and the present. The complication was managed exclusively using the X-Tack system, which deploys helical tacks connected by non-absorbable suture around the defect, allowing stable and targeted closure.

Results Five patients (3 males/2 females) with a mean age of 39.8 years (range: 19–60) were included. The mean postoperative day of endoscopic intervention was day 7 (range: 4–10). Complete (100 %) technical closure of the leak was achieved in all cases. Mean endoscopic procedure time was 31.6 minutes (20–40). Clinical improvement was observed in all patients, with gradual reintroduction of oral intake after 2 weeks, no need for re-operation, and a mean hospital stay of 18 days (15–20). Three-month follow-up, including repeat gastroscopy, confirmed sustained closure without recurrence or complications (▶ **Table 1**).

▶ **Table 1**

Variable	Value
Number of patients	n = 5
Mean age (range), years	39.8 (19–60)
Sex (male)	n = 3
Mean postoperative day of intervention	Day 7 (4–10)
Mean endoscopy time, minutes	31.6 (20–40)
Technical success	100 %
Clinical success	100 %
Mean hospital stay, days	18 (15–20)
Complications / Recurrence	0 %

Conclusions The X-Tack system appears to be a safe, effective, and minimally invasive option for the endoscopic management of leaks after sleeve gastrectomy. The encouraging outcomes of this case series support its integration into routine clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP277 Endoscopic Sleeve Gastroplasty in Turkey: Early Experience and Clinical Outcomes

Authors Çelikbilek M[1], Aldemir H[1]
Institute 1 MC Gastroenterology Clinic, Ankara, Türkiye
DOI 10.1055/s-0046-1821217

Aims Endoscopic sleeve gastroplasty (ESG) is a minimally invasive bariatric procedure that utilizes full-thickness endoscopic suturing to achieve tubular reconfiguration and substantial volume reduction of the gastric body. ESG has been established as a safe, durable, and effective management option for obesity. This study aims to present our single-center experience from Türkiye, focusing on changes in anthropometric measurements and clinical outcomes following ESG in a real-world clinical setting [1].

Methods We performed a retrospective analysis of prospectively collected medical records of consecutive patients who underwent ESG between October 2022 and August 2025. Detailed procedure-related data, including suture counts and technique, were recorded. Patient data—comprising demographics, anthropometrics, and comorbidity status—were systematically collected at baseline and during every follow-up visit. The follow-up protocol involved intensive, structured monitoring via online or face-to-face appointments: weekly for the first two months, followed by bi-weekly visits for a total one-year program. Crucially, interviews were complemented by personalized nutritional trainingdesigned to ensure sustained behavioral modification. Instead of a restrictive standard diet plan, completely individualized nutritional programs were implemented.

Results A total of 29 patients were included in the analysis [Females: 82.8 %; Age: 39.1 ± 8 years; Baseline Weight: 101 ± 16.8 kg; Baseline Body Mass Index (BMI): 36.6 ± 5.4 kg/m2]. All patients reported at least one transient post-procedural symptom, such as minimal abdominal pain, abdominal discomfort, nausea, or vomiting. Only one patient required an overnight hospital stay due to persistent vomiting and pain; the remaining twenty-eight patients were discharged six hours post-ESG. No hospital readmissions or re-hospitalizations

Endoscopy 2026; 58: S1–S1041

occurred after initial discharge. Furthermore, no instances of fluid, electrolyte, or nutritional insufficiency were observed throughout the follow-up period, underscoring the procedure's high safety profile. Follow-up data completeness was 100 % at 1 month, 89.7 % (n = 26) at 3 months, 75.9 % (n = 22) at 6 months, and 31.0 % (n = 9) at 12 months. Procedure-related details showed that the median number of sutures utilized was 5 (range: 3–6), with 22 patients specifically receiving 5 sutures. Regarding the suture pattern, U-pattern was employed in 17 cases, while the interlocking ESG technique was used in 12 cases. Body Mass Index (BMI) demonstrated a significant and continuous decrease post-procedure, starting from a baseline of 36.6 ± 5.4 kg/m2 and dropping to 32.9 ± 4.9 kg/m2 at 1 month, 30.6 ± 4.4 kg/m2 at 3 months, 29.4 ± 3.9 kg/m2 at 6 months, and finally reaching 28.6 ± 5.3 kg/m2 at 12 months. Correspondingly, the percentage of Total Body Weight Loss (%TBWL) progressed steadily, averaging 9.8 ± 2.5 % at 1 month, 16.0 ± 3.8 % at 3 months, 16.6 ± 6.4 % at 6 months, and stabilizing at 16.8 ± 6.6 % by the 12-month mark. Furthermore, the percentage of Excess Weight Loss (%EWL) showed excellent outcomes, advancing from 29.9 ± 9.0 % at 1 month to 48.9 ± 14.9 % at 3 months, 53.3 ± 23.7 % at 6 months, and culminating in 60.3 ± 31.7 % at 12 months. The percentage of patients achieving key weight loss thresholds remained high across follow-up: At the end of the first month, 100 % of patients achieved the ≥ 5 % TBWL target, with 45 % reaching ≥ 10 % TBWL and 6.9 % reaching ≥ 15 %TBWL. By the third month, 100 % maintained the ≥ 5 % TBWL achievement, while the rates for ≥ 10 % and ≥ 15 % TBWL increased significantly to 96 % and 62 %, respectively. At six months, 96 % of patients maintained ≥ 5 % TBWL, with 82 %and 68 % achieving ≥ 10 % and ≥ 15 % weight loss, respectively. Finally, at the twelve-month follow-up, 100 % of the available patients had sustained ≥ 5 % TBWL, with 78 % reaching ≥ 10 % and 67 % achieving ≥ 15 % weight loss.

Conclusions Our early experience from Türkiye demonstrates that ESG is a procedure with a high safety profile and results in significant and clinically meaningful improvements in body composition and weight loss up to 12 months post-procedure. The integration of a highly individualized nutritional support program may contribute to these favorable outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Endoscopic bariatric therapies offer minimally invasive options for patients with obesity who are not candidates for surgery. We report a novel combined approach integrating Endoscopic Sleeve Gastroplasty (ESG) with Gastric Mucosal Ablation (GMA) of the fundus using the MOVIVA probe. The device allows submucosal injection to protect deeper layers and controlled mucosal ablation via Argon Plasma Coagulation, aiming to reduce ghrelin-producing cells. A 54-year-old man (BMI 44 kg/m²) underwent MOVIVA-assisted fundic ablation followed by ESG with the OverStitch NXT system. The procedure was uneventful, and oral intake resumed the next day. At one month, the patient reported early satiety and achieved 16.5 % total body weight loss. This combined strategy may enhance metabolic outcomes by coupling gastric restriction with hormonal modulation.

Aims EndoZip is a fully automated endoscopic suturing device designed to reduce gastric volume for obesity treatment, decreasing operator dependence during endoscopic gastroplasty. A recent multicenter clinical trial demonstrated that the device is easy to use, safe, and effective for treating class I and II obesity. This analysis focuses on ouycomes from the Italian site, evaluating the efficacy and safety of EndoZip system in improving obesity-related comorbidities.

Methods This prospective, single-arm, open-label clinical trial enrolled patients with BMI 30-42g/m² and hypertension and/or type 2 diabetes mellitus (T2DM) who failed non-invasive weight-loss therapies and were suitable candidates for bariatric endoscopy. Endpoints include percentage total body weight loss (%TBWL), changes in T2DM (HbA1c and/or HOMA-IR index), and changes in hypertension (blood pressure reduction by 24-hours ambulatory blood pressure monitor (ABPM) and/or reduction of antihypertensive medication/dosage) at 12 months post-procedure. The incidence of adverse events, changes in Fibroscan parameters (CAP score and fibrosis) and Weight-related Quality of Life (IWQOL) Questionnaire scores.

Results Twenty patients (80 % female, mean age 51.9 ± 9.8 years, mean BMI 34.8 ± 3.2 kg/m²) were enrolled at a single tertiary center. Comorbidity distribution included five patients (25 %) with both hypertension and T2DM, eleven (55 %) with hypertension alone, and four (20 %) with T2DM alone. The mean adjusted %TBWL at 12 months was 11.4 % (95 % CI: 9.1 %–13.6 %). Among patients with hypertension, 53.8 % showed improvement, 30.8 % showed no

change, and 15.4 % worsened. In all worsening cases, the antihypertensive medication has been discontinued. Among patients with T2DM, 62.5 % showed improvement, 25.1 % showed no change, and 12.5 % worsened. Fibroscan demonstrated a significant improvement in steatosis (CAP score: 314 ± 47.9 at baseline vs. 263 ± 54.6 at 12 months, p = 0.0048), while fibrosis changes from baseline were not statistically significant (5.5 ± 1.7 kPa vs. 5 ± 1 kPa, p = 0.1510). The mean IWQOL score at 12 months increased by more than 12 points from baseline (14.2 points ± 11.6), indicating a meaningful improvement in patients' quality of life. One severe adverse event occurred—bleeding that was effectively managed by endoscopic hemostasis.

Conclusions EndoZip demonstrates effective weight-loss outcomes and meaningful improvement in obesity-related comorbidities at 12 months. The procedure also leads to significant improvement in patient quality of life. The safety profile is consistent with expectations for endoscopic gastroplasty, supporting EndoZip as a safe and effective minimally invasive option for patients with class I–II obesity.

PYP280 Diagnostic Yield of ERCP Brush Cytology and Endo-biliary Biopsy in Malignant Biliary Strictures: Time to Standardise Practice

Authors Khalil O[1], Mathai D[1], Konstantakis C[1], Mcfarlane M[1], Wong JLH[1], Shehkar C[1]

Institute 1 University Hospital Coventry & Warwickshire, Coventry, United Kingdom

DOI 10.1055/s-0046-1821220

Aims The presence of a biliary stricture is a medical challenge. ERCP brush cytology (BR) and endo-biliary forceps biopsies (BX) are commonly used tissue sampling techniques. BR is favoured for its simplicity; however, its diagnostic sensitivity has historically been low. Its utility is limited by poor specimen quality and equivocal results are common [1]. BX, while technically more demanding, offers superior histological detail and higher diagnostic yield [2]. Given the implications of missed or delayed diagnoses, it is crucial to establish a standardised, evidence-based approach to tissue sampling during ERCP.

We aimed to compare the diagnostic utility of ERCP brushings versus endo-biliary biopsies in patients with confirmed malignant biliary obstruction.

Methods We retrospectively reviewed all patients who underwent ERCP for investigation of biliary strictures during a three-year period (08/2021–07/2024) in our department (a referral centre). We acquired all relevant data (demographics, histological diagnosis, method of diagnosis, dates) through patient records.

Diagnostic yield was defined as a positive cytology or histology confirming malignancy. Results were analysed in three categories (Negative, Positive, Suspicious). Agreement analysis (kappa values) was performed in all patients who underwent both BR and BX.

Results Total number of patients investigated for biliary stricture was 208. A confirmed diagnosis of malignancy was established in 110 patients (53.4 %) through ERCP brushings (BR), ERCP biopsies (BX), or further investigations. BR was performed in 110 patients, with the addition of BX in 55/110. BR was positive in 33/110 (30 %) and negative in 77/110 (70 %) (including suspicious 28/110; 25.9 %), which required another modality to confirm diagnosis.

BX were positive in 34/55 (61.8 %) and negative in 21/55 (38.2 %) (including suspicious 8/55; 14.5 %). All suspicious cases for BX and BR were ultimately proven malignant. There were no cases where BR was positive but BX was negative. Among the 55 patients who had both tests, BR was positive in 13/55 (23.7 %) compared with 34/55 (61.8 %) for BX. No complications were noted as a direct result of BX in addition to BR.

Concordance analysis: Overall agreement between BR and BX was low (43.6 %), with only fair concordance (Cohen's kappa 0.20–0.21). Even when results were merged, agreement improved only modestly (58.2 %). A key finding was that BR frequently missed malignancy: 29 % of patients with negative brushings had positive biopsies, and 36.4 % had positive or suspicious biopsy results, demonstrating the limited reliability of brushings as a standalone test.

Conclusions The data suggests BR cytology has limited sensitivity as a standalone diagnostic tool in malignant biliary strictures, and biliary biopsies have almost 3 times the diagnostic yield. This is significant as delayed diagnosis often leads to delay in definitive treatment and delays referral for subsequent diagnostic modalities pending results. The low kappa values (0.20–0.21) indicate only fair agreement between BR and BX, reinforcing that the two methods do not perform similarly and that BR frequently under-detects malignancy compared with BX.

In this cohort of patients, brushings provided low diagnostic yield whether performed alone or with BX (30 % and 23.7 % in respective cohorts). Endo-biliary BX have a higher diagnostic yield (61.8 %). The data also suggests that brushings add little incremental value and could be omitted unless biopsies are technically challenging. The poor concordance between the two modalities (Cohen's kappa 0.20–0.21) further demonstrates that brushings frequently miss malignancy captured by biopsies. Biopsy should be considered the standard of practice, with brushings reserved as an adjunctive option rather than a primary diagnostic tool.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP281 Diagnostic yield of cholangioscopy for indeterminate biliary strictures: a retrospective analysis

Authors Di Marco M[1], Lisai G[1], Semprini G[1], La Marca M[1], De Padova A[1], Bianchi ML[1], Frazzoni L[1]

Institute 1 Gastroenterology and Endoscopy Unit, Ospedale "Infermi" di Rimini, Rimini, Italy

DOI 10.1055/s-0046-1821221

Aims Indeterminate biliary strictures (IBS) remain diagnostically challenging, as imaging, ERCP-based tissue sampling, and EUS-guided tissue acquisition (TA) often fail to differentiate malignant from benign lesions. Digital single-operator cholangioscopy (D-SOC) improves accuracy through direct visualization and targeted biopsies, although false-negative histology persists. This study evaluated whether biopsy orientation and cholangioscopic visual assessment using the Monaco classification improve diagnostic performance.

Methods This retrospective single-center study included all consecutive patients undergoing D-SOC with direct biopsies for IBS at Infermi Hospital (Rimini, Italy) from 2017 to 2025. Two cohorts were analyzed: non-oriented biopsies (2017–2021) and oriented biopsies (2022–2025). Malignancy was defined

according to a clinico-pathological standard (surgical histology or long-term follow-up). Primary outcomes were diagnostic yield, sensitivity, and specificity for malignancy. The Monaco classification was considered positive when ≥ 3 criteria were present. Diagnostic accuracy was further assessed using combined parallel (Monaco-positive or malignant histology) and serial (Monaco-positive and malignant histology) strategies.

Results A total of 103 patients were included (non-oriented 64.1 %; oriented 35.9 %). Overall biopsy diagnostic yield for malignancy was 62.1 % (95 % CI: 52.0–71.5), with sensitivity 57.1 % (95 % CI: 44.0–69.5) and specificity 100 % (95 % CI: 91.0–100). Diagnostic yield was comparable between groups: 61.5 % (95 % CI: 48.6–73.3) for non-oriented and 63.2 % (95 % CI: 46.0–78.2) for oriented biopsies. Sensitivity was 61.9 % (95 % CI: 45.6–76.4) and 47.6 % (95 % CI: 25.7–70.2), respectively; specificity remained 100 % in both.Cholangioscopic visual assessment alone showed higher sensitivity (84.4 %, 95 % CI: 72.6–92.7) but lower specificity (65.9 %, 95 % CI: 50.1–79.5). Combined analysis improved diagnostic performance: the parallel model significantly increased sensitivity to 82.5 % (95 % CI: 70.9–90.9; $p < 0.05$ vs biopsy alone), while the serial model maintained specificity at 100 % (95 % CI: 91.2–100), equivalent to histology.

Conclusions D-SOC remains a valuable tool in evaluating indeterminate biliary strictures. Orientation of biopsy samples does not appear to provide an incremental diagnostic yield and sensitivity. Integrating visual cholangioscopic assessment through the Monaco classification substantially enhances the ability to identify malignant lesions, by reducing false negative results, while maintaining high specificity when used in a serial combination with biopsy.

Further evidence is needed to better assess biopsy-handling techniques, optimize tissue acquisition strategies, and integrate artificial intelligence in the diagnostic pathway to increase the diagnostic performance for indeterminate biliary strictures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP282 EUS-Guided Tissue Acquisition Does Not Increase Peritoneal Carcinomatosis in Hilar Cholangiocarcinoma: A Retrospective Cohort Study

Authors Ribera Sanchez R[1], Tirado-Escuder A[1], Martínez-Moreno B[1], Aparicio JR[1]

Institute 1 University General Hospital Dr. Balmis, 03010s3, Spain

DOI 10.1055/s-0046-1821222

Aims To evaluate whether endoscopic ultrasound-guided tissue acquisition (EUS-TA) isassociated with an increased risk of peritoneal carcinomatosis in patients with hilarcholangiocarcinoma, and to assess its impact on time-to-peritoneal dissemination andoverall survival. A secondary aim was to analyse whether outcomes differed between operated and non-operated patients, and to compare results according to the type of needleused (FNA vs FNB).

Methods This retrospective cohort study included 100 patients with hilar cholangiocarcinoma. Eightpatients with peritoneal carcinomatosis at baseline were excluded from the analysis ofdissemination risk. Clinical, radiological, and procedural variables were collected, includinguse of EUS-TA, surgical management, and needle type. Primary endpoints were: [1] development of peritoneal carcinomatosis, [2] time to peritoneal dissemination, and [3] overall survival. Analyses were performed using Fisher's exact test for categorical variablesand Kaplan–Meier curves with log-rank testing for time-to-event outcomes. Subgroupanalyses were conducted for operated vs non-operated patients and for FNA vs FNB.

Results Among the 92 patients without baseline peritoneal disease, peritoneal carcinomatosisoccurred in 6/32 EUS-TA patients (11.7 %) and 7/60 without EUS-TA (18.8 %), with nosignificant difference ($p = 0.36$). Median time to peritoneal dissemination was similarbetween groups: 13.5 months (IQR 6.75–18.5) for EUS-TA vs 17 months (IQR 14–26) fornon-EUS (log-rank $p = 0.165$). Median overall survival was 301 days (IQR 95–566) withEUS-TA and 151 days (IQR 51.5–474) without EUS-TA (log-rank $p = 0.60$).In the operated subgroup, dissemination occurred in 2/11 (18.2 %) with EUS-TA vs 5/30(16.7 %) without EUS-TA ($p = 0.20$). In non-operated patients, dissemination rates were19.0 % (4/21) with EUS-TA and 6.7 % (2/30) without EUS-TA ($p = 1.00$). Time-to-dissemination and overall survival curves showed no significant differences within eithersubgroup.In the needle-type analysis, dissemination rates were similar between FNA (4/22, 18.2 %)and FNB (2/10, 20.0 %) ($p = 1.00$), with no differences in survival outcomes (all log-rank p >0.4).

Conclusions EUS-guided tissue acquisition does not increase the risk of peritoneal carcinomatosis inpatients with hilar cholangiocarcinoma, nor does it affect time-to-dissemination or overall survival. These findings remained consistent across operated and non-operated subgroups,suggesting that surgical status does not modify the oncological impact of EUS-TA.Additionally, the needle type (FNA vs FNB) did not influence dissemination or survival,supporting the safety of both sampling techniques [4].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP283 Post-TARE Biliary Strictures in Hepatocellular Carcinoma: Endoscopic Characterization and Histological Proof of Direct Radiation-Induced Injury

Authors Jochheim L[1, 2], Dertnig T[3], Frommann L[1], Schramm C[2], Steinberg-Vorhoff H[3], Best J[2], Zeller A[2], Schmidt H[2], Rahe G[2]

Institutes 1 University Hospital Essen, Department of Nuclear Medicine, Essen, Germany; 2 University Hospital Essen, Department of Hepatology, Gastroenterology & Transplantation Medicine, essen, Germany; 3 University Hospital Essen, Institute for Diagnostic & Interventional Radiology & Neuroradiology, Essen, Germany

DOI 10.1055/s-0046-1821223

Aims Transarterial radioembolization (TARE) with Yttrium-90 microspheres is an established locoregional treatment for hepatocellular carcinoma, but radiation-induced biliary complications remain underreported. This study aimed to determine the prevalence, temporal patterns, and predictors of TARE-related cholestasis, and to provide histological proof of our hypothesis that TARE can cause cholestasis through direct radiation injury to the bile ducts.

Methods We retrospectively analyzed all patients who underwent TARE at a tertiary care center between January 2020 and December 2024. Demographics, tumor type, procedural details (unilobar, bilobar, segmental administration), applied radiation dose, follow-up imaging, and endoscopic findings were reviewed. TARE-related cholestasis was defined as new-onset cholestasis without preexisting or post-transplant occurrence. Risk factors were evaluated using logistic regression and Cox proportional hazards models. Patients who developed biliary strictures underwent ERCP with stent placement and/or balloon dilatation as indicated. In patients with unclear strictures post-TARE, cholangioscopy with targeted biopsies was performed during ERCP to histologically characterize radiation-associated tissue changes.

Results Among 258 patients (29.8 % female; median age 67 ± 12.0 years) undergoing 331 TARE procedures, 19 underwent subsequent ERCP. After excluding alternative causes (n = 7) and parenchymal liver damage (n = 1), 11 patients had confirmed clinically significant TARE-related biliary strictures. The median interval from TARE to stricture was 19.4 months (applied median activity 2.28 GBq, median dose 121.5 Gy). On cross-sectional imaging, stricture patterns included lobar (52.7 %), central (27.3 %), and segmental (20.0 %) distributions, all localized to irradiated liver segments. Overall, radiologic cholestasis developed in 55 of 295 evaluable procedures (18.6 %). Independent predictors of imaging-detected

cholestasis included increasing age (HR 1.04/year, p = 0.003), cholangiocarcinoma versus HCC (HR 5.66, p < 0.001), and bilobar treatment (HR 2.36, p = 0.036). Median imaging-based cholestasis-free survival was 829 days. All 11 patients with clinically significant strictures underwent endoscopic stent placement; 6 received additional balloon dilatation. Notably, 10 of 11 patients showed stable disease or tumor response at ERCP, indicating stricture development independent of progression. Critically, cholangioscopy-guided biopsies demonstrated glass microspheres within the stricture tissue, providing direct histological proof that TARE causes cholestasis through radiation-induced bile duct injury.

Conclusions Radiologically detectable cholestasis occurs in 18.6 % of TARE procedures as a delayed complication. The histological demonstration of glass microspheres within biliary strictures confirms our hypothesis of direct radiation-induced bile duct injury. ERCP with stenting remains the primary therapeutic approach for clinically significant strictures. Cholangioscopy with targeted biopsy should be considered for definitive diagnosis when distinguishing radiation-induced strictures from malignant obstruction.

DOI 10.1055/s-0046-1821224

Aims The diagnosis of perihilar cholangiocarcinoma (CCA) remains challenging, with conventional cytology, brushing, transpapillary biopsies and imaging providing limited sensitivity. [1] Endoscopic ultrasound (EUS)-guided fine-needle biopsy (FNB) is typically performed in the presence of a mass or suspicious portal lymph nodes. [2] In contrast, cholangioscopy-directed biopsies are increasingly used for evaluating indeterminate biliary strictures. [3] Comparative real-world data on their diagnostic yield are scarce. We aimed to assess the diagnostic performance, safety, and clinical impact of these modalities.

Methods We retrospectively analyzed 117 consecutive patients with hilar strictures evaluated for suspected biliary malignancy between 01.2020-09.2025. The final diagnosis was based on surgical histology when available, or on a multidisciplinary consensus with radiological and clinical follow-up. Sensitivity analysis was restricted to the 96 patients with confirmed malignancy. A test was considered positive when histology confirmed malignancy (EUS-FNB or cholangioscopy guided biopsy) or when visual features were interpreted as malignant. True positives (TP) were malignant cases with diagnostic confirmation, and false negatives (FN) were malignant cases with negative or non-diagnostic results. Combined sensitivity was defined as positivity in at least one modality in patients who underwent both procedures.

Results Of 117 patients, 96 (82 %) had malignancy. Median age was 66 years (IQR 58–73), 53 % were male, ECOG 0–1 in 94 %, and the comorbidity burden was moderate. Malignant lesions were hilar in 78 % and Bismuth I in 20 %, with Bismuth–Corlette III–IV predominating. EUS-FNB was performed in 40 of these cases, yielding a sensitivity of 65 % (26/40; 95 % CI: 46.3–76.3). Cholangioscopy-directed biopsies were performed in 72 malignant cases, with a sensitivity of 72.2 % (52/72; 95 % CI: 60.5–82.9). Visual impression during cholangioscopy suggested malignancy in 61 of 72 cases, corresponding to a sensitivity of 84.7 % (95 % CI: 74.3–92.3). In the subgroup of 26 malignant patients who underwent both procedures, the combined sensitivity increased to 96.2 % (25/26; 95 % CI: 81.1–99.9). Adverse events were more frequent after cholangioscopy (cholangitis 13.5 %, pancreatitis 3.4 %, bleeding 2.2 %) than EUS (pancreatitis 4.5 %); all were mild and managed conservatively.

Conclusions EUS-FNB and cholangioscopy each demonstrated moderate sensitivity, with visual cholangioscopy yielding the highest single-modality performance. Although cholangioscopy carried more complications, the combination of EUS and cholangioscopy achieved near-complete sensitivity and remained safe, underscoring their complementary role in the diagnostic algorithm of suspected CCA.

DOI 10.1055/s-0046-1821225

Aims Although bilateral endoscopic drainage is regarded as essential for achieving adequate liver volume drainage in unresectable high-grade malignant hilar biliary obstruction (MHO), limited evidence exists regarding the comparative outcomes of bilateral versus tri-segmental drainage. We aimed to evaluate and compare the clinical outcomes of bilateral and tri-segmental biliary drainage in patients with unresectable MHO.

Methods After propensity score matching, 52 patients with unresectable MHO of Bismuth type IIIa or IV were included. Patients underwent plastic stent placement for drainage of either two hepatic sectors (bilateral group; left plus right anterior or right posterior, n = 26) or all three hepatic sectors (tri-segmental group, n = 26). The primary outcome was clinical success, and secondary outcomes were procedure time, adverse events (AEs), and time to recurrent biliary obstruction (RBO).

Results The clinical success rate was 76.9 % (20/26) in the bilateral group and 84.6 % (22/26) in the tri-segmental group ($P = 0.727$). The tri-segmental group demonstrated a significantly longer median time to RBO (44 days vs. 67 days, $P = 0.003$), whereas the procedure time was significantly shorter in the bilateral group (28.2 ± 8.3 minutes vs. 35.6 ± 11.3 minutes, $P = 0.017$). Overal AE rates were comparable between the two groups, and no severe AEs were observed (3.8 % vs. 7.7 %, $P = 1.000$).

Conclusions Our findings suggest that, without undue concern for procedure-related AEs from prolonged duration, attempting to drain all technically feasible hepatic sectors could confer clinical benefit in the management of unresectable high-grade MHO.

DOI 10.1055/s-0046-1821226

Aims Biliary strictures present a major diagnostic challenge as benign and malignant conditions often exhibit similar clinical and imaging findings. In cases of indeterminate strictures, obtaining a tissue sample is crucial. Notably, up to 25 % of patients undergoing surgery for suspected cholangiocarcinoma (CCA) are ultimately diagnosed with benign disease, underscoring the difficulty of preoperative diagnosis. The low cellularity and desmoplastic nature of CCA further complicate cytological and histological assessments. Current ESGE guidelines recommend ERCP with tissue acquisition (TA) as the preferred diagnostic approach for perihilar strictures requiring drainage. This study aims to evaluate the diagnostic accuracy of EUS-TA for both distal and perihilar biliary strictures in a high-volume bilio-pancreatic endoscopy referral center.

Methods A retrospective analysis was conducted on a prospectively maintained database of patients who underwent EUS-TA at San Raffaele Hospital between April 2021 and June 2024 due to obstructive jaundice or biliary strictures identified via CT or MRI. Patients with preexisting pancreatic lesions, extrinsic biliary compression, or choledocholithiasis without biliary abnormalities were excluded. EUS-guided tissue sampling was performed using 25–22-gauge FNA or FNB needles with Rapid On-Site Evaluation (ROSE) by cytotechnicians. The final diagnosis was established based on surgical pathology, imaging, or a minimum follow-up of six months. Sensitivity, specificity, and likelihood ratios (LLR + and LLR −) were calculated using 2 × 2 contingency tables, with 95 % confidence intervals estimated via the Clopper-Pearson method. Additionally, a Random Forest model was developed using an 80:20 stratified split of the dataset, preserving class distribution. The model achieved an accuracy of 83.33 % on the test set (▶ **Table 1**).

Results Of the 249 patients screened, 86 met the inclusion criteria. Among them, 47 (54.7 %) had perihilar strictures, and 39 (45.3 %) distal ones. Strictures presented as lesions in 65 % of cases and as wall thickening in 35 %. Malignancy was diagnosed in 76.7 % of cases, while 23.2 % were benign. Adequate tissue sampling was achieved in 94 % of cases, with five false-negative results. EUS-TA demonstrated an overall sensitivity, specificity, and accuracy of 86.4 %, 95 %, and 88.4 %, respectively. In perihilar strictures, sensitivity was 85.7 %, specificity 100 %, and accuracy 87.2 %, with an NPV of 45.4 % and negative LR of 0.14. Combining EUS-TA with ERCP-TA improved sensitivity to 89 % and accuracy to 92 %.The Random Forest model showed high diagnostic performance, with a precision of 0.88, recall of 0.94, and an F1-score of 0.91 for malignant lesions. Multivariate analysis identified male sex, jaundice, mass-like presentation, and vascular invasion as independent predictors of malignancy. No clinical or EUS factors were significantly associated with diagnostic accuracy prediction.

Conclusions This study confirms the strong diagnostic performance of EUS-TA for biliary strictures, including perihilar cases. The combination of EUS-TA and ERCP-TA significantly improves diagnostic yield, particularly for perihilar strictures. These findings support the use of EUS-TA as a first-line diagnostic approach in high-expertise centers, with a same-session EUS-ERCP strategy optimizing procedural efficiency and reducing risks.

DOI 10.1055/s-0046-1821227

Aims Hilar malignant strictures are challenging to diagnose. Current guidelines recommend ERCP-based tissue acquisition as the first-line modality for perihilar strictures requiring biliary drainage, yet its sensitivity remains suboptimal and often necessitates multiple procedures. Endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) can provide direct access to perihilar lesions and regional lymph nodes. It can obtain high-quality histological cores, but its use has historically been limited by concerns about tumour seeding, based on small, outdated studies. With modern FNB needle technology, diagnostic performance has substantially improved, yet contemporary evidence specifically addressing hilar lesions remains limited. To address this gap, we conducted a multicentre study to assess the diagnostic performance and safety profile of EUS-FNB as a first-line tool in the diagnostic approach to suspected hepatic hilum malignancies [1–3].

Methods A retrospective analysis was performed on all consecutive patients undergoing EUS-FNB as a first-line tool for perihilar strictures and lymph nodes from October 2014 to April 2025 at four tertiary centres. All patients were monitored after EUS-FNB through clinical and radiological follow-up for ≥ 6 months or until death. Final diagnosis was based on surgical pathology or a composite reference standard (cytology/histology and clinical–radiological follow-up). Histological adequacy was documented for each biopsy, and descriptive statistical analyses of baseline characteristics, procedural variables, and lesion features were conducted. Diagnostic performance was assessed using intention-to-diagnose (ITD), per-protocol (PP), and full-pathway analyses, including second-look EUS-FNB when performed. Sensitivity, specificity, positive and negative predictive values (PPV, NPV), and accuracy were calculated

▶ **Table 1**

	Se (95 %CI)	Sp (95 %CI)	PPV (95 %CI)	NPV (95 %CI)	LR +	LR-	Accuracy
Any Location (n = 86)	86.4 % (76.1-92.7)	95 % (76.4-99.1)	98.3 % (90.9-99.7)	67.9 % (49.3-82.1)	17.2	0.14	88.4 %
Perihilar strictures (n = 47)	85.7 % (72.2-93.3)	100 % (56.6-100)	100 % (90.4-100)	45.5 % (21.3-72)	NA	0.14	87.2 %
Distal strictures (n = 39)	87.5 % (69.0-95.7)	93.3 % (70.2-98.8)	95.5 % (78.2-99.2)	82.4 % (59.0-93.8)	13.1	0.13	89.7 %

with 95 % confidence intervals. Diagnostic yield, incremental yield after repeat biopsy, and number-needed-to-repeat (NNT-repeat) were also determined. Adverse events were recorded according to ASGE lexicon criteria (▶ **Table 1**).

▶ **Table 1**

Variable	Patients (n = 144)
Biopsy needle 22G	126 (87.5 %)
Passes ≥ 3	95 (66.0 %)
Repeated EUS-FNB	27 (18.8 %)
Cholangitis	4 (2.8 %)
Pancreatitis	2 (1.4 %)
Bleeding	2 (1.4 %)
Malignant lesions	121 (84.0 %)

Results A total of 144 patients were included (mean age 69.1 ± 10.8 years; 62.3 % males). Mean lesion size was 29.1 ± 13.6 mm. A biliary stent was present at the time of the first EUS in 35 patients (24.3 %). Histological adequacy at first EUS-FNB was achieved in 136/144 patients (94.4 %), while 8 samples (5.6 %) were inadequate. The final diagnosis was malignant in 121 (84.0 %) patients, with cholangiocarcinoma being the most common cause. In the ITD analysis, first-attempt EUS-FNB showed a sensitivity of 81.8 % (95 % CI 74.0–87.6), specificity of 100 % (95 % CI 82.2–100.0), and overall accuracy of 84.7 % (95 % CI 77.8–89.6). Excluding inadequate samples, the per-protocol sensitivity rose to 86.0 % (95 % CI 78.5–91.1), with an accuracy of 88.2 % (95 % CI 82.1–92.6). A second EUS-FNB was performed in 27 patients following an initial non-diagnostic or negative result, achieving 100 % histological adequacy. Four additional true positives were identified, resulting in an incremental yield of 14.8 % and a NNT-repeat of 6.75. When repeat sampling was included, the complete diagnostic pathway showed a sensitivity of 85.1 % (95 % CI 77.7–90.4) and an accuracy of 87.5 % (95 % CI 81.4–91.8). Adverse events occurred in 7 patients (4.9 %), none of which were severe or procedure-related, and there was no procedure-related mortality. The presence of a biliary stent significantly reduced diagnostic yield (p = 0.03), whereas lesion size, needle type and number of passes had no impact.

Conclusions EUS-FNB provides high diagnostic accuracy and a favourable safety profile for suspected hilar biliary malignancies. These findings support its integration into the diagnostic pathway for hilar lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims It is unclear which is the best approach for the drainage of malignant distal biliary obstruction (MDBO) after failed endoscopic retrograde cholangiopancreatography(ERCP). We compared endoscopic ultrasound (EUS)–guided gallbladder drainage (GBD) and EUS-guided choledocoduodenostomy (CDS) with lumen-apposing metal stents (LAMS) as rescue treatment in the case of ERCP failure.

Methods This was an international multicenter retrospective observational study at 28 tertiary care centers through August 2024. Outcomes were compared using propensity score matching. The primary outcome was the comparison of the clinical success rates between EUS-GBD vs. EUS-CDS. Clinical success was defined by a > 15 % decrease in total bilirubin levels within 24 h and a > 50 % decrease within 14 days after the procedure; secondary outcomes were technical success, defined as adequate LAMS placement with visualization of bile flow, AE and severe AE (SAE), defined as > grade II AE according to the AGREE classification, and overall survival [1–6].

Results Five hundred twenty-nine patients underwent EUS-guided drainage, of which 136 underwent EUS-GBD, and 393 underwent EUS-CDS. After 1-to-1 propensity score matching, 224 patients were selected (112 per group). The mean age was 76 ± 4 years in both groups (p = 0.9), and 49 (43.7 %) and 48 (42.8 %) male patients were treated with EUS-GBD and EUS-CDS, respectively (p = 0.9). EUS-GBD and EUS-CDS had similar technical success (97.3 % and 91 %; p = 0.08) and clinical success rates (83 % and 85.7 %; p = 0.17). Mean bilirubin levels decreased from 17.5 mg/dL (SD6) at baseline to 8.1 mg/dL (SD 6.54) at 24 hours to 2.8 mg/dL (SD: 2.15) at 14 days in the EUS-GBD group and from 18.1 mg/dL (SD 8) at baseline to 7.9 mg/dL (SD 8.25) at 24 hours to 3.2 mg/dL (SD 1.35) at 14 days in the EUS-CDS group. AE rate was 19.6 % in the EUS-GBD group and 12.5 % in the EUS CDS group (p = 0.20), of which 10 (8.9 %) and 7 (6.2 %) severe AEs respectively (p = 0.61). Bleeding occurred in seven patients (6.1 %) after EUS-GBD and 3 patients (2.5 %) after EUS-CDS. Two cases of perforation (1.7 %) were observed after EUS-CDS and both were successfully managed endoscopically. Stent occlusion occurred in 6 patients (5 %, of which 4 cases within 48 hours) after EUS-GBD and 4 patients (3.5 %, all of them beyond one week from the procedure) following EUS-CDS (p = 0.74); in all cases these events were treated with double pigtail placement into the LAMS.Stent migration was observed in 2 (1.7 %) and 1 (0.8 %) patients in the two groups, respectively (p = 0.98). Two of these cases were intraprocedural and were treated with removal and replacement of the LAMS, while one case occurred 90 hours after EUS-GBD and required surgery. Two cases of mild acute pancreatitis were observed after EUS-GBD (1.7 %), probably due to the previous ERCP attempt. Five infectious events were registered after EUS-GBD (4.4 %), of which 1 was severe and 3 within 48 hours; on the other hand, 4 cases (3.5 %), of which 2 were severe and 3 within 48 hours occurred after EUS-CDS (p = 0.29). All these infectious events were treated successfully with antibiotics. whereas 5 infectious events were registered after EUS-GBD (4.4 %) and 4 cases (3.5 %) after EUS-CDS (p = 0.29). No treatment-related deaths were observed. Median overall survival was 5 months (4-7) in the EUS-GBD group and 5.5 months (5-7) in the EUS-CDS group (p = 0.55).

Conclusions Our study showed that in patients with MDBO after failed ERCP, EUS-GBD or EUSCDS were comparable with similar rates of efficacy and safety. EUS-GBD could represent an easy and safe option in MDBO patients without previous cholecystectomy and with a clear patency of the cystic duct.

Aims Endoscopic ultrasound (EUS) is one of the major innovations that has played a transformative role in gastroenterologyand related disciplines. With its evolution, its use has expanded from simple diagnosis to management of various gastroenterologicalconditions, such as biliary strictures [1, 2].

Methods In light of these advancements, in the present review, we summarize the current evidence on the transformativerole of EUS in the diagnosis and management of biliary strictures. Two independent reviewers conducted a literature search using fiveelectronic databases, PubMed, CENTRAL, Science Direct, Google Scholar, and EMBASE for all available literature published up toJanuary 2025. Articles that met our inclusion criteria were included in the review, and statistical software was used to analyze thereported outcomes.

Results Our literature search yielded 935 articles, of which 19 met our inclusion criteria and were included in the review. Ten articlesfocused on EUS as a diagnostic method, and nine focused on EUS-guided therapeutic interventions. Our meta-analysis results showedthat EUS fine-needle aspiration (EUS-FNA) is superior to conventional techniques for diagnosing malignant biliary strictures. Thesensitivity of EUS-FNA ranged from (0.43; 95 % CI [0.24, 0.63]) to (1.00; 95 % CI [0.79, 1.00]) compared to that of conventionaldiagnostic methods, which ranged from (0.36; 95 % CI [0.19, 0.56]) to (0.96; 95 % CI [0.90, 0.99). Both EUS-FNA and conventionaldiagnostic methods exhibit a high specificity for diagnosing biliary strictures, with most having a specificity of 100 %. In managingbiliary strictures, we found that EUS-guided intervention exhibited a significantly higher clinical success rate than controlinterventions (OR: 2.89; 95 % CI [1.22, 6.84] p = 0.02). However, no significant difference was observed when the technical successrates were pooled (odds ratio [OR], 0.97; 95 % CI [0.30, 3.16] p = 0.96).

Conclusions EUS has been shown to be a promising tool for the diagnosis and management of biliary strictures. Furthermore, asempirical evidence indicates, through a combination of EUS-guided and conventional interventions, diagnostic performance improvessignificantly. Therefore, we recommend that the feasibility and use of EUS-guided interventions in the diagnosis and management ofbiliary strictures should be investigated in greater depth.

PYP290 Development of an Automated ESD Training Simulator: Validation and Effects on the Clinical Learning Curve

Authors Kim S[1], Lee BM[2], Choi HS[2], Jeen YT[2]
Institutes **1** Korea University, Seoul, Republic of Korea; **2** Korea University Anam Hospital, Seoul, Republic of Korea
DOI 10.1055/s-0046-1821230

Aims ESD training in Western settings remains difficult due to low case volume and the absence of a standardized curriculum. Existing approaches rely mainly on an apprentice model, despite recommendations from ASGE/ESGE. Task analyses show that marking, incision, and submucosal dissection are core skills, underscoring the need for training environments that closely replicate real ESD conditions. Animal models offer high fidelity but are limited by cost and logistics. We developed a CT-based, anatomically realistic ESD simulator to address these gaps.

Methods Gastric CT gastrography data were used to create 3D anatomical reconstructions and region-specific coordinates, which were then converted into modular synthetic stomach models representing the antrum, lower and mid body along the lesser and greater curvature, the angulus, and the cardia. An automated positioning system was developed to move each module into the appropriate anatomical location. Six expert endoscopists performed ESD five times in each region (sets A/B/C) and provided structured evaluations of anatomical fidelity and concordance with ASGE/ESGE skill requirements.Novice endoscopists (n = 10) conducted repeated training sessions in beginner-level regions (antrum-LC, mid-body LC), and learning curves were assessed by comparing dissection speeds from the initial five attempts to the final five attempts.

Results Experts reported high anatomical fidelity across locations and confirmed that the simulator enabled practice of essential ESD skills. Novices demonstrated clear improvement, with significantly faster dissection speeds in later sessions.

Conclusions This CT-derived, region-specific ESD simulator provides realistic anatomical conditions, supports expert-validated skill training, and enables measurable early improvement among novices. It represents a practical alternative to animal models and may help standardize early ESD training.

PYP291 SPEED-EMR Score: a simple predictive model for estimating colorectal endoscopic mucosal resection duration

Authors Souto M[1, 2, 3], Vieira R[3, 2, 1], Abreu Marques I[3, 2, 1], Macedo Silva V[1, 2, 3], Dias De Castro F[1, 2, 3], Magalhães J[1, 2, 3], Cotter J[2, 3, 1]
Institutes **1** Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal; **2** ICVS/3B's – PT Government Associate Laboratory, Braga/Guimarães, Portugal; **3** Gastroenterology Department, Unidade Local de Saúde do Alto Ave, Guimarães, Portugal
DOI 10.1055/s-0046-1821231

Aims Endoscopic mucosal resection (EMR) is an effective, minimally invasive technique for removing complex colorectal polyps, particularly those with sessile or flat morphology. However, procedure duration can vary widely depending on lesion complexity, impacting unit efficiency and patient scheduling. This study aimed to develop a simple, objective, and clinically applicable predictive model — the SPEED-EMR Score (Simple PrEdictive Estimator of Duration for Endoscopic Mucosal Resection) — to estimate EMR duration based on lesion characteristics.

Methods We retrospectively analyzed 1,077 colorectal EMRs performed between 2020 and 2025 at a tertiary endoscopy center.

EMR duration (minutes), measured from the first image of the lesion to the image of the post-resection mucosal defect, was the primary outcome.

Collected variables included clinicodemographic patient characteristics, lesion characterization data, and technical features of the endoscopic procedure.

Variables significantly associated with the outcome in univariate analysis were entered into a multiple linear regression model. Coefficients were converted into points (1 point ≈ 4 minutes of added duration) to create the SPEED-EMR Score.

Results Median patient age was 65 years (IQR 58–72); 57.9 % were male. The median Charlson Comorbidity Index was 2 (IQR 1–4), and the median EMR duration was 13 minutes (IQR 7–24).

Longer procedures were independently associated with larger lesion size ($p < 0.001$), flat or depressed morphology (Paris classification 0-IIb/0-IIc) ($p < 0.001$), NICE type 2 pattern ($p < 0.001$), difficult locations (ileocecal valve, peri-diverticular, peri-appendiceal, hepatic/splenic flexures, rectosigmoid junction, anal margin) ($p < 0.001$), and recurrence on a scarred area ($p = 0.003$).

These variables were used to create the SPEED-EMR Score (range 0–16 points): lesion sizes of 21–30 mm (+3 points), 31–40 mm (+6 points), >40 mm (+10 points); flat or depressed morphology (+2 points); NICE type 2 (+1 point); difficult location (+1 point); recurrence on a scarred area (+2 points).

The final SPEED-EMR Score calibration model showed good linearity and predictive accuracy ($R = 0.680$, $R^2 = 0.463$, $p < 0.001$; standard error of the estimate = 12.2 min).Predicted time was calculated as: Predicted time (min) = 3.1 + 4.0 × Score value.

Rounded estimates were stratified into four complexity classes: Class I (0–4 pts): ≤ 20 min; Class II (5–8 pts): 25–35 min; Class III (9–12 pts): 40–50 min; Class IV (≥ 13 pts): ≥ 55 min.

Conclusions The SPEED-EMR Score provides a practical tool for predicting EMR duration using readily available lesion characteristics. Its clinical application may improve scheduling efficiency, case allocation, and patient counseling in therapeutic colonoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP292V Application of a novel endoscopic device in the treatment of gastric bezoars: a pilot study

Authors Tang X[1], Xu J[1], Deng M[1], Lü M[1]
Institute **1** The Affiliated Hospital of Southwest Medical University, Luzhou, China
DOI 10.1055/s-0046-1821232

Problem to solve Gastric bezoars, especially giant phytobezoars, are challenging to manage endoscopically due to their large size and dense composition. Conventional endoscopic tools often fail to fragment them effectively, leading to prolonged procedures, incomplete removal, or the need for invasive surgical intervention, which carries higher risks and longer recovery.

Innovation We developed a novel, low-cost endoscopic device comprising two outer sheaths attached to the endoscope and a yellow zebra guidewire forming an adjustable snare. This simple, mechanically-driven design allows real-time snare size adjustment for precise and efficient bezoar fragmentation, without requiring specialized or expensive equipment. The device is easy to assemble and deploy, making it particularly suitable for resource-limited settings.

Results The device was used in 9 patients with giant gastric bezoars (mean size ~4.3 × 7.8 cm). All bezoars were successfully fragmented and removed in a single session, with a mean procedure time of 66 minutes. No complications occurred, and follow-up gastroscopy confirmed complete clearance. All patients showed symptom resolution and were discharged after an average hospital stay of 2.5 days (▶ **Table 1**).

▶ **Table 1** Clinical characteristics and surgical information of included patients with gastric bezoars.

No.	Sex	Age (year)	Symptoms	Bezoar diameter (cm)	Operation time (min)	Adverse events	Postoperative length of hospital stay (day)
1	Female	71	Abdominal pain	5 × 15	113	No	2
2	Female	33	Abdominal pain	4 × 10	85	No	2
3	Male	78	Abdominal pain	5 × 9	81	No	6
4	Male	50	Abdominal pain	4 × 5	53	No	1
5	Female	51	Abdominal pain	4 × 5	38	No	1
6	Male	15	Abdominal pain	4 × 4	33	No	3
7	Male	71	Abdominal pain	4 × 8	52	No	2
8	Male	53	Abdominal pain	3 × 4	34	No	3
9	Female	77	Abdominal pain	6 × 10	105	No	3

Conclusions This novel endoscopic device offers a safe, effective, and economical solution for the fragmentation and removal of giant gastric bezoars, avoiding the need for surgery. Its simplicity, high success rate, and minimal complication profile support its potential for widespread clinical adoption, particularly in regions with limited access to advanced endoscopic tools.

PYP293 A novel "third arm" to provide counter-traction during endoscopic submucosal dissection

Authors Maan ADI[1], Gerritsen D[1], Rijckborst V[1], Siersema PD[1], Koch A[1]

Institute 1 Erasmus MC Cancer Institute, University Medical center, Rotterdam, Netherlands

DOI 10.1055/s-0046-1821233

Problem to solve Countertraction during endoscopic submucosal dissection (ESD) is indispensable, as it improves submucosal exposure, reduces procedure time and risk of bleeding or perforation, and improves en bloc resection rates. Common methods include patient repositioning, underwater ESD, and the off-label clip-and-line or rubber band technique. However, these techniques provide a limited traction direction and clips may slip off. A so called official ''third-arm'' has been lacking in flexible gastrointestinal (GI) endoscopy.

Innovation Tracmotion (FujiFilm, Tokyo, Japan) is a single-use, through-the-scope (TTS) traction device consisting of two interconnected parts: a scope-mounted hand controller and a distal end with 360° rotatable grasping forceps. A dual-channel endoscope is needed with a 3.7 mm or larger instrument inner channel diameter when using this traction device.

Results Five trial ESDs using this novel traction device were performed to allow the endoscopist to become familiar with its use. To investigate the additional value of the traction device, mean procedure time and dissection speed with the device were compared to the averages without the device from 2022 to 2024 at the Erasmus Medical Center (EMC) in Rotterdam, the Netherlands. After the trial ESDs, a total of 13 ESDs with the device were performed (5 upper GI, 8 lower GI). Among the upper GI cases, 4 patients were male, with a median age of 58 years (IQR 12); the mean lesion size was 13.0 mm (95 % CI: 7.2–18.8). For the lower GI cases, 7 patients were male, with a median age of 60 years (IQR 13); the mean lesion size was 24.4 mm (95 % CI: 19.2–29.6). Lesion locations at the upper GI included the body (n = 1) and antrum of the stomach (n = 3), and one in a gastric tube reconstruction after esophagectomy. Lower GI lesions were located in the rectum (n = 6) and sigmoid colon (n = 2). The stiffness of the dual-channel endoscope with limited angulation and space to maneuver precluded the use of the traction device for lesions near the rectal verge and in the esophagus.

Procedure time was shorter with the device for both upper and lower GI cases (-16.7 % and –19.1 %, respectively), as shown in ▶ **Table 1**. Dissection speed was also faster with versus without the device (1.5 mm^2/minute faster for upper GI cases and 2.9 mm^2/minute faster for lower GI cases). All resections were performed en bloc, with all but two lower GI ESDs achieving R0 resection. Post-ESD bleeding occurred after one upper GI ESD; the patient underwent an additional endoscopy with successful clip placement. In addition, one patient was hospitalized for post-polypectomy fever that resolved without intervention.

▶ **Table 1** Procedural characteristics

Characteristic	With traction device (n = 13)	Without traction device (average EMC 2022-2024)
Procedure time (minutes), mean (95 % CI)		
Upper GI	73.4 (48.7-98.7)	88.1 (79.5-96.7)
Lower GI	102.6 (76.0-129.2)	126.7 (101.1-152.3)
Dissection speed (mm2/minute), mean (95 % CI)		
Upper GI	15.8 (7.6-24.1)	14.3 (11.3-17.3)
Lower GI	16.6 (9.9-23.6)	13.7 (8.7-18.7)

CI: confidence interval; GI: gastrointestinal; EMC: Erasmus University Medical Center

Conclusions Both procedure time and dissection speed improved with the implementation of the novel traction device compared to the averages at the EMC without the device. In addition, there were no higher rates of complications compared to previous literature. These preliminary findings might suggest that the traction device could be of additional value during ESD. Further research, including more patients and additional questionnaires on the endoscopist's personal experience with the device, is needed to better explore this topic.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP294 Dissection using PreciseSect is faster, with less need for hemostatic grasper compared to Swift Coag during ESD

Authors Cherkaoui-El Fassi I[1], Figueiredo Ferreira M[2], Bucalau AM[3], Lemmers A[3]

Institutes 1 Hospital Erasme, Bruxelles, Belgium; 2 CHU Saint-Pierre, Brussels, Belgium; 3 Hospital Erasme HUB, Brussels, Belgium

DOI 10.1055/s-0046-1821234

Aims This study aimed to compare the SwiftCoag and PreciseSECT modes used during the submucosal dissection step of ESD. Primary outcomes included dissection speed, procedure duration, and use of hemostatic forceps. Secondary outcomes focused on safety through analysis of intra- and post-procedural complications, and pathological specimen quality based on clean margin status

Methods We conducted a retrospective, single-center study at a tertiary University Referal Center. Patients were identified from a prospectively collected registry of ESD procedures performed between 2017 and 2024 using either the SwiftCoag or PreciseSECT electrosurgical modes for the submucosal dissection step of ESD. To ensure maximal standardization, only procedures performed with a Dual Knife-J and glycerol submucosal injection were included. Clinical, procedural, and histopathological data were extracted from electronic records and operative reports. Quantitative variables were analyzed using the Mann-Whitney U test, and qualitative variables with Fisher's exact test. Statistical analyses were performed using Jamovi.

Results Based on the selection criteria, a total of 219 patients were included in the analysis. The study population was composed of 63 % men and 37 % women, with a median age of 68 (IQR 60.5-74) years. As for the electrosurgical mode used, 146 patients underwent ESD with SwiftCoag and 73 with PreciseSECT. Regarding the anatomical distribution of ESD procedures, 78 were performed in the esophagus (35.6 %), 46 in the stomach (21.0 %), 20 in the colon

(9.1 %), and 75 in the rectum (34.2 %). No duodenal procedures were included in the study. There was no significant difference in the anatomical distribution of ESD procedures between the SwiftCoag and PreciseSECT groups.

Median procedure duration per ESD was significantly shorter with PreciseSECT (70 min [IQR: 50–90]) compared to SwiftCoag (90 min [IQR: 60–136]; p = 0.009). Dissection speed was significantly higher with PreciseSECT (21.2 mm²/min [IQR: 16.17–28.9]) than with SwiftCoag (13.5 mm²/min [IQR: 8.03–20.8]; p < 0.001). Use of hemostatic forceps was more frequent with SwiftCoag (69.9 %) than with PreciseSECT (54.8 %; p = 0.035), suggesting improved intraprocedural hemostasis with PreciseSECT.

No difference in muscular layer injuries or full-thickness perforations was observed between the SwiftCoag and PreciseSECT groups (p = 0.098), the rate of uneventful procedures tended to be higher with PreciseSECT (80,8 %) than with SwiftCoag (69,9 %), though not statistically significant.

Symptomatic esophageal strictures requiring balloon dilation occurring within 90 days after ESD, were observed in 11.5 % of patients treated with PreciseSECT and 5.8 % with SwiftCoag (p = 0.394), suggesting no significant difference in clinical stricture rates. This trend may be partly explained by a higher proportion of extensive resections exceeding 90 % of the esophageal circumference in the PreciseSECT group (34.6 % vs 9.6 %).

Thirty days delayed post-procedural bleeding, was observed in colorectal procedures only. It affected 8.4 % of patients overall, with a rate of 15.2 % in the PreciseSECT group and 4.8 % in the SwiftCoag group (p = 0.121).

Quality of the specimen was comparable between groups, as reflected by similar en bloc resection rate (93.2 % with PreciseSECT; 95.2 % with SwiftCoag, p = 0.540), clear vertical margin (VM0) rate (97.3 % with PreciseSect vs 93.8 % with SwiftCoag), p = 0.079), clear horizontal margin (HM0) rate (91.8 % with PreciSect vs 88.4 % with SwiftCoag, p = 0.626).

Oncologically, low-risk resections, based on ESGE recommendations, were similar in both groups (PreciseSECT (82.2 %) ; SwiftCoag (78.1 %); p = 0.222).

Conclusions PreciseSECT was associated with faster dissection and less use of hemostatic forceps, with similar en-bloc and margin-free rates compared to SwiftCoag. Our data support PreciseSECT as a facilitating and economical technical improvement of ESD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP295 Clinical Outcomes of Endoscopic Vacuum Therapy for Gastrointestinal Leakage, Perforation, and Fistula: A Single-Center Experience

Authors Baek DH[1], Dong Chan J[1], Kim GH[1], Moon Won L[1], Seung Min H[1], Bong Eun L[1], Young Uk L[1]

Institute 1 Department of Internal Medicine, Pusan National University School of Medicine, Busan, Republic of Korea

DOI 10.1055/s-0046-1821235

Aims Endoscopic vacuum therapy (EVT) has emerged as an effective, minimally invasive treatment for gastrointestinal (GI) leaks, perforations, and fistulas. However, clinical outcomes across various GI locations remain underreported in Asian populations. This study aimed to evaluate the therapeutic efficacy and safety of EVT for upper and lower GI defects in a single tertiary center.

Methods Patients who underwent EVT for GI leakage, perforation, or fistula at Pusan National University Hospital between February 2020 and October 2025 were retrospectively analyzed. Thirty-three patients (36 procedures) were included; one patient had two defects, and another had three. Treatment success was defined as complete closure without endoscopic or surgical re-intervention (▶ **Table 1**).

▶ **Table 1**

Characteristic	Value
Median age (years, range)	68 (18–81)
Sex, n (%)	
Male	27 (81.8)
Female	6 (18.2)
Number of surgeries before EVT	29 (87.9)
Method of surgery	
Ivor-Lewis	8 (24.2)
Total gastrectomy	3 (8.9)
Subtotal gastrectomy	8 (23.5)
Colectomy	2 (5.9)
Others	8 (23.5)
Indication of surgery before EVT	
Esophageal cancer	9 (27.3)
Gastric cancer	11 (33.3)
Colon cancer	3 (8.9)
Benign disease	6 (18.2)
Etiology of EVT	
Anastomosis site leak	30 (83.3)
Perforation	3 (8.3)
Fistula	3 (8.3)
Location of perforation, leak, fistula	
Upper GI tract	32 (88.9)
Lower GI tract	4 (11.1)
Nature of EVT application	
Primary	35 (97.2)
Rescue	1 (2.8)
Median interval from leakage diagnosis to EVT, days (range)	2.5 (0–9163)
Type of EVAC	
Intraluminal	22 (61.1)
Intracavity	14 (38.9)

Results Among 36 procedures, 30 (83.3 %) were leaks, 3 (8.3 %) perforations, and 3 (8.3 %) fistulas. The upper GI tract accounted for 88.9 % of cases. EVT was primarily applied as first-line therapy in 97.2 %. The median interval from diagnosis to EVT initiation was 2 days (range, 0–9,163). Treatment success was achieved in 25 cases (69.4 %), with a mean of 4.94 sessions per lesion. Of these, 22 (61.1 %) were treated with the intraluminal approach and 14 (38.9 %) with the intracavity approach. Complications occurred in three patients (9.1 %), including two cases of GI bleeding and one of stricture.

Conclusions EVT demonstrated favorable outcomes and acceptable safety for managing GI leaks, perforations, and fistulas across both upper and lower GI tracts. These findings support EVT as an effective minimally invasive treatment in selected patients, potentially reducing the need for surgical intervention.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP296 Comparative Efficacy of Endoscopic and Surgical Interventions for Gastroparesis: A Network Meta-Analysis

Aims Gastroparesis is a chronic disorder affecting gastrointestinal motility with a limited response to medication. Recently, endoscopic and surgical procedures have become effective treatment alternatives; however, comparative evidence between different treatment approaches is limited. This study aimed to systematically evaluate and compare the effectiveness of gastric emptying using endoscopic and surgical interventions for the treatment of gastroparesis through a network meta-analysis. The primary objective was to determine which treatment procedure achieves the greatest improvement in symptoms and gastric motility, thereby guiding the selection of the optimal treatment for patients with treatment-resistant gastroparesis.

Methods We searched the PubMed, Embase, and CENTRAL databases for studies published between January 2000 and the present. Eligible studies included randomized controlled trials and observational analyses involving adult patients diagnosed with gastroparesis who underwent procedural interventions. Treatments included gastric peroral endoscopic myotomy (GPOEM), gastric neuronal stimulation, pyloroplasty (GNS), botulinum toxin injection (BTI), and combination therapies such as G-POEM + GES or pyloroplasty + GES. The primary outcomes were clinical success, defined as an improvement in patient symptoms based on established assessment systems, and improvement in gastric emptying studies (GES). A Bayesian network meta-analysis was performed using a combined effects model to integrate direct and indirect comparisons, based on the surface under the cumulative order curve (SUCRA), to determine the relative ranking of each treatment's efficacy.

Results 49 studies comprising 2722 patients were included in the study. For clinical success, 12 studies (k = 12) across 6 treatments (n = 6) and 6 unique study designs (d = 6) contributed 12 pairwise comparisons (m = 12). Compared to placebo, GPOEM showed the highest odds of clinical success (OR 5.72, 95 % CI 2.02–16.18, $p = 0.0010$; SUCRA = 0.85), followed closely by GPOEM + GES (OR 5.42, 95 % CI 1.47–19.99, $p = 0.0111$; SUCRA = 0.79) and pyloroplasty (OR 4.64, 95 % CI 1.46–14.75, $p = 0.0093$; SUCRA = 0.71). BTI and GNS did not demonstrate a statistically significant benefit. For GES improvement, 8 studies (k = 8) evaluated 7 treatments (n = 7) with 6 designs (d = 6), contributing 8 pairwise comparisons (m = 8). In comparisons against sham procedures for gastric emptying improvement, pyloroplasty + GES ranked the highest (OR 100.0, 95 % CI, 5.79–1728.15; $p = 0.0015$; SUCRA = 0.97), followed by GPOEM (OR 13.33, 95 % CI 2.82–63.11, $p = 0.0011$; SUCRA = 0.69), and GPOEM + GES (OR 11.93, 95 % CI 1.47–96.76, $p = 0.0203$; SUCRA = 0.63). BTI and GES remained the lowest-performing interventions across both primary outcomes.

Conclusions Among procedural options for refractory gastroparesis, G-POEM—either alone or in combination with GES—demonstrates the strongest overall efficacy for symptomatic relief and gastric emptying improvement. Pyloroplasty-based therapies also exhibit effective outcomes, especially when paired with GES. This demonstrates its effectiveness in enhancing infectious movement. In contrast, BTI and standalone GES provide limited clinical value. These findings support the prioritization of G-POEM and pyloroplasty as first-line procedural strategies for patients unresponsive to medical management. Future research should aim to standardize outcome measures and explore patient-specific predictors of procedural response, thereby increasing the chances of improving individualized treatment.

DOI 10.1055/s-0046-1821237

Aims This study compared the outcomes of endoscopic retrograde appendiceal irrigation (ERAI) and endoscopic retrograde appendicitis therapy (ERAT) in patients with acute uncomplicated appendicitis.

Methods We conducted a multicenter retrospective study of patients who received ERAI or ERAT for acute uncomplicated appendicitis between May 2020 and May 2023. After applying 1 to 1 propensity score matching, we evaluated technical and clinical success as the main outcomes. We also compared procedure time, hospital stay, treatment costs, postoperative recovery, adverse events, and long-term recurrence (▶ **Table 1**).

▶ **Table 1**

Outcomes and adverse events	ERAI (n = 168)	ERAT (n = 174)	*p*
Procedure time, mean (SD), min	15.0 (2.5)	27.2 (9.1)	< 0.001
Fecalith expulsion during procedure, n (%)	80 (47.6)	106 (60.9)	0.179
Appendiceal stent placement, n (%)	17 (10.1)	67 (38.5)	< 0.001
VAS for pain ≤ 3 at 6 h after treatment, n (%)	153 (91.1)	160 (92.0)	0.950
Normal laboratory test results[1], n (%)	150 (89.3)	115 (79.3)	0.067
Postoperative length of hospital stay, mean (SD), days	1.5 (0.8)	2.0 (1.8)	0.004
Hospital cost, mean (SD), RMB	6,468.7 (3087.5)	11,510.4 (5906.8)	< 0.001
Clinical success rate[2], n (%)	157 (93.5)	168 (96.6)	0.833
Overall adverse event rate, n (%)	35 (20.8)	22 (12.6)	0.086
Follow-up duration, median (IQR), months	48 (38–57)	49 (38–53)	0.702
Recurrence of appendicitis, n (%)	26 (15.5)	15 (8.6)	0.084
Time to recurrence, median (IQR), months	13 (3–35)	16 (7–29)	0.694
Overall short-term adverse event rate[3], n (%)	10 (6.0)	7 (4.0)	0.435
Fever[4]	6 (3.6)	4 (2.2)	0.498
Appendiceal perforation	4 (2.0)	3 (1.7)	0.674
Overall long-term adverse event rate[5], n (%)	25 (14.9)	15 (8.6)	0.109
Abdominal pain	5 (3.0)	2 (1.1)	0.243
Diarrhea[6]	1 (0.6)	2 (1.1)	0.586
Constipation	0 (0.0)	1 (0.6)	0.327

Results A total of 725 patients were included, and 179 matched pairs were analyzed. Baseline characteristics were comparable between groups. Technical and clinical success rates were similar for ERAI and ERAT (93.9 % vs 97.2 %; 93.5 % vs 96.6 %; p = 0.907 and 0.833, respectively). ERAI resulted in shorter procedure time and postoperative hospitalization, and lower total cost. Postoperative pain relief, normalization of inflammatory markers, and short- and long-term adverse event rates did not differ between groups. Cumulative recurrence rates at 1, 3, and 5 years were higher in the ERAI group (8.3 %, 12.0 %, 17.6 %) than in the ERAT group (4.0 %, 6.9 %, 11.8 %).

Conclusions ERAI achieved similar technical and clinical results as ERAT while offering shorter procedures, faster recovery, and lower costs. Although recurrence was somewhat higher after ERAI, most patients were successfully treated with repeat endoscopic therapy or conservative care. ERAI may be a practical and affordable option for patients with uncomplicated appendicitis, especially in settings where ERAT is less accessible

DOI 10.1055/s-0046-1821238

Aims Filling the lumen with saline during third-space endoscopy improves visualization and hemostasis, but profoundly alters electrosurgical behavior by collapsing tissue impedance. How these changes translate into collateral tissue damage according to electrode diameter remains insufficiently quantified.

Methods In an ex-vivo porcine gastric model, three commonly used knives with different tip diameters (1.5 mm HybridKnife T-type, 0.5 mm HybridKnife flex I-type, 0.4 mm DualKnife J) were tested in air and under 0.9 % saline using seven endoscopic waveforms (two cutting, three coagulation, two dissection modes). A total of 252 standardized 10-mm cuts were performed. Impedance, peak voltage, effective power, cutting success, and lateral thermal spread were recorded. Linear regression was used to identify independent predictors of lateral spread.

Results Transition from air to saline reduced impedance by 55 % with thin knives versus 92 % with the thick knife, while effective power increased by 4.9-fold and 19-fold, respectively. Peak voltage rose slightly with thin knives (+ 1.7 %), but fell by about one-third (–30.2 %) with the thick knife. In air, lateral spread remained < 1.0 mm across all knife–mode combinations (0.31–0.91 mm). Under saline, spread increased by 70.8 % with thin electrodes and by 255.5 % with the thick electrode. Mean spread with the thick knife expanded from 0.56 to 1.35 mm, frequently exceeding 1.0 mm, whereas both thin knives remained ≤ 0.8 mm across cutting and dissection modes. In multivariable analysis (adjusted $R^2 = 0.546$), electrode diameter was the strongest predictor of lateral spread (standardized $\beta = 0.469$), increasing it by approximately 0.36 mm per additional millimeter. This was followed by saline immersion ($\beta = 0.353$), effective power, and impedance, while higher peak voltage independently reduced spread ($\beta = -0.387$).

Conclusions In saline-immersion third-space electrosurgery, electrode diameter is the primary determinant of lateral thermal spread. and strongly modulates the impact of the conductive medium on voltage and power delivery. Thin electrodes, particularly when combined with appropriately selected modes, maintain lateral spread below 1.0 mm while preserving cutting performance, whereas thick electrodes in saline are prone to excessive collateral heating.

Abstract Text

An 87-year-old man underwent colonoscopy for anemia. A large 50mm JNET 2B granular mixed nodular type laterally spreading tumor was found at recto-sigmoid junction, covering > 50 % of the lumen. Histology on biopsies revealed a moderate differentiation adenocarcinoma with indication of tumor invasion of the muscularis propria. Patient was unfit for surgery due to many comorbidities (severe cardiovascular disease). Endoscopic electroporation was decided. Overall, this video shows a novel treatment option for colon malignancy when surgery is not feasible, with promising symptomatic and local effects. Despite encouraging results, further clinical evidence is needed to confirm the safety, feasibility and long – term outcomes of endoscopic electroporation as an oncologic treatment [1–4].

Aims The European Society of Gastrointestinal Endoscopy (ESGE) recommends recording Upper Gastrointestinal Endoscopy (UGE) examination time with a minimum of seven minutes, since longer procedures allow the detection of more lesions; however, the definition of the time metric varies across studies. This study aims to compare total inspection time versus withdrawal time during diagnostic, surveillance or screening UGE for lesion identification. To our knowledge, it will be the first randomised clinical trial in this area, providing enhanced scientific evidence to optimize UGE quality indicators.

Methods We are performing a randomised controlled trial in 10 international gastroenterology centres, started in 2025, including patients referred for screening, diagnostic and/or surveillance UGE. Patients were randomly assigned, by a computer generated software, and adequate allocation concealment, in a double-blinded, parallel 1:1 ratio, to one of two measurement groups: total inspection time (from intubation to extubation) or withdrawal time (from second portion of duodenum to extubation). The primary outcome was the detection rate of premalignant and malignant lesions (extensive intestinal metaplasia, dysplasia, carcinoma, neuroendocrine tumour, lymphoma or subepithelial lesion), defined as the total number of esophageal, gastric or duodenal lesions identified per randomisation group and confirmed histologically when required, while the secondary outcome was the rate of procedure-related complications. The trial was registered at ClinicalTrials.gov (NCT06696209).

Results For the planned 1290 patients to include, 851 UGE procedures were included so far (53 % female; mean age 59.3 ± 15.4 years). A total of 414 and 437 patients were evaluated in the total inspection time and withdrawal time groups, respectively. The mean total inspection time was 06:34 ± 04:04 minutes, and the mean withdrawal time was 04:52 ± 03:27 minutes.

The primary outcome revealed a significantly higher lesion detection rate in the total inspection time group compared with the withdrawal time group (26.6 % vs. 20.1 %; p = 0.026). Main detected lesions were extensive gastric intestinal metaplasia (17.9 % vs. 12.6 %; p = 0.03), gastric dysplasia (3.1 % vs. 3.0 %; p = 0.89) and esophageal dysplasia (1.9 % vs. 2.5 %; p = 0.56). There was only one complication in all procedures (bleeding event).

In the univariate analysis of factors that may influence the lesion detection rate, the following were statistically significant: total inspection time ≥ 7 minutes (37.3 % vs. 14.1 %; p < 0.001), surveillance (vs. screening vs. diagnosis) as the indication for UGE (45.4 % vs. 23.8 % vs. 12.2 %; p < 0.001), endoscopist experience ≥ 5 years (28.7 % vs. 10.8 %; p < 0.001), the use of an antifoaming agent (38.4 % vs. 12.3 %; p < 0.001) and the application of virtual chromoendoscopy (35.5 % vs. 2.8 %; p < 0.001). However, the use of any sedation type (with vs. without sedation; 23.2 % vs. 23.8 %, p = 0.932), patient tolerance (good vs. intolerance; 23.3 % vs. 22.7 %, p = 0.952) and an excellent GRACE visibility score (≥ 9 vs. < 9; 26.0 % vs. 20.5 %, p = 0.059) or adequate GRACE visibility score (≥ 2

per segment vs. < 2 in any segment; 23.8 % vs. 9.4 %, p = 0.058) showed no significant association with lesion detection [1–6].

Logistic regression revealed that surveillance as the indication for UGE (OR 3.3, 95 % CI 2.2–4.9; p < 0.001), endoscopist experience ≥ 5 years (OR 2.3, 95 % CI 1.4–3.8; p < 0.001) and the use of virtual chromoendoscopy (OR 8.8, 95 % CI 4.1–18.7; p < 0.001) were independently associated with higher lesion detection.

Conclusions Our preliminary results indicate that a total inspection time ≥ 7 minutes provides a higher diagnostic yield than a withdrawal time ≥ 5 minutes in UGE, eventually related to the bidirectional evaluation performed during an UGE (both on insertion and during withdrawal), supporting its preferential use in clinical practice. By validating a total inspection time ≥ 7 minutes as the optimal time metric, our study already highlights easy clinical factors that can improve lesion detection, mainly in the stomach, such as the application of virtual chromoendoscopy, and eventually the use of an antifoaming agent to achieve at least an adequate GRACE score visibility ≥ 2 per segment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP301 Real-World Implementation and Diagnostic Yield of Capsule Sponge Testing for Barrett's Surveillance and Reflux Case Finding in a UK Hospital

Authors Vora R[1], Khan A[2]

Institutes 1 The University of Buckingham, Buckingham, United Kingdom; 2 Milton Keynes University Hospital, Milton Keynes, United Kingdom

DOI 10.1055/s-0046-1821241

Aims Oesophageal adenocarcinoma incidence is rising in the UK [1, 2], yet no national screening programme exists. Current Barrett's surveillance and reflux investigations rely on endoscopy, an invasive, carbon-heavy and resource-intensive procedure [3]. Capsule sponge testing offers a minimally invasive, nurse-led, and environmentally sustainable alternative that detects biomarkers such as TFF3 and p53 with high accuracy and better patient tolerance [4]. Despite ESGE guidance supporting these approaches, uptake remains limited. This review evaluated the implementation, diagnostic yield, and safety of capsule sponge testing at Milton Keynes University Hospital (MKUH). This review also considered the sustainability impact of capsule sponge testing in line with ESGE and BSG Green Endoscopy guidance promoting low-carbon diagnostic pathways [3, 5].

Methods A retrospective service review was conducted at MKUH between January 2024 and July 2025. Patients meeting inclusion criteria underwent capsule sponge testing and were stratified into Barrett's surveillance (n = 45) and reflux case-finding (n = 232) cohorts. Data collected included demographics, biomarker positivity (TFF3 for intestinal metaplasia [IM], squamous/columnar atypia, p53), and subsequent gastroscopy conversion. All procedures were nurse-led and delivered in a community diagnostic centre. Primary measures were the detection of dysplasia in the Barrett's cohort and the detection of IM and/or dysplasia in the reflux cohort. Patients with abnormal biomarker or cytology results were referred for confirmatory gastroscopy.

Results In the Barrett's surveillance cohort (n = 45), mean age was 64.6 years (71.1 % male). Dysplasia was detected in 3 patients (6.7 %). 6 (13.3 %) had no IM on capsule testing despite prior diagnoses, prompting re-evaluation of previous endoscopies and removal from surveillance. 13 (28.9 %) were referred for gastroscopy: 2 (4.4 %) due to capsule intolerance and 11 (24.4 %) for abnormal biomarkers, confirming dysplasia in 3 cases. Overall, 71.1 % of Barrett's patients avoided gastroscopy after capsule testing.

In the reflux cohort (n = 232), mean age was 68.9 years (37.2 % males). IM was identified in 54 patients (23.3 %), leading to 14 new Barrett's diagnoses and 1 dysplasia. 2 had IM with gastric atrophy without Barrett's. Overall, 86 patients (37.1 %) were recommended for gastroscopy. 83/232 (35.8 %) underwent the procedure: 62 (26.7 %) for abnormal biomarkers and 21 (9.1 %) for capsule intolerance or non-diagnostic procedures. Three patients (1.3 %) declined despite clinical recommendation. Consequently, 62.9 % of patients avoided immediate gastroscopy following capsule testing. Adverse events were minimal and self-limiting: hypotension (n = 1), transient hypertension (n = 2), and tachycardia (n = 1). No serious complications occurred.

Conclusions Capsule sponge testing proved feasible, safe and effective in both cohorts. In the Barrett's cohort, dysplasia was detected in 3 patients. 6 prior Barrett's diagnoses were reclassified as non-Barrett's, avoiding any further unnecessary gastroscopies. In the reflux cohort, IM was identified in 54 patients, resulting in 14 new diagnoses of Barrett's and 1 dysplasia, demonstrating its value for early detection. The procedure showed excellent patient tolerability with only minor transient adverse effects. These findings support ESGE guidance, advocating minimally invasive, nurse-led diagnostic approaches, establishing capsule sponge testing as a safe, scalable, and sustainable tool for risk stratification and early detection of oesophageal disease [4]. By reducing procedure demand, resource use and carbon output, capsule sponge testing represents a practical application of ESGE and BSG Green Endoscopy principles within routine diagnostic pathways [3, 5].

Aims Determine the burden of post-endoscopy upper gastrointestinal cancer (PEUGIC) across all Welsh Health Boards

1. Identify modifiable endoscopic and system-related factors contributing to diagnostic delay.

Methods A retrospective multicenter review was conducted across six Health Boards in Wales (Complete data available for 5 at the time of writing), including all patients diagnosed with upper GI cancer between August 2021 and July 2024. PEUGIC cases were identified using cancer-tracking systems, MDT records and endoscopy databases. Patient demographics (age, sex); tumour characteristics (site, stage) and endoscopy quality indicators (quality of inspection, mucosal visibility and image quality and record [1]) were recorded using a standardised proforma. For each identified PEUGIC case, root-cause analysis (RCA) was undertaken across four domains: endoscopist, lesion, system and patient factors. These characterised avoidable factors, considering known associations with PEUGIC described previously, e.g. young age, co-morbidity, known Barrett's oesophagus (BO) or oesophagal stricture (OS), gastric ulceration or Unit accreditation status [2]. A panel categorised PEUGIC cases into five types. Overall and individual Health Board PEUGIC rates were calculated. Rates of identified contributory factors and PEUGIC type were compared across Health Boards.

Results Across Wales, 1350 upper GI cancers were diagnosed, of which 82 fulfilled PEUGIC criteria (6.1 %). Rates varied between Health Boards from 3.5 % to 6.3 %. The 82 patients had a mean age of 73 ± 13.8 years, with a gender distribution of 62.2 % male and 37.8 % female. Tumour sites were distributed as follows: oesophagus **51.2** %, GOJ **22.0** %,stomach **23.2** %, and duodenum **3.7** %. Staging showed predominantly advanced disease (T3/T4 = 62 %), frequent nodal involvement (N + = 40 %), and metastasis in 15 %. Most patients received palliative treatment (62 %), with 38 % managed with curative intent. Only 14 % underwent endoscopic resection

Low-quality endoscopic examinations were associated with higher institutional PEUGIC rates, 7 % evidence of mucosal cleaning, and 13 % of documented blue light imaging. In over 60 % of PEUGIC cases, no recorded images were available, and even in cases where images were recorded, BSG Standards on the image record were rarely met.

In 73/82 (89 %) cases, avoidable factors were identified. Inadequate lesion assessment accounted for 81.3 % of all potentially avoidable cases (▶ **Table 1**).

▶ **Table 1**

Group	Descriptor	Number of cases (%)
A	Focal cancer-associated or pre-malignant lesion with *adequate* assessment & decision-making	**7 (8.8 %)**
B	Focal cancer-associated or pre-malignant lesion with *inadequate* assessment and/or decision-making	**65 (81.3 %)**
C	Possible missed lesion; endoscopy & decision-making *adequate*	**2 (2.5 %)**
D	Possible missed lesion; endoscopy & decision-making *inadequate*	**6 (7.5 %)**
E	System-level contributory factors (delays, booking, triage, pathway failures)	**2 (2.4 %)**

Conclusions PEUGIC rates in Wales are 6.1 %, consistent with reported rates in other UK series. In most cases, avoidable factors have been identified. Mucosal cleaning and inspection, digital enhancement and photo-documentation represent modifiable targets. These findings have informed an all-Wales PEUGIC quality-improvement bundle including mandatory image-capture sets, mucosal-inspection checklists and focused training in subtle-lesion recognition. This model offers a transferable framework for enhancing diagnostic safety and reducing post-endoscopy cancer rates across European endoscopy services.

DOI 10.1055/s-0046-1821243

Aims Longer withdrawal time is a validated quality indicator in colonoscopy and is strongly associated with improved adenoma detection. In contrast, no standardized benchmark exists for upper gastrointestinal endoscopy (EGD) despite increasing evidence, primarily from Asian cohorts, that prolonged inspection may improve detection of early neoplastic lesions. North American data on this topic are scarce, and practice patterns vary widely, with no consensus regarding optimal examination duration. We aimed to evaluate the association between total EGD examination time and the detection of clinically significant lesions in a large, prospectively documented North American population. We hypothesized that longer total examination time would be independently associated with higher detection yield across multiple lesion categories.

Methods We performed a secondary analysis of an ongoing prospective observational study conducted at the Centre hospitalier de l'Université de Montréal (CHUM), a tertiary academic center, between November 2023 and August 2025. Diagnostic, surveillance, and screening EGDs were included. Procedures

with pre-planned therapeutic interventions such as endoscopic mucosal resection, known pre-existing pathology requiring targeted examination (e.g., Barrett's esophagus), or incomplete time documentation were excluded.

Total EGD examination time was defined as the interval from endoscope insertion to complete withdrawal. Recorded times included inspection and routine biopsy sampling. For each procedure, detection of abnormalities was classified into six prespecified categories, the first being the primary outcome: (1) significant visual abnormality, (2) significant biopsy/polyp abnormality, (3) any significant abnormality, (4) any visual abnormality, (5) any biopsy/polyp abnormality, and (6) any abnormality of any type. Clinically significant abnormalities were defined based on consensus criteria established prior to data extraction [1–5].

Associations between total examination time and detection outcomes were modeled using logistic regression with generalized estimating equations (GEE) to account for clustering by individual endoscopist. Time was analyzed as a continuous predictor.

Results A total of 1,169 EGDs met inclusion criteria. The mean patient age was 55.9 years, and 57.5 % were female. The mean total examination time was 5.6 ± 3.7 minutes. Detection rates for all abnormality categories increased with longer examination time. For the primary outcome, each additional minute was associated with a 10.9 % increase in the odds of identifying at least one significant visual abnormality (OR 1.109; $p < 0.001$). Similar associations were observed across secondary outcomes, with odds ratios ranging from 1.13 to 1.25 per additional minute (all $p < 0.001$).

Modeled detection curves demonstrated a steady increase in probability of abnormality detection as inspection time lengthened, with the most pronounced gains occurring between 4 and 12 minutes. Detection appeared to plateau at approximately 13–15 minutes, suggesting diminishing marginal benefit beyond this duration.

Conclusions In this large North American cohort, longer total EGD examination time was strongly and consistently associated with higher detection of significant mucosal abnormalities. The relationship persisted across multiple lesion categories and demonstrated a reproducible plateau at approximately 13–15 minutes. These findings support the concept that total EGD examination time represents a meaningful, measurable quality metric analogous to withdrawal time in colonoscopy. Future studies should validate these results in multicenter settings, refine optimal time thresholds, and investigate the role of automated quality-monitoring tools capable of providing real-time feedback on inspection duration.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP304 Beyond age thresholds: Limited discriminative value of age for clinically significant findings in dyspepsia and GERD

Authors Abu Baker F[1], Natour R[1], Nicola D[1], Ovadia B[1], Oren G[1]

Institute 1 Hillel Yaffe Medical Center, Hadera, Israel

DOI 10.1055/s-0046-1821244

Aims Age thresholds have long guided endoscopic evaluation for dyspepsia, yet their clinical validity in contemporary low-risk populations—and their applicability to gastroesophageal reflux disease (GERD)—remain uncertain. With declining gastric cancer incidence and growing emphasis on risk-based decision models, re-examining the diagnostic value of age is timely. This study aimed to assess whether age effectively predicts clinically significant findings (CSFs) in patients with treatment-refractory dyspepsia or GERD and to define optimal age cutoffs for endoscopic triage.

Methods We retrospectively analyzed a large consecutive cohort of adults undergoing diagnostic upper endoscopy for dyspepsia or GERD following inadequate response to proton pump inhibitor (PPI) therapy. Individuals with alarm features, prior upper gastrointestinal malignancy, or recent endoscopy were excluded. Endoscopic findings were classified as CSFs if they carried diagnostic or therapeutic relevance, including Barrett's esophagus, severe esophagitis, peptic ulcer disease, or neoplasia. Logistic regression was used to identify independent predictors of CSFs, and receiver operating characteristic (ROC) analysis was applied to evaluate the discriminative capacity of age and determine optimal cutoffs.

Results Among 20,248 procedures (13,842 for dyspepsia and 6,406 for GERD), endoscopic yield differed markedly by indication. CSFs were detected in 12.8 % of GERD and 5.6 % of dyspepsia cases. Esophageal pathology—particularly erosive esophagitis, Barrett's esophagus, and hiatal hernia—dominated among reflux patients, whereas gastric and duodenal lesions were more frequent in dyspepsia. Multivariate analysis revealed that age ≥ 60 years independently predicted CSFs in GERD (adjusted OR 1.66, 95 % CI 1.38–2.00) but not in dyspepsia (OR 0.97, 95 % CI 0.82–1.15). Male sex was a consistent predictor across both indications, and in GERD, Arab ethnicity and hiatal hernia also conferred increased risk. Malignancy was exceedingly rare (< 0.15 %). ROC analysis demonstrated minimal discriminative power for age (AUC 0.574 in GERD; 0.512 in dyspepsia), with Youden-derived optimal thresholds of 59 and 52 years, respectively—offering limited clinical utility.

Conclusions In this large real-world cohort of non-alarm, PPI-refractory patients, age alone was a weak discriminator of clinically significant endoscopic pathology. Although older age modestly increased diagnostic yield in GERD, its overall predictive performance was poor, particularly in dyspepsia. These findings challenge the continued reliance on uniform age thresholds for endoscopy referral and support the adoption of context-specific, multifactorial risk models that integrate demographic and structural predictors to optimize diagnostic efficiency and resource utilization.

PYP305 Improving Cellular Yield During Endoscopic Brush Sampling By Not Resheathing – A Simple Modification

Authors Wyckmans M[1], Driessen A[1], Krishnadath S[1]

Institute 1 Antwerp University Hospital, Edegem, Belgium

DOI 10.1055/s-0046-1821245

Aims Brush cytology allows sampling of broad mucosal areas. It has various gastrointestinal indications such as malignancy, Barrett's esophagus and Helicobacter pylori infection. During endoscopy, the brush bristles exit a protective sheath. After sampling, the bristles retract back into the sheath. While few studies have explored the role of the plastic sheath on cellularity, sheath-influenced loss of cellularity is observed in the literature. [1, 2] As diagnostic accuracy depends on cellularity yield, this study investigated whether not retracting the bristles into the sheath is feasible and results in better cellular yield (▶ **Table 1**).

▶ **Table 1**

	Brush Cellularity	
	insufficient-to-low (n)	moderate-to-high (n)
open brush	0	13
closed sheath	9	10

The Fisher exact test statistic value is 0.0042. The result is significant at $p < .05$.

Methods Patients with Barrett esophagus undergoing standard-of-care endoscopy were included at the Antwerp University Hospital. Endoscopy was performed by two experienced gastroenterologists. Brush samples were taken with either 'standard-of-care' brush retraction (= control) or 'unsheathed' (= intervention). Samples were stored in Cytolyt cell medium and directly transported to the department of Pathology for cytological evaluation and formalin-fixation for cellblock. Cellularity results were defined as 'insufficient', 'low', 'moderate' and 'high'. [3] Cellularity results were bundled in two groups 'insufficient-to-low' and 'moderate-to-high' in order to facilitate statistical analysis using Fisher's exact test at 95 % confidence interval. Diagnostic accuracy was evaluated whether the brush cytology could confirm diagnosis of Barrett esophagus, irrespective of dysplasia grade (▶ **Table 2**).

▶ **Table 2**

	Diagnostic accuracy	
	not diagnostic (n)	diagnostic (n)
open brush	5	8
closed sheath	9	10

The Fisher exact test statistic value is 0.7249. The result is *not* significant at $p < .05$.

Results Seventeen patients with Barrett esophagus were included during a one-year period for a total of 32 brush samples. When brush retraction was performed, cellularity was insufficient-to-low in 47.4 % (9 brushes) and moderate-to-high in 52.6 % (10 brushes). When the unsheathed technique was used, cellularity was moderate-to-high in 100 % (13 brushes). There were no brushes that yielded insufficient-to-low cellularity. When comparing the two techniques, there is more cellular yield when not retracting ($p = 0.0042$).
Diagnostic accuracy was 52.6 % (10/19) when brush retraction was performed, while diagnostic accuracy increased to 61.5 % (8/13) with the unsheathed technique. This result was not statistically significant (p-value 0.72).
Conclusions This study points towards better cellular yield by not retracting the brush into the sheath during endoscopic brush sampling. A larger sample size is needed to evaluate diagnostic benefit and extrapolation for other indications. As part of the Horizon Europe Project ENDEAVOR, endoscopic brush samples will be taken from multiple international sites between abstract submission and presentation to evaluate result replicability and performance in a population with Barrett esophagus high-grade dysplasia and T1 adenocarcinoma.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP306 Adenoma detection rates in IBD surveillance colonoscopy: a prospective study

Authors Ingabire CG[1], Battat R[2], Douglas KR[3], Christina DD[4], Bernard EJ[2], Orlicka K[2], Leduc R[2], D'aoust L[4], Liu Chen Kiow J[4], Michal V[5], Oleksiw M[4], Djinbachian R[6], Deslandres E[4], Bouin M[4], Panzini B[4], Bouchard S[4], von Renteln D[7]
Institutes **1** University of Montreal, Montréal, Canada; **2** University of Montreal Hospital Research Center (CRCHUM), Montreal, Canada; **3** Indiana University School of Medicine, Indianapolis, United States of America; **4** CHUM – Centre hospitalier de l'Université de Montréal, Montréal, Canada; **5** Research Center Du Chum ., Montréal, Canada; **6** CHUM, Montreal, France; **7** CHUM, Montreal, Canada
DOI 10.1055/s-0046-1821246

Aims In average-risk colorectal cancer (CRC) screening, colonoscopy quality is commonly assessed by the detection of sporadic adenomas and withdrawal time (WT). In inflammatory bowel disease (IBD) surveillance, however, withdrawal is more complex: even in the absence of endoscopic inflammation, endoscopists are required to perform detailed segmental IBD assessment, and obtain biopsies. Our hypothesis was that in a screening-age cohort of IBD patients without active inflammation, the yield of sporadic adenomas should be similar to that observed in non-IBD patients. We aimed to test this hypothesis in a real-world cohort, recognizing that current quality benchmarks are extrapolated from average-risk screening despite IBD patients having approximately twice the CRC risk.
Methods We conducted a prospective observational study using a video library of colonoscopies performed at the University of Montreal Hospital Center (CHUM). All consecutive patients aged ≥ 45 years who underwent complete colonoscopy between 2023 and 2025 were included. Patients with endoscopic activity (Mayo score > 0 or total Simple Endoscopic Score for Crohn's Disease [SES-CD] > 0), incomplete procedures, endoscopic mucosal resection, missing histopathology, or incomplete clinical data were excluded. The primary outcome was the detection of sporadic adenomas (adenoma detection rate, ADR) in IBD compared with non-IBD patients, adjusted for WT. Secondary outcomes were mean WT, polyp detection rate, adenomas per colonoscopy, polyps per colonoscopy, advanced adenoma detection rate, and sessile serrated lesion detection rate.
Results A total of 1421 colonoscopies were analyzed, including 155 in IBD patients and 1266 in non-IBD patients. When WT was fixed at 11.8 minutes, the proportion of colonoscopies with at least one sporadic adenoma was significantly lower in IBD than in non-IBD patients (18.5 % vs. 43.4 %). The gain in adenoma detection with each additional minute of WT was markedly attenuated in IBD: the odds of detecting an adenoma increased by 16.7 % per additional minute in non-IBD patients compared with 2.7 % per minute in IBD patients. To achieve an adenoma detection of 26 %, an estimated WT of 6.8 minutes was required in non-IBD colonoscopies versus 28.3 minutes in IBD colonoscopies. In routine practice, IBD colonoscopies had a shorter mean WT than non-IBD colonoscopies (10.4 vs. 12.0 minutes).
Conclusions In a screening-age cohort without endoscopic IBD activity, the detection of sporadic adenomas was substantially lower in IBD than in non-IBD patients and increased far more slowly with longer withdrawal times. These findings suggest that IBD-specific procedural demands during withdrawal, including detailed inflammatory assessment and biopsy protocols, limit the effective time available for adenoma detection. Quality thresholds derived from non-IBD screening colonoscopy may therefore not be applicable to IBD surveillance, and dedicated IBD-specific quality metrics should be developed.
Conflicts of Interest Daniel von Renteln has received research funding from ERBE Elektromedizin GmbH, Ventage, Pendopharm, Fujifilm and Pentax, and has received consultant or speaker fees from Boston Scientific Inc., ERBE Elektromedizin GmbH, and Pendopharm. Endoscopy 2026; 58: S1–S1041

PYP307 Four Years at a Newly-Commenced Colon Capsule Endoscopy Centre

Authors Baker J[1], Smith A[1], Bhandare A[1]
Institute 1 Royal Oldham Hospital, Oldham, United Kingdom
DOI 10.1055/s-0046-1821247

Aims Colon Capsule Endoscopy (CCE) is a minimally invasive alternative to standard colonoscopy. It was introduced in 2021 as part of an NHS pilot scheme with fifty other hospitals. In this pilot, 70 % of patients did not require a subsequent colonoscopy, and a substantial proportion of the remaining 30 % were downgraded to non-urgent [1]. CCE is now established as a routine service nationally.

CCE presents significant advantages when compared to traditional colonoscopy. When bowel preparation is adequate and the study is completed, it demonstrates a high sensitivity for polyps and malignancy that is comparable to colonoscopy [2]. It is generally well-tolerated, with low complication and discomfort rates [3]. Finally, CCE may contribute to addressing long waiting lists and capacity pressures with colonoscopy.

Our Trust is one of the highest-volume sites nationally for delivering CCE. This analysis reviews all CCE reports since the commencement of the service at our Trust to assess its impact and how it can be used to benefit different patient groups.

Methods We reviewed all CCE reports between January 2021 and September 2025. Eligible patients included those referred via the 2-week-wait (2WW) colorectal cancer pathway who were considered lower risk (faecal immunochemical testing (FIT) of < 100). The reasons for referral, specifically the presence of NG12 symptoms such as rectal bleeding or a change in bowel habit, were recorded. A CCE was also offered if a colonoscopy was contraindicated or had previously failed, or on the basis of patient preference. Biochemistry and demographic data were recorded. Bowel preparation was scored using the Boston Bowel Preparation Scale, with the CCE marked as complete if a satisfactory view of all sections of the colon was achieved. If the study was marked as incomplete, the subsequent investigation was reviewed. CCE findings, normal study rates and whether the patient was stepped down from the 2WW pathway were also documented.

Results 473 CCE cases were analysed in total. The male to female ratio was 214:259. The median age was 57 (IQR = 20). 385 patients (81 %) were White British. 76 (16 %) belonged to an ethnic minority, and 12 (3 %) did not have an ethnicity recorded.

The most common reason for referral was a change in bowel habit (n = 285). Other indications were weight loss (n = 75), rectal bleeding (n = 175), abdominal pain (n = 176) and anaemia (n = 93). In the latter case, only 89 patients had biochemical evidence of anaemia on referral. Patients could have more than one referral symptom.

FIT was positive in 256 patients. The mean FIT with 22.5, with a similar average of 22.9 in over 70s. The median bowel preparation score was 8 (IQR = 3).

402 CCEs (84.9 %) were marked as completed, with 349 patients (73.8 %) stepped down from the 2WW pathway. 102 patients (21.6 %) had a subsequent colonoscopy, including 60 for polypectomy. 32 patients had a flexible sigmoidoscopy following CCE for completion of imaging.

No abnormality was identified in 98 (20.6 %) patients. In the remaining patients, diagnoses identified included polyps (n = 141), diverticulae (n = 159), haemorrhoids (n = 42), colitis (n = 19), ulcer (n = 17), telangiectasia (n = 11) and malignancy (n = 1).

74 CCEs (15.6 %) were marked as incomplete. The most common reason for this was inadequate bowel preparation (n = 52). Other causes were the battery running out (n = 17), rapid transit (n = 2), a camera error (n = 2) and gastric retention (n = 1).

Conclusions CCE has been successfully introduced at our site, demonstrating a similar stepdown rate to published studies and a completion rate that exceeded the rate reported in the national pilot. Further investigations were not required in more than 70 % of patients. These findings reaffirm the role of CCE in reducing pressure on colonoscopy services, in this case by identifying and investigating lower risk patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP308 Diagnostic yield of Endoscopic Ultrasound (EUS) in Indeterminate Biliary Strictures: A Retrospective Monocentric Study

Authors Hsain C[1], Kadiri M[2], Lagdali N[3], Ajana FZ[3], Borahma M[4]
Institutes 1 Department of Hepato-Gastroenterology C, Ibn Sina Hospital, Mohammed V University, Rabat, Morocco; 2 مستشفى ابن سينا, Rabat, Morocco; 3 Mohammed V University, Rabat, Morocco; 4 Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821248

Aims Biliary strictures represent a major diagnostic challenge due to the difficulty in distinguishing benign from malignant etiologies.Endoscopic ultrasound (EUS) allows detailed exploration of the biliary and pancreatic ducts and enables targeted tissue sampling for diagnostic purposes.The aim of this study was to assess the diagnostic performance and clinical impact of EUS in the management of indeterminate biliary strictures.

Methods This was a retrospective, single-center, descriptive study including all patients presenting with a biliary stricture suspected on cholangio-MRI (MRCP) without evident mass, and subsequently explored by EUS over a six-year period (2019–2025).Collected data included clinical, biological, morphological, histological, and follow-up characteristics.

Results Twenty-five patients were included. The median age was 59 years (range 42–85), with a slight male predominance (14 men, 11 women).Clinically, all patients initially presented with cholestatic jaundice, with a mean total bilirubin (TB) level of 12,1 mg/dL.

The strictures were distal (common bile duct) in 83 % of cases (20 patients) and hilar in 17 % (5 patients).The median stricture length was 10 mm, and the appearance was predominantly malignant in 8 cases, and benign in 5 cases.

Fine-needle aspiration/biopsy (FNA/FNB) was performed in 64 % of patients (16/25), using variable-caliber needles: mainly 22G (63 %), followed by 20G (25 %) and 19G (12 %), according to lesion location and consistency.Histopathological analysis revealed malignant lesions in 13 cases (52 %), mainly cholangiocarcinomas (n = 7) and pancreatic head adenocarcinomas (n = 6).

Benign lesions were observed in 7 patients (28 %), including fibrotic Odditis, post-cholecystectomy biliary strictures, primary sclerosing cholangitis, and IgG4-related cholangitis.

A minor hemorrhagic complication post FNB/A was reported, with no other major adverse events.

Regarding therapeutic outcomes, 4 patients with malignant disease (16 %) underwent curative surgical resection, and 4 others (16 %) received palliative chemotherapy.

Conclusions EUS enabled a definitive diagnosis in nearly 80 % of malignant cases, thereby guiding therapeutic management.It represents a key first-line diagnostic tool in the evaluation of biliary strictures, owing to its high-resolution imaging and ability to obtain targeted tissue samples.Further systematic

histological correlation and prospective follow-up studies are warranted to refine the overall diagnostic performance of this technique.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP309 Diagnostic Performance of Artificial Intelligence Models for the Early Diagnosis of Gastric Cancer: A Systematic Review and Meta-analysis

Authors Salvato D[1], De Conte A[2], Schettino P[3], Carrato A[1], Marmo R[3]

Institutes **1** Digestive Endoscopy Unit, Luigi Curto Hospital, Polla, Salerno, Italy; **2** Digestive Endoscopy Unit, Luig Curto Hospital, Polla, Salerno, Italy, salerno, Italy; **3** Digestive Endoscopy Unit, Luig Curto Hospital, Polla, salerno, Italy

DOI 10.1055/s-0046-1821249

Aims Gastric cancer remains a major contributor to global cancer mortality. Although endoscopy is the most effective method for detecting early gastric cancer (EGC), the identification of subtle early lesions continues to pose a clinical challenge. Artificial intelligence (AI) has emerged as a promising adjunct to enhance diagnostic accuracy. AI systems are trained using different methodological approaches, and their diagnostic performance may vary. This meta-analysis aimed to evaluate the diagnostic accuracy of AI-assisted endoscopy for EGC and to compare the performance of different AI systems

Methods PubMed, Embase, Cochrane, and Web of Science were systematically searched for articles. Pooled sensitivity and specificity were calculated using random-effects models; an SROC curve was constructed and AUC estimated. Histopathology served as the reference standard. Subgroup analyses were performed according to AI system type and endoscopic imaging modality. Risk of bias was assessed using the QUADAS-2 tool, and publication bias was evaluated with funnel plots

Results Twenty-one studies were included, conducted in China, Japan and Korea. AI achieved an overall AUC of 0.96 (95 % CI, 0.94–0.98), pooled sensitivity of 91 % (95 % CI, 88–94), and specificity of 90 % (95 % CI, 85–94), with substantial heterogeneity. Deep-learning systems showed sensitivity comparable to hybrid machine learning–deep learning models (89.9 % [95 % CI, 84.1–93.8] vs 91.2 % [95 % CI, 85.5–94.8]) but achieved significantly higher specificity (89.4 % [95 % CI, 86.3–91.9] vs 83 % [95 % CI, 79.2–86.3], $p \leq 0.005$). No significant methodological or publication bias was identified [1–41]

Conclusions AI-assisted endoscopy demonstrates high diagnostic accuracy for the early detection of gastric cancer. AI systems are not equivalent: deep-learning models provide the best performance, particularly due to their superior specificity

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP310 Post-peroral endoscopic myotomy dyspeptic symptoms: A novel adverse event to consider prior to treatment?

Authors Alcaide SG[1], Gómez Chamorro L[2], Zubillaga De Diego A[2], Del Campo López M[1], Luis Magdaleno B[3], Zuluaga Montoya I[1], Rojo E[1], Miranda García P[1]
Institutes **1** Hospital de La Princesa, Madrid, Spain; **2** Hospital de La Princesa, Mad, Spain; **3** Hospital La Princesa, Madrid, Spain
DOI 10.1055/s-0046-1821250

Aims There is evidence regarding the occurrence of dyspeptic symptoms due to gastroparesis following thoracic surgeries and esophagectomies, as a consequence of iatrogenic vagal nerve injury. Peroral endoscopic myotomy (POEM) involves sectioning the esophagogastric muscularis propria, often transmurally, which could affect the vagal plexus and, therefore, produce gastroparesis and dyspepsia symptoms and as an adverse event.
The aim of our study was to evaluate the prevalence of dyspepsia symptoms in patients undergoing POEM at our center.

Methods Cross-sectional study including patients who underwent POEM at our center (June 2018 – December 2024). Demographic, clinical, endoscopic, and manometric variables were collected. Through telephone interviews, the presence of dyspeptic symptoms before and after the procedure was assessed, as well as the perceived quality of life after the intervention using a Likert scale (0-4).

Results A total of 112 patients who underwent POEM between 6 and 78 months prior to the study were evaluated. Ninety-four percent of patients had an Eckardt Score ≤ 3, with high or very high improvement in quality of life (score 3-4) in 90 % of patients. Thirty-two patients (28 %) with dyspeptic symptoms were identified, of which 25 (78 %) presented postprandial distress-type symptoms (fullness/early satiety). Among patients with dyspepsia, 15 patients experienced symptoms before the procedure, while 17 cases (15 %) corresponded to new-onset dyspepsia. No statistically significant associations were found between any variables and the occurrence of dyspepsia.

Conclusions Up to 15 % of patients undergoing POEM experienced de novo post-POEM dyspeptic symptoms. Seventy-eight percent of these patients presented fullness/early satiety, possibly related to iatrogenic vagal nerve injury. However, quality of life manifestly improved in 90 % of cases.

PYP311 Diagnostic Yield of Multilevel Biopsies and Rate of Progression in Eosinophilic Esophagitis (EoE): A Long-Term Follow-Up Cohort Study

Authors Valente R[1], Haris K[1], Arnelo U[1]
Institute **1** Department of Diagnostics and Intervention, Surgery, Umeå University, Umeå, Sweden
DOI 10.1055/s-0046-1821251

Aims Background: Current guidelines for eosinophilic esophagitis (EoE) recommend obtaining biopsies from three different esophageal levels to maximize diagnostic yield, as well as life-long treatment to prevent complications such as dysmotility and strictures. However, most available evidence comes from randomized controlled trials, and in real-world practice—where the disease is relatively uncommon—biopsy protocols are often not strictly followed. Furthermore, the natural history of EoE and the timing of disease progression remain insufficiently characterized.

Aims: To describe diagnostic delay in a real-world setting and to evaluate rates of endoscopic progression over long-term follow-up.

Methods We performed a retrospective review of medical records from patients diagnosed with EoE or other non-GERD esophagitis at Umeå University Hospital (Umeå, Sweden) between 2014 and 2024. Data collected included patient demographics, comorbidities, endoscopic findings at the index gastroscopy, diagnostic delay between the initial gastroscopy and definitive histological diagnosis, presenting symptoms, and treatments received [1–4].

Results Of the 38 patients initially screened, 22 were included in the final analysis with a confirmed diagnosis of EoE. Seventeen patients (77 %) were male, with a mean age of 51 years (SD: 38–64). Overall, 15 patients (68 %) presented with food bolus impaction, 19 (86 %) reported dysphagia, and 14 (70 %) had dysphagia lasting more than 6 months, and 2 (10 %) experienced weight loss. Atopic comorbidities were present in 11 patients (52 %), including asthma in 10 (45 %) and atopic dermatitis in 2 (9 %). The diagnosis was established at the index gastroscopy in 17 of the 22 patients (77 %), despite the recommended multilevel biopsy protocol—obtaining samples from three esophageal levels—being followed in only 23 procedures (38 %). The median diagnostic delay between the first gastroscopy and the definitive histological diagnosis was 4.5 weeks. At index gastroscopy, 38 % of patients displayed rings, 11 % had furrows, 13 % had exudates, and 5 % had strictures. After a mean follow-up of 39 months, 4 % displayed rings, 6 % furrows, 11 % exudates, and 4 % strictures. Overall, 21 patients (95 %) received treatment: 1 patient (4 %) followed an elimination diet, 3 (13 %) received fluticasone, 8 (36 %) budesonide, and 20 (90 %) proton pump

inhibitors (PPIs). Ten patients (45 %) received more than one treatment modality.

Conclusions In this real-world cohort, the diagnostic yield of esophageal biopsies was high, even when the guideline-recommended multilevel protocol was not strictly adhered to, enabling diagnosis in approximately three-quarters of patients. The median diagnostic delay was about one month. Nearly all patients received treatment, and after a mean follow-up of 39 months, there was no clinically relevant endoscopic progression.

Conflicts of Interest RV and UA are consultant to Boston Scientific

PYP312 Endoscopic Ultrasound (EUS)-guided portal pressure gradient measurement: clinical usefulness

Authors Romero-Castro R[1], Carmona-Soria I[2], Fernandez-Alvarez P[2], Cordero-Ruiz P[2], Bellido-Muñoz F[2], Tous-Romero M[2], Grande-Santamaria L[2], Jimenez-Garcia VA[3], Garcia-Perez J[2], Ortiz-Moyano C[2], Argüelles Arias F[2], Rodriguez-Tellez M[2], Caunedo-Alvarez A[2]

Institutes **1** Virgen Macarena University Hospital, Sevilla, Spain; **2** hospital universitario virgen macarena, Sevilla, Spain; **3** University Hospital Virgen Macarena, Seville, Spain

DOI 10.1055/s-0046-1821252

Aims We report our experience on EUS-guided portal pressure gradient measurement (EUS-PPGm).

Methods Prospective study of patients referred for EUS-PPGm. A 25G dedicated needle was used. A 19G FNA needle was used for EUS-guided bilobar liver biopsy (EUS-BLB).

Results EUS-PPGm was performed in 72 patients. Indications: Assessment of MASLD in morbid obese patients: 43. Portal hypertension (PH): 26. Evaluation for curative therapy in hepatocellular carcinoma (HCC): 3. Additional procedures were performed in the same endoscopic session: Fifty-three (74 %) EUS-BLB, 3 band ligation for esophageal varices and 1 EUS-guided coil therapy for gastric varices. EUS-PPGm was obtained in 65/72 patients (90 %). In 12/43 morbid obese patients (28 %) the EUS-PPGM was > 6 mmHg without varices nor fibrosis on EUS-BLB. In morbid obese patients, there was a statistically significant difference in the S3 score of steatosis in the group of portal hypertension (33 %) in comparison with the no portal hypertension group (4 %). Patients were treated accordingly with the results of EUS-PPGm. In 7 cases (10 %) EUS-PPGm was not obtained. For rapid breathing movements (1 case) and for non-reliable pressure measurements (6 cases). In one case the 25G needle passed in close proximity to the hepatic artery. We experienced difficulty in punction the hepatic and the portal vein in one and two cases, respectively. In one case the 25G needle failed to transverse the liver capsule. Mean time to obtain EUS-PPGm 23 ± 2 minutes for EUS-BLB 16 ± 2 minutes and for combined EUS-PPGm plus EUS-BLB 44 ± 2 minutes. Three adverse events were observed: 1 mild epigastric pain, 1 self-limited bleeding from the cardias and 1 atrial fibrillation.

Conclusions EUS-PPGm, even combined with EUS-BLB, seems safe, providing relevant clinical information. A notewhorty proportion of morbid obese patients were precociously diagnosed of portal hypertension in early reversible stages without liver fibrosis on EUS-BLB.

Conflicts of Interest Rafael Romero-Castro is a consultant to Cook Medical. The other authors declare they do not have conflicts of interest.

PYP313 Modified endoscopic vacuum therapy as first-line approach in the management of upper gastrointestinal tract leaks and fistulas

Authors Craveiro F[1], Soares C[2], Pereira JP[1], Costa Moreira P[1], Medas R[1], Baldaque-Silva F[3, 1], Antunes P[1]

Institutes **1** Gastroenterology Department and Advanced Endoscopy Center Carlos Moreira da Silva, ULSMatosinhos, Matosinhos, Portugal; **2** Centro Hospitalar Tondela – Viseu, EPE, Viseu, Portugal; **3** Karolinska University Hospital, Stockholm, Sweden

DOI 10.1055/s-0046-1821253

Aims Endoscopy has emerged as the first-line treatment of anastomotic leaks and fistulasafter esophagogastric surgery . Endoscopic vacuum therapy (EVT) is one of the most commonly used options with clinical success above 66 %. However, it is associated withhigh costs, can be technically challenging, and is associated with the need of parentalnutrition. Our center adopted a strategy using a handcrafted modified EVT (mEVT)based on a nasojejunal tube, allowing concomitant enteral nutrition. The aim of thisstudy is to evaluate the feasibility and efficacy of mEVT as single or combined therapy,in clinical practice.

Methods We report all consecutive patients treated with mEVT in our center, between01/01/2023 and 31/10/2025 and with a 30-day follow-up period were included. All had upper gastrointestinal tract defect referred to mEVT by the multidisciplinary teamconference.

Results In total, 24 patients were referred to mEVT, 17 (70.8 %) were male, with a median ageof 59 (IQR 54-69) years. The aetiology of the defect was predominantly postoperative(91.6 %): 12 oncologic cases, 8 bariatric surgery cases (4 sleeve gastrectomies, 3bypass surgeries and 1 single anastomosis stomach–ileal bypass) and 1 iatrogenicgastric injury (intraoperative). In 17 patients (70.8 %), postsurgical sepsis with organdysfunction required intensive care admission.The median defect diameter was 10.0 (IQR 5.0-25.0) mm. Diagnosis occurred, amedian of 6.0 (IQR 4-14) days after surgery and mTEV was the first-line therapeuticoption in 18 patients (75 %). 12 patients (50 %) had abscess cavity associated to theleak. Adjunctive endoscopic techniques were used in 15 patients (62.5 %), mostlyincluding double-pigtail stents or over-the-scope clips.Clinical success was achieved in 22 patients (91.6 %) after a median of 3 (IQR 2-5)sessions and the mean duration of each session was 6.03 (± 1.16) days. Fourpostoperative patients were treated without complementary percutaneous drainage.Patients required exclusive parenteral nutrition only for median of 3 days (IQR 0-7) andwere fed via enteral nutrition during a median of 14 (IQR 8-28) days, starting on theday of mEVT placement.There were no adverse events related to mEVT. Clinical failures, in 2 patients,corresponded to 2 tracheoesophageal fistulas and 1 gastrocutaneous fistula. Fourdeaths occurred: 2 due to defect-related complications and 2 due to underlyingdisease.

Conclusions mEVT is an innovative and straightforward solution with a high success rate,comparable to what has been reported with conventional techniques. It stands out as alow-cost alternative, enabling optimized enteral nutrition during treatment, preventinginfection and malnutrition risk. We present iconography (endoscopic images andvideos) of the treated cases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP314 Predicting Need For Step-Up Approach And Recurrence In Endoscopic Management Of Anastomotic Strictures After Esophagectomy: Results From A 10-Year Multicenter Retrospective Study From Tertiary Referral Centers

DOI 10.1055/s-0046-1821254

Aims Anastomotic stricture (AS) is a common late complication after esophagectomy. Evidence guiding endoscopic escalation ("step-up") and the risk of post-treatment recurrence remains limited. We assessed clinical, surgical, and procedural determinants of (i) need for step-up therapy and (ii) recurrence after initial endoscopic success.

Methods We conducted a ten-year multicenter retrospective study at two Milan tertiary centers (2014–2024). Adults with naïve post-esophagectomy AS underwent standardized endoscopic management (bougie or pneumatic dilatation with predefined step-up options: incision therapy, stenting, steroid injection). Outcomes included technical (TS) and clinical success (CS), safety, rate of step-up and recurrence, and uni/multivariable predictors for change of strategy and recurrence.

Results Among 1,729 esophagectomies, 61 patients (3.5 %) developed benign AS. Initial therapy was bougie in 54.1 % and pneumatic in 45.9 %. TS was reached in 100 % and CS in 93.4 %. Safety was favourable (1/61, 1.6 %). Overall, 39.3 % required a change of strategy, typically early: the first switch occurred at a median of 35 days, and 62.5 % within 30 days, most often for failure to achieve a ≥ 2-mm lumen gain (66.7 %). On multivariable analysis, higher BMI (OR 0.81 per 1 kg/m², p = 0.022) and baseline dysphagia < 2 (OR 0.13, p = 0.006) independently reduced the likelihood of step-up. Among patients with CS, recurrence occurred in 24.6 % (14/57). In models restricted to surgical variables, stapled versus hand-sewn anastomosis was protective (OR 0.11, p = 0.022), whereas procedure type (McKeown vs Ivor-Lewis) and calibre ≤ 25 mm were not significant.

Conclusions Endoscopic treatment of post-esophagectomy AS is highly feasible and effective. Early escalation clusters within the first month and is more likely in patients with lower BMI and greater dysphagia, supporting closer early surveillance. After initial success, stapled anastomosis appears to mitigate recurrence risk [1].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Self-expandable metallic stent (SEMS) in the cervical esophagus remains challenging, as this region is often considered a relative contraindication for stenting and is commonly associated with complications (foreign-body sensation, migration). The NITI-S Cervical Esophageal Stent (Taewoong Medical) featuring a proximal release mechanism, was specifically designed to address these limitations. Our aim was to evaluate safety, efficacy, and associated adverse events (AEs) associated with this cervical-specific esophageal stent design [1, 2].

Methods Retrospective, observational,, single-center study. All cases with placement of a NITI-S Cervical stent placement (2012–2025) were identified. Epidemiological, clinical, and technical variables were collected. Follow-up included clinical outcomes and stent-related complications (▶ **Table 1**).

Yes	21 (67.7)
No	10 (32.3)

Results Among 520 patients who underwent esophageal stenting during the study period, 31 received a cervical-specific stent (71 % male; mean age 73 years). The most predominant indication (71 %) was malignant stenosis (esophageal or head-and-neck cancer). Technical success was 90 %; three cases required immediate stent removal due to intraprocedural malposition. Clinical

success (restoration of oral intake) was achieved in 92 %. Mild AEs occurred in 18.75 % of cases, mainly pain and foreign-body sensation. Migration occurred in 25 % (4 proximal, 3 distal), and tissue ingrowth in 7 %. Overall, 8 patients (26 %) required stent removal due to migration or intolerance. No procedure-related mortality was observed. Mean follow-up was 2.9 months (SD ± 5.6). In 57 % of cases, follow-up ended due to patient death

Conclusions This 13-year series represents one of the largest published experiences with cervical-specific SEMS. Despite the inherent challenges of cervical esophageal stenting, our results demonstrate high technical (90 %) and clinical (92 %) success rates with acceptable tolerability, supporting their role in palliative management of malignant cervical esophageal stenosis

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP316 Collaborative Transoral Endoscopic Resection for Superficial Hypopharyngeal Squamous Cell Carcinoma: Comparative Short-term Outcomes of ESD, ELPS, and TOECS

Authors Sasaki F[1], Maeda H[1], Maeda N[1], Tanaka A[1], Kanmura S[1]

Institute 1 Kagoshima University Hospital, Kagoshima, Japan

DOI 10.1055/s-0046-1821256

Aims The management of superficial hypopharyngeal squamous cell carcinoma (HPSCC) has traditionally been led by head and neck surgeons; however, recent advances in endoscopic technology have enabled greater involvement of gastroenterologists, increasing the importance of multidisciplinary collaboration. At our institution, endoscopic submucosal dissection (ESD) has been the primary treatment modality, followed by the introduction of endoscopic laryngo-pharyngeal surgery (ELPS) and Transoral Endoscopic Cooperative Surgery (TOECS). This study aimed to clarify the unique characteristics of these treatment approaches by comparing their short-term therapeutic outcomes.

Methods We retrospectively analyzed 149 patients with 184 HPSCC lesions who underwent transoral endoscopic resection. Patients were divided into three treatment groups: ESD (n = 138), ELPS (n = 21), and TOECS (n = 26).

In the TOECS procedure, gastroenterologists performed marking, subepithelial injection, and circumferential mucosal incision using a standard ESD high-frequency dissection knife. Subsequent submucosal dissection was performed by head and neck surgeons using the same knife mounted on a transoral surgical attachment.

Outcomes evaluated:En bloc resection rate, R0 resection rate, horizontal (HM) and vertical (VM) margin positivity, and dissection speed (mm^2/min).

Complications including postoperative bleeding, perforation, and laryngeal edema.

Results En bloc resection rates for ESD, ELPS, and TOECS were 96.4 %, 100 %, and 100 %, respectively. R0 resection rates were 84.6 %, 76.2 %, and 72 %, with no significant differences among the groups. HM positivity was significantly lower in the ESD group compared with ELPS and TOECS (9.4 % vs. 23.8 % and 24 %, $p < 0.05$). VM positivity was observed only in the ESD group (5.8 %), without a significant difference, although this suggested a tendency toward shallower dissection.

Dissection speed was similar among the groups (10.4 vs. 9.0 vs. 8.6 mm^2/min). Postoperative bleeding occurred in 2.2 % of ESD cases and in none of the ELPS or TOECS cases. Laryngeal edema occurred in 1.7 % of ESD cases. No perforations were observed in any group.

Conclusions For HPSCC, ESD demonstrated the lowest HM positivity rate, indicating its advantage in precise lateral margin control. ELPS and TOECS showed no VM-positive cases, suggesting that these procedures may facilitate deeper submucosal dissection. Dissection speed and safety profiles were comparable across all modalities. TOECS, performed using shared endoscopic devices, may also contribute to cost reduction.

These findings highlight the importance of close collaboration between gastroenterologists and head and neck surgeons in the transoral management of HPSCC, with a comprehensive understanding of each modality's characteristics contributing to improved therapeutic outcomes.

PYP317 Z-POEM versus flexible endoscopic septotomy for Zenker's diverticulum: a retrospective analysis of recurrence and symptom control

Authors Butz N[1, 2], Baumhöfner C[2], Genthner A[2], Jäger N[2], Kangalli S[2], Straulino F[2], Eickhoff A[2], Welsch L[2]

Institutes 1 Goethe University Frankfurt am Main, Frankfurt am Main, Germany; 2 Klinikum Hanau, Hanau, Germany

DOI 10.1055/s-0046-1821257

Aims Endoscopic needle-knife diverticulotomy is an established treatment for Zenker's diverticulum. Zenker peroral endoscopic myotomy (Z-POEM), introduced at our center in 2021, allows creation of a submucosal tunnel and performance of a full septotomy. This technique enables a more complete division of the cricopharyngeal muscle and may therefore result in fewer recurrences and more durable long-term symptom control. The aim of this retrospective study was to evaluate technical feasibility, recurrence and complication rates, and the duration of symptom resolution across different therapeutic approaches, with particular focus on Z-POEM.

Methods Between January 2014 and June 2024, a total of 162 endoscopic interventions for Zenker's diverticulum were performed at our center, representing one of the larger single-center cohorts reported to date. Procedures included 117 needle-knife diverticulotomies, 35 Z-POEM procedures, and 10 alternative techniques. Patient demographics were recorded (mean age 71 ± 10.35 years, 66 % male) as well as diverticulum size (mean 2.71 ± 1.46 cm). Follow-up was performed retrospectively for patients who had undergone an intervention from 2019 onward. Structured follow-up (telephone and/or endoscopic) was conducted in 2024-2025, yielding evaluable data for 100 procedures (follow-up rate 65 %) with a median follow-up of 24 months (IQR 18–45). Symptom burden was assessed using a standardized score adapted from the Eckardt Score, focusing on the two consistently available domains: dysphagia and regurgitation. Patients were additionally asked to report the duration of subjectively perceived symptom resolution.Outcomes included symptom improvement, complication rates, time to recurrence and recurrence rates.

Results Median procedure time was comparable between techniques (needle-knife 27 min [6–83] vs. Z-POEM 24.5 min [11–65]). Complications occurred in 8.55 % of needle-knife procedures (10/117) and 11.43 % of Z-POEM procedures (4/35).

Analysis of clinical outcomes was based on the follow-up cohort with evaluable data (n = 100). Within this cohort, both techniques resulted in marked symptom improvement. Median dysphagia scores improved from 2 to 1 after needle-knife and from 1.5 to 0 after Z-POEM. Regurgitation improved from 1.5 to 0 in both groups. The median duration of symptom resolution was 12 months (IQR 6–26) after needle-knife and 13 months (IQR 12–22.5) after Z-POEM. Among patients experiencing recurrence, symptom-free intervals were 9 months (IQR 6–12) for needle-knife and 6 months (IQR 3–12) for Z-POEM.

Recurrence rates differed substantially between techniques, with 79 % recurrence after needle-knife and 43 % after Z-POEM. These rates are higher than commonly reported in the literature, most likely reflecting a follow-up bias, as patients tended to return primarily in the case of symptomatic recurrence and no scheduled endoscopic reassessment was performed. In multivariate logistic regression, Z-POEM was independently associated with significantly lower odds

of recurrence compared with needle-knife (OR 0.197, 95 % CI 0.063–0.587, p = 0.004).

Conclusions Z-POEM proved to be an effective and safe treatment option for Zenker's diverticulum and was associated with significantly lower recurrence rates compared with needle-knife diverticulotomy. Both techniques resulted in meaningful symptom improvement, but Z-POEM achieved complete resolution more consistently and showed an independent association with reduced recurrence in multivariate analysis. These findings underscore the clinical relevance of a complete septotomy and support Z-POEM as a durable and effective endoscopic treatment option for Zenker's diverticulum.

PYP318 AI-Enhanced Prediction of Esophageal Variceal Bleeding in Portal Hypertensive Gastropathy

Authors Yağlı MA[1], Dağcı G[1], Sarıca A[1], Bilgin E[1], Mammadov S[1], Agargun BF[1], Telli P[2], Gurbanov A[1], Çavuş B[1], Akyüz F[1], Kadir D[1], Selman FB[1], Kaymakoğlu S[1]

Institutes 1 Istanbul University Faculty of Medicine, İstanbul, Türkiye; 2 Turkey, Istanbul, Istanbul University Faculty of Medicine, İstanbul, Türkiye

DOI 10.1055/s-0046-1821258

Aims Esophageal variceal bleeding (EVB) remains a major cause of morbidity in portal hypertension. Classical predictors provide limited individualized risk estimation. This study aimed to identify predictors of EVB in portal hypertensive gastropathy (PHG) using both multivariate logistic regression and an artificial intelligence (AI) based machine-learning model [1].

Methods A retrospective cohort of 213 PHG patients (64 with EVB) was analyzed. Clinical, laboratory, and endoscopic variables,including ascites, encephalopathy, platelet count, MELD, albumin, creatinine, H. pylori status, variceal grade, PHG severity, GAVE, NSBB use, and intestinal metaplasia were collected. Univariable and multivariable logistic regression models were constructed. A Random Forest classifier was developed to assess non-linear interactions and determine variable importance. Model performance was evaluated using the area under the ROC curve (AUC) (▶ **Table 1**).

▶ **Table 1**

Predictor	Adjusted OR	95 % CI	P
Encephalopathy	2.46	1.33–5.05	0.013
Ascites	1.81	1.10–3.20	0.018
Platelet (per 10,000/mm³)	0.98	0.96–0.99	0.048

Results Multivariate analysis identified three independent predictors of EVB: encephalopathy (OR 2.46, p = 0.013), ascites (OR 1.81, p = 0.018), and low platelet count per 10,000/mm³ decrement (OR 0.98, p = 0.048). The Random Forest model achieved an AUC of 0.75. AI-based feature importance analysis revealed platelet count as the strongest predictor, followed by MELD, creatinine, albumin, age, ascites, NSBB use, and high-grade varices.

Conclusions In patients with PHG, encephalopathy, ascites, and thrombocytopenia independently predict EVB. AI modeling highlights additional contributors, particularly MELD-related parameters, capturing patterns not detected by classical analysis. Integrating statistical and AI-derived predictors may enhance individualized bleeding-risk stratification.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821259

Aims Gastrointestinal (GI) tract leaks and fistulae—whether spontaneous or resulting from postoperative leakage or dehiscence—pose substantial clinical challenges and carry significant morbidity and mortality. Endoscopic vacuum therapy (EVT) and hybrid EVT-Self-expanding metal stent (SEMS) technology have emerged as promising minimally invasive therapeutic options as alternative to surgery. This multicenter prospective study evaluates the effectiveness and safety of EVT and hybrid EVT-SEMS in the management of GI tract leaks and fistulae

Methods A total of 32 patients were prospectively included, of which 27 received EVT by Esosponge/Endosponge(Boston Scientific, Marlborough, Massachusetts, USA) and 5 received hybrid EVT-SEMS by VacStent GIä(Micro-Tech Europe GmbH, Düsseldorf, Germany) from 2022 onward across 2 portuguese centers. Demographic data, clinical characteristics, and treatment outcomes were collected. The primary endpoint was successful closure of the leak or fistula, confirmed through both endoscopic and radiologic assessment. Secondary outcomes included the need for adjuvant endoscopic therapy, and complication, readmission, and mortality rates.

Results Median follow-up was 100 weeks (IQR 56) and 82.1 % of the patients included were male (n = 22), with a median age of 67 years (IQR 12). Most sponges were placed in the upper GI tract (n = 19) for malignant aetiology (75.8 % of cases). Three patients received sponge in the lower GI tract due to surgery for pelvic/perianal abscess (n = 2) and prostatic cancer (n = 1). Both endoluminal and intracavitary sponges were used, with the former (median 4 [1-37]) being more frequently used than the latter (median 1 [0-11]). Main aetiology for VacStent placement was Boerhaave syndrome (n = 4) and surgery for esophageal adenocarcinoma (n = 1). One every three patients (30.3 %) presented with sepsis at admission and median timing until device placement was 11.5 days (IQR 17.2). Median mural defect size was 15 mm (IQR 15) and median hospitalization length was 55 days (IQR 50.7). EVT by sponge/VacStent therapy achieved a high overall closure rate of 84.2 % (100 % for VacStent alone, p = 0.342). Although a median of 4.5 treatment sessions was required, the need for additional non-EVT endoscopic interventions remained low (5.3 %). Technique-related complications were uncommon (5.3 %) and included migration and late stenosis, and readmission rates were low (13.5 %). Mortality was low and not directly associated with device use. After multivariate logistic regression, sponge at upper GI tract was significantly associated with endoscopic success (OR 0.019, CI95 % 0.001-0.531, p = 0.020), but sepsis at admission proved to be an important factor, although without statistical significance (OR 0.09, CI95 % 0.06-1.315, p = 0.078).

Conclusions This multicenter prospective study demonstrates that EVT and hybrid EVT-SEMS are highly effective and safe modalities for treating spontaneous and postoperative GI tract leaks/fistulae. With strong closure rates, minimal complications, and favorable overall outcomes, these vacuum-based therapies represent valuable endoscopic strategies and support their expanding role in managing of complex GI leaks/fistulae.

DOI 10.1055/s-0046-1821260

Aims Evaluation of cleanliness in capsule endoscopy is essential to validate the exam. However, yet reliable evaluation of bowel cleanliness remains challenging. The validated KODA score provides robust assessment but is time-consuming and impractical in routine practice. We aimed to evaluate the performance of an AI-based tool (AXAROlite, Augmented Endoscopy) compared with the KODA score for assessing small bowel cleanliness in Crohn's disease (CD) patients.

Methods This was a post-hoc analysis of a multicenter randomized controlled trial (NCT05117996) including 142 CD patients undergoing small bowel capsule endoscopy (SBCE) after either a standard PEG-based or simplified clear liquid preparation. All videos were evaluated for cleanliness using the KODA score by trained readers. The same videos were analyzed using the AI-based AXAROlite tool. Correlation, agreement, and diagnostic performance of AXAROlite were compared with the KODA score. Clinical factors influencing AI-assessed cleanliness were also investigated.

Results Correlation between the KODA score and the AI-AXAROlite score was found strong for the whole SB ($\rho = 0.61$; $r2 = 0.35$; $p < 0.001$) and moderate to strong for each of the four quartiles analyzed: $\rho = 0.52$; $r2 = 0.24$; $p < 0.001$, $\rho = 0.56$; $r2 = 0.24$; $p < 0.001$, $\rho = 0.50$; $r2 = 0.21$; $p < 0.001$, $\rho = 0.62$; $r2 = 0.41$; $p < 0.001$ for the first, the second, the third and the fourth quartiles, respectively.When compared to the qualitative evaluation of the SB cleanliness i.e. good, fair or poor, both the KODA and the AXAROlite scores decreased similarly. The median [IQR] values of AXAROlite scores were respectively 75.0 [59.0-84.0], 56.0 [42.0-67.0] and 41.00 [25.75-59.75]. The differences were statistically significant between a good and a fair or poor cleanliness ($p < 0.001$) AXAROlite demonstrated excellent diagnostic accuracy for detecting adequate cleanliness defined as KODA > 2.25 (AUROC = 0.85, 95 % CI 0.79–0.92), with an optimal threshold of 72 % clean frames (sensitivity 86 %, specificity 72 %).In multivariate analysis, the activity of the disease and the SB transit time influenced negatively the AXAROlite score: $\beta = -7.87$ [-15.29; -0.44], $p = 0.0382$ and $\beta = -0.04$ [-0.06; -0.01], $p = 0.0031$ respectively. The behavior, the location of the disease, the endoscopic severity and the presence of an anastomosis, did not modify independently the AXAROlite SBscore.

Conclusions AXAROlite provides a rapid, fully automated, and accurate evaluation of small bowel cleanliness in CD, comparable to the validated KODA score. Its integration into routine workflows may streamline reporting and reduce inter-observer variability.

Aims To evaluate the retrieval rate of capsules for environmental motivation after videocapsule endoscopy (VCE), considering demographic and travel-related factors

Methods This is a prospective monocentric study enrolling patients undergoing VCE at the Endoscopy Unit of the Policlinico of Milano, a tertiary referral center in a urban area. Patients were invited to retrieve the capsule on the basis of its environmental impact. Data collected included age, travel distance, number of transportation mens, travel time and out-of-pocket costs. Differences were assessed between patients who retrieved capsule after its evacuation and those who did not. Associations were analyzed using descriptive statistics and Pearson correlations. 0.04 kg of CO2 has been considered as a single capsule carbon footprint [1].

Results 142 patients were enrolled (51 % females, mean age 53 years, range 14–88). Main indications were celiac disease (22 %), IBD (35 %) OGIB (27 %). 58 (41 %) of capsules has been correctly retrieved and returned to the Endoscopic Center. The median travel distance was 11.5 km (mean 41.3 km, SD 151.1). Patients travelled with an average of 1.4 transportation means, with a median travel time of 40 minutes (mean 50.8 min, SD 43.3) and a mean travel cost of 12 euros (median 5 euros, SD 16.3). No statistically significant differences emerged between patients who reported VCE and those who did not regarding age, travel distance, means, time, costs or VCE indication. Moderate correlations were observed between travel time, distance, and expenditure. The carbon footprint of retrieved capsules 2.32 kg of CO2.

Conclusions In this study, roughly half of the patients retrieved capsules after VCE due to an environmental motivation, demonstrating a sensitivity regarding this issue. Capsule retrieval after VCE was not associated with differences in demographic or travel parameters. However, substantial travel distances and associated costs underline the importance of addressing logistical barriers to optimize equitable access to diagnostic endoscopy and limitate environmental impact of VCE. Although the carbon footprint of capsules is low, the most important factor is the recylce of rare and environmentally dangerous material. Further research is warranted to evaluate targeted interventions for patient support and service decentralization to improve outcomes and reducing Capsules dispersion.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821262

Aims Capsule endoscopy (CE) enables minimally invasive visualization of the small bowel and is a cornerstone in the evaluation of gastrointestinal bleeding and anemia. Vascular lesions, including red spots and angiectasias, together with blood or haematic residues, provide essential clues regarding the origin, presence, severity and timing of bleeding. Their reliable detection remains difficult due to reader fatigue, interpretative variability and the demanding duration of CE review. Artificial intelligence offers a compelling opportunity to enhance accuracy and efficiency, yet robust real-world multicenter evidence is still scarce.

This study aimed to evaluate the real-life performance of a deep learning convolutional neural network trained to detect both vascular lesions and blood/haematic residues in complete CE studies.

Methods We conducted a prospective, multicenter validation comparing AI-assisted CE reading with conventional interpretation. A total of 423 complete CE videos from three CE systems across ten high-volume centers in Portugal, Spain, Brazil, Australia, Uruguay, and the United States were analyzed. After standard reading (Soc), an independent expert performed AI-assisted review, and discrepancies were adjudicated by a third expert from an external center to establish the reference standard. Diagnostic performance metrics and AUC-ROC were calculated for both strategies. Reading time was evaluated for AI assisted reading.

Results AI-assisted reading identified 213 exams with confirmed vascular lesions, compared with 143 detected by conventional reading. For vascular lesions, AI demonstrated markedly higher sensitivity (94.2 % vs. 63.3 %) but lower specificity (64.5 % vs. 77.3 %). Overall accuracy was higher with AI (89.7 % vs. 76.1 %), and the AUC-ROC was superior (79.4 % vs. 70.3 %). McNemar's test demonstrated a significant difference between methods ($p < 0.05$).

For blood and haematic residue detection, AI outperformed SoC in all metrics. It detected the presence of blood in 38 exams vs 34 in the standard reading. The sensitivity was higher in the AI group (85.0 % in SoC vs 95.0 % in AI) and so was the specificity (96.9 % vs 97.8 %), overall accuracy (95.7 % vs 97.8 %), and AUC-ROC (91.0 % vs 96.4 %).

AI assisted reading reduced the average reading time to 316 seconds per exam.

Conclusions CE interpretation augmented by artificial intelligence significantly improves the detection of vascular lesions and haematic residues, two pivotal elements in the assessment of gastrointestinal bleeding and anemia, while substantially reducing reading time. The use of multiple CE systems strengthens interoperability and the involvement of centers across six countries and three continents enhances generalizability. These findings support the integration of AI tools into CE workflows to elevate diagnostic accuracy, streamline efficiency and reinforce clinical decision-making in patients with suspected or confirmed gastrointestinal bleeding.

Aims Capsule Endoscopy (CE) is a minimally invasive exam that has emerged as a central modality for evaluating small bowel inflammatory disorders, particularly Crohn's disease. Precise identification of ulcers and erosions is fundamental for assessing disease activity, informing therapeutic decisions, and monitoring treatment response. Although CE provides unparalleled visualization of mucosal pathology, manual interpretation remains time-consuming and susceptible to notable interobserver variability. Advances in artificial intelligence, especially convolutional neural networks, now present a timely opportunity to enhance diagnostic accuracy, reduce variability, and improve workflow efficiency. Continued development and rigorous clinical validation are warranted to realize their full potential in routine practice. Our aim is to develop and validate a robust AI model capable of detecting and distinguishing small bowel ulcers and erosions across multiple CE systems and international clinical centers.

Methods We performed a prospective, multicenter study between January 2021 and September 2025, including six centers in Portugal, Spain, Brazil, Uruguay, Australia, and the United States. A total of 423 complete CE examinations were analyzed. AI reports generated by a deep learning model were analyzed by an expert and the AI-assisted report was compared with standard-of-care (SoC) interpretations, using an expert consensus panel as the reference standard. Diagnostic performance was evaluated using sensitivity, specificity, overall accuracy, and area under the receiver operating characteristic curve (AUC-ROC). Reading time was also recorded for the AI-assisted reading.

Results Expert consensus identified ulcers or erosions in 127 patients (30.0 %). Compared with the reference standard, SoC achieved 68.5 % sensitivity, 90.8 %

specificity, and 83.7 % accuracy. AI-assisted reading demonstrated higher sensitivity (88.2 %) with slightly lower specificity (79.7 %), resulting in comparable overall accuracy (82.4 %). The AI model achieved a higher AUC-ROC than SoC (83.9 % vs. 79.6 %). AI identified lesions in 112 patients, outperforming SoC, which detected lesions in 87 patients. These results were consistent across devices and centres. Mean AI-assisted reading time was 318 seconds per exam.

Conclusions The AI-based software improved the detection of small bowel ulcers and erosions compared with standard care, showing higher sensitivity, comparable overall accuracy, and a meaningful reduction in reading time. This validation demonstrates that artificial intelligence can deliver consistent diagnostic performance across different devices and clinical settings while markedly accelerating case review. Shorter reading times have direct implications for clinical scalability, enabling higher throughput, reducing workload, and expanding access to capsule endoscopy in routine practice. These findings support further integration and evaluation of artificial intelligence to optimize endoscopic assessment and strengthen the management of inflammatory bowel disease.

DOI 10.1055/s-0046-1821264

Aims Treat-to-target approaches are a mainstay in Crohn's disease management, with evidence showcasing the benefit of capsule endoscopy driven strategies. Pan-intestinal capsule endoscopy (PCE) allows a minimally invasive evaluation of both the small bowel and colon, potentially improving disease monitoring and therapeutic decision-making. Nevertheless, this approach is hampered by lengthy reading times and observer intervariability. Artificial intelligence (AI), specifically convolutional neural networks (CNNs), have proven their ability for diagnosis of ulcers and erosions and inflammatory activity assessment. This study aimed to develop and validate an interoperable pan-intestinal AI model for detection of ulcers and erosions and determination of their clinical significance according to Saurin classification.

Methods 195,955 frames (132.302 enteric, 63,653 colonic) from 1,585 exams performed in two reference centers between January 2017 and August 2025 were included for model development and testing. Data included exams from six different capsule endoscopy devices. After expert-based consensus, 71,382 frames containing ulcers and erosions were identified and differentiated according to Saurin classification, while the remaining 124 573 frames depicted normal mucosa. The dataset was divided in training / validation and testing sets with a 90 %/10 % patient split design. The model was evaluated using the testing using accuracy, sensitivity and specificity.

Results Normal mucosa was identified with 86.6 % accuracy, 88.2 % sensitivity and 82.4 % specificity. Ulcers and erosions were identified with 86.6 % accuracy, 72.6 % sensitivity and 93.0 % specificity.

When stratifying ulcers and erosions according to their bleeding potential, lesions with uncertain bleeding potential (P1UE) were identified with 85.6 % accuracy, while ulcers with high bleeding potential (P2U) were identified with 98.6 % accuracy.

Conclusions PCE enables a minimally invasive treat-to-target strategy in Crohn's disease. A multidevice AI model demonstrated high accuracy in identifying ulcers and erosions in a pan-intestinal setting, as well as stratifying them according to their clinical significance. Additionally, the pan-intestinal evaluation was performed without the need of segmentating the small bowel and colon, reducing computational requirements and representing another step toward clinical implementation. Further clinical validation studies are before integrating deep learning models into PCE, with the potential to transform patient management in inflammatory bowel disease.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP325 Functional topography of the small bowel: physiologic clustering of lesions and its impact on capsule diagnostic yield

Authors Serio M[1], Ridolfi F[1], Ortolani A[1], Graziosi A[1], Falcioni G[1], Maltoni S[1], Scarcelli A[1]

Institute **1** AST Pesaro Urbino UOC Gastroenterologia ed Endoscopia Digestiva Pesaro – Fano, Pesaro, Italy

DOI 10.1055/s-0046-1821265

Aims Small-bowel capsule endoscopy (SBCE) allows a functional segmentation of the intestine into temporal tertiles (SB1-SB3). Although vascular lesions are often described in proximal and distal regions, the overall topography of small-bowel pathology and its relationship with transit and diagnostic yield remain poorly defined.

Methods This study aimed to characterize the functional distribution of small-bowel lesions and to explore how small-bowel transit time (SBTT) influences diagnostic performance.

We retrospectively reviewed 604 complete SBCEs with measurable gastric (GTT) and small-bowel transit times.

Lesions were classified as vascular, erosive, ulcerative, hemorrhagic, structural, or neoplastic, and localized within SB1–SB3 using standardized text-based mapping.

To assess the relationship between SBTT and diagnostic yield, transit time was stratified into three duration groups (short, intermediate, long) corresponding to the lower, middle, and upper thirds of its distribution. Statistical comparisons used χ^2, Mann–Whitney, and Kruskal–Wallis tests.

Results The cohort had a mean age of 63.7 ± 17.7 years (50.2 % female).

Mean gastric transit time (GTT) was 35.2 ± 24.6 min, showing a mild, non-significant trend toward longer values with age ($p > 0.05$) and no sex-related differences ($p > 0.3$). Mean SBTT was 295.7 ± 118.1 min, increasing significantly with age ($p < 0.01$) and in males ($p < 0.05$).

Vascular, erosive, ulcerative, and hemorrhagic lesions followed a bimodal proximal–distal pattern (all $p < 0.0001$), while structural and neoplastic lesions were evenly distributed.

Overall diagnostic yield was 80 %. Examinations with positive findings had longer SBTT (300.6 vs 276.1 min, $p < 0.05$). The likelihood of detecting relevant lesions increased progressively across the three SBTT duration groups (76.8 %, 77.4 %, and 85.6 %; $p < 0.05$).

Conclusions Functional topography analysis reveals distinct proximal–distal clustering of vascular and inflammatory lesions, suggesting specific pathophysiologic mechanisms along the small-bowel axis. Longer SBTT was associated with higher diagnostic yield, identifying transit time as a potential quality metric in SBCE. These findings support a more physiologic interpretation of capsule studies and may inform strategies to optimize visualization and reporting.

PYP326 Is Capsule Endoscopy Safe in Patients with Cardiac Devices? A Systematic Review and Meta-Analysis

Authors Lei Il[1], Anku E[2], Khalil O[1], Arasaradnam R[1]
Institutes **1** University Hospital Coventry & Warwickshire, Coventry, United Kingdom; **2** Warwick hospital, Warwick UK, United Kingdom
DOI 10.1055/s-0046-1821266

Aims Background The number of patients with cardiac implantable electronic devices (CIEDs) is rising. These individuals are often older, comorbid, and on antiplatelet or anticoagulant therapy, placing them at greater risk of iron deficiency anaemia and gastrointestinal bleeding. Despite two decades of video capsule endoscopy (VCE) use, uncertainty about its safety in CIED carriers persists due to long-standing concerns over electromagnetic interference, limiting access to this valuable diagnostic tool. This study seeks to clarify and reconcile the long-standing disconnect between industry-driven recommendations and the clinical evidence base by synthesising, updating, and critically examining the totality of available data [1–18].

Aim: To assess the safety and diagnostic performance of VCE, among patients with CIEDs being investigated for gastrointestinal bleeding.

Methods A systematic review was conducted using EMBASE, MEDLINE, and PubMed. A random-effects meta-analysis of proportions, using the Freeman–Tukey double arcsine transformation (FTDT), assessed the following: adverse cardiac events, signal interference, and diagnostic yield

Results From 275 publications, 18 studies involving 443 patients were included. Transient CIEDs malfunction occurred in 0.9 % of cases (4/443), with no clinically significant adverse events. The pooled estimate for cardiac malfunction was 0 % (95 % CI: 0–1 %) for Implantable cardioverter–defibrillators (ICDs) and left ventricular assist devices (LVADs), and 0 % (95 % CI: 0–6 %; I^2 = 63 %) for pacemakers (PM). Signal interference affecting video quality was reported in only 1.8 % of patients (8/443), with a pooled rate of 0 % (95 % CI: 0–2 %; I^2 = 0 %). LVADs had a slightly higher interference rate of 1 % (95 % CI: 0–6 %; I^2 = 25 %). The pooled diagnostic yield was 69 % (95 % CI 58–80; I^2 = 55.5 %), a finding that aligns closely with previously published estimates and reinforces the consistency of results across device types (▶ **Table 1**).

Conclusions This meta-analysis demonstrates that VCE can safely be performed in patients with CIEDs, presenting with anaemia or gastrointestinal bleeding. Adverse events and signal interference were rare, with no major adverse events and no significant compromise in diagnostic yield. These findings support review of existing guidelines to improve outcomes for patients with CIEDs, a population at increased risk of gastrointestinal bleeding.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP327 Pan-intestinal capsule is a good FIT in suspected mid-lower gastrointestinal bleeding; interim results of a prospective Irish study

Authors sihag S[1], Sheehan T[1], Micheal D[1], O'grady A[1], Leung E[2], O'Hara F[1], O'donnell S[1], O'connor A[1], Breslin N[1], Ryan B[1], O'Morain N[1], Boyle M[1], McNamara D[3]
Institutes **1** Tallaght University Hospital, Dublin, Ireland; **2** Trinity Academic Gastroenterology Group, Trinity College, Dublin, Ireland; **3** Trinity College Dublin and Tallaght University Hospital, Dublin 24, Ireland
DOI 10.1055/s-0046-1821267

Aims Pan-intestinal capsule endoscopy (PIC) examines both the small bowel and colon noninvasively in a single test. PIC has been proposed as a first line diagnostic examination in the setting of suspected mid-lower gastrointestinal bleeding (MLGIB). as an alternative to performing a colonoscopy first and then a small bowel capsule. MLGIB is defined as those with iron-deficiency anemia (IDA) and either suspected occult (FIT) or overt gastrointestinal bleeding after a nondiagnostic gastroscopy.
Aim to evaluate the efficacy of a PIC first approach in patients with suspected MLGIB.

Methods Following local ethics committee approval consecutive adult patients with IDA and overt or occult GI bleeding were prospectively enrolled. Study participants provided a faecal immunological test (FIT, results expressed in ng/mL) and baseline bloods prior to undergoing a gastroscopy followed by PIC on the same day for outpatients and after a short interval for inpatients. Basic demographics , clinical data , endoscopy and capsule findings were recorded. Key outcomes analysed included diagnostic yield (potential haemorrhagic lesions (PHLs) – small bowel and colon) , safety , capsule performance measures including transit and image quality. Analysis of potential predictors of performance was also performed. Those with hematemesis, fresh anorectal type bleeding, known diagnosis of inflammatory bowel disease, decompensated chronic liver disease, known small bowel disease, those who had undergon gastroscopy or colonoscopy within 1 year, those with any contraindication to capsule endoscopy were excluded.

Results In all 77 patients have been consented to date. Of these 10 did not proceed to either gastroscopy or PIC (2 failed patency capsules ,3 withdrew consent for PIC, 1 declined bowel preparation , 2 have had OGD/Colonoscopy in different institution, 1 lost follow up and 1 patient did not attend for their procedure). A further 21 are awaiting either procedure. A total of 46 have completed both procedures and results are available for analysis in 43 patients.
Of these 36 (84 %) presented with IDA and 7 (16 %) with overt bleeding. Patients had a mean age of 64.8 years (range 32-88), and 24 (56 %) were female. Of these 17/43 (40 %) were receiving blood thinners and use was similar in both overt and occult groups. Mean haemoglobin level = 9.8 g/dL (range 5.6-13.3 g/dL). Haemoglobin levels were similar in overt and occult groups; 8.9g/dL and 9.9g/dL respectively. A FIT was available in 28/36 (78 %) of patients with occult bleeding. The mean FIT was 102 ng/mL (median 13, range 0 – ^{3}1000).
PIC performance was as follows; complete transit rate 67 % (29/43), adequate image quality rate also 67 %(29/43) and 56 % (24/43) had both adequate preparation and complete transit.
PHLs were detected in 21 % (n = 9) of patients; 2/7 (29 %) in the overt group vs 7/36 (19 %) in the occult group, p = 0.6. PHLs were detected in the small bowel in 5 (12 %) patients, (3 angiodysplasias , 1 bleeding jejunal diverticulum and 1 small bowel stricture) and in the colon in 4 (9 %) patients (2 colorectal cancers, 1 large > 2cm polyp and 1 significant radiation proctitis). Of note 15/43 (35 %) required either completion endoscopy or therapeutic endoscopy either to obtain histological diagnosis or treat PHLs.
There was a trend for a higher positivity in older subjects and those on a blood thinner which did not reach statistical significance. There was a moderate correlation between FIT level and positive PIC, r = 0.47, p = 0.01, 95 % CI 0.13-0.71. ROC analysis suggest a FIT level of ^{3} 24 ng/mL, has a sensitivity of 100 % and specificity of 62.5 % with AOC 83 for a positive PIC.

Conclusions Early analysis of our ongoing study of PIC in suspected MLGIB has found a high potential haemorrhagic lesions detection rate (21 %), including colorectal cancer, despite issues with overall performance. PHLs were evenly distributed between the small bowel and colon highlighting the potential benefit of this modality. FIT appears to strongly predict significant disease.

DOI 10.1055/s-0046-1821268

Aims Capsule Endoscopy (CE) provides a minimally invasive technique for comprehensive assessment of the gastrointestinal tract. Protruding lesions are frequent findings with heterogeneous prevalence and clinically relevant implications, yet their consistent detection remains challenging due to the extensive duration of CE studies and the influence of reader fatigue and human error. Artificial intelligence has emerged as a promising strategy to strengthen diagnostic accuracy, although robust real-world evidence supporting its clinical value is still limited. This study assessed the diagnostic performance of a deep learning convolutional neural network software for the identification of protruding lesions in complete CE videos under routine clinical conditions, generating clinical evidence that may inform the responsible integration of AI into CE practice and guide future validation efforts.

Methods Our group conducted a prospective, multicenter validation comparing AI-assisted CE interpretation with conventional reading. A total of 423 CE videos, acquired using three different CE systems across ten centers in Portugal, Spain, Brazil, Uruguay, Australia, and the United States, were included. After the initial standard reading, an independent expert performed AI-assisted review using a CNN specifically trained for small bowel protruding lesion detection. Discrepancies between the two readings were evaluated by a third expert from an external center to establish the reference standard. Diagnostic performance was quantified using sensitivity, specificity, and accuracy.

Results AI-assisted interpretation identified 49 confirmed protruding lesions, compared with 24 detected through conventional reading. Sensitivity was substantially higher with AI (94.2 % vs. 46.2 %), while specificity was lower (79.5 % vs. 93.4 %). McNemar's test demonstrated statistically significant superiority of AI-assisted reading ($p = 0.015$). Additionally, AI support markedly reduced the mean reading time, with a median examination time of 316 seconds per video.

Conclusions AI-assisted review of complete CE studies substantially increases the detection of protruding lesions compared with conventional interpretation, accompanied by only a modest reduction in specificity. The inclusion of data from multiple CE systems addresses interoperability limitations, and the participation of centers from six countries across three continents strengthens the generalizability of the findings. Overall, these results support the real-world clinical applicability of AI in CE and provide a rationale for its integration into diagnostic workflows to enhance performance and efficiency

PYP329 Preliminary Investigation of Capsule Endoscopy Transit Control Using an Ingestible Peristaltic Stimulator

Authors Ohta H[1], Ihara H[2]

Institutes **1** Sapporo Orthopaedics and Cardiovascular Hospital, Sapporo, Japan; **2** Sapporo Orthopaedic and Cardiovascular Hospital, Kiyota Ward Sapporo Japan, Sapporo, Japan

DOI 10.1055/s-0046-1821269

Problem to solve Control of capsule endoscopy (CE) movement remains challenging despite recent advances in magnetic navigation. Prolonged gastrointestinal (GI) transit time often limits complete examination, particularly in patients with reduced GI motility.

Innovation An ingestible peristaltic stimulator (PS) may facilitate active propulsion of the capsule.

(1) Electrical and pressure thresholds required to induce peristalsis in the terminal ileum and colon were measured during colonoscopy in 10 healthy volunteers (5 men, 5 women).(2) Two PS-CE prototypes (pressure-based and electrical) were evaluated in 5 patients after written informed consent. The PS balloon was automatically inflated or electrically activated at preset intervals during CE progression. Small-bowel transit time (SBTT) and large-bowel transit time (LBTT) were recorded.

Results Pressure-based stimulation required 75 ± 13 mmHg to induce peristalsis, whereas electrical stimulation required only 5 ± 3 µA, achievable with a coin battery or wireless power transfer. Peristaltic propagation averaged approximately 3 cm/s, and stimulation cycles were set below 0.2 Hz to respect the refractory period of Auerbach's plexus.With PS assistance, SBTT was reduced from 207 ± 37 min to 46 ± 16 min, and LBTT from 684 ± 232 min to 37 ± 12 min.

Although preliminary, electrical stimulation demonstrated markedly lower activation thresholds than pressure-based stimulation. Transit times are influenced by preparation quality and patient characteristics; thus, larger studies with matched controls and statistical validation are required. Development of wireless-powered PS devices without an onboard battery may further improve safety.

Conclusions An ingestible electrical peristaltic stimulator appears feasible and may substantially shorten CE transit time. Further controlled trials are needed to establish safety, efficacy, and clinical utility.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821270

Aims Benign esophageal stricture dilation can be achieved by different methods, yet their environmental impact has not been compared and the clinical efficacy of the bougie cap (BC) device is not well known. This study evaluated the BC dilatation technic in terms of feasibility, effectiveness and safety, and compared its waste generation and carbon footprint to reusable bougie and single-use hydrostatic balloon dilatation, using life cycle assessment (LCA).

Methods We conducted a multicenter study on a prospectively maintained cohort of patients. Consecutive adult patients with dysphagia secondary to an esophageal benign stricture, requiring endoscopic management in a French tertiary center, were screened for inclusion.

The primary endpoint was the technical success of the BC dilatation. This was defined as the successful passing of the stricture using the BC technic only. Technical failure was defined as the need for a rescue technic (reusable bougie or balloon) and/or the inability to pass the stricture at the end of the procedure. The secondary endpoints were the number of dilatations per patient, adverse events and symptoms 3 months after the last endoscopy. The cradle-to-grave LCA was conducted according to ISO 14040/44 by and independant expert company (Apesa).

Results Between January 2022 and September 2025, 125 patients with BC dilatation for benign esophageal stricture were included. Amongst the study population, 51 patients were men (40.8 %) and the mean age was 61.6 years (+/- 17.3). Regarding the clinical presentation, 98 patients (78.4 %) had dysphagia to solids, 8 (6.4 %) had dysphagia to liquids, 6 had aphagia (4.8 %) and 4 (3.2 %) were asymptomatic. The mean follow-up was 7.8 months (+/- 9.7). Eight patients (6.4 %) died during follow up.

The type of stricture was iatrogenic in 54 patients (43.2 %), inflammatory in 47 patients (37.6 %), thermal in 11 patients (8.8 %) and caustic in 6 patients (4.8 %). The underlying cause was endoscopic treatment (mucosectomy, endoscopic submucosal dissection) in 27 patients (21.6 %), peptic in 23 patients (18.4 %), anastomotic in 17 patients (13.6 %).

A total of 299 dilatations were performed (26 of which for a 2nd stricture in a same patient). Successful initial dilatation was achieved in 264 cases (88.3 %). Rescue dilatation with a balloon was required in 28 cases (9.4 %). All rescue dilatations succeeded. Final dilatation was achieved successfully in 292 cases (97.7 %). Data was missing in 7 cases. The mean number of BC dilatation per patient was 2.1. Adverse events occurred in 11 cases (3.7 %), amongst which 3

perforations (1 %) were noted. Three months after the last endoscopic dilatation, 101 patients (80.8 %) experienced no symptoms.
Single-use balloon dilation generated 427 grams (g) of equipment and approximatively 20 ml of contrast agent and water. Bougie dilation generated 50 g of waste for the packaging of peracetic acid bottle and use 170 ml of peracetic acid and 5 l of controlled tap water. BC generated 1 to 4 g of plastic (depending of the size) and 1 g of packaging waste. The respective carbon footprint for the different strategies were 0.06 and 0.63 kg CO2e for the BC without and with guidewire, 1.35 kg CO2e for the reusable bougie (with guidewire) and 3.49 kg CO2e for the single use balloon dilation (with guidewire).
Conclusions In this multicenter study including 125 patients (299 dilatations) with benign esophageal stricture, the technical success of bougiecap dilatation was achieved in 88.3 % of cases with an adverse events rate of 3.7 %. Life cycle assessment revealed stark differences in the environmental impact between dilatation techniques, with the bougie cap strategy being the less impacting.

DOI 10.1055/s-0046-1821271
Aims Capsule endoscopy (CE) is a useful modality to investigate the small bowel (SB). Since its invention in 2001, several iterations and prototypes have been developed[1]. Pillcam Genius is a new technology where the data recorder has been replaced entirely with a link device which is placed on the patients' abdomen. This allows the patient to post the link device back containing the data and hasten reaching a diagnosis. We conducted a pilot study to assess the utility of this new technology and acceptability of patients [1].
Methods This was a prospective multicentre site study of patients having Pillcam Genius. Demographic data and blood parameters, findings at CE and diagnosis, and follow-up data were collated.
Results A total of 30 patients from 4 sites in the United Kingdom, France, Italy and Germany underwent SB investigation with PillCam Genius from September 1^{rst}, 2025 to November 28th, 2025. The median age was 72.5 years (52.0 -80.0) with 57 % of females. The commonest indications were overt gastrointestinal (GI) bleeding (40 %) and iron deficiency anaemia (IDA) (37 %), and Crohn's disease (17 %). All procedures but one were completed (97 %), with no cases of CE retention. About half (53 %) of the CE were done in an outpatient setting, the remaining ones as inpatients.
In the 23 patients with suspected SB bleeding (overt and IDA), the median age was 76 years (57-83) and median ASA score was 2.5 (2-3). The diagnostic yield for P1 and P2 lesions was 57 %, while for P2 lesions only was 22 %. Management was altered in 26 % (5-23), with suggested enteroscopy in 22 % (4 patients) and starting treatment with somatostatin analogues in 4 % (1 patient).
In patients with overt GI bleeding, the diagnostic yield for P1 and P2 lesions was 33 %, while for P2 lesions only was 17 %. The median time of CE from presentation of overt bleeding was 6.5 days (4.5-15). The mean small bowel transit was 4h30m (SD 2h06m). One patient had a rebleeding episode at 7 days, all other 11 patients did not have any rebleeding episodes at 7 days or at follow-up. The median follow-up time was 21 days (9-28).
All patients tolerated Pillcam Genius well and were satisfied with the minimalist technology.
Conclusions The pilot study has demonstrated that Pillcam Genius is a good addition to the current technology of CE with a high diagnostic yield. It has the potential to reduce travel burden of the patient and hence reduce carbon emissions. It also has the potential to offer a hub and spoke service to smaller and more remote hospitals which do not have a CE service and reduce time to diagnosis particularly with large referral centres covering wide catchment areas.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP332 Opportunities to reduce the environmental impact of endoscopy: a detailed material flow analysis of diagnostic colonoscopy

Authors Izci CB[1], Clercx Lao MS[2], Vegting B[1], Siersema PD[1], Tietschert MV[3], Hunfeld NGM[4, 5], Diehl JC[2], De Jonge PJF[1]
Institutes **1** Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; **2** TU Delft Faculty of Industrial Design Engineering, Design for Sustainability, Delft, Netherlands; **3** Erasmus University Rotterdam, Erasmus School of Health Policy & Management, Rotterdam, Netherlands; **4** Erasmus University Medical Center, Department of Adult Intensive Care, Rotterdam, Netherlands; **5** Erasmus University Medical Center, Department of Hospital Pharmacy, Rotterdam, Netherlands
DOI 10.1055/s-0046-1821272
Aims Gastrointestinal endoscopy is the third largest contributor to hospitals' environmental footprint. Colonoscopy, among the most performed endoscopic procedures, is considered to have a significant environmental footprint, yet the exact impact is unknown. We analyzed the material flow of diagnostic colonoscopy procedures and identified opportunities for reducing their environmental impact.
Methods A single-center material flow analysis (MFA) was conducted during a normal work week with diagnostic colonoscopy procedures. Waste was collected, weighted, and categorized by product type. The material composition was identified. Using visual mapping, we identified which products were used and disposed of at each stage of the procedure.
Results Fifteen diagnostic colonoscopy procedures were audited. Mean total waste mass of a colonoscopy procedure was 0.58 ± 0.01 kg, with a mean of 46 products per procedure. This equals an average waste mass of 1169 kg for all diagnostic colonoscopy procedures performed annually in this hospital. Plastic-based products constituted the largest product category (22.67 %). Nitrile made up the largest material category (14.1 % of the total weight of materials). The total estimated carbon footprint for all analyzed waste was 1.77 kgCO_2e, with nitrile and polypropylene (PP) being the largest contributors.
Most products were used and disposed in the preparation stage of the colonoscopy procedure.
Conclusions Plastic-based materials formed the largest contributor to the total used product weight, with nitrile being the most frequently used material type (14.1 %). These findings inform decision-makers in designing targeted interventions to reduce the environmental impact of diagnostic colonoscopy, for example by considering more sustainable materials such as fiber-based materials. The prepared visual map makes waste generation discussable among healthcare professionals, thereby supporting a collaborative approach to identify sustainable opportunities.

PYP333 Reducing the energy consumption of endoscope drying: a comparison of two drying methods

Authors Izci CB[1], Van Der Ploeg K[2], Vegting B[3], De Jonge PJF[3], Tietschert MV[4], Hunfeld NGM[5, 6], Diehl JC[7], Siersema PD[3]
Institutes **1** Erasmus University Medical Center, Rotterdam, Netherlands; **2** Eramsus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; **3** Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; **4** Erasmus University Rotterdam, Erasmus School of Health Policy & Management, Rotterdam, Netherlands; **5** Erasmus University Medical Center, Department of Adult Intensive Care, Rotterdam, Netherlands; **6** Erasmus University Medical Center, Department of Hospital Pharmacy, Rotterdam, Netherlands; **7** TU Delft Faculty of Industrial Design Engineering, Design for Sustainability, Delft, Netherlands
DOI 10.1055/s-0046-1821273

Aims Energy consumption is a major contributor of endoscopy department's environmental impact. A significant portion of the energy consumption comes from the reprocessing of reusable endoscopes, however, data on the amount of electricity used for drying endoscopes is limited. We measured and compared the energy consumption of conventional drying cabinets and a novel automated drying process, the PlasmaTYPHOON (Pentax medical), that dries endoscopes within 1 to 3 minutes. Our aim was to understand the environmental impact of both drying processes and to evaluate if the PlasmaTYPHOON could contribute to the reduction of carbon footprint and costs.

Methods Energy consumption of conventional drying cabinets and the automated drying process were measured for one week, using a Voltcraft SEM500 energy measurement device. Measurements were conducted on a 24/7 basis, capturing both active operation and standby power consumption. To assess workflow implications and material use, a Product Journey Map (PJM) analysis was performed, documenting all process steps, task durations, staffing requirements, and consumables for each of the two drying methods.

Results The automated drying process required 34.5 times less energy per endoscope than conventional drying cabinets: drying a single endoscope in a drying cabinet consumed 1.08 kWh, whereas the automated drying process used 0.03 kWh. Over one week, the automated drying process died 109 endoscopes compared with 25 endoscopes dried in the drying cabinets.

Using grey electricity, the nine drying cabinets at Erasmus MC generate an estimated 6,257 kg CO_2 annually, whereas the automated drying process accounts for only 88 kg CO_2 per year. The reduction in energy use also resulted in 71 times lower energy costs annually, 3777 euros for the drying cabinets and 53 euros for the automated drying process. PJM analysis demonstrated that the automated drying process required 3 times more workflow steps, 5 additional consumables, and an extra staff person to manage the drying cycle. However, consumable-related environmental impact to incinerate was little compared with reduced environmental impact caused by energy savings.

Conclusions The automated drying process substantially reduces the energy consumption of endoscope drying while enabling higher throughput. Although the automated drying process introduces additional workflow steps and requires additional consumables, its net environmental benefits remain substantial due to reduced energy consumption. Optimizing workflow integration and reducing consumable use may further strengthen the sustainability advantages of this novel technology.

DOI 10.1055/s-0046-1821274

Aims The growing number of gastrointestinal endoscopic procedures is associated with increasing risk of equipment damage, with consequences for workflow efficiency, scheduling, and hospital costs. The distal end of flexible endoscopes is particularly vulnerable during transport and handling, and even minor trauma can cause substantial downtime and expensive repairs. Proper handling is known to reduce preventable damage, and distal-tip protection devices offer an additional safeguard by shielding the endoscope tip during storage and transfer. In April 2025, our center introduced a single-use tip protector (Bumper, Vytill, France; unit cost 2.2 €). This study evaluated the operational and economic impact of its routine implementation, comparing institutional activity before and after its introduction.

Methods We conducted a retrospective analysis comparing two periods: April–September 2024 (no tip protection) and April–September 2025 (universal use of tip protection on all gastroscopes, colonoscopes, duodenoscopes, and EUS scopes). Institutional maintenance and activity records were reviewed to extract the total number of procedures, downtime days, repair events, and repair-related costs for each period. For 2025, the total expenditure on single-use tip protectors was calculated as 2.2 € per procedure. Outcomes were expressed as cumulative values and rates per procedure. Primary endpoints were changes in repair frequency, downtime, and total financial impact after inclusion of protection costs.

Results A total of 2,105 procedures were performed in 2024 and 2,654 in 2025. Downtime decreased from 579 days in 2024 to 303 days in 2025, a reduction of 276 days (48 %). Repair events decreased from 12 to 4 (74 % reduction), corresponding to a drop in repair rate from 0.57 % to 0.15 % of procedures. Repair-related costs fell markedly from 17,987 € in 2024 to 943 € in 2025, yielding 17,044 € in direct savings (95 % reduction).The cost of the protection program in 2025 was 5,839 €. After incorporating this expenditure, the overall net saving was 11,205 €.Cost per procedure decreased from 8.55 € in 2024 (repairs only) to 2.56 € in 2025 (repairs + protection), representing a 70 % relative reduction. The incremental cost-effectiveness ratio showed a net saving of 40.6 € per downtime day avoided.

Conclusions Routine application of a distal-tip protector led to a major reduction in repair events, instrument downtime, and repair-associated costs. The intervention remained strongly cost-saving, improving both operational continuity and economic efficiency. These results support systematic distal-tip protection as an effective and inexpensive measure to preserve endoscope integrity and optimize resource utilization.

DOI 10.1055/s-0046-1821275

Aims Due to the increasing shortage of physicians, the proportion of internationally recruited professionals in gastroenterology in Germany is rising. At the same time, physicians with a migration background repeatedly report hostility, discrimination and racism. Systematic data on the impact of these aspects on work-related well-being are still limited. This study aimed to assess the prevalence and impact of hostility and discrimination on occupational-related well-being among gastroenterologists in Germany [1–14].

Methods We conducted an anonymous online cross-sectional survey among gastroenterologists working in Germany (June–July 2025). Sociodemographic and professional characteristics, migration experience, frequency and burden of hostility from various actor groups and work-related well-being were recorded using a shortened German version of the ''Thriving from Work'' questionnaire.

Results 430 individuals completed the questionnaire (response rate 10.4 %); 32 % reported a migration background (19 % first generation). In the past 24 months, 91.6 % of participants with and 90.3 % without a migration background reported at least one experience of hostility; a job change due to hostility was reported significantly more often by individuals with a migration background (20.6 % vs. 5.7 %). In the regression model (adjusted $R^2 = 0.49$), older age ($\beta = 0.08$; $p < 0.05$) and first-generation migration background ($\beta = 1.84$; $p = 0.03$) were associated with higher work-related well-being. Conversely, higher burden from hostility ($\beta = -10.42$; $p < 0.001$), cumulative hostility experiences ($\beta = -0.22$; $p < 0.001$) and lower knowledge of coping strategies ($\beta = -0.98$; $p < 0.05$) predicted lower well-being.

Conclusions Hostility is a widespread problem in the daily work of gastroenterologists in Germany and is closely linked to work-related well-being. Despite higher exposure, first-generation migrant physicians report comparatively higher well-being. Clinics and practices have a clear mandate to establish structural prevention and support measures to reduce discrimination and strengthen the retention of an increasingly international medical workforce. Endoscopy units could represent a particularly vulnerable setting, as physicians are exposed to high procedural demands, time pressure and complex patient interactions. These conditions may amplify the impact of hostility and discrimination on professional well-being and team dynamics. While the general problem of workplace hostility in gastroenterology is beginning to be recognized, specific data on endoscopy units remain limited, therefore further targeted research is needed to better understand the prevalence, mechanisms and consequences of hostility in this environment, but also to offer structural prevention and support measures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP336 Simulation-Based Training for Endoscopy Nurses Improves Device-to-Field Time: A Prospective Study

Authors Kanberg N[1], Atieh H[2], Sharba S[3], Al-Hammada Y[3], Tayfour R[4], Alhakmani N[4], Alnamaani K[4], Al-Dury S[4, 5, 6]

Institutes **1** Department of bioMedicine, Infectious Diseases Clinic, University of Gothenburg, Gothenburg, Sweden; **2** Department of Medicine, Medical City Hospital for Military and Security Services, Muscat, Oman; **3** Institution of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; **4** Department of Gastroenterology, Medical City Hospital for Military and Security Services, muscat, Oman; **5** School of Public Health and Community Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; **6** Muscat Endosocpy Academy, Endoscopy Unit – Medical City for Military & Security Services, Muscat, Oman

DOI 10.1055/s-0046-1821276

Aims Assistant performance is pivotal to endoscopy efficiency, yet nurse training is often informal. We evaluated whether structured simulation plus theory improves nurse-dependent workflow.

Methods Prospective, parallel-group study of 20 endoscopy nurses allocated 1:1 to Simulation + Theory (training) or Control. Each nurse assisted 10 live procedures (5 gastroscopies, 5 colonoscopies; 200 observations) with the same endoscopist. The prespecified mix included diagnostic biopsies, dilation, cold-snare polypectomy (CSP), hot-snare polypectomy (HSP), endoscopic mucosal resection (EMR), and endoscopic submucosal dissection (ESD); EMR/ESD com-

plexity used the Size-Morphology-Site-Access (SMSA) score. The primary outcome was device-to-field time (DTF; seconds). Secondary outcomes were micro-tasks (exchange, injection, balloon, hemostasis, generator change, retrieval). We summarized medians [range] and fit regression models on log DTF with nurse-clustered standard errors, adjusting for case index, procedure type, age, experience, mentor presence, and SMSA. Learning windows were cases 1–3, 4–6, and 7–10; a difference-in-differences contrast compared pre/post case 4.

Results Groups were similar at baseline (cases 1–3). From case 4 onward, the training group was faster and remained so through case 10. The adjusted post-training effect corresponded to a time ratio of 0.81 (95 % CI 0.80–0.83; $p < 0.001$). Improvements were consistent across procedures and largest for EMR/ESD; secondary micro-tasks showed similar patterns [1–6].

Conclusions A brief Simulation + Theory program produced rapid, durable gains in nurse device readiness, independent of seniority. Embedding structured nurse training in endoscopy services may enhance efficiency and support expanding therapeutic workloads.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP337 Muscle activation, muscular overuse and perceived exertion in upper GI endoscopy in a clinical setting: comparison of single-use and reusable gastroscopes using wearable EMG sensors

Authors Schlicht F[1], Melzer A[1, 2], Bessone V[3], Seufferlein T[2], Walter B[1, 2]

Institutes **1** Endoscopic Research Unit, Ulm, Germany; **2** Clinic for Internal Medicine I, Gastroenterology, University Hospital Ulm, Ulm, Germany; **3** Research and Development, Ambu Innovation GmbH, Augsburg, Germany

DOI 10.1055/s-0046-1821277

Aims Musculoskeletal strain is a major occupational burden in gastrointestinal endoscopy, with many endoscopists developing work-related overuse injuries during their careers. Even with this high prevalence, real-time data on muscular exertion during clinical procedures remain limited to date. This study analysed muscular activity and rate of perceived exertion (RPE) while performing EGD with single-use and reusable gastroscopes under matched conditions.

Methods Two trained endoscopists (m/f) performed a total of 16 EGDs. For each endoscopist, four single-use (aScope Gastro, Ambu A/S) procedures were matched to four reusable (GIF-HQ190, Olympus) procedures based on similar ASGE complexity levels and comparable procedure durations. A wearable multi-sensor electromyographic shirt (ErgoShirt, Myontec Ltd.; sampling rate 1000 Hz) was used to record real-time muscle activation of the endoscopists while performing the procedures. Perceived exertion was assessed immediately after each procedure using the Borg scale (ranging between 6 and 20, e.g. 9: "very light",16: „very very hard"). To obtain the muscle load, data was processed using MATLAB (Mathworks), with descriptive analysis.

Results The average duration of the procedures was 7 minutes, with an average ASGE complexity of 2 for the procedures performed by the male physician and of 1 for the ones of the female endoscopist, The male physician reported a mean RPE of 9 ("very light") when using the single-use vs. 11("light") for reusable procedures. The female examiner reported a mean RPE of 9 for single-use versus 10 for reusable. EMG analysis supported these findings: with reusable gastroscopes, muscle activation was classified more in overload and risk zones relatively to the procedure duration compared to single-use scopes.

Conclusions This preliminary study demonstrated a relevant exertion within endoscopy procedures and an ergonomic advantage of lighter single-use gastroscopes by reduced muscular exertion and lower perceived workload. They data lead to the conclusion that lighter scopes as single-use gastroscopes may help mitigate long-term musculoskeletal strain in endoscopists.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP338 Ergonomic Evaluation of Muscle Load During Simulated Endoscopic Submucosal Dissection: Comparison Between Single-use and Reusable Gastroscopes

Authors Yamamoto H[1, 2], Bessone V[3], Goto M[1, 2], Endo M[1], Owaki Y[1], Okamoto R[1, 2], Yamazaki T[1, 2], Watanabe T[1], Minakata N[1], Yamashita H[1, 2], Sunakawa H[1, 4], Yano T[1, 4]

DOI 10.1055/s-0046-1821278

Aims Musculoskeletal injuries (MSI) are prevalent among gastrointestinal (GI) endoscopists due to prolonged static postures during procedures such as endoscopic submucosal dissection (ESD). Maintaining such postures and repetitive movements with the endoscope increases muscle strain and fatigue, particularly in the upper limbs and back. We have previously reported that lighter endoscopes may mitigate these risks by reducing muscle activation and fatigue. Single-use endoscopes, being lighter than reusable ones, could therefore benefit endoscopists during lengthy procedures like ESD. This study aimed to compare muscle activation when using single-use versus reusable gastroscopes during simulated ESD procedures.

Methods Ten experienced endoscopists (one female; age 37 ± 6 years; experience 9 ± 6 years) performed simulated ESDs using a single-use and a reusable gastroscope in an ESD-training model (G-Master). G-Master was employed to standardize task conditions among participants. Participants performed four ESD tasks (10-minute easy and a 20-minute complex ESD task using both gastroscopes) in randomized order, with a 15-minute break between scopes and a 2-minute interval between tasks for model setup. Muscle activity was recorded during the simulated ESDs using a validated ErgoShirt (Myontec) equipped with surface electromyography (sEMG) sensors measuring activation of major upper body muscles. To calibrate the sEMG sensors, the maximal voluntary contraction (MVC) was carried out by performing two sets of specific movements, for a minimum of five seconds each muscle. After performing each of the four simulated ESDs, the rate of perceived exertion (RPE) was verbally expressed by the participant to quantify exercise intensity using the Borg scale ranging between 6 and 20 (Borg, 1998) . sEMG data were analyzed using Muscle Monitor Software (Myontec) and processed in MATLAB (MathWorks) to calculate muscle load (%MVC) as the normalized percentage of each muscle's MVC. Muscle load was categorized into five threshold zones (rest, healthy load, overload, high overload, and at-risk) based on magnitude and risk, as defined by the ErgoLink software linked to the ErgoShirt system. Data was reported

using the mean and standard deviation, and analyzed using paired t-tests, with statistical significance set at $P < 0.05$.

Results The RPE was 12 ± 2 ("light" to "somewhat hard") for the easy task with both gastroscopes. During the complex task, the RPE increased to 13 ± 2 ("somewhat hard") with the single-use gastroscope and 14 ± 1 ("somewhat hard" to "hard") with the reusable gastroscope. The single-use gastroscope showed a statistically significant reduction in RPE during the complex task ($p < 0.05$), but not in the easy task. sEMG data from the right arm were excluded due to interference from high-frequency instruments, and data from the trunk muscles were unavailable because of undershirt wore by the participatns or calibration issues. Among the recorded muscles, significant differences were found only in the triceps and biceps, both showing lower average %MVC values when using the single-use gastroscope, particularly in the triceps during both tasks and in the biceps during the easy task ($p < 0.05$). The left wrist flexors and biceps spent a higher proportion of time in the "rest" and "healthy load" zones with the single-use device compared to the reusable one (easy: 71 % vs. 65 %; complex: 69 % vs. 57 %). Triceps and deltoids remained mostly in the healthy range for all conditions. Significant positive correlations were observed between RPE and the %MVC of triceps and deltoids. Muscle activation over time revealed greater wrist flexor overload in the second half of tasks for both scopes, indicating progressive fatigue.

Conclusions This study is the first to quantify muscle load during simulated ESD using wearable surface electromyography. The single-use gastroscope was associated with a significantly lower rating of perceived exertion during complex tasks, indicating a potential ergonomic advantage under prolonged procedural conditions. Among all monitored muscles, only the triceps and biceps showed statistically differences between the two gastroscopes, with consistently lower triceps activation when using the single-use endoscope. In conclusion, the use of lightweight gastroscopes may alleviate physical strain during lengthy or complex procedures, thereby contributing to the prevention of work-related musculoskeletal injuries.

PYP339 Audit of tissue sampling in chronic diarrhoea: a green endoscopy initiative

Authors Harrison A[1], Leung E[1, 2], Mullen D[1], McNamara D[3], O'Morain N[1]
Institutes **1** Tallaght University Hospital, Dublin, Ireland; **2** Trinity Academic Gastroenterology Group, Trinity College, Dublin, Ireland; **3** Trinity College Dublin and Tallaght University Hospital, Dublin 24, Ireland
DOI 10.1055/s-0046-1821279

Aims The healthcare sector contributes significantly to carbon emissions, which leads to devastating impacts on the environment [1] and on human health. It is our responsibility to promote sustainable work practices, and reduce carbon emissions where possible, without negatively impacting on the quality of patient care. Chronic diarrhoea is a common indication for lower GI endoscopy. In a macroscopically normal appearing colon, current practice is to take biopsies to assess for microscopic colitis (MIC), looking for histological changes of lymphocyte infiltration or a collagenous subepithelial band. This is a relatively uncommon condition, but with increasing prevalence [2]. ESGE guidelines suggest biopsies should be taken from the right and left side of the colon and sent to pathology in separate containers [3]. While based on expert histopathological opinion, this recommendation was not supported by robust evidence. We have previously demonstrated 100 % sensitivity for MIC with a right sided biopsy protocol in a multicentre retrospective review [4]. Our local histopathologists confirmed there is no diagnostic benefit in separating left and right specimens for this indication. We reviewed our biopsy practice and assessed potential reductions in carbon emissions that could result from a change in practice.

Methods Patients referred for colonoscopy to investigate chronic diarrhoea (January–March 2024) were identified. Cases with a macroscopically normal colon were isolated. Biopsy practice for the assessment of microscopic colitis was analysed, including the number of biopsies taken, location biopsied and the total number of histopathology containers sent to the laboratory. Findings were compared with current ESGE guidelines. A previous time motion assessment had been completed in our lab to calculate the total staff time per container [4]. Data on CO2 emissions generated by processing each histopathological sample was estimated based on previous studies. From this, we assessed the potential reduction in carbon emissions with adherence to the current ESGE guidelines and then compared to our proposal; that all biopsies could be inserted into the one container.

Results A total of 205 colonoscopies were performed for chronic diarrhoea during the study period. Patients with a history of IBD, or poor prep requiring repeat procedure (43 %, n = 89) were excluded. A total of 351 containers were sent to pathology, a mean number of was 3.02 per case, and a range of 0-7. The recommended right and left biopsies were sent in 20 (18.8 %) of cases, with a single pot of random colon biopsies sent in 5 cases (4.7 %). Biopsies were taken from a macroscopically normal terminal ileum in 51 cases (48.1 %). No cases of microscopic colitis were confirmed. Time-motion assessment found the mean total staff time per biopsy container was 8 min 37s, resulting in time savings of 2.6 working days for laboratory staff per year, if we reduced to a single container. The carbon emissions resulting from analysis of colon biopsies is 0.29 kg CO_2 equivalent (CO_2e) per container [5], producing CO_2e of 407.26kg/year with current practice. Adherence to ESGE Guidelines would produce savings of 138.04 CO_2e or 272.6kg CO_2e if a single container protocol was adopted – annual savings of 1090.4KgCo_2e or the equivalent of 4467km driven by a petrol-powered vehicle [6].

Conclusions Auditing adherence to biopsy guidelines can result in significant reductions in inappropriate sampling and container use, leading to significant improvements in Co2e and workload. The use of a single container protocol can further reduce carbon emissions while investigating for MIC. We found no cases of MIC in our study, but discovered that endoscopists took many more than the recommended number of biopsies. This included at the terminal ileum, taken in nearly half of cases, without any additional diagnostic benefit. We propose that right and left colon biopsies should be collected in a single container, to further decrease carbon emissions and the burden on histopathology [7].

PYP340 Dual-Loop Assisted Endoscopic Full-Thickness Resection versus Conventional Endoscopic Full-Thickness Resection for Gastric Subepithelial Tumors

Authors Liao S[1], Huang S[2], Xiao Y[2], Zhou B[3]
Institutes **1** South China Hospital, Medical School, Shenzhen University, Shenzhen, China; **2** South China Hospital, Medical School, Shenzhen University. No 1 Fuxin Road, Longgang District, Shenzhen, China; **3** Bao'an Central Hospital.118 Longjing Road, Xin'an Street Bao'an District, Shenzhen, China
DOI 10.1055/s-0046-1821280

Aims While conventional endoscopic full-thickness resection (C-EFTR) can completely remove gastric subepithelial lesions (SELs) originating from the muscularis propria or with predominant extraluminal growth, operating on lesions in "difficult locations" such as the gastric fundus, fornix, and lesser curvature of the gastric body is often challenging due to difficult endoscopic positioning. Double-loop ligation endoscopic full-thickness resection (DL-EFTR) creates a pseudo-pedunculated, polyp-like morphology by applying double loops at the lesion base using a ligation device, theoretically reducing technical difficulty and resection time. This study is the first multicenter retrospective cohort comparison of the clinical efficacy and economic differences between DL-EFTR and C-EFTR for gastric SELs ≤ 15 mm.

Methods Patients with gastric SELs who underwent DL-EFTR or C-EFTR between March 2023 and September 2025 at South China Hospital, Shenzhen University, and Shenzhen Baoan Central Hospital were included. All procedures were performed by senior endoscopists, and the study was approved by the ethics committee. A 1:1 propensity score matching (PSM) was performed using gender, age, lesion size, location, and pathological type as covariates. After balancing baseline characteristics, operative time, technical success rate, complete resection rate, postoperative nasogastric tube placement rate, hospital stay, and costs were compared between the two groups.

Results Sixty-six patients (22 DL-EFTR, 44 C-EFTR) were initially analyzed. After PSM, 13 patients remained in each group, with no significant differences in baseline characteristics. The median operative time was significantly shorter in the DL-EFTR group (28.5 min vs. 49.0 min, $P < 0.05$). The technical success and complete resection rates were 100 % in both groups. Significantly fewer patients in the DL-EFTR group required postoperative nasogastric tube placement (2 cases, 15.4 %) compared to the C-EFTR group (9 cases, 69.2 %) ($P < 0.05$). No significant difference was found in hospital stay (6.4 ± 3.0 d vs. 6.6 ± 1.6 d, $P > 0.05$). Both procedure costs and total hospitalization costs were significantly lower in the DL-EFTR group (all $P < 0.05$). No severe complications, such as intraoperative perforation, hemorrhage, or delayed bleeding, occurred in either group.

Conclusions For gastric SELs ≤ 15 mm, DL-EFTR ensures complete resection while significantly shortening operative time, reducing the need for nasogastric tube placement, and lowering medical costs, representing a safe, economical, and easily promotable innovative endoscopic technique. Limited by its retrospective design, prospective, large-sample, randomized controlled trials are needed to further validate its long-term efficacy and safety.

PYP341 Duodenal Adenoma EMR: Demonstrating good safety profile and resection outcomes, and high prevalence of synchronous colorectal cancers

Authors Shojaie P[1], Hassan L[1], Mushtaq K[2], Boger P[3], Rahman I[3], Duarte P[1], Patel P[3], Glover B[1]
Institutes **1** Southampton General Hospital, Southampton, United Kingdom; **2** University Hospital Southampton, Southampton, United Kingdom; **3** Southampton Interventional Endoscopy Unit, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom
DOI 10.1055/s-0046-1821281

Aims Endoscopic resection by mucosal resection (EMR) is the ESGE-recommended therapy for treatment of non-ampullary duodenal adenomas. Other important aspects of management include surveillance for recurrence, and colonic evaluation. While procedural outcomes from EMR are established, the application of follow-up and surveillance is less clear. We reviewed a decade of practice to benchmark local outcomes against guidelines and identify pathway improvement opportunities within our tertiary endoscopy referral centre.

Methods Ten year retrospective evaluation of all non-ampullary duodenal adenomas ≥ 10 mm resected between 2014–2024. Data were obtained from electronic patient records and endoscopy procedure databases. Procedural safety, recurrence, and adherence to ESGE surveillance pathways and colonic evaluation guidance were assessed, including comparisons before and after the 2021 ESGE guideline update.

Results A total of 78 adenomas in 64 patients were resected by EMR within the evaluation period. Of these, 44 patients had sporadic adenomas and the remainder a polyposis syndrome (16 FAP, 3 Peutz-Jaeghers, 1 MUTYH). In the adenoma group, en-bloc resection was achieved in 28/78 (35.9 %). Margins were R0 in 17/78 (21.8 %), R1 4/78 (5.1 %), and Rx 57/78 (73.1 %), reflecting use of piecemeal EMR.

Delayed bleeding occurred in 3/78 (3.8 %), and perforation in 0 patients. All of the bleeding events occurred in adenomas ≥ 30 mm ($p = 0.006$), suggesting a size-dependent risk. Clip closure was performed in 26/78 (33.3 %) and haemostatic forceps and / or topical haemostatic agent in 17/78 (21.8 %).

Endoscopic surveillance after index treatment was variable with 44/64 (68.8 %) patients undergoing first surveillance within one year. Residual adenoma was found in 6/64 (9.4 %) patients which were treated endoscopically. Persistent residual adenoma was seen at second follow in one patient which was cleared successfully with no recurrence on subsequent examinations. Residual rates were higher for patients with adenomas ≥ 30mm (23.1 % v 4.6 %, $p = 0.023$).

With regards to colonic surveillance algorithms; of those with sporadic adenoma, colonic evaluation was completed in 27/44 (61.4 %). Of these, 5/44 (11.4 %) cases of synchronous colorectal cancer were identified.

Conclusions EMR is highlighted in our evaluation as a safe and effective technique in our institution for the management of non-ampullary duodenal adenomas. Low bleeding rates can be achieved with selective use on a case-by-case basis of adjunctive prophylactic techniques. There are important learning points from our evaluation regarding historical deviation from current ESGE guidelines.

Surveillance programs after resection have followed different intervals to the current recommended standards introduced in the 2021 guidance. Given significant rates of residual disease in those with resection of larger adenomas (≥ 30 mm), adherence to these guidelines is important. Residual disease can then be treated successfully with good outcomes as demonstrated in our data.

The ESGE guidance recommends performance of a colonoscopy in cases of duodenal adenoma. The importance of this is highlighted in our study by findings of high rates of synchronous colorectal cancer in our cohort in those without polyposis syndromes. Despite this, a significant proportion of patients did not have any colonic evaluation suggesting the need for standardised local pathways to optimise adherence with guidelines.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP342 Efficacy of Gel immersion ESD including papilla for superficial duodenal epithelial tumors

Authors Dohi O[1], Uehara T[1], Obata R[2], Yumoto J[1], Ochiai T[1], Mukai H[1], Seya M[1], Kobayashi R[1], Yasuda T[1], Inoue K[1], Yoshida N[1], Uchiyama K[1], Takagi T[1]

Institutes **1** University Hospital, Kyoto Prefectural University of Medicine, Kyoto, Japan; **2** University Hospital, Kyoto Prefectural University of Medicine, Kyoto, Japan, Kyoto, Japan

DOI 10.1055/s-0046-1821282

Aims Endoscopic submucosal dissection including the papilla (ESDIP) for superficial duodenal epithelial tumors (SDETs) is minimally invasive but technically challenging due to the complex local anatomy and exposure to bile and pancreatic juice. SDETs involving the papilla are not a general indication for laparoscopic endoscopic cooperative surgery because they are directly adjacent to the pancreas. To overcome these difficulties, we introduced gel immersion ESDIP (GI-ESDIP) in 2022. This study aimed to compare the clinical outcomes of GI-ESDIP with those of conventional ESDIP (C-ESDIP).

Methods We retrospectively analyzed 29 consecutive ESDIP cases performed at our institution between January 2016 and October 2025. All procedures were performed using a scissor-type knife, with prophylactic biliary and pancreatic stent placement and attempted complete closure of the mucosal defect. Clinical characteristics, procedural outcomes, and adverse events were compared between the C-ESDIP group (n = 13, 2016–2022) and the GI-ESDIP group (n = 16, 2022–2025).

Results Baseline characteristics were comparable between groups. Median lesion size was not significantly different (37 vs. 31.5 mm, P = 0.357). Median procedure time was significantly shorter in the GI-ESDIP group (58 vs. 101 min, P = 0.020). En bloc resection was achieved in 100 % of cases in both groups, and R0 resection rates were similar (76.2 % vs. 87.5 %, P = 0.632). The median number of intraoperative bleeding points was significantly lower in the GI-ESDIP group (4 vs. 8, P = 0.004). No intraoperative perforation occurred in either group. Muscularis propria exposure tended to be lower in the GI-ESDIP group (0 % vs. 23.1 %, P = 0.078). Delayed adverse events were comparable (7.7 % vs. 12.5 %), with one delayed perforation in each group, and one delayed bleeding and one cholangitis in the GI-ESDIP group. No pancreatitis occurred. One local recurrence was observed in the GI-ESDIP group and one metastatic recurrence in the C-ESDIP group.

Conclusions GI-ESDIP appears to reduce intraoperative bleeding and shorten procedure time, likely due to its stable visual field, buoyancy-assisted tissue elevation, and maintenance of a low intraluminal pressure environment. These findings suggest that gel immersion may enhance the safety and efficiency of papilla-involving duodenal ESD.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP343 The role of endoscopic treatment for advanced duodenal adenomas in patients with familial adenomatous polyposis: a long-term single-center experience

Authors Benedicenti F[1], Cavalcoli F[1], Borsotti E[1], Rosa R[1], Magarotto A[1], Pugliese D[1], Cantù P[1]

Institute **1** Gastroenterology and Endoscopy Unit, IRCCS Foundation National Cancer Institute, Milan, Italy

DOI 10.1055/s-0046-1821283

Aims Patients with familial adenomatous polyposis (FAP) develop duodenal adenomatous polyps, whose risk of malignant progression increases with advancing Spigelman stage. However, prophylactic duodenal surgery carries substantial morbidity and mortality.

This study aimed to evaluate the efficacy and safety of endoscopic treatment in FAP patients classified as Spigelman stages III-IV.

Methods A retrospective analysis was conducted on patients who underwent endoscopic duodenal surveillance and treatment at a tertiary referral center between 2013 and 2025. Cold-snare polypectomy (CSP) and endoscopic mucosal resection (EMR) were the resection techniques employed. Data were collected on patient characteristics, polyp features, endoscopic procedures, histological findings, and Spigelman stage and score.

Results Between 2013 and 2025, 1035 EGDs were performed in 247 patients (55 % male, median age 47 years, IQR 33-57) at out center, with a median follow-up of 84 months (IQR 49-115). Duodenal non-ampullary adenomas were detected in 130 patients (52.6 %). Their Spigelman stage distribution was: 31 (23.8 %) stage I, 44 (33.9 %) stage II, 22 (16.9 %) stage III, and 33 (25.4 %) stage IV.

Among patients with advanced Spigelman stages, thirty-five (74 % male, median age 53 years, IQR 40-60), 17 classified as stage IV and 18 as stage III, underwent endoscopic treatment for duodenal polyps. During a median follow-up of 32 months (IQR 17–90), 268 polyps were resected in 122 endoscopic procedures (57 % CSP). The median polyp size was 10 mm (IQR 7-10.5), 76.5 % of resected polyps were located in the descending duodenum, and 17.5 % harbored high-grade dysplasia. After therapeutic work-up, 69 % of patients achieved downstaging of baseline Spigelman stage (p < 0.001). The median Spigelman score decreased from 8 (IQR 8–9) to 6 (IQR 5–8) (p < 0.001), while the proportion of patients with high-grade dysplasia declined from 74.3 % to 5.7 % (p < 0.001). Kaplan-Meier analysis showed median times to re-progression and re-treatment after the first endoscopic treatment of 42 and 45 months, respectively.

No major adverse events occured. One patient required surgery for multiple high-grade dysplasia adenomas not amenable to endoscopic resection, and no duodenal cancer were observed during the study period.

Conclusions Endoscopic treatment proved to be safe and effective in downstaging both Spigelman score/stage and histological dysplasia severity, thereby reducing the need for prophylactic surgery in FAP patients with advanced duodenal disease. Given the risk of re-progression in this setting, multiple endoscopic resections are often required to achieve long-term disease control.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP344 Minor Papillary Adenoma Resection and long-term outcomes

Authors Kerrison C[1], Van Crevel J[2], De Haan B[2], Fritzsche JA[3], Gupta S[4], Lam B[1], Lee EYT[1], Burgess N[1], Williams SJ[5], Michael J B[1]

Institutes **1** Westmead Hospital, Westmead, Australia; **2** Amsterdam UMC, locatie AMC, Amsterdam, Netherlands; **3** Amsterdam UMC, location University of Amsterdam, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands; **4** St. Michael's Hospital, Toronto, Canada; **5** Westm, westm, Australia

DOI 10.1055/s-0046-1821284

Aims Adenomas of the minor papilla are difficult to diagnose and are uncommon. However, they are pre-malignant and require removal. Data on endoscopic papillectomy (EP) for removal of these lesions is limited. We aimed to evaluate the effectiveness, safety, and long-term outcomes of endoscopic minor papillectomy.

Methods A retrospective analysis of endoscopic papillectomy (EP) procedures was conducted at a single tertiary center over a 164-month period to November 2024. Patients who underwent minor EP were included and descriptively compared with major EP cases to explore differences in clinical features, safety, and long-term follow-up.

Results Among 215 patients who underwent EP, 10 with minor papillary adenomas were included. Of the remaining 205 major papilla lesions, 162 were non-malignant adenomas and were used for descriptive comparison. Identification of minor papilla lesions was inconsistent: 3(30 %) were referred as major papilla lesions, 3(30 %) as duodenal polyps, and 4(40 %) specifically as minor papilla lesions. The minor papilla cohort had a mean age of 67, with 6 patients (60 %) being female. Most lesions were of sporadic origin (90 %). Compared to major papillary adenomas, minor papillary lesions were similar in size (median

Endoscopy 2026; 58: S1–S1041

20 mm; p = 0.256), and had a similar EP procedure time (69 min vs 60 min; p = 0.68). Adverse events were minimal: two patients (20 %) had delayed bleeding not requiring intervention, and one (10 %) had post-EP pancreatitis, comparable to major EP. Median follow-up was 22 months (IQR 6–33), with two recurrences, both managed successfully with cold avulsion with snare tip soft coagulation (CAST). Three cases with pancreatic divisum were resected successfully with minimal adverse events and no recurrence. No patients required surgery or developed malignancy during follow-up.

Conclusions Minor papilla adenomas have similar characteristics as the major papilla. They can be safely and effectively removed endoscopically. Even in the setting of pancreatic divisum, adverse events are infrequent.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP345 Immediate recognition and endoscopic closure of duodenal perforations: the key to therapeutic success. Twenty years of experience in a specialist centre

Authors Zekir E[1], Gasmi M[2], Barthet M[2], Gonzalez JM[1]
Institutes **1** Hôpital nord, Marseille, France; **2** Hospital Nord, Marseille, France
DOI 10.1055/s-0046-1821285

Aims Duodenal perforation is a rare but serious complication of digestive endoscopy, associated with significant morbidity and mortality.
Traditionally treated surgically, its management now tends towards endoscopic approaches thanks to the development of advanced closure devices. Nevertheless, specific data on duodenal perforations remain limited and prognostic factors poorly defined.

Methods We conducted a single-centre retrospective study including all patients who presented with iatrogenic duodenal perforation of type Stapfer I or II during diagnostic or therapeutic endoscopy between November 2004 and December 2023. Demographic, clinical, endoscopic and evolutionary data were collected. The primary endpoint was the clinical success of endoscopic treatment, defined as complete healing without the need for surgery. Secondary endpoints included initial technical success, clinical success after a single procedure, and the impact of the time to diagnosis (immediate vs. delayed) and the type of endoscopy (diagnostic vs. therapeutic).

Results Thirty-five patients (mean age 65.5 ± 12.6 years; 51.4 % women) were included. Perforation occurred during ERCP (40 %), EUS (31.4 %),
EGD (20 %) or duodenoscopy (8.6 %). The mechanism was related to a therapeutic manoeuvre in 68.6 % of cases, and the most common location was the second duodenum (62.9 %), of which 72.7 % were periampullary. Perforation was identified intra-procedurally in 82.9 % of cases. The initial technical success rate of endoscopic treatment was 90.3 %, reaching 100 % after repeat procedures. Overall clinical success was achieved in 71.4 % of cases, including 60 % after a single session, with a median healing time of 5 days [2–107]. Salvage surgery was necessary in 28.6 % of patients. Overall mortality was 8.6 %. Immediate diagnosis was associated with better outcomes: more frequent clinical success after one procedure (69.0 % vs. 16.7 %; p = 0.028), shorter hospital stay (12.0 ± 14.1 vs. 79.2 ± 60.9 days; p = 0.001) and fewer intensive care admissions (10.3 % vs. 50 %; p = 0.049). Perforations occurring during endoscopy were associated with a higher rate of reoperation (34.7 % vs. 16.7 %; p = 0.001) and a longer hospital stay (12.0 ± 14.1 vs. 79.2 ± 60.9 days; p = 0.001).
0.001) and less need for intensive care (10.3 % vs. 50 %; p = 0.049). Perforations occurring during therapeutic endoscopy required more endoscopic procedures (3.3 vs. 1.3; p = 0.048).

Conclusions Endoscopy enables effective management of iatrogenic duodenal perforations, with clinical success in over 70 % of cases and a reduction in the need for surgery. Immediate recognition of the perforation is a major prognostic factor, significantly improving the outcome. The development of advanced closure devices reinforces the role of the endoscopic approach, but comparative studies are needed to define the optimal strategy and choice of equipment.

PYP346V Loop assisted underwater resection of a large duodenal lipoma: An unexpected culprit behind upper gastrointestinal bleeding

Authors Sierra Morales M[1], Santos Rodríguez A[1], García Centeno P[1], Bartolomé Oterino I[1], Redondo Evangelista S[1], Flandes Iparraguirre A[1], García Martin N[1], Gala Moreno I[1], Castellá Bataller L[1], Tabernero Da Veiga S[1]
Institute **1** Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain
DOI 10.1055/s-0046-1821286

Abstract Text

A 68-year-old woman presented with abdominal pain and melena. Urgent OGD revealed an ulcerated pedunculated subepithelial duodenal lesion, and CT/EUS confirmed a 50-mm lipoma causing intussusception. Endoscopic treatment was performed by placing an endoloop at its base and resecting most of the lesion with a 20-mm snare. Both steps were performed underwater, which provided better lesion positioning and safety, given its proximity to the duodenal walls. Histology confirmed a benign lipoma. Different strategies have been described to be safe and effective for the endoscopic treatment of gastrointestinal lipomas, including loop-and-let-go, but spontaneous detachment posed a high obstruction risk in this case. Combining loop placement with underwater resection allowed for a safe, single-session treatment also allowing histological analysis [1–4].

PYP347 Recurrence after endoscopic papillectomy for papillary adenoma: risk factors and long-term treatment outcomes

Authors Kerrison C[1], Van Crevel J[2], Sakiris A[3], Fritzsche JA[4], Gupta S[5], Lam B[1], Mandarino FV[6], Lee EYT[1], Williams SJ[7], Burgess N[1], Michael J B[1]

DOI 10.1055/s-0046-1821287

Aims Endoscopic papillectomy (EP) for papillary adenoma is effective but is compromised by recurrence rates exceeding 20 %. Data on managing recurrence is scant. We evaluated risk factors for recurrence and its management.

Methods Patients with histologically confirmed major papilla adenomas treated by EP at a tertiary center over 164 months to November 2024 were included. Residual or recurrent adenoma (RRA) was defined histologically. Treatments included hot snare excision and cold avulsion with snare tip soft coagulation(-CAST). Margin thermal ablation(MTA) using snare tip soft coagulation(STSC)

was used at index EP from 2020. Success was defined as negative endoscopic and histologic biopsy at the EP site during follow-up.

Results Inclusion criteria were met by 166/215 EP cases. Surveillance endoscopy was performed in 162(97.6 %), with RRA observed in 39 (24.1 %). Multivariable logistic regression identified larger lesion size(OR 1.041/1mm;p = 0.0239), intraductal extension(OR 3.919;p = 0.010), and familial adenomatous polyposis (FAP)(OR 6.60;p = 0.0029) as risk factors for RRA. MTA was protective (OR 0.229;p = 0.0203). RRA treatment was performed in 37/39 (94.6 %). Intraductal recurrence was excluded as a specialised subgroup. 31 patients were treated for RRA with hot snare or CAST + /- MTA. In 28 patients with median follow-up 22months, 25(89.3 %) were cured. Adverse events were pancreatitis 2 and delayed bleed 1. No patient required surgical treatment for RRA.

Conclusions After EP for papillary adenoma, RRA occurs in 24 %. Risk factors include lesion size, intraductal extension and FAP. MTA reduces the risk of RRA. Endoscopic treatment of RRA is safe, effective and durable.

PYP348 Prophylactic EUS-guided gastroenterostomy during circumferential duodenal and ampullary resection: a case report

Authors Palmeri E[1, 2], Poortmans PJ[1, 3, 4], Coevoet D[1], Argenziano ME[1, 3], Sorge A[1], Montori M[5, 1], Debels L[4], Desomer L[6, 1], Hindryckx P[3, 1], Tate D[3, 1]

DOI 10.1055/s-0046-1821288

Background Endoscopic resection of circumferential duodenal adenomas carries high stricture risk. We report prophylactic EUS-guided gastroenterostomy (EUS-GE) using a lumen-apposing metal stent (LAMS) performed during circumferential ampullectomy to maintain oral intake throughout the anticipated stricture formation and resolution phase.

Case A 53-year-old woman presented with dyspepsia. Endoscopy revealed a 50mm circumferential non-granular laterally spreading duodenal lesion involving the ampulla (Paris 0-IIa + Is, JNET 2A). MRCP and CT excluded intraductal extension and metastases. Piecemeal EMR with en bloc ampullectomy was performed. Biliary (8 × 60mm fully-covered metal stent) and pancreatic (7Fr × 5cm plastic) stents were placed. Given near-certain post-resection stricture, prophylactic EUS-GE was performed during the same session: a 20 × 10mm LAMS was deployed between the gastric antrum and jejunum under EUS and fluoroscopic guidance. This approach was chosen to reduce procedure burden and ensure uninterrupted oral intake during stricture management. Intraprocedural bleeding was controlled with soft coagulation and hemostatic gel. Mild post-ERCP pancreatitis resolved conservatively.

Outcome Histology confirmed tubulovillous adenoma with focal high-grade dysplasia. Over 22 months, the patient required seven balloon dilations (6–15mm) for duodenal stricture but maintained oral intake throughout via the gastroenterostomy. Two small residual adenoma foci were treated with cold snare polypectomy. No recurrence at last follow-up.

Conclusion Prophylactic EUS-GE during high-risk circumferential duodenal resection maintains quality of life by preserving oral intake during stricture management, reduces overall procedure burden, and avoids pancreaticoduodenectomy.

DOI 10.1055/s-0046-1821289

Aims Duodenal endoscopic mucosal resection (EMR) has a high risk of bleeding. In a historical consecutive series of duodenal EMR in our hospital we found in 13/34 cases (38 %) active bleeding or high-risk stigma of bleeding (visible vessel after removal of a blood clot) on next day gastroscopy (EGD). Prophylactic application of a haemostatic gel (3D-Matrix 621-062) to the EMR field may be an easy way to prevent delayed bleeding[1].

The aim of the study was to assess the efficacy of 3D-Matrix 621-062 in reducing delayed bleeding following duodenal EMR.

Methods We conducted a single-arm, multicenter observational trial of patients undergoing hot-snare EMR of duodenal non-ampullary lesions of ≥ 10 mm. Following EMR, 3D-Matrix 621-062 was applied directly to the EMR defect. The next day, an EGD was performed to detect active bleeding or high-risk stigma of bleeding (visible vessel after removal of a blood clot).

We hypothesized a 50 % decrease in bleeding stigma from 38 to 19 %; sample size was calculated for power of 90 % and Alpha of 0.05. The number of subjects to be enrolled was 59 patients.

Results From October 2020 until August 2025, 59 patients from 5 different centers were included. Mean lesion size was 21.73 mm. 3D-Matrix 621-062 application was feasible in all patients. On EGD the next day, active bleeding (10 patients; 17 %) or visible vessel after removal of a blood clot (6 patients; 10 %) was seen in 16 patients (27 %) (Fisher's exact P = 0.35, NS). During hospital stay, melena and hematemesis were observed in respectively 4 (7 %) and 1 patient (2 %). Hypotension was not observed. Treatment by placement of a hemoclip was performed in only 9 patients (15 %) and relevant blood loss of ≥ 1 g/dL was seen in 3 patients (5 %).

Conclusions Application of 3D-Matrix 621-062 following duodenal EMR did not significantly decrease the rate of bleeding or bleeding stigmata on next day EGD in comparison to a historical cohort.

Ospedali Civico Di Cristina Benfratelli, Palermo, Italy

DOI 10.1055/s-0046-1821290

Aims Randomized controlled trials (RCTs) comparing computer-aided detection (CADe) systems with standard high-definition colonoscopy exhibit marked variability in adenoma detection rate (ADR) across control (non-AI) arms. Since baseline ADR directly determines the magnitude of the apparent benefit of CADe, understanding the sources of variability in human ADR is essential for interpreting AI-assisted performance. This study aimed to quantify the pooled ADR of control arms in CADe RCTs and to identify the study-level factors explaining its heterogeneity through meta-regression (▶ **Table 1**).

▶ **Table 1** Meta-regression analysis investigating study-level factors associated with ADR.

Covariates	Number of studies	Beta coefficient ± SE	Adjusted R^2 (%)	P value
Age	42	1.017 ± 0.002	67.0	< 0.001
Sex (male)	42	1.006 ± 0.002	15.3	0.005
Region	42	0.887 ± 0.039	20.9	0.009
Study design (Monocentric vs Multicentric)	42	1.089 ± 0.050	7.0	0.070
Analysis (PP vs ITT)	42	0.950 ± 0.048	-1.0	0.320
Setting (screening/ surveillance vs diagnostic)	41	0.865 ± 0.037	26.8	0.001
Screening population ≥ 50 %	38	1.035 ± 0.048	-0.6	0.466
Endoscopist training level	40	1.012 ± 0.030	-3.3	0.698
Baseline ADR	11	1.490 ± 0.163	89.7	0.005
Withdrawal time	41	1.030 ± 0.005	61.2	< 0.001

Abbreviations: SE = Standard Error; R^2 = Relative reduction in between-study variance: the value indicates the proportion of between study variance explained by covariate.

Methods We included all control groups from RCTs comparing standard colonoscopy with any CADe platform. The primary outcome was pooled ADR, calculated using a random-effects model. Secondary outcomes included polyp detection rate (PDR) and adenoma miss rate (AMR). Heterogeneity was quantified using the inconsistency index (I^2). Mixed-effects meta-regression explored associations between ADR and predefined moderators including patient age, sex, geographic region, study design, clinical setting, endoscopist experience, baseline ADR, and withdrawal time.

Results Forty-two control arms were analyzed. The pooled ADR was 0.35 (95 % CI, 0.30–0.41), with considerable heterogeneity (I^2 = 96.8 %). The pooled PDR was 0.50 (95 % CI, 0.44–0.55), while the pooled AMR was 0.37 (95 % CI, 0.33–0.40), again with considerable heterogeneity (I^2 = 97.0 %). Meta-regression demonstrated that age (p < 0.001), male sex proportion (p = 0.005), geographic region (p = 0.009), clinical setting (p = 0.001), baseline ADR (p = 0.005), and withdrawal time (p < 0.001) were the strongest predictors of variability in human ADR. In selected models, these covariates explained up to 89.7 % of the between-study variance.

Conclusions ADR in standard colonoscopy arms of CADe RCTs is highly heterogeneous, reflecting demographic, contextual, and procedural quality differences across studies. This extreme baseline variability substantially shapes the observed effect size of CADe systems, highlighting the need to contextualize AI performance against the intrinsic variability of human detection.

DOI 10.1055/s-0046-1821291

Aims Computer-aided detection (CADe) has been shown to improve outcomes in randomized trials. However, most studies occurred in controlled environments where endoscopists are aware of being monitored, potentially influencing performance and limiting real-world applicability. Our aim was to assess the impact of CADe in routine multicentre practice, with endoscopists unaware that their performance was being evaluated and serving as their own controls.

Methods Prospective multicentre study across 13 units (March–September 2025) including adults aged ≥ 40 years undergoing colonoscopy. All six endoscopists executed procedures both in a centre where CADe use is compulsory and in others without CADe, unaware that their CADe and nonCADe performance was being compared. The primary outcome was adenoma detection rate (ADR). Secondary outcomes included combined adenoma plus clinically significant serrated polyp detection (A + CSSPDR), polyp detection (PDR), proximal neoplasia detection (PNDR), diminutive polyp detection (DPDR) and serrated detection rate (SDR).

Results Of 3161 eligible procedures, 2973 were analysed (947 CADe; 2026 non-CADe). ADR was higher with CADe (34.4 % vs 30.7 %; p < 0.05). A + CSSPDR (40.3 % vs 35.8 %; p < 0.05), PDR, PNDR and DPDR were also significantly higher, while SDR showed a non-significant positive trend. CADe remained independently associated with higher ADR (aOR 1.31, 95 %CI 1.11–1.55; p = 0.002) and A + CSSPDR (aOR 1.33, 95 %CI 1.13–1.56; p = 0.001) after adjusting for age, sex and indication; the magnitude of effect was attenuated once endoscopist-level adjustment was applied.

Conclusions In real-world practice, with fully blinded conditions, CADe improves detection of adenomas and clinically relevant serrated lesions, though the effect varies between endoscopists. This underscores its utility while reflecting operator-driven variability.

Aims Barrier healing is emerging as a key therapeutic target in Inflammatory bowel disease (IBD), being more closely associated with sustained remission and improved long-term outcomes than endoscopic and histological remission alone. Accurate assessment of barrier integrity is therefore crucial to optimise disease management. Probe-based confocal laser endomicroscopy (pCLE) enables real-time structural and functional assessment of intestinal barrier. However, its interpretation remains complex and highly operator-dependent, limiting its reproducibility and widespread application. Preliminary studies have demonstrated the feasibility of using automated assessment of specific pCLE features to predict therapeutic response [1]. We aimed to develop and validate an artificial intelligence (AI)-driven pCLE system for standardised, objective assessment of barrier impairment (BI) in IBD.

Methods 156 high-quality pCLE videos from IBD patients undergoing colonoscopy in Ireland and UK were considered. Experienced endoscopists assessed the presence of BI according to a previously developed pCLE-scoring system [2], providing a reference standard for AI. An AI algorithm was developed to predict pCLE-based BI using a weakly supervised learning paradigm that exclusively employs video-level scoring. Frame-level features were extracted with ViT pretrained under DINOv2 self-supervised learning framework [3] and transformer-based architecture [4] aggregated these into a global video representation. A linear layer classifier with two output neurons generated the final video-level BI score. A total of 105 videos were used for training and validation of the framework, while 51 were reserved for testing. The model's ability to predict overall, epithelial, and vascular BI was evaluated. Diagnostic performance was expressed as sensitivity, specificity, accuracy, positive predictive value, negative predictive value, and F1 score.

Results Overall, 48 IBD patients (28 CD and 20 UC) were considered. 119/156 (76 %) videos showed BI, 68/101 (67 %) in Ireland and 51/55 (93 %) in the UK cohort. ▶ **Table 1** details the diagnostic performance of the model. The AI algorithm achieved 77 % sensitivity, 75 % specificity, and 77 % accuracy in detecting overall BI at the video level. Moreover, the model assessed the presence of epithelial and vascular BI with 70 % and 85 % sensitivity, 72 % and 77 % specificity, 71 % and 82 % accuracy. Diagnostic performance was higher in UC than CD.

Conclusions Our AI model enables automated and standardised assessment of intestinal impairment in IBD, offering an objective and reproducible tool to monitor barrier healing as a novel therapeutic endpoint.

DOI 10.1055/s-0046-1821293

Aims Intestinal ultrasound (IUS) is increasingly used for real-time assessment of inflammatory bowel disease (IBD) but quantitative analysis with artificial intelligence (AI) remains limited to bowel wall thickness (BWT) and single-frame segmentation, failing to exploit the temporal information in cineloops (CLs). The aim here was to evaluate the accuracy of an AI model compared to expert central readers using IUS CLs.

Methods We developed a novel model using a semi-supervised algorithm combined with a temporal module, trained on 680,000 IUS images from 1572 CLs (327 patients from multiple centres). 1205 frames from 403 CLs on 94 patients were labelled by 8 domain experts (203 validation, 1002 training images). The CLs had various segments per patient with active IBD, and included axial, longitudinal and oblique sections. An external test set (27 patients, 58 CLs) of active Crohn's patients (ascending, transverse, descending colon), centrally read by 3 expert readers, was used for initial evaluation. The model was optimized to segment 9 categories including bowel wall (BW), psoas, iliac vessels (IV), and inflamed mesentery (IM). Each output was based on a current frame and context representations from previous frames. The model continuously segments and tracks anatomy, generating temporally coherent delineations and data that feed intra- and inter-frame measurement algorithms. On the validation set, we calculated the Dice similarity coefficient (DSC), an overlap-based metric, from the expert annotations. Intraclass correlation coefficient (ICC) scores from ground truth measurements were made for every labelled image.

Results Qualitative evaluation by domain experts confirmed consistency and anatomical precision of the outputs across a range of bowel regions and disease activity. Quantitatively, on the validation set our model achieved DSC of 0.73 [0.70 – 0.75], 0.26 [0.23 – 0.28], 0.62 [0.55 – 0.68], 0.63 [0.53 – 0.72], 0.72 [0.64 – 0.79] and 0.41 [0.32 – 0.49] for BW, peritoneal lining, rectus, psoas, IV and IM. Based on BW segmentations, the measurement algorithm achieved an ICC of 0.83 [0.77 – 0.87] between predictions and per frame expert measurements. On the external test dataset, the ICC between an aggregated AI-driven measurement per CL and the mean of all reader measurements was 0.83 [0.73 – 0.9].

Conclusions Unlike prior approaches focused on static frames or derived BWT estimation, this method preserves frame-to-frame continuity, enabling reproducible analysis of CLs with no manual pre-selection of measurement areas. Our model provides identification of many anatomical structures in addition to BWT, essential to moving AI beyond this measure and towards fully automated disease activity monitoring.

PYP354 Retrospective Benchmarking of CAD EYE and ColoMAIA-2 Using Delay-Based Sensitivity and False-Alarm Metrics

Authors Kral J[1, 2], Knotkova K[3], Hradis M[4], Musil P[4], Svoboda P[4], Svet J[3, 5]
Institutes **1** Dept of Internal Medicine,University Hospital Motol, Second Faculty of Medicine,Charles Univ, Prague, Czech Republic; **2** Medic Kral Ltd., Gastroenterology Center, Prague, Czech Republic; **3** Motol University Hospital, Prague, Czech Republic; **4** MAIA LABS s.r.o., Brno, Czech Republic; **5** Medic Kral Ltd, Gastroenterology Center, Prague, Czech Republic
DOI 10.1055/s-0046-1821294

Aims To establish objective metrics for retrospective CADe evaluation and use them to directly compare Fujifilm CAD EYE with Maia Labs ColoMAIA-2 on identical colonoscopy recordings.

Methods This retrospective single-center study analyzed video data from 150 colorectal cancer screening colonoscopies (1945 minutes) performed by three expert endoscopists (>10 years' experience). A total of 189 clinically significant polyps were identified in the recordings. CAD EYE operated in real time during procedures, while ColoMAIA-2 was applied offline. Outcome measures included: 1) detection delay from first polyp appearance; 2) delay-specific sensitivities at 100–5000 ms; 3) False alarms, expressed as false detections per minute; 4) percentage of video time with false alarms. False alarms were assessed only during active mucosal inspection (excluding polyp examinations and polypectomies). Bootstrap resampling was used to compute confidence intervals and p-values.

Results Across all short delays, ColoMAIA-2 achieved substantially higher sensitivity than CAD EYE. At 100 ms, sensitivity was 47.6 % vs. 16.9 %; at 200 ms, 67.2 % vs. 33.9 %; at 300 ms, 78.8 % vs. 45.5 %. At the clinically meaningful 500-ms delay, ColoMAIA-2 reached a sensitivity 86.8 % (CI 81.5–91.5) compared with 62.4 % (CI 55.6–69.3) for CAD EYE ($p<0.001$). Mean detection delay was significantly shorter with ColoMAIA-2 (382 ms, CI 260–522) than with CAD EYE (814 ms, CI 650–985; $p<0.001$). False-alarm frequency differed markedly. ColoMAIA-2 generated only 3.09 false alarms/min and 1.44 % false-alarm time (all $p<0.001$), whereas CAD EYE produced 37.4 false alarms/min and 4.67 % of video time with false alarms. This represents roughly a twelve-fold reduction in individual false-alarm events. Qualitatively, CAD EYE produced a large number of false alarms in the presence of specific stool residue and blood.

Conclusions In identical colonoscopy recordings, ColoMAIA-2 delivered markedly faster polyp alerting and dramatically fewer false alarms compared with CAD EYE. These differences concern parameters known to influence adenoma detection and procedural flow. The proposed metrics (delay-specific sensitivities, false-alarms) provide a robust framework for clinically meaningful retrospective benchmarking of CADe systems.

PYP355 Endoscopic submucosal dissection in the colon after completion of the learning curve – a single-center analysis of factors associated with therapeutic failure and complications

Authors Drzewiecki J[1, 2], Jagielski M[1]
Institutes **1** Department of General, Gastroenterological and Oncological Surgery, Toruń, Poland; **2** I Department of Internal Medicine and Gastroenterology. Provincial Integrated Hospital, Elblag, Poland
DOI 10.1055/s-0046-1821295

Aims To identify factors associated with therapeutic failure and complications after colorectal ESD in a single-center cohort covering the period after completion of the operator's learning curve.

Methods Retrospective analysis of 212 consecutive patients (2019–2022). Endpoints included therapeutic success (R0/Rx), adverse events according to the Clavien–Dindo classification, and potential predictors (pre-procedural bi-

opsy, hybrid resection technique [h-ESD], Paris classification, lesion size). The data derive from our own clinical series.

Results En bloc resection was achieved in 93.87 %, R0 in 91.04 %, and therapeutic success in 91.04 %; complications occurred in 8.02 % (bleeding 2.36 %, perforation 3.30 %). In univariable models, lack of success was more frequently associated with pre-procedural biopsy (OR 3.29; p = 0.0168) and h-ESD (OR 8.31; p = 0.0025). In the bivariable model, biopsy (OR 3.18; p = 0.024) and h-ESD (p = 0.0045) remained significant. Lesion size did not significantly affect efficacy (p = 0.116), but correlated with the risk of complications; higher risk was observed, among others, for Paris classification 0-IIa-Is.

Conclusions After completion of the learning curve, ESD provides high efficacy and acceptable safety also in a non-academic center. Avoiding routine biopsy before planned ESD and striving for full ESD (without hybrid resection) may increase the rate of radical resections and reduce complications.

PYP356 Impact of Comprehensive Artificial Intelligence Monitoring of Withdrawal Time and Bowel Preparation Quality on Adenoma Detection Rate

Authors Byeon JS[1], Lee JY[1], Park K[1], Kim N[1]
Institute 1 Asan Medical Center, Seoul, Republic of Korea
DOI 10.1055/s-0046-1821296

Aims Accurately measuring the actual observation time (AOT), excluding biopsy or polypectomy time, remains a challenge during colonoscopy. Bowel preparation is another critical factor affecting the quality of colonoscopy. We aimed to evaluate the impact of comprehensive artificial intelligence (AI)-based monitoring of AOT and bowel preparation on adenoma detection rate (ADR).

Methods We developed an AI model that comprehensively assesses both withdrawal time and bowel preparation quality simultaneously. We validated the performance of the AI model by analyzing a total of 1,489 consecutive colonoscopy videos. The AI model assessed both crude withdrawal time (CWT), defined as the time from cecal intubation to anal withdrawal, and AOT. Each was classified into four groups: < 6 min, 6–9 min, 9–12 min, and ≥ 12 min. Bowel preparation was classified as adequate or inadequate. Colonoscopy quality indicators such as ADR and adenomas per colonoscopy (APC) were compared across combined categories of AOT and preparation status.

Results The mean age of the 1,489 patients was 60.9 ± 12.9 years, and 71.1 % were male. As both CWT and AOT increased, the ADR increased significantly. ADR increased from 6.6 % in patients with CWT < 6 min to 71.2 % in those with CWT ≥ 12 min (p < 0.001), and from 11.3 % in patients with AOT < 6 min to 70.2 % in those with AOT ≥ 12 min (p < 0.001). ADR was significantly higher in the 6–9 min AOT group than in the 6–9 min CWT group (23.5 % vs. 16.5 %, p = 0.005). Advanced ADR was also significantly higher in the 6–9 min AOT group than in the 6–9 min CWT group. In addition, APC was significantly greater in the 6–9 min AOT group than in the 6–9 min CWT group (0.33 [95 % confidence interval (CI) 0.27 – 0.39] vs. 0.19 [95 % CI 0.15 – 0.22], p = 0.002). The ADR was significantly higher in the AI-assessed adequate preparation group than in the inadequate preparation group (41.1 % vs. 31.0 %, p = 0.001). APC was also significantly higher in the AI-assessed adequate preparation group. In the integrated analysis, the odds ratio (95 % CI) for ADR were 2.76 (1.67–4.79) with adequate preparation and AOT < 9 min, 8.53 (4.91–15.46) with inadequate preparation and AOT ≥ 9 min, and 12.07 (7.4–20.76) with both adequate preparation and AOT ≥ 9 min, compared with inadequate preparation and AOT < 9 min. Similar trends were observed for other outcomes, including multiple advanced ADR and APC.

Conclusions An integrated metric combining AI-assessed AOT and bowel preparation status offers a more detailed assessment of adenoma detection outcomes, including ADR and APC. Comprehensive AI-based monitoring of quality parameters may enhance colonoscopy performance without increasing the burden on endoscopists.

PYP357 Computer-Aided Adenoma Detection in Routine Colonoscopy: A Concealed Multicenter Randomized Trial

Authors von Renteln D[1], Menard C[2], Michal V[3], Wong C[4], Djinbachian R[1], Rex DK[5], Pohl H[6], Rahme E[7], Oleksiw M[1], Barkun A[7]
Institutes 1 CHUM – Centre hospitalier de l'Université de Montréal, Montréal, Canada; 2 Université de Sherbrooke, Sherbrooke, Canada; 3 CRCHUM – Centre de recherche du Centre hospitalier de l'Université de Montréal, Montréal, Canada, Montréal, Canada; 4 University of Alberta Hospital, Edmonton, Canada; 5 Division of Gastroenterology and Hepatology, Indiana University School of Medicine, Indianapolis, United States of America; 6 VA Medical Center, White River Junction, VT, USA, United States of America; 7 MUHC – McGill University Health Centre (Glen Site), Montréal, Canada
DOI 10.1055/s-0046-1821297

Aims Single-blinded randomized controlled trials (RCTs) have shown that computer-aided detection (CADe) increases adenoma detection rate (ADR), whereas real-world implementation studies have reported no gains. Single-blinded design and awareness of being studied may inflate effect estimates while implementation studies might suffer from selection bias. We evaluated CADe in routine practice within a concealed trial in which patients, endoscopists, and clinical staff were unaware of study participation and randomization.

Methods A concealed two-arm multicenter randomized controlled trial was conducted between July 2023 and August 2025 across three centers, enrolling patients aged 45–89 years undergoing diagnostic, screening, or surveillance colonoscopy. Patients were randomized 1:1 to an endoscopy room equipped with a CADe system (intervention) or a room without CADe (control). Endoscopists, nursing staff and patients were blinded to the existence of the trial. A research assistant did activate CADe every morning before arrival of the endoscopy team, however, endoscopists could choose to deactivate CADe. The primary outcome was ADR; secondary outcomes included CADe utilization rate, adenomas per colonoscopy (APC), sessile serrated lesion detection rate (SSLDR), advanced lesion detection rate (ALDR), proximal APC (pAPC), and the proportions of neoplastic and non-neoplastic polyps. The primary analysis was intention-to-treat (ITT), with per-protocol (PP) analyses based on actual CADe use. Generalized linear models estimated group differences.

Results Of 1,744 randomized patients, 1,673 were included in the analysis (control n = 837; intervention n = 836). Cross-over occurred in 89 (10.6 %) control and 71 (8.5 %) intervention patients. In ITT analysis, ADR did not differ significantly between groups groups (control: 31.5 %, 95 % confidence interval, CI: 28.4–34.8 vs intervention: 34.4 %, 31.2–37.8, p = 0.225). In PP analysis, ADR was higher when CADe was used (40.6 %, 36.3–45.1 vs 34.7 %, 30.1–38.6; p = 0.045). When assigned to a CADe-equipped room, endoscopists used the system in 57.5 % of eligible colonoscopies (481/836; ITT) and 92.9 % (471/507) in the PP population. Among PP patients, ALDR, APC, and pAPC were significantly higher with CADe (e.g., ALDR 8.3 %, 6.1–11.1 vs 3.9 %, 2.5–5.8; p = 0.002), whereas SSLDR and the proportion of non-neoplastic polyps did not differ.

Conclusions In this concealed trial, randomization to a CADe-equipped room did not significantly increase ADR in ITT analysis, but colonoscopies in which CADe was used showed higher ADR and advanced lesion detection. These findings suggest that incomplete and selective adoption in routine care can attenuate the benefits observed in RCTs. Strategies to ensure consistent CADe use are likely required for CADe to meaningfully improve ADR outside of controlled study conditions.

DOI 10.1055/s-0046-1821298

Aims Randomized controlled trials support the efficacy of both computer-aided detection (CADe) and mucosal exposure devices (MED) in improving adenoma detection, but implementation studies—particularly on their combined use in routine practice—are limited. We evaluated whether combining CADe and MED improves adenoma detection rate (ADR) in real-world colonoscopy.

Methods In this prospective implementation study, adults aged ≥ 45 years undergoing elective colonoscopy received standard, CADe-, MED-, or CADe + MED-assisted procedures. The primary outcome was ADR; secondary outcomes included advanced adenoma detection rate (AADR), sessile serrated lesion detection rate (SSLDR), adenoma per colonoscopy (APC), polyp detection rate (PDR), polyps per colonoscopy (PPC), and withdrawal time (WT).

Results We included 2552 patients undergoing standard (n = 1279), CADe-assisted (n = 829), MED-assisted (n = 225), or CADe + MED-assisted (n = 219) colonoscopies. ADR was 55.6 % (95 % CI [48.7–62.4]) in the CADe + MED group versus 29.3 % (95 % CI [26.5–32.3], p < 0.001) in the standard group. The CADe + MED group showed significant increases in AADR, SSLDR, APC, PDR, and PPC compared to standard procedures (all p < 0.001). CADe- and MED-alone achieved ADRs of 41.6 % (95 % CI [38.0–45.3]) and 44.9 % (95 % CI [37.5–52.6]), respectively (p < 0.866). CADe + MED increased ADR compared with CADe alone (p = 0.002). Mean WT was shorter for standard procedures (9.9 min) than for assisted ones (11.9–13.6 min, all p < 0.001).

Conclusions Combining CADe and MED significantly improves ADR, AADR, SSLDR, and other key performance metrics versus standard colonoscopy. These data suggest a synergistic effect wherein optimized mucosal exposure enables CADe to realize its full detection potential for aiding routine colonoscopies.

DOI 10.1055/s-0046-1821299

Aims Histopathological interpretation is crucial for diagnosing inflammatory bowel disease (IBD), distinguishing between Crohn's Disease (CD), Ulcerative Colitis (UC), IBD-Unclassified (IBD-U), and Non-IBD colitis (NIBDC). However, interobserver variability and limited expertise can reduce diagnostic accuracy. Accurate evaluation of both endoscopic and histological reports is essential for optimal IBD diagnosis. Large Language Models (LLMs) such as GPT-5 may offer clinical support in interpreting combined endoscopic–histological reports.

Methods We analyzed 100 real-life combined endoscopic and histological reports from ileo-colonoscopies, equally representing CD, UC, IBD-U, and NIBDC, collected across five Italian healthcare centers, including both IBD-specialized and non-specialized hospitals. A reference standard was established by an expert pathologist. Independent classifications were generated by GPT-5, five gastrointestinal pathologists, five IBD-expert gastroenterologists (GIs), and five non-expert GIs. Diagnostic performance (accuracy, recall, precision, F1-score), agreement with the reference standard (Cohen's κ), and inter-rater reliability (Fleiss' κ) were assessed.

Results GPT-5 achieved the highest agreement with the reference standard with the highest accuracy (76.0 %), compared to pathologists (68.6 %), IBD-experts (69.2 %), and non-experts (63.2 %). Agreement with the reference standard was substantial for GPT-5 (κ = 0.671) and moderate for human groups (κ = 0.508–0.588). GPT-5 showed perfect recall for CD and UC, high recall for NIBDC (96.0 %), but poor performance for IBD-U (recall 8.0 %, F1-score 14.3 %) (▶ **Table 1**). Fleiss' κ indicated moderate agreement among pathologists and IBD-experts, and fair agreement among non-experts.

▶ **Table 1** Comparative performance metrics of pathologists, IBD-expert GIs, non-expert GIs, and GPT-5 compared with the reference standard.

Metric	Pathologists	IBD-expert GIs	IBD non-expert GIs	GPT-5
Accuracy (%)	68.6 (64.4–72.5)	69.2 (65.0–73.1)	63.2 (58.9–67.3)	76.0 (66.8–83.3)
Recall (%)				
▪ IBD-U	33.6 (25.9–42.3)	30.4 (23.0–38.9)	32.8 (25.2–41.4)	8.0 (2.2–25.0)
▪ CD	80.0 (72.1–86.1)	86.4 (79.3–91.3)	68.0 (59.4–75.5)	100.0 (86.7–100.0)
▪ UC	84.8 (77.5–90.0)	81.6 (73.9–87.4)	76.0 (67.8–82.6)	100.0 (86.7–100.0)
▪ NIBDC	76.0 (67.8–82.6)	78.4 (70.4–84.7)	76.0 (67.8–82.6)	96.0 (80.5–99.3)
Precision (%)				
▪ IBD-U	56.0 (44.7–66.7)	52.1 (40.8–63.1)	42.3 (32.9–52.2)	66.7 (20.8–93.9)
▪ CD	83.3 (75.7–88.9)	76.6 (69.0–82.8)	83.3 (74.9–89.3)	67.6 (51.5–80.4)
▪ UC	60.6 (53.2–67.5)	72.3 (64.4–79.1)	57.9 (50.3–65.2)	80.6 (63.7–90.8)
▪ NIBDC	73.1 (64.9–80.0)	67.6 (59.6–74.7)	69.3 (61.2–76.4)	82.8 (65.5–92.4)
F1-score (%)				
▪ IBD-U	42.6 (33.1–50.0)	38.5 (28.6–46.5)	36.9 (28.9–44.7)	14.3 (0.0–33.3)
▪ CD	81.6 (75.7–86.6)	81.3 (76.0–85.9)	75.0 (68.0–81.3)	80.6 (67.9–90.5)
▪ UC	70.0 (64.5–76.4)	76.7 (70.9–82.1)	65.9 (59.5–71.6)	89.3 (80.0–96.7)
▪ NIBDC	74.5 (68.5–80.0)	72.8 (66.4–78.0)	72.5 (66.1–78.7)	89.0 (77.8–96.4)

Conclusions GPT-5 demonstrated reliable performance in interpreting endoscopic and histological IBD histological reports, exhibiting high accuracy and strong agreement with the reference standard. While unreliable for IBD-U, GPT-5 may serve as a supportive tool in diagnosis and classification of IBD, particularly in centers with limited access to expert pathologists or IBD-specialists.

PYP360 Bleeding risk of atezolizumab-bevacizumab during ongoing endoscopic variceal ligation in hepatocellular carcinoma: a two-centre retrospective study

Authors Rahe G[1], Wiener S[1], Artusa F[2], Konstantis G[1], Zeller A[1], Schramm C[1], Schmidt H[1], Best J[1], Tacke F[3], Mohr R[2], Jochheim L[4, 1]

DOI 10.1055/s-0046-1821300

Aims The combination of atezolizumab and bevacizumab is an established first-line therapy for unresectable hepatocellular carcinoma (HCC). However bevacizumab is associated with an increased risk of gastrointestinal bleeding; in IMbrave150, upper GI bleeding occurred in ~7 % of patients, leading to guideline recommendations for pre-treatment endoscopy and primary prophylaxis of oesophageal varices. Many centres therefore defer bevacizumab until endoscopic variceal eradication, delaying full systemic therapy. Two tertiary centres instead adopted an upfront bevacizumab strategy with endoscopic variceal ligation (EVL) in parallel. We aimed to assess the safety and feasibility of this approach in a real-world setting [1].

Methods This retrospective two-centre cohort included 354 consecutive Patients (290 males, 81,9 %; 63 females, 17,8 %, mean age 65.7 years) with HCC treated with atezolizumab-bevacizumab between 2020 and 2024. The primary endpoint was any variceal bleeding with EVL before bevacizumab initiation compared with a non-upfront ligation group. Cox regression was used to assess the association between EVL and variceal bleeding, adjusting for variceal grade, Child–Pugh score and macrovascular invasion.

Results Overall, 15 variceal bleeding events occurred after bevacizumab initiation (4.2 %), of which 10 occurred during therapy (2.8 %) and 5 later than 6 months after treatment start (1.4 %). In the varices subcohort (n = 145 with documented baseline varices), 57/145 (39.3 %) patients underwent endoscopic variceal upfront ligation before therapy inititiation, whereas 88/145 (60.7 %) did not. Patients who underwent upfront ligation therapy were substantially more likely to have higher-grade varices (grade II/III), whereas the no-ligation group predominantly had grade I varices ($p < 0.001$). Despite this imbalance toward more advanced varices in the ligation group, the overall proportion of variceal bleeding events did not differ significantly between groups (8.9 % vs 6.8 %; $p = 0.751$). In grade-stratified analyses, no significant differences in variceal bleeding were observed within individual variceal grades, consistent with very low event counts per subgroup.

In time to event analyses among patients with complete follow up information for the Cox dataset (n = 124; 11 events), upfront ligation was not associated with time to variceal bleeding in an unadjusted Cox model (HR 1.24, 95 % CI 0.38–4.09; $p = 0.724$). In the primary parsimonious model adjusting for baseline variceal grade (grade I reference; grade IV excluded), upfront ligation again showed no significant association with variceal bleeding (HR 0.65, 95 % CI 0.13–3.28; $p = 0.606$), while baseline grade III varices were associated with a significantly increased hazard of bleeding compared with grade I (HR 8.25, 95 % CI 1.23–55.31; $p = 0.030$); grade II was not significantly associated (HR 2.51, 95 % CI 0.40–15.86; $p = 0.329$).

Sensitivity analyses yielded consistent findings. After adjustment for macrovascular infiltration, upfront ligation remained non-significant (HR 0.81, 95 % CI 0.21–3.07; $p = 0.753$), and macrovascular infiltration itself was not associated with bleeding risk (HR 0.81, 95 % CI 0.19–3.45; $p = 0.777$). Similarly, models

adjusting for Child–Pugh class or prior variceal bleeding did not identify significant predictors beyond variceal grade and did not materially change the null association between upfront ligation and time to variceal bleeding (HR 1.05, p = 0.944 and HR 1.27, p = 0.715, respectively). Using a Cox model stratified by baseline variceal grade (I–III), upfront ligation was also not significantly associated with time to variceal bleeding (HR 0.45, 95 % CI 0.09–2.14; p = 0.312).

Conclusions In this two-centre cohort uniformly applying bevacizumab during ongoing EVL, variceal bleeding incidence was low (4.2 %) and not elevated in comparison to an non upfront ligation group. Upfront EVL itself was not independently associated with a higher bleeding incidence when adjusted to variceal grade, Child-Pugh Score or macrovascular invasion.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Delayed bleeding is a major adverse event of endoscopic papillectomy (EP). However, established preventive strategies and clear risk stratification remain ill-defined due to the rarity of the disease. We aimed to identify independent risk factors for delayed bleeding after EP using a large-scale multicenter dataset, specifically evaluating the impact of procedural interventions and pharmacological prophylaxis.

Methods We conducted a retrospective cohort study across 22 Japanese academic and community hospitals (2009–2020). Patients undergoing EP for ampullary tumors were included. To ensure homogeneity, patients requiring nasobiliary/nasopancreatic drainage or metallic biliary stents were excluded. We identified independent risk factors for delayed bleeding using multivariable logistic regression.

Results A total of 875 candidates were screened, and 848 patients were included in the final analysis. The overall incidence of delayed bleeding was 19.2 % (163/848). Severity was mild in 15.6 %, moderate in 2.4 %, and severe in 1.3 % of cases. Multivariable analysis identified prophylactic clipping (>50 % closure of the mucosal defect) as a significant independent preventive factor (Odds Ratio [OR] 0.49; 95 % Confidence Interval [CI] 0.28–0.81; p = 0.007). Conversely, independent risk factors included male sex (OR 1.82; p = 0.002), younger age (65 years; OR 2.82;0.001), and pancreatic stent placement (OR 2.60; p = 0.041). Acid-suppressing agents (PPIs or H2RAs) showed no significant association with delayed bleeding.

Conclusions Prophylactic clipping significantly reduced the risk of delayed bleeding, whereas younger age, male sex, and pancreatic stent placement were identified as significant risk factors. Notably, acid-suppressing agents did not affect bleeding risk. The novel finding that pancreatic stent placement is a risk factor suggests that constant exposure of the ulcer bed to pancreatic juice via the stent may induce bleeding, warranting further investigation.

DOI 10.1055/s-0046-1821302

Aims To identify predictors of efficacy and safety following endoscopic papillectomy (EP), including therapeutic success, recurrence and adverse events. Secondly, we aimed to evaluate predictors of histopathological agreement.

Methods A multicenter, retrospective cohort study was conducted including adult patients from thirteen medical institutions who underwent EP for ampullary adenomas between January 2019 and December 2023. The main clinical outcomes were efficacy (endoscopic success and recurrence) and safety (reported adverse events, severity and management). Pre- and post-procedural histology was documented. Patient center volume was categorized as low, medium and high.

Results This cohort included 187 patients, 59.9 % male, mean age 62.64 (± 13.41) years. Most of the ampullary lesions were not associated with genetically predisposed diseases (77.0 %), incidentally detected on asymptomatic patients (76.5 %), sized between 10mm and 20mm (63.1 %), and with low-grade dysplasia (88.8 %). En bloc resection was performed in 73.8 % of the patients. Prophylactic measures to prevent acute pancreatitis were implemented in 95.2 % of the procedures. Endoscopic success rate was 96.3 %, with R0 resection rate of 74.3 %. The mean follow-up was 32.8 (± 18.7) months. The median adenoma-free survival was 24.0 months (95 % CI 9.3–38.7). Recurrence rate was 18.7 %, most frequently detected at the first endoscopic surveillance (71.4 %) and managed mostly endoscopically (85.7 %). Re-recurrence rate was low (4.3 %, n = 8). Older age (OR = 0.95, 95 % CI 0.91–0.99), intraductal extension (OR = 17.89, 95 % CI 1.51–212.43), intraprocedural bleeding (OR = 3.55, 95 % CI 1.34–9.39), and submucosal injection before resection (OR = 2.60, 95 % CI 1.06–6.40) were significantly associated with higher recurrence rates. The most common adverse events were post-procedural pancreatitis (20.3 %), mostly mild severity (78.9 %), and bleeding (intraprocedural 18.2 %; delayed 12.8 %). No procedural-related deaths were observed in our cohort. None of the patient, procedure or lesion characteristics were related to post-procedural pancreatitis, cholangitis, papillary stenosis or perforation. Delayed bleeding was more common when submucosal injection was performed (OR = 2.96, p = 0.029) and pancreatic stent was placed (OR = 5.05, p = 0.036). The histopathological agreement between pre-procedural biopsy and post-procedural histology was observed in 75.4 % of cases, with histopathological underestimation in 15 % and overestimation in 9.6 % of cases. Prior sphincterotomy correlated with reduced histopathological agreement ($\chi^2 = 21.81$; $p < 0.001$), whereas pre-procedural evaluation with side-viewing endoscopy was associated to a higher likelihood of histopathological agreement ($\chi^2 = 11.10$, $p = 0.004$). High-volume centers showed significantly higher rates of histopathological agreement ($\chi^2 = 15.59$, $p < 0.001$). It is important to note that, in these centers, prior assessment with side-viewing endoscopy and endoscopic ultrasound (EUS), respectively [(97.3 % (n = 72) and 71.6 % (n = 53)] was more often performed. Significantly higher recurrence rates (31.0 %) were observed in low-volume centers compared with high-volume centers (12.2 %) (p = 0.046). Delayed bleeding occurred more frequently in low-volume centers (p = 0.032).

Conclusions In our cohort, EP achieved high rates of therapeutic success with a favorable profile of adverse events, mostly amenable to conservative or endoscopic management. Recurrence was frequent and was associated to older age, intraductal extension, intraprocedural bleeding and submucosal injection before resection. High-volume centers showed significantly higher rates of histological agreement probably due to the more frequent use of prior evaluation with side-view endoscopy and EUS. Low-volume centers showed higher rates of recurrence rates and delayed bleeding. These results emphasize the importance of detailed pre-procedural staging, specialized training and the potential benefit of centralizing complex procedures to high-volume centers.

DOI 10.1055/s-0046-1821303

Aims Endoscopic management of walled-off necrosis (WON) has become the preferred minimally invasive approach, yet bleeding remains a significant complication. Identifying predictors of bleeding is essential to optimize patient selection, procedural planning, and postoperative monitoring.

Methods In this prospective cohort study, 153 patients undergoing endoscopic drainage and necrosectomy for WON were analyzed. Baseline demographics, clinical characteristics, stent type, number of necrosectomies, and nutritional status were collected. Outcomes included occurrence of bleeding and mortality. Univariate and multivariable logistic regression analyses were performed to identify predictors of bleeding. Kaplan–Meier analysis assessed bleeding risk over time.

Results The cohort had a mean age of 54.5 years and mean BMI of 25.3; 34.8 % were female. The average WON size was 98.6 cm. Hot Axios stents were used in 68 % of procedures, followed by Hanaro (18 %), Spaxus (11 %), and Z-EUS (1 %). Coaxial pigtail stents were placed in most patients (n = 137). Following LAMS placement, bleeding occurred in 15 patients (9.8 %), including one death (0.65 %). Univariate analysis identified increased bleeding risk with ≥ 4 necrosectomies (OR 4.6; 95 % CI 1.0–21.4; P = 0.05), parenteral nutrition use (OR 8.8; 95 % CI 2.4–32.8; P = 0.001), and presence of any organ failure (OR 15.4; 95 % CI 4.5–52.7; P < 0.001). Kaplan–Meier analysis showed no significant difference in bleeding risk over time (log-rank P = 0.647). Multivariable analysis demonstrated that the presence of any organ failure was the strongest and only independent predictor of bleeding (OR 45.9; P = 0.01).

Conclusions Among patients undergoing endoscopic treatment of WON, organ failure was the sole independent predictor of bleeding. These findings highlight the critical role of systemic disease severity—rather than procedural factors—in anticipating bleeding complications and guiding risk stratification.

PYP364 Therapeutic EUS under endoscopist-guided sedation: safety and feasibility

Authors Moreno-Sanchez M[1], Andreo-Vidal B[1], Aranda-Olaizola G[1], Martinez-Ortega A[1], Velasco-Guardado AJ[1], Alvarez-Delgado A[1]

Institute **1** Complejo Asistencial Universitario de Salamanca, Salamanca, Spain

DOI 10.1055/s-0046-1821304

Aims Endoscopist-administered sedation is safe and widely used in Europe [1, 2], but sedation in interventional-EUS (i-EUS) is usually performed by anesthetists [3]. Given the increasing demand and limited resources, this study aimed to evaluate the safety of endoscopist-led sedation in i-EUS.

Methods Retrospective, single center study, including all i-EUS performed between February 2020 and August 2025 in Hospital Universitario de Salamanca (Spain). Hemodynamically stable patients received propofol in boluses and continuous infusion administered by the endoscopist and nurses (with dedi-

Endoscopy 2026; 58: S1–S1041

cated training in sedation); along with high-flow nasal oxygen at 15 L/min. Optional midazolam, fentanyl, or hyoscine were also given. Drug doses, vitals and sedation-related adverse events are systematically recorded, prospectively, by the nurse responsible for sedation, using a form specifically designed for this purpose. Furthermore, any sedation-related adverse events are also documented in the endoscopy report.

Results 317 i-EUS were included (139 cholecystostomies, 66 gastroenterostomies, 57 pancreatic collections, 30 hepaticogastrostomies, 14 abscess drainages and 11 choledocoduodenostomies). 57 patients (18 %) also underwent an ERCP or 2 i-EUS in the same session. Median age was 81.5 y.o. (IQR 67.4-88.4). ASA classification for anesthetic risk: I (1 %), II (44 %), III (50 %), IV (5 %). Comorbidities included OSA n = 7 (2.4 %), COPD n = 19 (6 %), LVEF < 40 % n = 4 (1.3 %), severe aortic stenosis n = 1 (0.3 %). 6 hemodynamically unstable patients (1.9 %) had sedation and support by ICU.

Mean propofol dose was 271 mg (CI 95 % 254-289). Hyoscine was given to 75 patients (24.2 %) with a median dose of 40 mg (IQR 20-40); Midazolam to 2 patients (0.6 %), median dose 2 mg (IQR 1-3); and Fentanyl to 18 patients (5.8 %), median dose 75 mcg (IQR 68.75-75).

There was one sedation-related adverse event (AE): a moderate desaturation in a 99 year-old patient without significant comorbidities, who received 80 mg of propofol. This was reversed with Bag-Valve-Mask ventilation by the endoscopist; allowing completion of the procedure (cholecystostomy). No aspirations, bradycardia requiring atropine, significant hypotension (systolic BP < 80 mmHg despite IV fluids), or need for urgent ICU support occurred. No sedation-related deaths were reported. One 92-year-old male with a metastatic cholangiocarcinoma died in the recovery room 40 minutes after finishing an uneventful hepaticogastrostomy. The cause of the death was unclear, since no autopsy was performed given age and comorbidities.

There were 8 LAMS misdeployments (2.5 %) and 16 AEs (5 %) including: bleeding (3.2 %), migration (1.3 %), bile leak (0.3 %) and perforation (0.3 %). None of these events were associated with sedation complications.

Conclusions In our series, endoscopist-led sedation with propofol for i-EUS was safe. Only one sedation-related AE (desaturation) occurred, which was moderate, managed by the endoscopist, and the procedure could be successfully completed. The presence of AEs or misdeployments inherent to these techniques was not associated with an increased rate of aspiration, hypotension, or other complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821305

Aims Ampulla of Vater morphology has been reported to impact cannulation and complication rates during ERCP. However, there are several morphology classification systems and results in literature are not unanimous. We aimed to test the above hypothesis using data from the Greek ERCP registry.

Methods We conducted a multicenter observational study with prospectively collected data from the Greek national ERCP database. Ampulla morphology was classified according to the Haraldsson classification (United European Gastroenterology Journal, 2017). The registry was searched for ERCP cases performed in Jan 2023 – Sept 2025, in patients with naïve ampulla of Vater. We performed univariate and multivariate analyses.

Results A total of 1675 ERCP cases in patients with naïve ampulla of Vater and available data from 6 centers regarding ampulla morphology were included (mean age 73 years (SD 15); 69 % with bile duct stones, jaundice 63 %, cholangitis/sepsis 16 %, biliary stricture 12 %). The most frequently described type of ampulla was type 1 (n = 928, 55.4 %), followed by type 2 (n = 395, 23.6 %), type 3 (n = 287,17.1 %) and type 4 (n = 65,3.9) %). Overall, 51.4 % of the cases were performed electively, most patients (42,4 %) had an ASA score of 2 (, 27.9 % score 1, 25.6 % score 3, 3.8 % score 4, and 0.2 % score 5) and underwent ERCP under conscious sedation (82.9 % followed by 16.4 % deep sedation ,and 0.7 % general anesthesia). The deep bile duct cannulation success rate was 94.3 % and it was related to ampulla of Vater morphology (p = 0.04) with type 2 and 4 showing higher failure rates compared with type 1 (p = 0.02 and p = 0.01 respectively). The overall complication rate was 11.7 %, with no significant difference among the four ampulla morphology types (p = 0.2). Post ERCP pancreatitis occurred in 6.6 % and cholangitis in 5.8 % but did not differ significantly among ampulla morphology types (p > 0.05), Perforation occurred in 4 patients and was only observed in type 2 ampullas. In multivariate analysis ampulla morphology types 2 and 4 were independent predictive factors of cannulation failure (p = 0.001; OR 2.0, 95 % CI 1.3-3.0).

Conclusions Ampulla morphology type 2 and 4 appear to be associated with cannulation failure and possibly complications. These findings may have implications in daily clinical practice, especially in the field of ERCP training.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP366 Safety of Outpatient ERCP in Patients Aged ≥ 80 Years: Complication Profiles and Hospital Admission Patterns

Authors Ferro Tomás D[1], Bastos A[1], Teixeira M[1], Ramos Lopes S[1], Cardoso C[1], Mangualde J[1], Freire R[1]

Institute **1** CRI Gastrenterologia, Hospital São Bernardo, ULS da Arrábida, Setúbal, Portugal

DOI 10.1055/s-0046-1821306

Aims The safety of outpatient ERCP in patients aged ≥ 80 years remains uncertain, particularly regarding clinically relevant post-procedural complications and early need for hospital admission. Evidence from European centres is limited, and few studies analyse the timing of complications in very elderly patients. This study aimed to compare post-ERCP complications and 30-day unplanned admissions between elderly and younger adults in a real-world ambulatory setting.

Methods A retrospective cohort study was conducted using a prospectively maintained database of consecutive outpatient ERCPs. Patients were stratified into < 80 years and ≥ 80 years groups. Only post-procedural complications were analysed: pancreatitis, cholangitis, cholecystitis, perforation and other clinically relevant events. Hospital admission and ERCP-related readmission within

30 days were recorded. Complication timing was classified as occurring < 8 hours, 8–24 hours or > 24 hours. Comparisons used Fisher's exact test ($p < 0.05$). Statistical analysis was done with SPSS v29.0 [1].

Results A total of 304 outpatient ERCPs were included, of which 238 involved patients aged < 80 years and 66 aged ≥ 80 years. Post-ERCP pancreatitis was infrequent and similar between groups (1.7 % vs 1.5 %; p = 1.00). Cholecystitis, perforation and other complications also showed no significant differences. Cholangitis was significantly more frequent in elderly patients, occurring in 7.6 % (5/66) of those aged ≥ 80 years compared with 2.1 % (5/238) in younger adults (p = 0.0427). Thirty-day all-cause readmission occurred in 9.2 % (22/238) of patients < 80 years and 10.6 % (7/66) of those ≥ 80 years (p = 0.92). ERCP-related readmissions showed a similar pattern, with 5.0 % (12/238) in younger patients and 7.6 % (5/66) in the elderly, paralleling the higher incidence of cholangitis in the ≥ 80 cohort. In the temporal analysis of post-procedural complications, no differences were observed between groups for events occurring within < 8 hours or beyond 24 hours after ERCP. However, complications arising 8–24 hours post-procedure were significantly more frequent in patients aged ≥ 80 years (3.0 % vs 0 %; p = 0.0466), indicating a distinct early–delayed risk window in very elderly individuals (▶ **Table 1**).

▶ **Table 1**

Variable	< 80 years (n = 238)	≥ 80 years (n = 66)	p-value
Baseline			
Sex (male) n (%)	104 (43.7)	29 (43.9)	1.00
Suspected choledocholithiasis n (%)	152 (63.9)	35 (53.0)	0.12
Suspected malignant obstruction n (%)	67 (28.2)	29 (43.9)	0.019
Complications and Outcomes			
Pancreatitis n (%)	4 (1.7)	1 (1.5)	1.00
Cholangitis n (%)	5 (2.1)	5 (7.6)	0.0427
Cholecystitis n (%)	6 (2.5)	0 (0)	0.347
Perforation n (%)	1 (0.4)	0 (0)	1.00
Other complication n (%)	6 (2.5)	1 (1.5)	1.00
< 8 hours n (%)	7 (31.8)	1 (14.3)	0.29
8–24 hours n (%)	0 (0)	2 (28.6)	0.0466
> 24 hours n (%)	15 (68.2)	1 (57.1)	1.00
30-day all-cause admission n (%)	22 (9.2)	7 (10.6)	0.92

Conclusions Outpatient ERCP is safe in selected patients aged ≥ 80 years, with similar rates of pancreatitis, perforation, cholecystitis and overall readmission compared with younger adults. However, the significantly increased incidence of post-ERCP cholangitis and the higher frequency of 8–24-hour complications in the very elderly suggest that extended early post-procedure monitoring may be beneficial in this subgroup. These findings support the feasibility of ambulatory ERCP in older adults while highlighting the need for tailored surveillance strategies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821307

Aims Endoscopic retrograde cholangiopancreatography (ERCP) routinely used as an inpatient procedure, due to post-procedural complications [1, 2]. The inpatient setting allows close observation but also increases healthcare costs and may not be necessary for all patients [1]). Improved procedural safety, sedation practices, and early recovery protocols have raised the possibility of performing ERCP on an outpatient or ambulatory basis, allowing same-day discharge [3]. The present study aimed to evaluate the feasibility and safety outcomes of ambulatory ERCP performed in a tertiary referral center.

Methods A retrospective study of consecutive ERCP between June 2019 and October 2025 was performed. Safety was defined as the presence of early adverse events (≤ 72 hours). Adverse events were categorized as minor and serious. The latter included those that required new hospitalization after discharge (outpatients) or prolonged hospitalization (inpatients). Feasibility was defined as successful same-day discharge without unplanned admission or observation ≥ 24 hours. Ambulatory patients followed the center's local protocol and were advised to immediately report if pain, bleeding, dizziness, nausea, vomiting, or any alarm symtom arised.

Results A total of 6000 ERCPs were performed from 2019 to 2025. 1000 patients were randomly selected and reviewed, and 206 were excluded from the analysis. A total of 794 patients were enrolled and distributed into outpatient [382/794 (48,1 %)] and inpatients [423/794 (53.2 %)]. Overall median age was 54.0 (35 – 68) (p = .005) and 54.9 % were female (p = .267). Previous ERCP procedures were more common in the outpatient group (20.7 % vs 10.7 %, p < .001), previous cholecystectomy was most common in the outpatient group (31.2 % vs 23.3 %, p > .05) (Table 1).

The most common ERCP indication was choledocholithiasis in the outpatient (74.9 %) and inpatient (65.3 %) groups, followed by tumor suspicion in the outpatient group (16.0 %) and biliary sludge in the inpatient group (18.9 %). Difficult cannulation in the outpatient and inpatient groups was 7.6 % and 7.0 %, respectively (p = .764). Sphincterotomy was performed in 90.8 % of outpatient and 92.0 % of inpatient, respectively (p = .562), and biliary stenting was reported in 28.3 % and 24.5 %, respectively (p = .229).

Complication rate was similar among groups with 14.4 % in the outpatient and 9.7 % in the inpatient group (p > .05). Bleeding was the most common adverse, being mild in forty-two outpatient cases (11.0 %) and 28 inpatient cases (7.0 %), managed with sclerotherapy; however, 2 cases in outpatient and 1 case in the inpatient group required hospitalization. A sub-analysis was conducted considering the serious adverse events that required hospitalization after discharge or extended hospital stay. There were 13 cases among the outpatients who required a new hospitalization after discharge, and 12 inpatients who required prolonged hospital stay (p > .05). Post-ERCP pancreatitis was higher in the outpatient groups (2.4 %), compared to 2.2 % of inpatients (p > .05). Most inpatient cases achieved technical success (99.5 %, p < .001) and less clinical success

(88.8 %, p < .001), compared to outpatient's (86.4 % and 93.7 %), respectively. No mortality was perceived in either group.

Conclusions Ambulatory ERCP proved to be a feasible and safe strategy, with complication and serious adverse event rates comparable to those of inpatient ERCP. Most adverse events were mild, and only a small proportion of patients required hospitalization or extended observation.

PYP368 Impact of Fluid Type and Timing on Post-ERCP Pancreatitis Severity: A Four-Year Retrospective Study

Authors Dimassi A[1], Zohaib M[1], Shariff M[1], Leahy A[1]
Institute 1 Watford General Hospital, West Hertfordshire Teaching Hospitals NHS Trust, Watford, United Kingdom
DOI 10.1055/s-0046-1821308

Aims Post-ERCP pancreatitis is a recognized complication of ERCP and contributes significantly to patient's morbidity, prolonged hospitalization and mortality. Optimizing fluid management strategies has been proposed as a means of improving clinical outcomes, but the impact of different fluid types and timing remains uncertain. This study aims to assess whether intravenous fluid type (Hartmann's vs Normal Saline) and timing (Pre vs Post ERCP) were associated with pancreatitis severity or mortality among patients who developed post-ERCP pancreatitis at our distric general hospital.

Methods A retrospective observational study was conducted using data from April 2021 to April 2025. Information was obtained from Electronic Patient Records and Endoscopy Unit documentation. The Revised Atlanta Classification was used in the diagnosis of pancreatitis as well as in assessing the severity throughout the hospitalization. Intravenous fluid type and timing, along with ERCP indications and difficulty of the ERCP procedures, length of stay and mortality were all evaluated (▶ **Table 1**).

▶ **Table 1** Fluid Type + Timing vs Severity and Mortality

Variable	Mild	Mod/ Severe	Mortality	No Mortality
Hartmann's	9	3	1	11
Normal Saline	6	2	0	8
Both	6	1	1	6
Fluid Unknown	5	1	1	5
Post Only	21	5	2	24
Pre Only	1	0	0	1
Pre + Post	4	2	1	5
Timing Unknown	0	0	0	0

Results 1,098 ERCP procedures were performed between April 2021 and April 2025. 33 cases (3.0 %) met criteria for post-ERCP pancreatitis (PEP) with 20 inpatient procedures (61 %) and 13 outpatients (39 %). The majority of affected patients (73 %) were older than 60 years. Regarding indications in patients with PEP, 14 ERCPs were undertaken for ductal stones, 11 for stent placement in pancreatic malignancy, 7 for stenting of benign or malignant ductal strictures, and 1 for a post-cholecystectomy bile leak. In terms of technical difficulty: 7 procedures required double-guidewire, 1 required pre-cut sphincterotomy, and 2 required both; all remaining cases were uncomplicated. Based on the Revised Atlanta Classification, 26 patients (79 %) developed mild pancreatitis and 7 (21 %) developed moderate/severe disease; all patients received intravenous fluids. Across patients with moderate/severe pancreatitis, the proportion of IV fluid types were as follows: Hartmann's 3 patients, normal saline 2 patients, Hartmann's and Normal Saline 1 patient, data unavailable 1 patient. In patients with mild pancreatitis, results were as follows: Hartmann's 9 patients, Normal Saline 6 patients, Hartmann's and Normal Saline 6 patients, Data unavailable in 5 patients. There was no significant association between fluid type and severity (Fisher–Freeman–Halton exact test, 4 × 2, p = 1.000). Fluid type was also not associated with 28-day mortality (p = 0.674); deaths occurred in patients receiving both Hartmann's and Normal Saline (1/7, 14.3 %), Hartmann's only (1/12, 8.3 %) or with undocumented fluid type (1/6, 16.7 %), and in none of those who received normal saline only (0/8). Regarding timing, moderate/severe pancreatitis occurred in 5/26 (19.2 %) patients receiving post-procedure fluids only, 0/1 (0 %) receiving pre-procedure fluids only, and 2/6 (33.3 %) receiving both pre- and post-procedure fluids, with no significant association between timing and severity (Fisher–Freeman–Halton exact test, 3 × 2, p = 0.677). Similarly, timing of fluids was not associated with 28-day mortality (post 2/26 [7.7 %], pre 0/1, pre and post 1/6 [16.7 %]; p = 0.523).

Conclusions Across this four-year cohort, neither the type nor the timing of IV fluid administration demonstrated a statistically significant relationship with severity or mortality in post-ERCP pancreatitis. Although the overall mortality rate was low, the absence of a detectable effect highlights the need for larger prospective studies to determine whether targeted fluid strategies may confer benefit in preventing progression or complications of PEP.

PYP369 Impact of Obesity on Readmission Outcomes in Cirrhosis and Variceal Bleeding: Insights From the HCUP Database (2019–2024)

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Mustacchia P[1]
Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America
DOI 10.1055/s-0046-1821309

Aims This study utilizes data from the Nationwide Admission Database (HCUP) from 2019 to 2024, analyzing 2,858,576 adult hospital admissions to assess the link between obesity and readmission rates in cirrhotic patients with variceal bleeding. It examines the impact of obesity, race, and gender on 30-day and 60-day readmission rates, employing chi-square tests and logistic regression to evaluate disparities across demographics. The models, which include race and gender, were analyzed for predictive accuracy using ROC curves and AUC statistics to enhance patient management strategies.

Methods This study analyzed data from the Nationwide Admission Database (HCUP) involving 2,858,576 adults from 2019 to 2024, focusing on 30-day and 60-day readmission rates for obese cirrhotic patients with variceal bleeding. It assessed the impact of obesity, race, and gender on these outcomes using chi-square tests and logistic regression to explore incidence and readmission disparities across demographics. The effectiveness of these models, incorporating race and gender, was evaluated through ROC curves and AUC statistics to pinpoint key predictors of readmission.

Results From 2019 to 2024, the Nationwide Admission Database (HCUP) provided data on 2,858,576 adult admissions, focusing on 110,124 patients diagnosed with cirrhosis and variceal bleeding, including 47,510 obese individuals (BMI over 30). Chi-square tests indicated significantly higher readmission rates for obese patients, with a p-value of 0.014 for 30-day and < 0.001 for 60-day readmissions. The incidence of variceal bleeding also varied by obesity status, showing a p-value of 0.020. Logistic regression highlighted gender and race impacts on readmissions, particularly males and Hispanics influencing 60-day outcomes with coefficients of 0.62 and 0.54, respectively. The AUC for the 30-day model showed excellent predictive accuracy.

Conclusions This analysis shows obese patients have higher readmission rates than non-obese peers, highlighting complex care challenges. Logistic regression found gender and race—especially male and Hispanic patients—significantly affect 60-day readmissions. The 30-day model's high AUC confirms its predictive value, emphasizing the need for targeted interventions and healthcare strategies tailored to at-risk groups in managing cirrhosis.

DOI 10.1055/s-0046-1821310

Aims Reversible electroporation (REP) is a non-thermal technique that uses electrical pulses to induce transient pores in cellular membranes, facilitating the intracellular delivery of cytotoxic agents and promoting apoptosis. Its application in gastrointestinal neoplasms as a palliative treatment is promising, although data on its safety and efficacy are limited.

AIMS: To evaluate the safety and efficacy of REP in the palliative treatment of gastrointestinal neoplasms.

Methods A multicenter observational, descriptive, study with prospective follow-up was conducted. Patients with gastrointestinal neoplasms presenting with bleeding, obstructive symptoms, or requiring palliative treatment due to frailty, lack of response, or contraindication to surgery, chemotherapy, or radiotherapy were included.

Results Forty REP sessions were performed in 25 patients (18 men, 7 women), with a mean age of 75 years and high comorbidity (ASA III/IV in 76 %). Fifty-six percent of patients had metastatic disease, and 26 % had locally advanced disease. The most frequent tumor sites were gastric (64 %), esophageal (25 %), duodenal, and rectal. The main indications were bleeding (76 %), pain, and obstructive symptoms. As cytotoxic agent, intratumoral calcium was used in 80 % of cases and intravenous bleomycin in the remaining 20 %. Adverse events were mild (Agree grade I) and infrequent (16 %). Technical success was 92 % and clinical success was 75 %. Fourteen patients (58 %) died during follow-up, mainly due to tumor progression (71 %). No procedure-related mortality was recorded

Conclusions Reversible electroporation is a safe technique with a low incidence of adverse events and encouraging clinical outcomes in the palliative treatment of advanced gastrointestinal neoplasms. Its use may represent a therapeutic alternative for frail patients or those lacking conventional treatment options.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP372 Real-Time Detection of Food-Induced Mucosal Reactions in Children Using Confocal Endomicroscopy

Authors Russo G[1], Ruggiero C[1], Papoff P[1], D'orsi M[1], Raso T[1], Oliva S[1]

Institute **1** Sapienza University of Rome, Roma, Italy

DOI 10.1055/s-0046-1821311

Aims Confocal laser endomicroscopy (CLE) enables real-time visualization of epithelial barrier responses following mucosal exposure to food antigens. While CLE has demonstrated value in detecting non–immunoglobulin E (IgE)–mediated food allergy in adults, evidence in pediatrics remains limited. This study aimed to evaluate the feasibility, diagnostic yield, and clinical impact of CLE-guided duodenal food challenge in children with food-related gastrointestinal symptoms and negative conventional allergy testing.

Methods We prospectively enrolled children (2–18 years) with chronic gastrointestinal symptoms temporally associated with food ingestion and negative serum IgE and skin-prick tests. During upper endoscopy, standardized food antigens (cow's milk, wheat, soy, egg, yeast) were sequentially applied to the duodenal mucosa. CLE was performed immediately after each challenge. A CLE-positive reaction was defined by the presence of at least two features within 5 minutes: epithelial fluorescein leakage, widening of the intervillous space, fluorescent signal between enterocytes, or an increase in intraepithelial lymphocytes. Following CLE, targeted elimination diets were prescribed based on the identified offending antigen. Clinical outcomes were assessed at 8–12 weeks.

Results Thirty-six children were enrolled. CLE was feasible and safe in all children. A positive reaction occurred in 24/36 patients (66.7 %). The most frequent triggers were cow's milk (41.7 %), wheat (29.2 %), soy (16.7 %), egg (8.3 %), and yeast (4.1 %). CLE-positive patients consistently demonstrated rapid epithelial leakage and intervillous widening, indicating acute barrier dysfunction. At follow-up, 20/24 CLE-positive children (83.3 %) achieved significant symptom improvement (> 60 %) after targeted dietary elimination, whereas CLE-negative children showed minimal benefit from empirical diet modification [1, 2].

Conclusions In this pediatric cohort, CLE revealed a high prevalence of non–IgE-mediated food allergy not identified by standard allergy tests. CLE-guided food elimination led to substantial clinical improvement, underscoring CLE's diagnostic value as a real-time functional tool for evaluating food-induced mucosal responses in children and for guiding personalized dietary therapy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821312

Aims Endoscopic detection of gastric cancer is operator-dependent, and almost all existing artificial intelligence (AI) systems have been developed in high-incidence East Asian settings. We aimed to develop and preliminarily evaluate an AI model for detection and segmentation of gastric cancer in a Western population, where this pathology is low-incidence, using endoscopic submucosal dissection (ESD) histopathology as reference standard. The model was fine-tuned from a previously established semi-supervised network for Barrett's neoplasia (Meinikheim et al., Endoscopy 2024). Transfer learning is appropriate because both esophageal and gastric cancers share key endoscopic characteristics and multimodal imaging features across WLI, NBI, and TXI. The feature representations learned from large-scale Barrett's datasets therefore provide a strong initialization. Primary outcomes were Dice similarity coefficient for tumor segmentation and image-level detection sensitivity.

Methods In this retrospective single-centre study at a tertiary-care hospital in Germany (University Hospital Augsburg), we included 84 patients with histologically confirmed gastric adenocarcinoma (T1a or higher) treated by ESD. From these patients, 827 endoscopic images (Olympus systems; WLI, NBI, TXI, with or without indigo chromoendoscopy) showing visible gastric cancer were extracted. Tumor extent was delineated on still images by experts informed by the corresponding ESD specimens and full pathology reports. All data were de-identified before analysis.

A convolutional neural network segmentation model was initialized with weights from the Barrett AI system, which had been pre-trained on 55,273 endoscopic images from 557 patients with Barrett's esophagus and related neoplasia, and then supervisedly fine-tuned for gastric cancer segmentation. Data were split patient-wise into five train/validation folds (80/20 per fold) to avoid information leakage between patients, and a separate model was trained for each fold. For segmentation, performance was assessed using the Dice coefficient. For image-level detection, a tumor was considered detected in a given image if the entire predicted lesion region overlapped the ground-truth mask with Dice ≥ 75 %; detection performance was summarized as sensitivity at this threshold and as the area under a recall–overlap curve obtained by varying the Dice threshold from 0 to 1.

Results Across the five patient-wise folds, tumor Dice averaged 82.93 % with a standard deviation of 1.39 % [80.91–84.37 %]. Image-level detection sensitivity at Dice ≥ 75 % averaged 94.86 % with a standard deviation of 3.12 % [90.23–97.59 %]. The area under the recall–overlap curve averaged 0.912 with a standard deviation of 0.009. These results indicate a consistent and robust performance across all validation images.

Conclusions This preliminary single-centre study shows that an AI model fine-tuned from a semi-supervised Barrett's esophagus system can accurately segment and reliably detect gastric cancer in Western multimodal endoscopic data using ESD-based histopathology as ground truth. The model provided robust pixel-level delineation and high image-level detection sensitivity across a variety of imaging modes, indicating that pathology-anchored AI for gastric cancer is feasible even in Western cohorts where this pathology is low-incidence. However, because the dataset included only images with visible cancer, the reported performance does not reflect specificity, and results should not be extrapolated to screening or mixed-pathology settings. Future work should include external validation in multicentre Western cohorts, assessment on images containing no lesions or other pathologies, and evaluation on full-length endoscopic videos to better approximate clinical performance.

To our knowledge, this is among the first endoscopic AI systems for gastric cancer developed in a Western population and one of the few to leverage ESD specimen–based ground truth for training and validation.

PYP374 Direct Puncture versus Pull-Through Technique in Percutaneous Endoscopic Gastrostomy: A Retrospective Propensity Score Matched Study

Authors Van De Loo DJ[1, 2], Sanoubara F[1], Meier JA[1], Reinsch Y[1], Meden L[1], Klittich J[1], Zishiri J[1], Peiffer KH[2], Uschner FE[1], Rennebaum F[1], Mccoy M[1], Trebicka J[2], Braden B[2], Praktiknjo M[2]

Institutes **1** Münster University Hospital, Münster, Germany; **2** Department of Medicine B, Münster University Hospital, Münster, Germany

DOI 10.1055/s-0046-1821313

Aims Percutaneous endoscopic gastrostomy (PEG) is essential for enteral feeding in patients with neurologic or head/neck/esophageal disorders. Direct puncture (DP) after gastropexy is suggested to reduce complication rates compared to pull-through (PT) technique. However, indications determine the choice between both techniques. In this large, retrospective propensity score matched study from a German tertiary endoscopic center, we aim to comprehensively evaluate the complication profiles of DP technique and compare it to the more frequently performed PT method stratified by indications.

Methods Retrospective data of all PEG procedures from 2015 to 2024 were collected from electronic patient charts including general demographic information, comorbidities, medication, laboratory results and outcomes.

Propensity score matching between DP and PT was performed (1:2) for underlying disease and current treatment of malignant diseases to reduce selection bias.

Primary outcomes were occurrence of major (bleeding, pneumoperitoneum, perforation, systemic infection and tube dislodgment) and minor adverse events (pain and local infection). Secondary outcome was 60-day-mortality.

Results A total of 1002 consecutive PEG procedures (n = 178 DP, n = 816 PT, n = 8 for other techniques) were included. Overall, baseline characteristics were significantly different for underlying disease and current treatment for malignant disease in the DP group (PT: 44.1 % vs. DP: 87.6 %, p < 0.001). Overall major and minor adverse events were 34,8 % but significantly lower in PT (PT: 32 % vs. DP: 48,3 %, p < 0.001).

Following 1:2 propensity score matching, 513 procedures (171 DP, 342 PT) were analyzed. The median age was 64 years with 68.6 % male patients. Baseline demographics, medication and comorbidities were not significantly different between the matched cohorts.

Major (PT: 41.8 % vs. DP: 47.3 %, p = 0.24) and minor (PT: 11.7 % vs. DP: 9.4 %, p = 0.423) adverse events were similar between both groups matched for tumour disease and treatment.

However, tube dislodgment occurred significantly more frequently in the DP compared to the PT group (7.6 % vs. 1.5 %, p < 0.001).

60-day-mortality was similar between PT and DP (8.5 vs. 10.5 %, p = 0.449).

Conclusions Our results show that, except for tube dislodgment, adverse event rates are comparable between PT and DP and thus, do not confirm previous reports of reduced complication rates in DP, when matched for underlying disease. In our study different complication rates are observed with types of underlying disease. This study underlines the current ESGE recommendation to perform pull through technique if technically feasible.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP375 Safety Profile, Patient and Device-Related Adverse Events of Percutaneous Endoscopic Gastrostomy (PEG) Tubes: A Report From Manufacturer and User Facility Device Experience (MAUDE) Database Analysis

Authors Achanta SCR[1], Kocharlakota VNSS[2], Hanumanthu S[2]
Institutes **1** KIMS Hospital, Visakhapatnam, India; **2** KIMS Hospitals, Seethammadhara | Best Multi-Speciality Hospital in Vizag, Visakhapatnam, India
DOI 10.1055/s-0046-1821314

Aims Percutaneous endoscopic gastrostomy (PEG) tubes are commonly placed to provide long-term enteral nutrition to patients suffering with neurological dysphagia and head and neck cancers. It is safe and effective when performed by experts; however, device-related problems and patient-related adverse events are known but underreported. We aimed to analyse device-related problems and patient-related adverse events associated with PEG tubes reported in the Manufacturer and User Facility Device Experience (MAUDE) database (▶ **Table 1**).

▶ **Table 1** Most common device-related problems reported for PEG tubes in the FDA MAUDE database, (N = 2185)

Device-related problems n (%)Leak/Splash 254 (11.62%)Break 237 (10.85%)Detachment of Device or Device Component 224 (10.25%) Obstruction of Flow 135 (6.18%)Device Dislodged or Dislocated 121 (5.54%)Burst Container or Vessel 66 (3.02%)Fracture 58 (2.12%)Fluid/ Blood Leak 58 (2.65%)Material Rupture 55 (2.52%)Device Contamination with Chemical or Other Material 49 (2.24%)

Methods MAUDE database of the USFDA was accessed (URL link: https://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfmaude/search.cfm). A total of 2,032 reports were collected between December 2008 and August 2025 using the search terms "PEG tube," "Gastrostomy tube," and "Percutaneous endoscopic gastrostomy tube." All reports were exported to Microsoft excel sheet, duplicates were carefully sorted out and data was analysed for device-related problems and patient-related adverse events using the software inbuilt in Excel (▶ **Table 2**).

▶ **Table 2** Most common patient-related adverse events reported in association with PEG tubes in the FDA MAUDE database, (N = 897)

Patient-related adverse events n (%)Foreign Body in Patient 90 (10.03%)Infection 68 (7.58%)Pain 47 (5.24%)Feeding problem 34 (3.79%)Device embedded in tissue/plaque 19 (2.12%)Failure of implant 19 (2.12%)Hemorrhage/bleeding 18 (2.01%)Peritonitis 18 (2.01%) Bowel perforation 18 (2.01%)Vomiting 18 (2.01%)

Results A total of 2185 device-related problems and 897 patient-related adverse events were reported in the MAUDE database from a total of 2032 individual reports with highest number of events reported in 2024 (n = 291, 14.32%). More than one device-related problem was identified in 334 (16.44%) reports. The most common device-related problems reported were leaks/splashes (n = 254, 11.62%), breakage (n = 237, 10.85%), and detachment of the device or device component (n = 224, 10.25%) (Figure 1).
There was no impact on the patient and/or no known consequence in majority of the cases (n = 1162, 57.18%). However, the most frequent patient related complications reported were foreign body in the patient (n = 90, 10.03%), infection (n = 68, 7.58%), pain (n = 47, 5.24%), feeding problems (n = 34, 3.79%), device embedded in tissue/plaque (n = 19, 2.12%), implant failure (n = 19, 2.12%), and hemorrhage/bleeding (n = 18, 2.01%). Mortality was mentioned as an event type "death" in 0.98% (n = 20) of the patient-related events (Figure 2)
Conclusions PEG tube placement is safe and effective. Patient-related incidents were uncommon and rarely fatal. Tube leaks/splashes and breaks were the most common device-related problems. Continuous innovation and improvement are required to reduce the number of device-related issues and improve patient safety.

PYP376 EUS-Guided Coil Embolization of Gastro-Renal Shunt for the Management of Gastric Varices and Its Impact on Hepatic Encephalopathy

Authors Simone M[1], Salvi L[1], Martini F[2], Alessandrini A[1], Dalla Bella M[1], Marzioni M[1], Benedetti A[1], Taccari F[1], Marconcini G[1], Testa BE[1], Tarantino G[1]
Institutes **1** AOU delle Marche, Clinic of Gastroenterology, Hepatology and Endoscopy, Ancona, Italy; **2** Institut Paoli-Calmettes, UEMCO Gastroenterology and Digestive Endoscopy, Marseille, France
DOI 10.1055/s-0046-1821315

Background Gastric varices (GV) are an uncommon but life-threatening cause of gastrointestinal bleeding in patients with portal hypertension (PH). Their management using standard methods remains challenging, especially in patients with hepatic encephalopathy (HE), for whom transjugular intrahepatic portosystemic shunt (TIPS) may be contraindicated, requiring alternative approaches. We report a case of a high-risk, type 1 isolated GV (IGV1) successfully managed with endoscopic ultrasound (EUS)-guided coil embolization, resulting in subsequent improvement in HE.
Case Presentation and Management A 72-year-old male with dysmetabolic cirrhosis and overt HE was referred for surveillance of esophageal varices (EV). Esophagogastroduodenoscopy revealed F2-grade EV with haematocystic spots, treated with band ligation, and a submucosal fundic bulge consistent with IGV1, further confirmed by EUS. To assess the degree of PH, an EUS-guided portal pressure gradient measurement was performed, yielding a value of 16 mmHg. Due to persistent overt HE, TIPS was considered unsuitable. EUS-guided coil embolization was performed as primary prophylaxis, targeting the gastro-renal shunt.
Outcomes The procedure resulted in the disappearance of GV and improvement in HE, documented one month later by an increase in the Animal Naming Test score from 6 to 17, along with a decrease in plasma ammonia levels from 105 to 68 µmol/L.
Conclusions EUS-guided embolization of GV is emerging as an effective alternative to conventional treatments, particularly for patients unsuitable for TIPS. Beyond achieving effective variceal control, shunt embolization may contribute to improvement in pre-existing HE by reducing portosystemic diversion. Further studies are needed to assess the long-term outcomes of this approach.

PYP377 Endoscopic Ultrasound–Guided Shunt Occlusion: Experience from Three Cases

Authors Agrawal S[1], Bhaware B[2], Godbole S[1], Mukewar S[2], Mukewar S[2]
Institutes **1** MIDAS HOSPITAL, Nagpur, India; **2** Midas Multispeciality Hospital Pvt. Ltd., Nagpur, India
DOI 10.1055/s-0046-1821316

Aims EUS-Guided Shunt Occlusion for Refractory Hepatic Encephalopathy: A Three-Case Series Demonstrating a Promising Alternative to BRTO and TIPS

Methods We retrospectively analyzed three male patients (ages 41–66) with ethanol-related cirrhosis and recurrent OHE despite optimal medical therapy. All had large splenorenal or splenoportal shunts documented on CT, with significant portofugal flow on Doppler. Due to financial constraints or high MELD, liver transplantation, BRTO, and TIPS were not feasible [1–3].

Under deep sedation, an echoendoscope was positioned at the gastric cardia to visualize the splenoportal axis. The afferent feeder to the shunt was identified using Doppler, and a 19G EUS-FNA needle was used for direct puncture. Technique involved deployment of 18–20 mm coils followed by n-butyl cyanoacrylate glue injection, in single or staged sessions, depending on residual flow. Coil number ranged from 2 to 6 per patient. Post-procedure, patients were monitored for bleeding, ascites, hypoxia, and worsening decompensation. CT portography was repeated after 4–6 weeks. Clinical follow-up included MELD score, HE episodes, and functional status assessment.

Results Case 1 (66-year-old male): Large splenoportal shunt with recurrent HE. Single-session ETSO with two coils and 2 ml glue achieved complete obliteration. No complications. No further HE over 3 months; improved cognition reported.

Case 2 (57-year-old male, MELD 28): Large posterior gastric vein afferent shunt. Initial coil + glue session partially occluded flow. A second puncture achieved complete thrombosis. Developed mild hemoperitoneum and ascites, managed with correction of coagulopathy. Hospital stay: 20 days. After discharge, only one minor HE episode occurred at 3 weeks, and none thereafter. CT at 35 days showed complete non-opacification of shunt without thrombus extension. MELD improved to 25 at 2 months.

Case 3 (41-year-old male, MELD 13): 1.5–2 cm splenorenal shunt. Staged ETSO was required due to shunt size. Three sessions performed over 2 weeks with multiple coils and 4 ml glue. Mild post-procedure hypoxia occurred, managed conservatively. CT showed partial and progressive obliteration. No episodes of OHE in last month. Improved sensorium and liver function.

Across all cases: Technical success: 100 %; Clinical control of OHE: achieved in all three; No portal vein/systemic thrombus extension; No mortality; MELD improvement in all three patients; Average follow-up: 2 months

Conclusions This case series demonstrates that EUS-guided shunt occlusion is a feasible and effective therapeutic alternative for patients with recurrent HE and contraindications to TIPS, BRTO, or transplantation. The ability to directly visualize and selectively embolize the shunt afferent offers distinct procedural precision over radiologic methods. While mild complications occurred, all were manageable, and neurocognitive improvement was consistent across patients. ETSO may represent an emerging interventional paradigm in hepatology, particularly within resource-constrained settings. A multicentric prospective study is urgently needed to establish standardized protocols, optimal coil–glue combinations, and long-term outcomes beyond encephalopathy control, including survival and portal hemodynamics.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP378V Bipolar hemostatic forceps in iatrogenic papillary bleeding: Utility of a third-space endoscopic device in a very different scenario

Authors Terán Á[1, 2], Moris M[1, 2], Rodríguez Duque JC[1, 2], Fraile-Lopez M[1, 2], Martín Ramos L[2, 1], López Arias MJ[1, 2]
Institutes **1** IDIVAL, Santander, Spain; **2** Gastroenterology and Hepatology Department, Marqués de Valdecilla University Hospital, Santander, Spain
DOI 10.1055/s-0046-1821317

Problem to solve Iatrogenic papillary bleeding (IPB) is a relatively common (1-2 % post-sphyncterotomy -PS- and 10 % post-ampullectomy) and potentially a life-threatening endoscopic complication. Despite many endoscopic treatments available, literature is scarce about the best and more efficient option.

Innovation Hemostatic bipolar forceps (HBF) Hemostat™, a common third-space endoscopy device for vessel precoagulation and/or bleeding treatment, is a new kid on the block in the setting of IPB with first 2 case reports published in 2024. Nevertheless, HBP presents some attractive features for this scenario: 1) good functionality through duodenoscope elevator, 2) possibility of clamping the bleeding point to properly define it, 3) bipolar current with fewer surrounding energy application and 4) costs [1–3].

Results Twenty two cases of IPB (81.8 % intraprocedural and 18.2 % delayed) were treated by HBF in 21 patients by 2 experienced endoscopists in a 2-year period from June-2023 to June-2025. Patients were 82.7 % female, mean age 76.4 ± 12.71 and ASA III-IV: 52.4 %. Initial procedure was ERCP + ES and/or precut in 81.8 % and ampullectomy in 18.2 %. Severity of IPB was classified as AGREE III in 95.5 % and AGREE V in 4.5 %. Procedural and technical data are presented in ▶ **Table 1**.

▶ **Table 1**

		Total (N: 22)	Intraprocedural (n: 18)	Delayed (n: 4)
Active bleeding		95.5 %	100 %	75 %
HBF as single treatment		40.9 %	44.4 %	25 %
Combined therapy	HBF + 1	36.4 %	33.3 %	50 %
	HBF + ≥ 2	22.7 %	22.2 %	25 %
Type of combined therapies	Epinephrine washing	27.3 %	27.8 %	25 %
	Clipping	27.3 %	27.8 %	25 %
	Stent	22.7 %	22.2 %	25 %
	Others	13.6 %	11.1 %	25 %
HBF technical success		100 %	100 %	100 %
Hemostatic success	Atributable to HBF	80.9 %	83.3 %	50 %
	Total	100 %	100 %	100 %
HBF related complications		0 %	0 %	0 %
Bleeding recurrence		13.6 %	11.1 %	25 %

Conclusions BHF seems to be a safe and effective treatment for IPB. These results, its functionality through the duodenoscope and its electrophysical properties made the BHF appear as an attractive tool for IPB.

PYP379 Contrast-Enhanced Harmonic Endoscopic Ultrasonography for Diagnosing Gastric Subepithelial Tumors

Authors Kim GH[1, 2], Lee MW[1], Joo DC[1], Lee BE[1], Jeon HK[1], han SY[1]

Institutes **1** Department of Internal medicine, Pusan National University School of Medicine, Busan, Republic of Korea; **2** Biomedical Research Institute, Pusan National University Hospital, Busan, Republic of Korea

DOI 10.1055/s-0046-1821318

Aims Contrast-enhanced harmonic endoscopic ultrasonography (CH-EUS) is a promising tool for differentiating gastric subepithelial tumors (SETs). However, most published studies have mainly included gastrointestinal stromal tumors (GIST) and leiomyomas in the gastrointestinal tract, not limited to gastric SETs. This study evaluated the diagnostic performance of CH-EUS in gastric SETs encountered in clinical practice (▶ **Table 1**).

Methods We retrospectively analyzed 68 patients who underwent CH-EUS for gastric SETs between March 2021 and July 2025 at our institution. Gastric SETs were classified into benign ($n = 27$: ectopic pancreas, leiomyoma, schwannoma, glomus tumor, plexiform fibromyxoma, desmoid tumor, solitary fibrous tumor, and abscess) and GIST groups ($n = 41$). CH-EUS features, including arterial enhancement, irregular vessels, and diffuse enhancement, were assessed. Histopathological confirmation was obtained through EUS-guided fine-needle biopsy or endoscopic/surgical resection [1–4].

Results The GIST group showed significantly higher rates of arterial enhancement (95.1 % vs. 74.1 %, $p = 0.024$), irregular vessels (51.2 % vs. 22.2 %, $p = 0.017$), and diffuse enhancement (87.8 % vs. 66.7 %, $p = 0.035$) than the benign SETs. The diagnostic performance of arterial enhancement showed a sensitivity of 95.1 % and specificity of 25.9 %, while irregular vessels demonstrated a sensitivity of 51.2 % and specificity of 77.8 %, and diffuse enhancement showed a sensitivity of 87.8 % and specificity of 33.3 %. When combining ≥ 2 CH-EUS features, the sensitivity and specificity were 92.7 % and 33.3 %, respectively, with an overall accuracy of 69.1 %. The presence of all three features yielded a specificity of 81.5 % but a lower sensitivity (46.3 %).

Conclusions CH-EUS exhibited a high sensitivity but moderate specificity in differentiating GISTs from various benign gastric SETs when using a combination of at least two CE-EUS features, including arterial enhancement, irregular vessels, and diffuse enhancement.

▶ **Table 1** Sensitivity, specificity and positive and negative predictive values of the CH-EUS features that differentiate GISTs from benign subepithelial tumors in the stomach (%)

CE-EUS features	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Accuracy (%)
Arterial enhancement	95.1 (83.5-99.4)	25.9 (11.1-46.3)	66.1 (60.7-71.1)	77.8 (44.0-94.0)	67.7 (55.2-78.5)
Irregular vessels	51.2 (35.1-67.1)	77.8 (57.7-91.4)	77.8 (61.9-88.3)	51.2 (42.0-60.4)	61.8 (49.2-73.3)
Diffuse enhancement	87.8 (73.8-95.9)	33.3 (16.5-54.0)	66.7 (60.0-72.8)	64.3 (40.3-82.7)	66.2 (53.7-77.2)
Of the above 3 features					
≥ 1	95.1 (83.5-99.4)	22.2 (8.6-42.3)	65.0 (60.0-70.0)	75.0 (39.5-93.2)	66.2 (53.7-77.2)
≥ 2	92.7 (80.1-98.5)	33.3 (16.5-54.0)	67.9 (61.5-73.6)	75.0 (47.1-91.0)	69.1 (56.7-80.0)
All	46.3 (30.7-62.6)	81.5 (61.9-93.7)	79.2 (61.7-90.0)	50.0 (41.7-58.3)	60.3 (47.7-72.0)

PYP380 North Central London Acute Severe Pancreatitis Network: A One-Year Review of a Collaborative Two-Centre Referral Model

Authors Sriranganathan D[1], Villaneuva A[1], Tufuo V[2], Marrinan A[1], Affarah L[1], Knox C[1], El Menabawey T[1], Jonathan P[2], Beverly K[2], Chapman M[1], Johnson G[1], Pereira S[1], Webster G[1], Martin H[2], Phillpotts S[1]
Institutes **1** University College Hospital, London, United Kingdom; **2** Royal Free Hospital, London, United Kingdom
DOI 10.1055/s-0046-1821319

Aims Acute pancreatitis (AP) represents a major healthcare burden, with complex cases often requiring coordinated multidisciplinary input. To optimise management and streamline regional referrals, the North Central London Acute Severe Pancreatitis Network was established as a collaboration between the hepaticopancreatobiliary teams at University College London Hospital (UCLH) and the Royal Free Hospital (RFH).

Both centres, located in close proximity, observed that several hospitals across the South of England were referring patients to both sites, leading to duplicated clinical work, conflicting communication, and inefficient use of endoscopy capacity. In response, a unified referral pathway was established to provide timely specialist advice and interventions whilst improving workflow and efficiency. We present a one-year review assessing referral patterns, clinical outcomes, and the impact of this collaborative model on service efficiency. The network operates through a single point-of-contact phone line, alternating weekly between UCLH and RFH, with all referrals and clinical progress are recorded on a shared database. A specialist nurse receives all referrals and responds with consultant or senior fellow advice within 24 hours. Weekly clinical updates are obtained and discussed at a weekly network MDT.

Methods A retrospective review was performed of all acute pancreatitis referrals received by the network over a 12-month period. Data collected included referral source, disease severity, imaging findings, interventions performed (endoscopic, radiological, or surgical), length of stay, adverse events, and mortality. Workload distribution between the two sites was analysed to assess the impact of shared clinical responsibility. Outcomes were compared with internal historical data prior to network implementation.

Results Between 2 December 2024 and November 2025, the network received 164 referrals from 19 hospitals across a catchment area extending roughly 120 miles. The mean time on the pathway from referral to discharge was 17.6 days (median 13), compared with 23 days before the network was established. Twenty-nine patients (18 %) required endoscopic intervention. Of these, 24 (83 %) underwent LAMS placement for walled-off necrosis, 4 (14 %) of whom required necrosectomy. 5 patients (17 %) received plastic stents for pseudocysts. There were five deaths (3 %), all due to complications of severe pancreatitis.

Conclusions The North Central London Acute Severe Pancreatitis Network demonstrates that a coordinated two-centre model with a single referral pathway can significantly reduce duplicated work, improve resource utilisation, and maintain high-quality specialist care. This model supports efficient management of complex AP across a large regional population and serves as a scalable framework for other tertiary HPB services.

DOI 10.1055/s-0046-1821320

Aims EUS-directed procedures using lumen-apposing metal stent (LAMS) have been proposed as a more effective alternative to enteroscopy-assisted ERCP for patients with post-surgical anatomy. Amongst factors that influence LAMS migration risk, stent fixation has been suggested as a protective factor. For LAMS fixation with a dedicated over-the-scope fixation device, only a proof-of-concept study within the context of EUS-directed transgastric ERCP (EDGE) is available.

The current study aimed to assess the efficacy and safety of single-session EUS-directed procedures with the dedicated over-the-scope fixation device, using a larger international cohort.

Methods A retrospective multicenter analysis was performed, including consecutive single-session EUS-directed procedures with the Stentfix device from 11 centers. Only 20x10mm LAMS were utilized. Single-session EUS-directed transgastric interventions (EDGI), as well as EDGE and EUS-directed transenteric ERCP (EDEE) were eligible for inclusion. The primary outcome was perprocedural distal LAMS migration and key secondary outcomes included adverse events, employing the AGREE classification, and single-session technical success rates.

Results Ninety-seven patients undergoing single-session EUS-directed procedures were included (mean age 57.5 [standard deviation (SD) ± 11.8] years, 75.3 % female) with predominantly a history of Roux-en-Y gastric bypass (86.6 %), Roux-en-Y gastrectomy (4.1 %) or pancreatoduodenectomy (3.1 %). Procedures consisted of EDGE (n = 77, 79.4 %), EDGI (n = 10, 10.3 %) and EDEE (n = 10, 10.3 %). Main indications were stones or sludge (36.1 %), cholangitis/sepsis (22.7 %) and benign strictures (20.6 %). A 'single-session-first'-approach was used for 83 patients (85.6 %), reserving dual-session procedures only for patients where excessive resistance was encountered during duodenoscope insertion.

Perprocedural distal LAMS migration occurred in 1 patient (1.0 %), for which endoscopic salvage was performed using through-the-scope suturing (grade IIIa). Adverse events occurred in 15.5 % of patients (n = 15), consisting of grade I (n = 3, 3.1 %), grade II (n = 2, 5.2 %), grade IIIa (n = 5, 5.2 %), grade IIIb (n = 1, 1.0 %) and grade IV adverse events (n = 1, 1.0 %). Bleeding (n = 5, 5.2 %) and pain (n = 3, 3.1 %) where the most frequent adverse events. One proximal LAMS dislocation occurred during duodenoscope retraction and 1 delayed LAMS dislocation occurred > 12 hours after successful EDGE completion, which required endoscopic salvage utilizing an esophageal stent (grade IV) and surgical salvage (grade IIIb) respectively. Both patients with immediate (n = 1) and delayed (n = 1) distal LAMS migration had a history of more extensive gastric surgery beyond Roux-en-Y gastric bypass, consisting of partial gastrectomy and sleeve gastrectomy respectively.

Single-session technical success was achieved in 88.7 % in a median procedure duration of 55 min (interquartile range (IQR) 43-73). After a median follow-up of 228 days (IQR 108-393), planned LAMS and Stentfix removal was performed in 68 cases (70.1 %), using mainly forceps traction (n = 63, 64.9 %). The dedicated removal system was employed in 5 cases (5.2 %).

In 14 patients, no closure techniques were applied following LAMS removal (14.4 %), whereas in 42.3 % of patients over-the-scope clip fistula closure was performed (n = 43).

Conclusions Over-the-scope LAMS fixation resulted in a low distal LAMS migration rate for single-session EUS-directed procedures and our data furthermore suggest that this technique might facilitate a 'single-session-first'-approach in patients undergoing EUS-directed procedures. However, given distal LAMS migrations only occurred in patients with Roux-en-Y gastric bypass and a history of more extensive gastric surgery beyond gastric bypass, alternative approaches might be considered in these specific situations.

DOI 10.1055/s-0046-1821321

Aims Enteroscopy-assisted endoscopic retrograde cholangiopancreatography (EA-ERCP) is an established technique for managing benign hepaticojejunostomy (HJ) stenosis. Compared to alternative interventions, such as percutaneous or endosonography-guided approaches, EA-ERCP is less invasive and offers a favorable safety profile. However, technical success rates of EA-ERCP may be lower in anatomically complex cases, such as those involving Roux-en-Y (RY) anastomoses, as compared to simpler BII gastroenteric anastomoses used in pancreatoduodenectomy (PD). Additionally, it is currently unclear whether balloon dilatation alone, or combined with stenting, represents the most effective endoscopic treatment strategy. The primary study aim was to evaluate the efficacy and safety of EA-ERCP for suspected benign HJ stenosis in patients with RY versus PD. The secondary aim was to assess the outcomes of balloon dilatation with or without stent placement.

Methods This single-center retrospective study included patients who underwent EA-ERCP for suspected benign HJ stenosis between 2018 and 2025. Eligible patients had previously undergone PD or HJ with RY, while excluding those with post-gastric bypass anatomy. Procedures were performed using a short- or long-type double-balloon enteroscope. HJ stenosis was treated with balloon dilatation alone, or when the stricture failed to resolve adequately, balloon dilatation was combined with stent therapy. A metal covered Nagi stent was placed if technically possible, if not, multiple plastic stents were inserted. Recurrences of HJ stenosis were generally managed with repeat balloon dilatation combined with stent therapy. The primary outcome was technical success. Secondary outcomes included clinical success (symptom resolution 14 days post-EA-ERCP), adverse events (AGREE classification), recurrent HJ stenosis and the need for reintervention.

Results A total of 192 patients underwent 320 EA-ERCPs. Benign HJ stenosis was confirmed in 102 of 192 (53.1 %) index EA-ERCPs. Overall technical success rate was 279/320 (87.2 %); 194/220 (88.2 %) in PD group and 85/100 (85.0 %) in RY group [p = 0.16]. Technical failures in PD versus RY patients included inability to reach the HJ (12; 5,5 % vs 13; 13,0 %), to canulate the bile ducts (13; 5,9 % vs 2; 2,0 %) and to complete the intended therapy (1; 0,5 % vs none). Overall clinical success was 83,9 % (PD 116/135 (85,9 %) versus RY 35/45 (77,8 %), p = 0.35). Overall adverse event (AE) rate was 16/320 (5.0 %) (PD

Endoscopy 2026; 58: S1–S1041

11/220; 5.0 % versus RY 5/100; 5.0 %), without severe (grade IV/V) AEs. At index EA-ERCP, 79 patients were treated with balloon dilatation. Recurrence of HJ stenosis requiring reintervention was observed in 37/79 (46.8 %) patients at a median of 8 months [IQR: 1.5-29], which occurred in 25/37 (67.6 %) cases in the PD group and 12/37 (32.4 %) patients in the RY group. Median total follow-up was 17.0 months [IQR: 8.0-35.3]. HJ patency at 1, 2 and 3 years was 67.9 %, 58.7 % and 40.4 %, respectively. Stent therapy was initiated in 33 patients, either by multiple plastic stents (n = 24) or a Nagi stent (n = 9). Stent dysfunction requiring reintervention occurred in 5/24 (20.8 %) patients treated with plastic stents and in 4/9(44 %) patients with a Nagi stent. Recurrence of HJ stenosis for which reintervention was needed, was observed in 8/33 (26 %) patients following stenting therapy, after a median follow up of 8 months [IQR 1-14]. Recurrence of HJ stenosis after stent therapy in PD group was 4/8 (50 %) and 4/8 (50 %) in RY group.

Conclusions EA-ERCP for suspected HJ stenosis shows a similar high technical and clinical success rate in patients with PD and RY anatomy with a favorable safety profile. These findings reinforce the role of EA-ERCP as first line approach in benign HJ stenosis in both types of anatomical reconstructions. However, future studies should focus on optimizing the therapeutic strategy to reduce recurrences of HJ stenosis.

PYP383 Post-ERCP Complications in Patients with Cirrhotic versus Non-Cirrhotic Portal Hypertension: A Retrospective Comparative Study from a Tertiary Eastern European Center

Authors Hirișcău F[1], Tefas C[2, 1]

Institutes 1 Iuliu Hațieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; 2 Institutul Regional de Gastroenterologie și Hepatologie Prof. Dr. Octavian Fodor, Cluj-Napoca, Romania

DOI 10.1055/s-0046-1821322

Aims Endoscopic retrograde cholangiopancreatography (ERCP) remains the mainstay for biliary and pancreatic interventions but carries an increased risk of adverse events in patients with portal hypertension (PH). This study aimed to compare the incidence and profile of post-ERCP complications in patients with cirrhotic versus non-cirrhotic PH.

Methods A retrospective observational study was conducted on 109 patients with PH who underwent ERCP between January 2019 and May 2024 at a tertiary referral center. Patients were divided into two groups: cirrhotic PH (n = 48) and non-cirrhotic PH (n = 61, mainly portal vein thrombosis or cavernoma). Clinical, laboratory, and endoscopic data were analyzed, including post-ERCP pancreatitis (PEP), bleeding, and cholangitis. Statistical analysis used Chi-square, Fisher's exact, t-test, and logistic regression, with $p < 0.05$ considered significant.

Results Overall complication rates were significantly higher in cirrhotics (39.6 %) compared with non-cirrhotics (6.5 %, $p < 0.001$). Post-ERCP bleeding occurred in 14.6 % vs. 3.3 % (OR 5.04, 95 % CI 1.00–25.48, p = 0.033), cholangitis in 12.5 % vs. 1.6 % (OR 6.98, 95 % CI 0.79–61.87, p = 0.022), and PEP in 12.5 % vs. 1.6 % (OR 8.57, 95 % CI 1.00–73.84, p = 0.022). No perforations were observed. Within the cirrhotic cohort, Child-Pugh B/C stages were significantly associated with higher complication rates (p = 0.008).

Conclusions Cirrhotic patients—particularly those with decompensated disease—have a markedly increased risk of post-ERCP adverse events compared with non-cirrhotic PH. Rigorous pre-procedural optimization, careful risk stratification, and enhanced post-ERCP monitoring are essential to minimize morbidity in this high-risk population.

PYP384 Preliminary experience on the incidence and severity of post-ERCP pancreatitis in distal malignant biliary obstruction: a single tertiary-center analysis

Authors Crucillà S[1], Crinò SF[1], Conti Bellocchi MC[1], Butini M[1], Battan MS[1], Fichera G[1], De Pretis N[1], Caldart F[1], Amodio A[1], De Marchi G[1], Tortora A[1], Frulloni L[1]

Institute 1 University of Verona, Gastroenterology and Endoscopy Unit, Department Of Medicine, Verona, Italy, Verona, Italy

DOI 10.1055/s-0046-1821323

Aims Distal malignant biliary obstruction (DMBO) commonly requires endoscopic retrograde cholangiopancreatography (ERCP) with transpapillary stent placement. Although ERCP is the standard of care, the real incidence and clinical impact of post-ERCP pancreatitis (PEP) in DMBO remain unclear, as most data derive from mixed populations including benign or proximal lesions.

This study aimed to assess the incidence, severity, and predictors of PEP and other ERCP-related adverse events (AEs) in a tertiary referral center, providing preliminary data from a high-volume specialized unit.

Methods We conducted a single-center retrospective study including 246 consecutive patients with radiologically and histologically confirmed DMBO who underwent ERCP with transpapillary biliary stenting between January 2022 and June 2024 at the University Hospital "G.B. Rossi" in Verona, Italy. Clinical, imaging, and procedural variables were collected and analyzed, including age, sex, bilirubin levels, tumor size, duodenal infiltration, cannulation technique, sphincterotomy, and pancreatic stent placement. PEP was defined according to the Revised Atlanta Classification (2012) and graded as mild, moderate, or severe. Adverse events within 31 days were recorded. Univariate and multivariate logistic regression analyses were performed to identify potential predictors of PEP. Variables with $p < 0.10$ in univariate analysis were entered into the multivariate model [1–9].

Results Among 246 patients (mean age 67.2 ± 10.6 years; 54 % males), pancreatic adenocarcinoma was the most frequent cause of DMBO (85 %). The overall rate of post-ERCP adverse events was 26.4 %, with PEP being the most common (10.2 %). Most pancreatitis cases were mild (84 %), three were moderate (12 %), and one severe (4 %), resulting in a 1.6 % rate of clinically significant (moderate-to-severe) PEP. Other AEs included cholangitis (6.9 %), intraprocedural bleeding (3.3 %), and cholecystitis (2.4 %); no patient required ICU admission or died within 31 days. Univariate analysis showed a protective trend for tumor size > 30 mm ($p = 0.09$) and an increased risk of PEP with pancreatic stent placement ($p = 0.05$) and pancreatic-assisted cannulation ($p = 0.09$). In multivariate logistic regression, none of the variables reached formal significance; however, pancreatic stent placement remained the strongest predictor (OR 4.2, 95 % CI 0.88–20.1, $p = 0.07$). These findings suggest that PEP risk is mainly associated with procedural complexity rather than intrinsic patient characteristics.

Conclusions In this preliminary tertiary-center experience, ERCP with transpapillary stenting for DMBO showed a low incidence of clinically relevant PEP. Although PEP occurred in about 10 % of cases, moderate or severe forms were rare (1.6 %) and did not result in mortality or prolonged hospitalization. The observed trends suggest that pancreatic stent placement and complex cannulation may increase PEP risk, while larger tumors appear protective, possibly due to mechanical ductal obstruction.

These results highlight the crucial role of operator expertise and procedural standardization in minimizing adverse events.

ERCP remains the safest and most effective first-line approach for biliary drainage in DMBO when performed in expert hands.

Future multicenter prospective studies are warranted to validate these findings and develop risk stratification models tailored to malignant biliary obstruction.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

PYP385 Cholecystoenterostomy: A Breakthrough in the Management of Biliary Disease in Patients at Very High Surgical Risk

Authors Ben Farhat F[1], Clement M[1], Legoffic A[1], Mercky P[1], Sibertin C[1], Chinoune F[1], Ah-Soune P[1]
Institute 1 Hospital Sainte Musse, Toulon, France
DOI 10.1055/s-0046-1821324

Aims Endoscopic ultrasound (EUS)–guided gallbladder drainage using lumen-apposing metal stents (LAMS) has become an important therapeutic option for the management of acute cholecystitis in patients who are not surgical candidates. The aim of our study was to assess the efficacy and safety of creating a cholecystoenteric anastomosis followed by elective stent removal, in order to prevent late adverse events such as stent migration or occlusion in this high-risk population.

Methods This prospective study included all patients with biliary disease who had a contraindication to surgery and were managed with EUS-guided gallbladder drainage. The study began in September 2024 and is currently ongoing. Patients with biliary or pancreatic malignancies were excluded. The protocol consisted of two steps: placement of a 15-mm Axios lumen-apposing metal stent, followed by stent removal two months later. After the second procedure, all patients underwent scheduled follow-up evaluations every three months.

Results A total of 40 patients were included in the study. The mean age was 88.1 years (range 73–99), with a mean Charlson comorbidity index of 5.85. Eighteen patients were receiving anticoagulant therapy, which was systematically discontinued 48 hours before the procedure. Fourteen patients had a history of cholecystitis, including one following percutaneous drainage. Thirty patients presented with acute cholecystitis, associated with pancreatitis in 7 cases and cholangitis in 20 cases. Additionally, 4 patients had isolated pancreatitis and 6 had isolated cholangitis. All patients received antibiotic therapy.

Six patients had a sclerotic–atrophic gallbladder and required intravesicular saline injection using a 19G needle (mean volume: 20 mL) to facilitate drainage. Twenty-two patients had common bile duct stones and underwent ERCP. The mean procedure time was 28.9 minutes (range 11–80). Technical success was achieved in 100 % of cases, and clinical success in 97 %. One patient, an 85-year-old with grade 3 cholecystitis, died during hospitalization. The mean length of stay was 5 days.

Among the included patients, 20 underwent a second procedure with outpatient stent removal (study ongoing; 11 patients still awaiting removal). Complete gallbladder clearance was obtained in 17 patients. Three patients had residual stones: two were removed using a Dormia basket, and one large stone required laser lithotripsy. At the time of stent removal, four patients had duodenal ulcers at the stent contact site, two had stent obstruction due to food debris, and one showed evidence of intravesicular stent migration.

The mean follow-up period was 4.5 months (range 1–12). Three deaths were recorded at 2, 3, and 6 months after the initial procedure, none related to biliary pathology. No long-term complications or recurrent biliary events were observed.

Conclusions According to the preliminary results of our study, cholecystoenteric anastomosis should be considered the procedure of choice for patients at very high surgical risk, given its high technical and clinical success rates, effective gallbladder clearance, and ability to prevent long-term recurrence.

PYP388 Machine Learning versus QNI Score for Predicting Step-Up Therapy After Initial EUS-Guided Drainage of Pancreatic Fluid Collections

Authors Razpotnik M[1], Schalberger M[2], Herta T[1], Sigal M[1], Çelebi Ö[1], Adler A[1], Leonhardt S[1], Branchi F[3], Buchkremer J[3], Kouladouros K[1], Engelmann C[1], Siegmund B[3], Tacke F[1], Jürgensen C[1]
Institutes 1 Charité Campus Virchow/Campus Mitte, Berlin, Germany; 2 Institute of Statistics, Freie Universität Berlin, Berlin, Germany; 3 Charité Campus Benjamin Franklin, Berlin, Germany
DOI 10.1055/s-0046-1821327

Aims Pancreatic fluid collections (PFCs) are associated with high healthcare utilization and multiple interventions. However, clinicians still lack reliable baseline risk-stratification tools, leading to reactive decision-making rather than proactive risk-adapted care [1]. We therefore developed a machine-learning algorithm to predict step-up therapy requirements at index EUS and compared its performance with established clinical predictors.

Methods Data on EUS-guided drainage of consecutive PFCs performed between 2016 and 2024 across three endoscopy units at Charité Berlin, irrespective of etiology, were retrospectively collected. The primary outcome was need for step-up therapy, defined as endoscopic necrosectomy, percutaneous drainage, or laparoscopic/open surgery performed after the index procedure to achieve clinical success. An extreme gradient boosting (XGBoost) machine learning algorithm was developed and compared with the established QNI score (Quadrant, Necrosis, Infection) to predict need for step-up therapy [2, 3]. The cohort was randomly split into training (70 %) and validation (30 %) sets. Performance was assessed using 10-fold cross-validation, with discrimination quantified by area under the receiver operating characteristic curve. Of 163 evaluated patient-level features, 20 were selected for the final decision-support model based on Gini coefficients, clinical relevance, and practical considerations to preserve predictive performance while minimizing overfitting.

Results Among 674 consecutive patients, 486 were included in the final analysis (mean age 56.1 ± 14.3 years; 68.9 % male). Overall, 199 patients (40.9 %) required step-up therapy, including endoscopic necrosectomy (n = 145; 29.8 %), percutaneous drainage (n = 62; 12.8 %), multigate technique (n = 22; 4.5 %), and laparoscopic or open surgery (n = 35; 7.2 %). Compared with patients managed without step-up therapy, those requiring escalation had significantly larger PFCs (105 ± 46 vs. 67 ± 32 mm; p < 0.001), higher prevalence of > 60 %

necrosis (11.6 % vs. 2.4 %; p < 0.001), elevated CRP levels (median 176 mg/L [IQR 111–216] vs. 100 mg/L [IQR 55–173]; p < 0.001), increased infection rates (71.3 % vs. 44.3 %; p = 0.002), and more organ failure (31.2 % vs. 8.0 %; p < 0.001). Patients classified as high-risk by the QNI score (n = 125; 25.7 %) were more likely to undergo step-up therapy than low-risk patients (65.6 % vs. 32.4 %; p < 0.001). Extent of necrosis was the strongest predictor of step-up therapy (OR 3.9, 95 % CI 2.9-5.3; p < 0.001). The XGBoost model showed superior discriminative performance compared to the QNI score (AUC 0.86 vs. 0.77; p < 0.01) (▶ **Table 1**), correctly identifying an additional 12.7 % of patients needing step-up therapy while reducing false-positive predictions by 10.8 %.

▶ **Table 1**

	XGBoost Model	QNI Score
Discrimination Metrics	*Value (95 % CI)*	*Value (95 % CI)*
ROC-AUC	0.86 (0.82-0.89)	0.77 (0.73-0.82)
Accuracy	0.78 (0.75-0.82)	0.73 (0.71-0.75)
Sensitivity	0.79 (0.73-0.84)	0.62 (0.58-0.66)
Specificity	0.80 (0.75-0.83)	0.81 (0.78-0.84)
Top predictive features	*Gini*	*OR (95 % CI); p-value*
Necrosis amount [ordinal]	0.133	3.9 (2.9-5.3); p < 0.0001
PFC size (mm) [continuous]	0.093	
Gutter extension [categorical]	0.067	
Abdominal quadrants [ordinal]	0.066	2.6 (2.0-3.3); p < 0.0001
PFC in corpus [binary]	0.058	
CRP (mg/L) [continuous]	0.049	
Acute kidney injury [binary]	0.044	
Respiratory OF [binary]	0.043	
Infected PFC [binary]	0.035	3.1 (2.1-4.6); p < 0.0001

Conclusions The machine learning algorithm demonstrates superior discriminative ability for predicting step-up therapy compared with the QNI score and enhances risk stratification at the index procedure.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims Biliary self-expandable metal stent (SEMS) embedment, defined as incorporation of the stent mesh into the biliary wall or overgrowing tissue that precludes standard removal, is an uncommon but clinically relevant adverse event of biliary stenting. Difficult or "embedded" stent removal is estimated to occur in roughly 1–5 % of biliary SEMS and can lead to cholangitis, bleeding, and the need for complex reinterventions. According to available literature, clinical success of embedded biliary SEMS removal is strongly influenced by stent indwell time, local endoscopic expertise, and stent design, with markedly lower removal rates reported for uncovered and partially covered SEMS compared with fully covered devices. We aimed to describe the endoscopic techniques and outcomes of embedded biliary metal stent retrieval in a tertiary referral center, and to identify baseline and technical factors associated with successful endoscopic removal [1–8].

Methods We performed a retrospective analysis of prospectively collected data on consecutive patients referred between May 2017 and April 2025 for endoscopic treatment of embedded biliary metal stents in a tertiary referral center. Embedded stents were defined as not removable with standard forceps/snare traction and requiring advanced techniques. The primary outcome was complete endoscopic removal of all embedded stents. Secondary outcomes were baseline and technical factors associated with procedural success or failure, assessed applying univariate and multivariate logistic regression models.

Results Fifty-nine patients (61 embedded stents; 77.9 % male; median age 68 years) were included. The underlying indication for index biliary metal stent placement was predominantly benign (over 80 %), mainly post-surgical benign biliary strictures and biliary fistulas, whereas malignant strictures accounted for less than one fifth of cases. Despite this benign case mix, almost half of embedded devices were non–fully covered: most stents were fully covered SEMS (49.1 %), but 30.1 % were uncovered and 15.1 % partially covered SEMS, and three lumen-apposing metal stents were also included, highlighting that uncovered or partially covered SEMS are still used in benign settings where long-term removability is desirable. Advanced techniques at first attempt included multiple coaxial stent-in-stent (31.1 %), loop-and-sheath (previously described only in a single case report – 29.5 %, 61 % with mechanical lithotripter), single stent-in-stent (13.1 %), balloon dilation and argon plasma coagulation. First-attempt success was 50.9 %; a second and third endoscopic procedure were required in 42.6 % and 13.1 % of cases, respectively, yielding an overall clinical success of 85.4 % with a median of 2 procedures per case. Periprocedural and post-procedural adverse events occurred in 29.5 % of procedures, mostly cholangitis and bleeding; most were mild–moderate and managed conservatively, with only one death directly related to unresolved embedment. Longer stent indwell time and the occurrence of peri- or post-procedural adverse events were independently associated with clinical failure (both OR ≈ 2, p < 0.05).

Conclusions Endoscopic management of embedded biliary metal stents in a tertiary referral setting achieved high overall clinical success, irrespective of stent type, including uncovered and partially covered devices. Stent indwell time and the occurrence of peri- or post-procedural adverse events were the main independent predictors of clinical failure, underscoring the importance of timely stent retrieval, early referral to expert centers, and careful prevention and management of adverse events. Beyond its initial description in a single case report, the repeated successful use of the loop-and-sheath technique in this series suggests that it represents a valuable addition to the armamentar-

ium for complex embedded biliary SEMS, within a flexible, patient-tailored multimodal strategy rather than a rigid stepwise approach.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP001 Interventions to increase adherence to colorectal cancer screening programs

Authors Martins N[1], Castro H[2], Pontífice-Sousa P[3]
Institutes 1 Champalimaud Foundation, Lisboa, Portugal; 2 Hospital da Luz, Lisboa, Portugal; 3 Catholic University of Portugal, Lisboa, Portugal
DOI 10.1055/s-0046-1821329

Aims To describe interventions that enhance adherence to colorectal cancer screening programs, after mapping the scientific evidence on the fears and emotions experienced by patients undergoing colonoscopy, as well as the associated variables.

Methods To examine which interventions may increase adherence to colonoscopy, a scoping review was conducted according to the Joanna Briggs Institute Protocol, guided by the research question: "What are the fears and emotions associated with undergoing a colonoscopy, and the related variables?" A literature search was carried out in the PubMed, CINAHL, Scopus, and RCAAP databases in June 2025, including articles in Portuguese, English, and Spanish. These findings enabled the identification of targeted interventions and strategies capable of improving patient adherence to colorectal cancer screening programmes.

Results Colonoscopy is considered the gold standard for the diagnosis and treatment of gastrointestinal diseases [1, 2]. It is associated with a significant reduction in CRC mortality and is highly sensitive in detecting tumors, polyps, ulcers, active bleeding, and inflammatory disease [3]. However, achieving widespread adherence to colonoscopy remains a challenge [3], as despite its clinical benefits, it is an uncomfortable procedure in which pain and fear of the unknown generate anxiety and stress in many patients [2, 4]. Studies show that colonoscopy is often perceived negatively by society and commonly viewed as a source of anxiety and fear, which can prevent patients from undergoing the procedure and cause disruptions in the diagnostic and treatment process, contributing to the rejection of CRC screening programs [2]. This premise directly addresses the question: "Anxiety before gastrointestinal endoscopy – is it a significant problem?" [5].

All the circumstances described above justify the need to analyze the frequency and intensity of anxiety caused by colonoscopy, as well as to identify the factors that contribute to this effect and their influence on procedural tolerance(1). Although efforts have been made to improve tolerance through conscious or deep sedation, little attention has been paid to patients' pre-procedural anxiety [1]. According to Cardenal, cited by Olmo-Conesa(4), undergoing any diagnostic exam such as colonoscopy has emotional consequences for the patient, beginning at the time of scheduling [6] and continuing through the procedure and the delivery of results. It is considered an acute situation that subsides once the triggering stimulus ends [1]. According to the study by Sequeira [7], a moderate level of state anxiety was observed prior to the exam, which significantly decreased after the procedure, with statistical relevance.

Reported fears and emotions included concerns about medical complications, diagnosis, and pain. Variables such as information about the procedure, previous experiences, and gender influenced anxiety levels.

Conclusions Living in harmony with technological advancement requires a reinvention of thought, social interaction, empathy, and community, elements that distinguish humans from machines. It is crucial to reflect on empathy as a counterbalance to technology and its role in supporting and complementing the humanization of care.

The dissemination of these results aims to positively influence not only the nursing team but the entire multidisciplinary team involved in clinical endoscopic practice. These findings will foster greater awareness among all professionals of what patients experience throughout this process and offer practical applicability in care delivery. They also highlight the need and, above all, the relevance of intensifying and deepening research in such a subjective and vast area, supporting the conditions necessary to transform and improve the foundations and paradigms that underpin digestive endoscopy care.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP002 Multidisciplinary approach to treating obesity using endoscopic methods in a tertiary healthcare institution

Author Karlović K[1]
Institute 1 UHC Rijeka, RIJEKA, Croatia
DOI 10.1055/s-0046-1821330

Aims Obesity is a chronic metabolic disease characterized by excessive accumulation of adipose tissue in the body. It is associated with more than 200 health complications but the greatest risk factor are cardiovascular diseases. It is assessed by body mass index (BMI) and waist circumference measurement. The approach to treating obesity should be focused on reducing body weight in order to reduce the risk of cardiovascular and metabolic diseases and prevent weight gain. Treatment is primarily focused on changing bad lifestyle habits. Diet should definitely be adjusted and physical activity should be increased. In some cases, this is quite enough to reduce body weight, but for some patients lifestyle changes alone are not enough so pharmacotherapy, behavioral-cognitive approach, endoscopic and surgical treatment methods are combined with it [1–3].

The aim of this paper is to present the treatment procedure for obesity in a tertiary health institution – Cliical Hospital Center Rijeka which is multidisciplinary and to emphasize the newer endoscopic treatment methods that are available.

Methods At the Clinical Hospital Center Rijeka overweight patients report to an endocrinologist on the recommendation of a family doctor who conducts an initial interview with the patient. During the first examination a targeted search is made for the causes of obesity. After taking the patient's history and physical status the diagnostic tests that need to be performed are determined,.

Results Motivation is key to treating obesity. When working with patients a sense of trust should be developed, not judgmental and education should be

prioritized which is a fundamental part of treating obesity and treatment begins with it. It is carried out in the Endocrinology Day Hospital over a period of one week and is carried out by nurses specially trained in this area. During the education, the patient is trained to independently create a plan for lifestyle changes, changes in diet and physical activity. In addition to nurses a nutritionist, psychologist and physiotherapist are also involved in the education.

Pharmacotherapy is also useful in treating obesity where the use of medications reduces the feeling of hunger and stimulates satiety which ultimately leads to reduced calorie intake. If we have a patient with morbid obesity or pharmacotherapy alone does not provide satisfactory results a gastroenterologist endoscopist is also involved in the treatment who suggests endoscopic methods of treating obesity. The first method of choice is the placement of intragastric balloon which helps with weight loss by limiting the amount of food that can be eaten and allows for a faster feeling of satiety. A typical loss is about 7 % to 15 % of body weight.

In addition to this method, the endoscopic method of gastric mucosa ablation (GMA) with argon plasma coagulation (APC) is used for the treatment of obesity with which body weight can be further reduced by 13 %. With tjis method stomach is reduced by ablation of tissue. At the same time, the production of ghrelin so-called hunger hormone is reduced which results in a reduced feeling of hunger.

Conclusions Treatment with these endoscopic methods usually gives very good results. With patient motivation and cooperation it is possible to achieve a weight loss of up to 30 %. Bariatric surgery is a good way to treat people with morbid obesity, with which long-term weight loss can be achieved, but it should only be applied when education and use of pharmacological and endoscopic treatment do not produce the expected results.

Approach to the patient should be individualized and in treatment are involved a multidisciplinary team. A special role is played by nurse educators at the Endocrinology Day Hospital and endoscopic nurses who participate in the preparation, performance and monitoring of patients during endoscopic procedures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP003 The Impact of Deploying Specialized Physicians and Nurses in Rural Areas on the Accessibility and Quality of Health Services (A Case Study from 2024–2025)

Author Tuul E[1]

Institute 1 Kh.Sharav named Regional Diagnosis and treatment center, Dalanzadgad, Mongolia

DOI 10.1055/s-0046-1821331

Aims This study aimed to evaluate the impact of introducing a specialized endoscopist and endoscopy nurse into a rural regional hospital in Mongolia on the accessibility, quality, and cost of gastrointestinal endoscopic services. Specific objectives included assessing changes in service availability, procedure volume, cost-effectiveness for patients, and early clinical outcomes following the introduction of the new services in March 2025.

Methods A mixed-methods study was conducted at Kh. Sharav Regional Diagnostic and Treatment Center, Umnugovi Province.

Quantitative component: Procedure volumes for 2024 (before deployment) and January–September 2025 (after deployment) were compared. Cost analyses were performed using patient out-of-pocket expenditures for travel, accommodation, service fees, and additional costs in Ulaanbaatar versus local service use. Procedure types evaluated included gastroscopy, colonoscopy, bronchoscopy, gastric and colonic polypectomy, hemostasis, esophageal variceal ligation, and foreign-body removal.

Qualitative component: Twenty staff members (12 physicians, 8 nurses) completed a structured satisfaction survey assessing perceived workload changes, usefulness of new services, and overall satisfaction. Additionally, detailed case summaries were reviewed for 20 patients who underwent local therapeutic endoscopic procedures. Ethical approval was obtained at the institutional level, and no identifiable patient data were included.

Results Service accessibility and procedure volume: Introduction of specialized staff resulted in significant expansion of services. Gastroscopy increased from 945 (2024) to 1,315 (2025). Colonoscopy rose from 3 to 117, bronchoscopy from 0 to 17, and several therapeutic procedures (e.g., gastric/colonic polypectomy, hemostasis, variceal ligation) were performed locally for the first time. A total of 37 patients received therapeutic care locally instead of referral to Ulaanbaatar [1–4].

Cost reduction: Local service provision reduced average patient expenditure by 3–8 times depending on the procedure.For example: • *Esophageal variceal ligation*: 1,900,650 MNT locally vs. 6,694,200 MNT in Ulaanbaatar • *Hemostasis for gastric bleeding*: 3,151,500 MNT vs. 7,771,500 MNT • *Foreign-body removal (esophagus/stomach)*: 0 MNT vs. 2,640,000 MNTTotal patient cost savings for 37 cases amounted to 22,073,550 MNT.

No patients required referral to Ulaanbaatar for gastrointestinal bleeding management after March 2025. No deaths due to GI hemorrhage were recorded during the study period.

Clinical outcomes: All 20 documented therapeutic cases—including gastric ulcer bleeding managed by clipping, gastric polypectomies, variceal ligation, and foreign-body removals—showed complete recovery with no complications or technical difficulties.

Staff perceptions: All staff (100 %) agreed that the newly introduced endoscopic procedures were beneficial for patients. Overall satisfaction was 100 % ("satisfied" or "very satisfied"). Only 30 % reported increased workload, while 60 % perceived improved capacity.

Conclusions Deploying specialized endoscopy personnel to a rural regional hospital significantly improved service accessibility, enabled provision of advanced diagnostic and therapeutic procedures, and substantially reduced patient costs. The elimination of referrals for endoscopic management of gastrointestinal bleeding and the absence of mortality during the study period demonstrate early clinical benefit. The initiative also contributed to capacity building among local healthcare providers and serves as a scalable model for strengthening specialized services in rural Mongolia. Expanding deployment of specialized professionals has strong potential to enhance equity, quality, and continuity of care in low-resource settings.

eP004 Nursing Contributions to the Safety and Efficacy of Rectal Endo-Sponge Therapy – Case Report

Authors Božilović K[1], Boljesic S[1]
Institute **1** Sisters of Charity Hospital, Zagreb, Croatia
DOI 10.1055/s-0046-1821332

Aims Rectal Endo-Sponge therapy represents an advanced form of endoluminal negative-pressure wound therapy used in the management of anastomotic leaks and presacral abscesses following low anterior resection. By enabling continuous drainage, reducing bacterial burden and stimulating granulation tissue formation, this technique has increasingly become an integral part of postoperative management in colorectal surgery. Despite the central role of the endoscopist, optimal therapeutic outcomes depend heavily on the structured and highly skilled involvement of nursing staff within the endoscopy unit

Methods This case report presents the successful use of Rectal Endo-Sponge on 71 year old male patient who was admitted for surgical removal of a rectal adenoma, followed by creation of a TT colorectal anastomosis. In the postoperative course, the patient developed rectal bleeding, prompting referral for colonoscopy. Endoscopic evaluation revealed a 2 cm defect of the colorectal wall with communication into a 3 cm cavity. Rectal Endo-Sponge therapy was initiated, and throughout the treatment course the sponge was exchanged nine times, leading to progressive collapse of the cavity and favourable clinical healing.

Results The abstract synthesizes current nurse competencies procedural standards across all procedural stages for Endo-Sponge placement and exchange: pre-procedural assessment of patient and tools, intraprocedural equipment assistance, patient monitoring, and post-procedural care. Nurses play a pivotal role in preparing specialized equipment, verifying patient preparation and ensuring adherence to aseptic protocols. During the procedure, the endoscopy nurse provides operational support—optimizing instrument flow, maintaining visualization conditions, coordinating suction systems and continuously monitoring hemodynamic and respiratory parameters, particularly in sedated patients. Documentation of cavity characteristics, sponge dimensions and applied negative pressure contributes to consistent therapeutic evaluation. Post-procedurally, nursing responsibilities extend to patient education, symptom surveillance and coordination of scheduled sponge exchanges, typically required every 48–72 hours.

Conclusions Rectal Endo-Sponge therapy is a highly effective, minimally invasive strategy for managing complex anastomotic complications. The expertise of endoscopy nurses is indispensable, enhancing procedural efficacy, reducing risk and ensuring high-quality, patient-centered care throughout the entire therapeutic course. Nurses' responsibilities in this procedure, together with effective coordination and collaboration with the endoscopic team, significantly influences the overall safety profile and clinical success of therapy.

DOI 10.1055/s-0046-1821333

Aims Aim of the study was to evaluate the satisfaction and compliance of patients undergoing endoscopy at the Gastroenterology Clinic of the General Hospital "Konstantopoulio – Patision" regarding adherence to instructions to avoid driving for 24 hours after sedation and the need for assistance following the procedure.

Methods Telephone interviews were conducted 24 hours after endoscopy with outpatients who underwent diagnostic or therapeutic digestive endoscopy at our department as part of their participation in a prospective randomized study. During the interview, patients were asked about their level of satisfaction and their and compliance with instructions regarding abstaining from driving for 24 hours after sedated endoscopy and their need for assistance upon returning to daily activities.

Results All study participants (n = 1300, 100 %) completed the telephone interview. Of these, 709 (54.5 %) were women with a mean age of 62.5 ± 10.3 years. The majority underwent colonoscopy (n = 712, 54.8 %), followed by gastroscopy (n = 298, 22.9 %). Additionally, 671 (51.6 %) subjects underwent digestive endoscopy for the first time. Most participants complied with the given instruction to avoid driving for 24 hours after sedated endoscopy n = 1129 (86.8 %), while only 3/1300 (0.02 %) reported needing assistance from another person afterward). All examinees (100 %) reported feeling very or very safe upon leaving the recovery area, and 99.5 % stated they were very or very satisfied with the examination process.

Conclusions Patient satisfaction with endoscopy in our unit is high. However, a small proportion of patients still fail to comply with the recommendation to avoid driving for 24 hours after sedation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP006 Nurse-Led Identification of High-Risk Patients for Post-ERCP Symptom Burden to Guide Targeted Post-Procedure Nursing Education

Authors Reyes W[1], Khalaf K[1], Mahjoob M[1], Clancy J[1]
Institute **1** St. Michael's Hospital, Toronto, Canada
DOI 10.1055/s-0046-1821334

Aims Endoscopic retrograde cholangiopancreatography (ERCP) is frequently associated with transient post-procedural symptoms such as abdominal pain, bloating, nausea, and throat discomfort, which can generate considerable anxiety for patients and families. Little is known about which patients are most likely to experience early post-ERCP symptom burden, and how nursing teams can proactively tailor education and reassurance for these individuals.

Methods We conducted a retrospective observational cohort study of 8,357 ERCP procedures performed between 2010 and 2024 at a tertiary academic centre. Adult patients who developed post-recovery symptom burden (abdominal pain, bloating, nausea, or generalized pain) were identified from recovery and nursing documentation. Patients who experienced in-hospital cardiac arrest or code events, or admitted to the inpatient ward were excluded. This yielded a cohort of 88 symptomatic patients for detailed analysis (▶ **Table 1**).

▶ **Table 1**

	N = 88	P value
Age	58.8 (16.0)	0.026
Sex		0.001
Female	40 (74.1 %)	
Male	14 (25.9 %)	
Comorbidities		
Renal Disease	1 (1.14 %)	0.186
Liver Disease	3 (3.41 %)	0.260
Hypertension	20 (22.7 %)	0.045
Diabetes Mellitus Type 2	13 (14.8 %)	0.241
Congestive Heart Failure	13 (14.8 %)	0.010
Any Malignancy	8 (9.09 %)	0.117
Adverse Events		
Immediate Bleeding	3 (3.45 %)	1.000
Delayed Bleeding	0 (0.00 %)	1.000
Pancreatitis	8 (9.41 %)	< 0.001
Post Procedural Perforation	3 (3.53 %)	< 0.001
Procedural Characteristics		
Sphincterotomy	35 (47.3 %)	0.031
Pancreatic Duct Cannulation	3 (4.55 %)	0.012
Dilation	27 (35.1 %)	0.031
Stone Extraction	26 (36.1 %)	0.152
Stent Placement or Removal	20 (31.2 %)	0.735

Results Patients exhibiting post-procedural symptoms had a mean age of 58.8 years (p = 0.026) and were predominantly female (74.1 %, p = 0.001). Significant comorbid predictors included hypertension (22.7 %, p = 0.045) and congestive heart failure (14.8 %, p = 0.010), indicating a physiologic vulnerability to post-sedation or post-procedural stress. Overall clinical success remained high (85.2 %), with procedural factors associated with increased symptom reporting included sphincterotomy (47.3 %, p = 0.031), duct dilation (35.1 %, p = 0.031), and pancreatic duct cannulation (p = 0.012). Symptomatic patients were overwhelmingly managed under conscious sedation (92 %, p = 0.001). Adverse outcomes in this cohort included post-ERCP pancreatitis (9.4 %, p < 0.001) and post-procedural perforation (3.5 %, p < 0.001), underscoring that early subjective symptoms may reflect evolving complications.

Conclusions Older female patients with cardiovascular comorbidities undergoing more complex therapeutic ERCP appear more likely to experience early post-procedural symptom burden and stress. Embedding a structured, nurse-led education pathway for these patients by normalising expected transient symptoms, clearly explaining red-flag warning signs, and providing tailored written discharge instructions may reduce post-procedure anxiety, unnecessary emergency visits, and overall stress for patients and families, while supporting safer, more patient-centred ERCP care.

eP007 Novel methods of endoscopic submucosal dissection – case report

Authors Brusic V[1], Karlović K[1]
Institute 1 Clinical Hospital Center Rijeka, Rijeka, Croatia
DOI 10.1055/s-0046-1821335

Aims development of biomedical technology has led to an increase in the possibilities of endoscopic treatment of patients with growths in the digestive tract. Today's techniques pose increasing challenges for the endoscopic team to perform endoscopic procedures for the removal of growths in the safest possible conditions for patients, which will reduce the patient's stay in the hospital and allow faster recovery after the procedure. The endoscopic submucosal dissection method that is available to us today uses a combination of bipolar radiofrequency (RF) cutting and microwave coagulation for hemostasis, making it suitable for various endoscopic procedures. The device consists of a needle for submucosal injection and tissue irrigation, and an insulated body which prevents thermal injuries. Although it seems like a simple technique, it requires teamwork and coordination between the endoscopist and the nurse/technician in order to successfully perform the procedure, given the long duration of the procedure itself [1, 2].

Methods in this abstract we will present case report of endoscopic submucosal dissection technique in 65 years old female patient by new endoscopic device.

Results the patient presented to the gastroenterology clinic on the recommendation of general practitioner due to weight loss, abdominal pa in and aversion to certain foods. We performed gastroscopy which was normal, and a colonoscopy was recommended. The colonoscopy revealed a laterally spreading lesion in the rectum approximately 8 centimeters from the anocutaneous border, measuring approximately 40 x 30 millimeters in diameter, LST-G (Paris IIa + Is), predominantly JNET 2a superficial vascular pattern, with a lesser extent JNET 2b. A pelvic magnetic resonance imaging scan was recommended to assess invasion of the rectal wall and surrounding structures, where it was determined that there was a possible shallow infiltration of the muscular layer of the wall without penetration into the serosa. By decision of the council consisting of a gastroenterologist, digestive surgeon, oncologist, pathologist and radiologist, an endoscopic submucosal dissection was performed using a *Speed boat knife*. The procedure lasted 4.5 hours. It proceeded without complications. Two endoscopic clips were implemented in the distal rectum because there was a lesion of the muscle layer. Visible blood vessels were coagulated and a preventive hemostatic clip was placed on lumen of one blood vessel. The resected area was removed with forceps and stretched on cork. The dimensions were 47 x 35 mm. The patient was admitted to the hospital for observation and was discharged home the next day with the recommendation of rest and a lighter diet. Six months after the procedure, a control rectoscopy was performed, which showed a neat scar without residue as well as a neat vascular drawing under WLE and NBI. It was recommended endoscopic follow-up in one year.

Conclusions during the procedure the coordination of the endoscopist and the nurse/technician stands out and is necessary for the success of the procedure.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP008V Cholangioscopy Revealing Extensive Macronodular Recurrence of Intraductal Papillary Neoplasm of the Bile Duct After Left Hepatectomy: A Case Report

Authors Alioua SA[1], Abdeslam O[2], Salah A[2]
Institutes 1 Béni messous, Beni Messous, Algeria; 2 Department of Hepatology and Gastroenterology, Fatema El Azhar Clinic, Dely Brahim, Algiers, Algeria
DOI 10.1055/s-0046-1821336

Endoscopy 2026; 58: S1–S1041

Abstract Text

We present a 65-year-old woman with prior left hepatectomy for Intraductal Papillary Neoplasm of the Bile Duct (IPNB), who developed recurrent febrile cholangitis one year later. ERCP revealed an elongated intraductal lesion involving the right hepatic duct and mid-common bile duct. Cholangioscopy was performed for direct visualization and targeted biopsies, showing a papillary lesion extending through the right hepatic duct, common hepatic duct, and upper mid-common bile duct, with a macroscopically visible obstructive nodule. Histology confirmed recurrence of IPNB with high-grade dysplasia. This case highlights the role of cholangioscopy in mapping complex post-hepatectomy biliary lesions, allowing direct visualization, precise tissue sampling, and guiding further therapeutic decisions. Cholangioscopy is increasingly essential in evaluating suspected biliary neoplasms, particularly after prior surgery.

eP009 An innovative endoscopic treatment of difficult collections of walled-off pancreatic necrosis using an extraperitoneal approach.

Authors Mateusz J[1], Chwarścianek A[2], Jackowski M[3]

Institutes **1** Klinika Chirurgii Ogólnej, Gastroenterologicznej i Onkologicznej Collegium Medicum UMK w Toruniu, Toruń, Poland; **2** General, Gastroenterological and Oncological Surgery Clinic, Collegium Medicum UMK in Toruń, Toruń, Poland; **3** Klinika Chirurgii Ogólnej, Gastroenterologicznej i Onkologicznej Collegium Medicum UMK, Torun, Poland

DOI 10.1055/s-0046-1821337

Aims In recent decades, constant development of minimally invasive techniques for the treatment of the consequences of acute necrotizing pancreatitis can be observed. The choice of access to the necrotic collection should mainly depend on the location of necrotic changes and experience of the medical center. Endoscopic transmural drainage of extensive necrotic collections may require the use of an additional route of access to the necrosis. In this article, an attempt was made to clarify the role of percutaneous endoscopic necrosectomy (PEN) in the interventional treatment of pancreatic necrosis [1–40].

Methods 513 consecutive patients with symptomatic walled-off pancreatic and peripancreatic necrosis treated in the Department of General, Gastroenterological and Oncological Surgery, Collegium Medicum, Nicolaus Copernicus University in Toruń, Poland between 2018 and 2025 were included. The analyzed patients were treated withusing the novel method of endoscopic percutaneous necrosectomy, in which percutaneous access to the necrotic collection was achieved with use ofby retroperitoneal route; consequently, the access was then widened, and a self-expanding metal stent was placed percutaneously,, which allowed to introduce the endoscope percutaneously into the necrotic area and to perform endoscopic necrosectomy.

Results In 39/513 (7.60 %) patients with symptomatic walled-off pancreatic and peripancreatic necrosis an, additional percutaneous drainage was performed during the endotherapy. Within this group, In 9/39 (23.07 %) patients (2 females and 7 males; average age 46.72 [31-–65] years) were qualified to percutaneous endoscopic necrosectomy. The aAverage size of the necrotic collection was 25.96 (15.24-–32.5) cm. AAn active percutaneous drainage during transmural endoscopic drainage lastedwas continued for 15 (11-31) days. The aAverage number of procedures of percutaneous endoscopic necrosectomy procedures was 3.12 (1-–7). Complications of treatment were stated observed in 2/9 (22 %) patients. Clinical success was achieved acknowledged in 8/9 (88.8 %) patients. Long-term success was stated achieved in 8/9 (88.8 %) patients.

Conclusions Percutaneous endoscopic necrosectomy during in the course of transmural endoscopic drainage of walled-off pancreatic and peripancreatic necrosis is an effective method of minimally invasive treatment, especially in cases of spreading necrotic changes spreading within the pelvic area.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP010 Assessment of internist competency for Upper- and Lower-GI Endoscopy: A Systematic Review and Meta-Analysis

Authors Alijani E[1], Abbasi N[1]
Institute 1 Iran University of Medical Sciences, Tehran, Iran, Islamic Republic of
DOI 10.1055/s-0046-1821338

Aims Endoscopy competency—technical, cognitive, and integrative—has well-established metrics for gastroenterology trainees, but the evidence base specifically addressing competency among internists (internal-medicine trained physicians who perform endoscopy) is scattered. The aim of this systematic review and meta-analysis is to synthesize the literature on internist competency for upper GI endoscopy (EGD) and lower GI endoscopy (colonoscopy), evaluate assessment tools and performance benchmarks, and identify knowledge gaps.

Methods We performed a systematic search of PubMed/Medline, Embase, Scopus and Web of Science (inferred search window: inception–May 2025) for studies reporting objective competency outcomes (e.g., cecal intubation rate [CIR], adenoma detection rate [ADR], complication rates, validated observation tools such as ACE, DOPS, GAGES) and/or validated assessment scores for endoscopists trained in internal medicine. We included observational studies, training evaluations, and trials that reported outcomes for internists (alone or compared to other specialties). Risk of bias was assessed using standard tools for observational studies. Where comparable numeric outcomes were reported, random-effects meta-analysis was planned [1–6].

Results High-quality validated assessment tools exist (ASGE's ACE for colonoscopy/EGD; other tools include DOPS, GAGES and several direct-observation tools). Competency frameworks emphasize objective metrics (CIR, ADR, withdrawal time, procedure time) and structured observation with feedback. For colonoscopy, professional guidance indicates ADR benchmarks (≥ 25 % overall screening ADR) and CIR targets (> 90 %) as key quality indicators. Training literature reports minimum procedural volumes and structured assessment before declaring competence (for colonoscopy, major societies have suggested thresholds and objective assessment tools rather than sole procedure counts). However, direct comparative evidence specifically isolating internists (vs GI specialists or surgeons) is limited, heterogeneous, and often confounded by setting and case-mix. Where internists are included in multidisciplinary cohorts, overall performance (CIR, ADR when reported) is generally within published quality thresholds when structured training, supervision, and assessment are applied. Assessment-tool validation studies show acceptable validity evidence for several tools but highlight variable interrater reliability and limited data specifically in internal-medicine populations.

Conclusions Internists can achieve recommended endoscopy competency metrics when training follows accepted curricula, uses validated assessment tools (ACE/DOPS/GAGES), and measures quality indicators (ADR, CIR). High-quality, specialty-stratified studies are lacking — future research should

prospectively compare internist vs GI-fellow training outcomes using standard assessment tools and report core quality metrics (ADR, CIR, complication rates, and validated global skills scores).

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP011 Mimicry in the Bile Ducts: Sarcoidosis Presenting as Sclerosing Cholangitis

Authors Abdul haqq M[1], Shantan V[1], Anand K[1], Harika C[1], Mithun S[1], Reddy DN[2], Manasa A[1]

Institutes **1** AIG Hospitals, Hyderabad, India; **2** Asian Institute of Gastroenterology (AIG Hospitals), Department of Medical Gastroenterology, Hyderabad, India

DOI 10.1055/s-0046-1821339

Abstract Text

Sarcoidosis-induced sclerosing cholangitis is an exceptionally rare manifestation of multisystem sarcoidosis, often mimicking primary sclerosing cholangitis (PSC). Hepatic involvement occurs in 50–70 % of patients, though only 10–15 % develop symptoms.Biliary tract involvement is exceedingly uncommon, with fewer than 30 cases reported.A 28-year-old female presented with insidious cholestatic symptoms progressive pruritus, dark urine, and 10 kg weight loss over six months. Laboratory evaluation revealed markedly elevated alkaline phosphatase (1143 U/L) and γ-glutamyl transferase (757 U/L), with total bilirubin 3.8 mg/dL and direct 2.0 mg/dL. Mild normocytic anemia was present. The pattern reflected a cholestatic injury with an ALP-to-ALT ratio of\ 15:1.Ultrasound demonstrated proximal common bile duct stricturing with intrahepatic biliary dilatation. MRCP showed multifocal biliary strictures with loss of flow enhancement and splenic lesions.PET-CT revealed hypermetabolic lymphadenopathy (cervical, hilar, abdominal),pulmonary ground-glass opacities, and splenic involvement—suggestive of multisystem granulomatous disease.Histopathology from splenic FNAC and cervical lymph node biopsy revealed non-caseating granulomas with multinucleated giant cells, no necrosis. Serum ACE levels were markedly elevated, supporting sarcoidosis.The collective findings confirmed **sarcoidosis-induced secondary sclerosing cholangitis** after exclusion of infectious and autoimmune causes.Systemic corticosteroid therapy was initiated, resulting in rapid improvement: bilirubin reduced to1.3 mg/dL,ALP to 471 U/L, with symptomatic relief and partial resolution of biliary strictures on follow-up MRCP.Pathophysiologically, granulomatous infiltration of portal tracts causes inflammatory bile duct stricturing. Unlike PSC, these lesions are potentially reversible with immunosuppression. Diagnostic clues favoring sarcoidosis include multisystem involvement, elevated ACE, absence of p-ANCA/AMA, and steroid responsiveness.

Conclusion Sarcoidosis-induced sclerosing cholangitis, though rare, is a treatable cause of cholestatic liver disease. Comprehensive evaluation for systemic sarcoidosis should be performed in all patients with atypical sclerosing cholangitis. Prompt corticosteroid therapy can yield substantial clinical, biochemical,and radiologicalmprovement.

KeyMessages Evaluate for extrahepatic granulomatous disease in sclerosing cholangitis. Elevated ACE and multisystem involvement suggest sarcoidosis. Exclude infectious and autoimmune causes before diagnosing PSC.Early immunosuppressive therapy offers favorable, reversible outcomes [1–3].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP012 Cholangioscopy Revealing Extensive Macronodular Recurrence of Intraductal Papillary Neoplasm of the Bile Duct After Left Hepatectomy, A Case Report

Authors Alioua SA[1, 2], Salah A[3], Abdeslam O[3]

Institutes **1** Department of Hepatology and Gastroenterology, Beni Messous Hospital, Algiers, Algeria; **2** Department of Hepatology and Gastroenterology, Erasme Hospital, Brussels, Belgium; **3** Department of Hepatology and Gastroenterology, Fatema el Azhar clinic, Dely Brahim, Algiers, Algeria

DOI 10.1055/s-0046-1821340

Abstract Text

Intraductal Papillary Neoplasm of the Bile Duct (IPNB) is a rare biliary tumor with malignant potential. Recurrence may occur as extensive intraductal lesions after hepatectomy.

A 65-year-old woman with prior left hepatectomy presented one year later with recurrent cholangitis. Biological tests showed cholestasis. ERCP revealed an elongated intraductal defect in the right hepatic duct and mid-common bile duct. Cholangioscopy showed a continuous, macronodular papillary lesion with an obstructive nodule. Targeted biopsies confirmed high-grade dysplasia.

This case highlights cholangioscopy's role in post-surgical biliary neoplasms, allowing accurate lesion mapping, differentiation from postoperative changes, and safe guidance of management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP013 Intraductal papillary neoplasm of the bile duct in a patient with familial adenomatous polyposis: expanding the extracolonic spectrum

Abstract Text

Familial adenomatous polyposis (FAP) is associated with extracolonic manifestations such as duodenal and ampullary neoplastic lesions, but biliary tract tumours have rarely been described. We present a unique case of intraductal papillary neoplasm of the bile duct (IPN-B) in a patient with FAP, supported by molecular confirmation of *APC*-driven tumorigenesis.

A 57-year-old female with a pathogenic germline *APC* variant (exon 15 c.1960C > T, p.Q654X) and prior pancreas-preserving duodenectomy presented with acute cholangitis. MRCP and ERCP revealed intraductal masses causing intra- and extrahepatic bile duct dilatation. Cholangioscopy showed villous mucosal lesions rather than mobile stones or debris. Targeted biopsies demonstrated tubulovillous adenomas with low-grade dysplasia. Following multidisciplinary discussion, the patient underwent liver transplantation combined with a Whipple procedure with curative intent. Surgical pathology confirmed IPN-B with focal high-grade dysplasia, as well as a synchronous intraductal papillary mucinous neoplasm of the pancreas with low-grade dysplasia. Molecular

analysis of the biliary lesion demonstrated a second somatic *APC* pathogenic variant, providing evidence for a two-hit carcinogenic mechanism similar to colorectal and duodenal FAP-associated neoplasms. Six months post-operatively, the patient remains clinically well. This case highlights IPN-B as a potential, under-recognized extracolonic manifestation of FAP. Awareness of this rare manifestation may aid timely recognition in FAP patients presenting with unexplained cholangitis.

eP014 Assessment of bowel preparation quality and predictors of inadequate bowel preparation for colonoscopy in Rwanda: a cross-sectional study

Authors Felicien S[1], Eric R[2], Berhane R[3], Vincent D[2], Rosenvinge VE[4], Gamal A[5], Zainab I[3], Solange M[2], Dyna N[2], Dadamessi I[6], Hanna A[3]
Institutes **1** Butare University Teaching Hospital, Kigali, Rwanda; **2** Kigali University Teaching Hospital, Kigali, Rwanda; **3** King Faisal Hospital, Kigali, Rwanda; **4** University of Maryland School of Medicine, Maryland, United States of America; **5** Rwanda Military Hospital, Kigali, Rwanda; **6** Centre Hospitalier de Saint-Quentin, Paris, France
DOI 10.1055/s-0046-1821342

AimsGeneral objective

To assess the overall quality of bowel preparation in patients undergoing colonoscopy at Tertiary level Hospitals in Rwanda.

Specific objectives

- To determine the proportion of inadequate bowel preparation in patients undergoing colonoscopy.
- To identify factors associated with inadequate bowel preparation in the Rwandan population.

Methods Study design

This was a multi-center cross-sectional study

Study Site

The study was conducted at four tertiary level hospitals in Rwanda namely Kigali University Teaching Hospital, Butare University Teaching Hospital, Rwanda Military Hospital and King Faisal Hospital.

Study Population and duration

The study was conducted in adult population (age ≥ 18 years)

The study was conducted from August, 2023 to August, 2024

Inclusion criteria

Referred patient in endoscopy unit for colonoscopy

Able to provide informed consent

Exclusion criteria

Age less than 18 years old

Patients requiring urgent colonoscopy

Data collection process and analysis

Demographics, clinical characteristics and information related to the procedure were collected

Collected data were entered in Epidata version 3.1 and exported to Stata version 13 for statistical analysis

Results We enrolled 429 participants. The mean age was 50 ± 15.7 years and 54.1 % were male. Inadequate bowel preparation (total Boston Bowel Preparation Scale < 6) was observed in 24.9 % of cases. The most common indications for colonoscopy was constipation (48.3 %), abdominal pain (27.5 %) and lower gastrointestinal bleeding (23.5 %) .With regards to colonoscopy findings, normal results were observed in 34 % of cases, hemorrhoids were detected in 16.5 % of patients, while polyps were found in 16.3 %. On multivariate analysis, advanced age (> 65 years), lower levels of education, inpatient status, constipation and incomplete dosage of purgative solution were predictors of inadequate bowel preparation [1–3].

Conclusions The inadequate bowel preparation rate was 24.9 %. Risk factors for inadequate bowel preparation included chronic constipation, elderly age, low educational attainment, incomplete dosage of purgative agents and inpatients status. Our findings suggest that an individualized approach is required for patients with risk factors of inadequate bowel preparation, including patient comprehensive educational program about bowel preparation before colonoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP015 Is it worth performing a duodenal biopsies during gastroscopy in patients with bloating to exclude coeliac disease?

Authors Tamondong R[1], Estrella A[1], Bhatkar K[1], Besherdas K[2, 1]
Institutes **1** Royal Free Hospital, London, United Kingdom; **2** Royal Free Hospital, London, United Kingdom, United Kingdom
DOI 10.1055/s-0046-1821343

Aims Coeliac disease is a long-term autoimmune disorder affecting the small intestine. Patients develop intolrence to gluten. Symptoms of Coeliac disease can range from mild to severe and be intermittent. Common symptoms include diarrhoea, abdominal pain, bloating, dyspepsia, along with fatigue, weight loss and a rash to name a few. It may also present with vitamin deficiencies and osteoporosis. Coeliac antibody testing along with biopsy of the duodenum at endoscopy are the standard ways to confirm a diagnosis of coeliac disease. Patients attending for upper gastrointestinal with symptoms of bloating as an indication often have a duodenal biopsy to exclude coeliac disease.

We aimed to assess the findings at duodenal biopsy on patient endoscopied with the indication of abdominal bloating to assess presence of coleiac disease

Methods A single centre, retrospective analysis 100 consequetive patients with bloating as in indication for gastroscopy from April 2024 at a hospital in North London was undertaken. A review of whether duodenal biopsies and its findings were scrutinized with data collected using the Medilogic endoscopy reporting tool, and the electronic patients record.

Results 60 of 100 patients with indication of bloating having a gastroscopy had duodenal biospies performed. 2/60 (3 %) had evidence of coeliac disease on histology. One of the patients had a positive tissue transglutamase antibody as an indication for duodenal biopsy. The second patient had anaemia with bloating as an indication to biopsy the duodenum. 58/60 (97 %) patients with bloating as an indication of duodenal biopsies had no evidence of coeliac disease.

Conclusions From this study we do not advocate routine duodenal biopsy at gastroscopy for the sole indication of bloating unless accompanied by anaemia or a positive TTG antibody. This will help reduce cost per endoscopic procedure along with making the procedure more 'greener'.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP017 CAP Polyposis: A case report

Authors Pardilla-Moraleda FJ[1], Andrade CA[1], Martínez-Benito B[1], Martínez-Fernández R[1], Xu L[1], Santander C[1], Jiménez-Gómez M[1]
Institute **1** Hospital de La Princesa, Madrid, Spain
DOI 10.1055/s-0046-1821344

Introduction: Cap polyposis is a rare benign inflammatory condition characterized by inflammatory polyps covered with a fibrinopurulent exudate. It is more commonly observed in women and the elderly, although it can present

at any age. The disease typically affects the rectum and sigmoid colon. The most frequent symptoms include mucous diarrhea and rectal bleeding. It has been associated with mucosal prolapse due to altered intestinal motility, *Helicobacter pylori* infection, and even intestinal dysbiosis [1–4].

Endoscopy A 46-year-old male with no relevant personal or family medical history presented with altered bowel habits, characterized by increased stool frequency, decreased consistency, and the presence of mucus and blood, along with tenesmus and urgency. *H. pylori* testing was negative. Colonoscopy revealed numerous sessile and pedunculated polyps with an inflammatory appearance distributed throughout the colon, predominantly in the sigmoid and rectum. Most polyps were covered at their apex by a fibrinopurulent exudate. The colonic mucosa adjacent to the polyps appeared normal. Multiple biopsies were taken, confirming inflammatory polyps. A first therapeutic colonoscopy was performed, during which multiple polyps consistent with cap polyps were resected. Additional sessions were scheduled to complete polyp resection. Furthermore, a molecular study was performed using next-generation sequencing (NGS) with a multigene panel with negative results.

Conclusions The clinical course of cap polyposis remains unclear. The need for and timing of colonoscopy should be individualized based on the number of polyps and symptom severity. Initial treatment should be conservative, focusing on resolving constipation and eradicating *H. pylori.* In cases with persistent symptoms, endoscopic resection of the lesions should be considered.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Lymphogranuloma venereum (LGV) is a sexually transmitted infection caused by *Chlamydia trachomatis* serotypes L1–L3. It's incidence has been increasing in recent years, particularly among men who have sex with men with concomitant HIV infection, often associated with high-risk practices such as chemsex. Clinical presentation frequently involves proctitis and can mimic neoplastic disease, leading to diagnostic challenges [1, 2].

We report the case of a 45-year-old HIV-positive male on antiretroviral therapy with undetectable viral load and CD4 count of 270. He presented with a 20-day history of diffuse abdominal pain, predominantly in the left hemiabdomen, hyporexia, abrupt constipation, 5 kg weight loss, and self-limiting rectal bleeding. Abdominopelvic CT revealed heterogeneous rectal wall thickening highly suggestive of malignancy. Colonoscopy showed findings compatible with infectious proctitis, without suspicious neoplastic lesions. Biopsies and microbiological studies were obtained, and PCR testing confirmed *C. trachomatis* serotype L2b, consistent with LGV.

In conclusion, LGV is an underdiagnosed re-emerging infection whose presentation may simulate malignancy. Clinician awareness, early colonoscopy, and appropriate sampling are crucial for timely diagnosis and treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821346

Abstract Text

Pancreatic tuberculosis is a rare condition that may closely mimic malignancy. A 40-year-old woman presented with cholestasis and recent cholangitis. EUS revealed a heterogeneous hypoechoic pseudomass in the pancreatic head (32 × 25 mm) with confluent necrotic hilar lymph nodes compressing the bile duct and portal vein. EUS-guided biopsies showed chronic inflammatory changes with necrotizing lymphadenitis, without malignant cells. Based on clinical and imaging findings, a tuberculous origin was suspected and anti-tuberculous therapy initiated. Follow-up EUS demonstrated complete resolution of lymphadenopathies and regression of the pancreatic pseudomass, confirming the diagnosis. EUS with tissue acquisition is essential to differentiate tuberculous lymphadenitis from pancreatic malignancy, enabling curative medical therapy and avoiding unnecessary surgery.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP020 When self-medication becomes a life-threatening risk. A case report

Authors Iglesias Sobrino C[1], Llanas Marco M[1], Manso Rodriguez H[1], Cejas Dorta L[1]

Institute **1** Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain

DOI 10.1055/s-0046-1821347

Abstract Text

Acute gastrointestinal bleeding in children is a potentially life-threatening medical emergency that requires prompt evaluation and muldisiciplinary management.

We report the case of a three-year-old boy with no prior medical history, who was brought to the Emergency Room due to sudden pallor and lethargy. According to the mother, the child experienced a sudden intense abdominal pain followed by ematemesis, along with a single melena episode. Twenty-four hours earlier, he had vomited food content without other gastrointestinal symptoms. The patient had a history of several recent respiratory infections but no trauma or ingestion of toxic substances [1, 2].

On examination, he presented with altered Pediatric Assessment Triangle parameters, including tachypnea, tachycardia, hypotension, pallor, and lethargy. The inicial laboratory analysis revealed severe anemia (Hb 6 g/dL). Urgent gastroscopy showed a pale mucosa but without visible lesions. In the fundus and

body, mild oozing bleeding was observed originating from multiple diffuse points. After irrigation, no mucosal abnormalities were identified that could explain the bleeding, which recurred following the lavage.

The patient was admitted to the Pediatric Intensive Care Unit for close monitoring, receiving IV proton pump inhibitors and tranexamic acid. Given the endoscopic findings and normal coagulation tests, the family was re-interviewed, revealing that the child had received multiple daily doses of oral ibuprofen over the past two weeks. After 24 hours, he was transferred to the general pediatric ward, remaining clinically stable with adequate oral intake, and was discharged on day five.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Caustic ingestion represents a medical and surgical emergency capable of causing chemical injury to the gastrointestinal tract, ranging from mucosal erosions to full-thickness necrosis with risk of perforation. Endoscopy is the initial diagnostic tool to assess the extent and depth of injury, often using grading systems such as the Zargar classification to stratify severity and predict complications.

We report the case of a 60-year-old female with a history of caustic ingestion in 2017, which had required partial gastrectomy and duodenectomy due to perforation. She presented again to the Emergency Department following a second episode of caustic ingestion. Urgent gastroscopy revealed extensive necrosis involving the esophageal mucosa, gastric remnant, and intestinal loop, with violaceous nodules and purulent exudate. General surgery was consulted and recommended an urgent exploratory laparotomy, which revealed transmural necrosis extending to the cecum. Due to the severity and extent of the injury, surgical resection was deemed incompatible with life and was not performed.

This case underscores the importance of correlating endoscopic and surgical findings. While endoscopy allows direct assessment of mucosal injury, it may underestimate transmural involvement and deep complications, which are only confirmed surgically. Concordance between both modalities is critical for accurate diagnosis, appropriate therapeutic planning, and optimization of prognosis.

eP022 Diagnostic performance of visual assessment by single-operator peroral cholangioscopy in indeterminate biliary strictures: experience of a North African center

Authors Salah A[1], Alioua SA[2, 3], Abdeslam O[1]

Institutes 1 Department of Hepatology and Gastroenterology, Fatema el Azhar clinic, Dely Brahim, Algiers, Algeria; 2 Department of Hepatology and Gastroenterology, Beni Messous Hospital, Algiers, Algeria; 3 Department of Hepatology and Gastroenterology, Erasme Hospital, Brussels, Belgium

DOI 10.1055/s-0046-1821349

Aims Indeterminate biliary strictures remain a major diagnostic challenge due to the high prevalence of underlying malignancy. Single-operator peroral cholangioscopy enables direct intraductal visualization and targeted biopsies. This study aimed to assess the diagnostic performance of visual assessment alone in differentiating malignant from benign biliary strictures.

Methods We conducted a retrospective single-center study including 26 patients (February 2023–May 2025) with indeterminate biliary strictures despite inconclusive imaging and cytology. Cholangioscopic appearances were categorized as suggestive of malignancy (irregular mucosa, neo-vessels, nodules) or non-suggestive (regular mucosa, inflammatory/postoperative changes). The final diagnosis was established by histopathology or ≥ 6-month clinical follow-up. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated with 95 % confidence intervals (CI).

Results Cholangioscopy was technically successful in all patients (26/26). Visual assessment suggested malignancy in 14 cases, of which 10 were confirmed malignant and 16 benign. Visual evaluation demonstrated excellent diagnostic performance :

- Sensitivity of 100 % (95 % CI 69.2–100)
- Specificity of 87.5 % (95 % CI 61.7–98.4)
- PPV of 83.3 % (95 % CI 51.6–97.9)
- NPV of 100 % (95 % CI 76.8–100)
- Accuracy of 92.3 %.

No major adverse events were observed.

Conclusions In this North African series, visual assessment by cholangioscopy showed excellent sensitivity and negative predictive value for indeterminate biliary strictures. Direct visualization can reliably guide early clinical decisions and biopsy targeting, reducing the need for additional invasive testing, while maintaining a favorable safety profile.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP023 Endoscopic Ultrasound-Guided Fine Needle Biopsy for Periportal Lymphadenopathy: Clinical Utility, Diagnostic Accuracy, and Correlation of Imaging Features with Etiology

Authors Chudasama J[1], Kokate Y[1], Pravin R[1]

Institute 1 Topiwala National Medical College, Mumbai, Mumbai, India

DOI 10.1055/s-0046-1821350

Aims To evaluate the diagnostic yield, accuracy, and safety of Endoscopic Ultrasound-Guided Fine-Needle Biopsy (EUS-FNB) for isolated periportal lymphadenopathy of unclear etiology. A secondary objective was to identify specific EUS morphological features predictive of underlying pathology, particularly tuberculosis (TB), a common cause in our setting [1, 2].

Methods This prospective study, conducted at a single tertiary care centre, analyzed data from 68 patients who underwent EUS-FNB for isolated periportal lymphadenopathy between January 2021 and July 2022. Patients with a known primary malignancy were excluded. All procedures were performed by an experienced endosonographer using a 22-gauge core biopsy needle. Samples were systematically processed for histopathological examination and microbiological analysis, including GeneXpert ULTRA and MGIT culture. Final diagnoses were established using a composite gold standard of positive tissue analysis or clinical-radiological follow-up. Logistic regression was used to identify EUS predictors of TB (▶ **Table 1**).

▶ **Table 1**

Parameter	Univariate OR (95 % CI)	p-value	Multivariate OR (95 % CI)	p-value
Irregular shape	6.94 (2.10 – 22.95)	0.0018	4.71 (1.08 – 20.57)	**0.039**
Hypoechoic	2.36 (0.25 – 22.60)	0.452	–	–
Hyperechoic	1.42 (0.47 – 4.28)	0.543	–	–
Heterogeneous	0.58 (0.21 – 1.62)	0.299	–	–
Necrosis	4.43 (1.51 – 13.00)	0.006	3.28 (1.01 – 10.62)	**0.049**
Calcification	2.00 (0.54 – 7.40)	0.294	–	–
Matting	4.06 (1.12 – 14.63)	0.033	3.03 (0.75 – 12.29)	0.118
Long-axis diameter	1.39 (0.74 – 2.60)	0.303	–	–
Short-axis diameter	1.33 (0.80 – 2.22)	0.272	–	–

▶ **Table 2**

p	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Accuracy (%)	AUROC
Tuberculosis	94.0	100.0	100.0	85.7	95.6	0.97
Malignancy	87.5	100.0	100.0	98.4	98.5	0.93
TB + Malignancy	93.1	100.0	100.0	71.4	94.1	0.96

Results Of 710 EUS procedures performed during the study period, 82 patients were referred for EUS-FNB of periportal lymph nodes, with 68 ultimately enrolled for analysis. The final diagnosis was tuberculosis in 47 patients (69.1 %), malignancy in 7 (10.3 %), and reactive lymphadenopathy in 10 (14.7 %). On multivariate logistic regression, an irregular lymph node shape (adjusted OR: 4.71, p = 0.039) and the presence of necrosis (adjusted OR: 3.28, p = 0.049) were identified as independent predictors of a tubercular etiology. The integration of microbiological testing significantly enhanced diagnostic yield for tuberculosis; GeneXpert ULTRA and MGIT combined confirmed TB in 35 of 47 cases (74.5 %), proving superior to histopathology alone, which was diagnostic in only 18 cases (40.4 %) (p = 0.00084). Overall, EUS-FNB demonstrated excellent diagnostic accuracy, with 94 % sensitivity and 100 % specificity for tuberculosis, and 87.5 % sensitivity with 100 % specificity for malignancy. The procedure was very safe, with no major complications reported among the patients (▶ **Table 2**).

Conclusions EUS-FNB is a highly accurate, safe, and effective first-line diagnostic modality for isolated periportal lymphadenopathy. In regions where TB is prevalent, it is the most common etiology. Our findings strongly support a multi-modal diagnostic strategy, combining EUS imaging, histopathology, and advanced microbiological testing (GeneXpert and MGIT) to maximize diagnostic yield, particularly for lymph node tuberculosis. Furthermore, EUS features such as irregular shape and necrosis are valuable independent predictors that can guide clinical suspicion and ensure timely patient management. This integrated approach should be considered the standard of care

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP024 "Scoring GERD from the Voice: The G-HARP and G-HARP + Models for GERD Diagnosis in idiopathic hoarseness of voice "

Authors Chudasama J[1], Pravin R[1]

Institute 1 Topiwala National Medical College, Mumbai, Mumbai, India

DOI 10.1055/s-0046-1821351

Aims Gastroesophageal reflux disease (GERD) is a frequent yet often underrecognized cause of idiopathic hoarseness. Correlating voice-based acoustic changes with objective reflux measures may enable earlier diagnosis through non-invasive screening. This study aimed to develop and validate two diagnostic models for predicting GERD in patients presenting with idiopathic hoarseness, using comprehensive clinical, endoscopic, manometric, and pH-impedance data as the diagnostic standard [1–2]

Methods This was a prospective, single-centre, open-label, interventional study conducted between January 2021 and June 2023 across ENT, speech pathology, and gastroenterology departments. Patients aged 18–65 years with idiopathic hoarseness ≥ 6 weeks' duration were included; those with structural, infectious, neurological, or functional laryngeal disorders were excluded. All participants underwent video laryngoscopy (to determine Reflux Finding Score [RFS] and Reflux Symptom Index [RSI]), acoustic voice analysis using computerized software (Multi-Speech 3700, MDVP, KayPentax), esophagogastroduodenoscopy (EGD), high-resolution esophageal manometry, and 24-hour impedance pH-metry. GERD was diagnosed based on Los Angeles grade ≥ B esophagitis or abnormal acid exposure time (AET > 6 %) or DeMeester score > 14.72 (▶ **Table 1**).

▶ Table 1

Scoring System	Parameter	Cutoff Value	Points Assigned	Maximum Score
G-HARP Scoring System	NHR	≥ 0.21	10	14
	Absolute Jitter	≥ 1.02	2	-
	Shimmer Percentage	≥ 3.14	2	-
G-HARP + Enhanced Scoring System	NHR	≥ 0.21	5	20
	Absolute Jitter	≥ 1.02	2	-
	Shimmer Percentage	≥ 3.14	2	-
	RSI	≥ 13	6	-
	Erosive Esophagitis on Endoscopy	Present	5	-

Results Out of 242 screened subjects, 40 were enrolled. Mean age was 38.6 ± 14.8 years, with equal sex distribution. GERD was confirmed in 25 patients (62.5 %); 15 were classified as non-GERD (including reflux hypersensitivity and normal findings). GERD patients had significantly higher RSI (14.2 ± 3 .1 vs 11.4 ± 2.4; p = 0.002), RFS (10.3 ± 3.2 vs 6.6 ± 3.4; p = 0.04), absolute jitter (77.1 vs 50.4; p = 0.03), jitter percentage (1.98 vs 1.04; p = 0.04), and shimmer percentage (5.42 vs 3.62; p = 0.02). Multivariate analysis identified erosive esophagitis (OR 4.32; p = 0.04), RSI (OR 1.8; p = 0.018), absolute jitter (OR 1.01; p = 0.005), shimmer percentage (OR 0.93; p = 0.04), and NHR (OR 19.11; p = 0.03) as independent predictors. The G-HARP + Score, integrating acoustic, clinical, and endoscopic predictors, achieved AUROC 0.87 with 88 % sensitivity and 85 % specificity. The G-HARP Score, based solely on acoustic markers (jitter, shimmer, NHR), achieved AUROC 0.82 with 85 % sensitivity and 80 % specificity, demonstrating robust non-invasive diagnostic performance.

Conclusions This study demonstrates that voice-based acoustic markers, particularly jitter, shimmer, and NHR, significantly correlate with reflux severity in idiopathic hoarseness. The proposed G-HARP and G-HARP + scores provide practical, quantitative tools for predicting GERD and can guide clinicians in identifying patients needing confirmatory reflux testing. These models offer a promising, non-invasive adjunct for early diagnosis and targeted management of reflux-associated voice disorders.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP025 Interest of Endoscopic Ultrasound-Guided Fine Needle Aspiration in Mediastinal and Abdominal Lymphadenopathy

Authors Aksim H[1], Belhamdiya M[1], Gharbi K[1], Akka R[1]

Institute 1 L'hôpital militaire Avicenne, Marrakesh, Morocco

DOI 10.1055/s-0046-1821352

Aims Endoscopic ultrasound (EUS), combined with fine-needle biopsy (FNB) and histopathological examination, represents a key diagnostic tool for the assessment of deep-seated lymphadenopathy (mediastinal or abdominal). This technique provides excellent diagnostic accuracy, particularly in differentiating benign from malignant etiologies, thereby guiding appropriate therapeutic strategies. The aim of this study was to evaluate the contribution of EUS-guided fine needle aspiration (EUS-FNA) in the workup of mediastinal and abdominal lymphadenopathy.

Methods We conducted a retrospective descriptive study over a 4-year period (January 2020 – December 2024) in the Department of Hepato-Gastroenterology. All patients who underwent EUS-guided FNB for lymphadenopathy were included. Exclusion criteria were: a prior diagnosis of granulomatous disease, known metastatic digestive cancer, and cases of inaccessible or sub-centimetric lymphadenopathy [1–3].

Results Out of 192 EUS procedures performed, 22 patients were included. The mean age was 53 years [20–82], with a male-to-female ratio of 0.8. The main presenting symptom was obstructive jaundice (45 %), sometimes associated with epigastric pain (9 %). Additional clinical findings included weight loss (4 cases), incidental discovery during the evaluation of a pancreatic mass (3 cases), hemorrhagic syndrome (1 case), dyspnea with hemoptysis (1 case), and isolated abdominal pain (1 case).

Initial imaging (thoraco-abdominopelvic CT in 85 % of cases, MRCP in 20 %) revealed: confluent mediastinal and/or abdominal lymphadenopathy in 41 % of cases, pancreatic mass with lymph node involvement in 32 %, common bile duct thickening in 18 %, and gastric wall thickening in 2 cases.

EUS-FNB targeted abdominal lymph nodes in 64 % of cases, mediastinal in 23 %, and combined abdominal and mediastinal in 14 %. Abdominal lymph node locations included hepatic hilum (50 %), celiac (36 %), and perigastric (21 %); mediastinal lymph nodes were mainly at station 7 (85 %) and station 9 (15 %). The mean lymph node size was 23 mm [10–45]. Needles used were 20G (55 %) and 22G (45 %). The number of passes per biopsy ranged from 1 to 3, with fanning technique applied.

Histopathological analysis yielded malignant etiologies in 36 % of cases (5 pancreatic adenocarcinomas, 1 lymphoma, 1 neuroendocrine carcinoma, 1 undifferentiated carcinoma), granulomatous disease in 18 % (2 sarcoidosis, 2 tuberculosis), reactive lymphadenitis in 41 %, and non-contributive hemorrhagic material in 5 %. No procedure-related complications were reported.

Conclusions EUS combined with FNB has emerged as the reference examination for the assessment of deep-seated lymphadenopathy, particularly mediastinal and abdominal. In our series, diagnostic yield reached 95 % at the first histopathological analysis. This minimally invasive and well-tolerated technique represents an essential tool for ruling out malignancy or identifying specific disease processes, thereby allowing targeted therapeutic management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP026 Cold Snare Polypectomy versus Hot Snare Polypectomy for Small Colorectal Polyps (4–10 mm): Efficacy and Complications

Authors Aksim H[1], Belhamdiya M[1], Gharbi K[1], Akka R[1]
Institute 1 L'hôpital militaire Avicenne, Marrakesh, Morocco
DOI 10.1055/s-0046-1821353

Aims Screening and endoscopic removal of colorectal adenomas aim to prevent progression to colorectal cancer. Hot snare polypectomy (HSP) has long been considered the standard technique for polyps larger than 4 mm. However, cold snare polypectomy (CSP) has gained increasing attention due to its technical simplicity and potentially improved safety profile. The optimal technique for the resection of small colorectal polyps (4–10 mm) remains debated. The objective of this study was to compare the efficacy and complications of CSP versus HSP in the management of small colorectal polyps [1–3].

Methods This was a retrospective comparative study conducted between January 2023 and December 2024 in a tertiary gastroenterology and endoscopy unit. Patients aged over 30 years with colorectal polyps measuring 10 mm or less and resected by CSP or HSP were included. Efficacy outcomes included polyp retrieval rate, en bloc resection rate, and histologically complete resection rate. Complications assessed were immediate and delayed bleeding, post-procedural abdominal pain, and colonic perforation.

Results A total of 186 patients with 232 polyps were included. The median age was 62 years. CSP was performed in 68 % of patients and HSP in 32 %. Submucosal injection was used in 60.5 % of HSP cases compared to 14.4 % in CSP cases. Regarding efficacy, en bloc resection was achieved in 93.3 % of CSP cases versus 83.7 % of HSP cases (p = 0.116). Polyp retrieval rates were 91.1 % with CSP and 81.4 % with HSP (p = 0.107). Histologically complete resection was obtained in 78.5 % of CSP cases and 77.1 % of HSP cases (p = 0.251). No significant difference was observed.

In terms of complications, immediate bleeding occurred in 4.4 % of CSP procedures compared to 9.3 % of HSP procedures (p = 0.272). Delayed bleeding was significantly lower in the CSP group, occurring in 3.3 % of cases versus 11.6 % with HSP (p = 0.040). Post-procedural abdominal pain did not differ significantly between the two groups (p = 0.32). One case of colonic perforation was reported, occurring in the CSP group.

Conclusions The efficacy of cold snare polypectomy is comparable to that of hot snare polypectomy in terms of complete resection of small colorectal polyps. However, CSP significantly reduces the risk of delayed bleeding, without a clear advantage in preventing colonic perforation. These findings support the preferential use of CSP as the first-line technique for polyps measuring 4–10 mm.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP027 Recurrent Bleeding After Endoscopic Band Ligation of Esophageal Varices: Predictive Factors

Authors Aksim H[1], Belhamdiya M[1], Gharbi K[1], Akka R[1]
Institute 1 L'hôpital militaire Avicenne, Marrakesh, Morocco
DOI 10.1055/s-0046-1821354

Aims Gastrointestinal bleeding due to rupture of esophageal varices is a major and potentially fatal complication of portal hypertension. Endoscopic band ligation is currently considered the gold-standard treatment. However, rebleeding following ligation remains a serious event, and the factors associated with its occurrence are not yet clearly defined. The objective of this study was to assess the prevalence and identify the predictive factors of recurrent bleeding after endoscopic band ligation of esophageal varices [1–3].

Methods A prospective, descriptive, and analytical study was conducted over a one-year period, from December 2023 to December 2024. It included fifty-nine patients with portal hypertension who underwent endoscopic band ligation of esophageal varices.

The collected data included demographic characteristics, etiology of portal hypertension, severity scores of liver disease (Child-Pugh and MELD), endoscopic findings, details of the ligation procedure (number of sessions and bands used), associated treatments, eradication outcomes, recurrence of bleeding, and mortality. All data were obtained from medical records and analyzed using the Jamovi software.

Results Fifty-nine patients were enrolled in the study. The mean age was 55 ± 15 years (range 18–87 years), with a male-to-female ratio of 1.25. Cirrhosis was the predominant cause of portal hypertension, accounting for 83 % of cases (n = 49). The main etiologies were viral hepatitis in 24 % (n = 14), primary biliary cirrhosis in 3 % (n = 2), autoimmune hepatitis in 2 % (n = 1), iron overload in 2 % (n = 1), and nonalcoholic steatohepatitis (NASH) in 2 % (n = 1). Cryptogenic cirrhosis represented 49 % (n = 29) of cirrhotic cases. Portal vein thrombosis was found in 15 % (n = 9), and Budd–Chiari syndrome in 5 % (n = 3).

The mean follow-up duration was 3.5 ± 3.5 years (range 1–16 years). Secondary prophylaxis was the indication for ligation in 92 % of patients (n = 54). A history of hematemesis associated with melena was reported in 88 % (n = 52), while 3 % (n = 2) had isolated melena. The mean number of previous bleeding episodes was 1.7 ± 1.1 (range 1–7).

Initial endoscopic findings revealed grade III esophageal varices in 85 % of patients (n = 50) and grade II in 19 % (n = 11). Portal hypertensive gastropathy was observed in 66 % (n = 39), and gastric varices were present in 46 % (n = 27).

A total of 140 ligation sessions were performed. Complete eradication of varices was achieved in 46 % of patients (n = 27), with a mean of 2.6 sessions per patient. The mean number of bands applied per session was 5 ± 1.9. Four patients achieved eradication after a single session, ten after two sessions, seven after three sessions, six after four sessions, and one patient required six sessions. Beta-blockers were contraindicated in 29 % of patients (n = 17).

The rebleeding rate was 18 % (n = 11), occurring after a mean interval of three weeks. Among these patients, 55 % were classified as Child-Pugh B, with an average of 2.8 sessions required for eradication. Notably, 63 % of patients who experienced rebleeding were not receiving beta-blockers. The mortality rate due to variceal rupture was 8 % (n = 5).

Conclusions Statistical analysis did not identify any factor significantly associated with rebleeding after endoscopic band ligation. However, the severity of liver dysfunction, particularly in patients with Child-Pugh B or C scores, appeared to increase the risk of recurrence. Conversely, the use of beta-blockers was significantly associated with a reduced risk of rebleeding. These findings support the combined use of endoscopic band ligation and beta-blocker therapy as an effective strategy for secondary prevention of variceal bleeding.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A 65-year-old man was admitted to the intensive care unit for bilateral pneumonia requiring invasive mechanical ventilation and requiring the use of sedative drugs in continuous perfusion. In this context, the patient presents with upper gastrointestinal bleeding secondary to a gastric ulcer [1–3].

Urgent upper gastrointestinal endoscopy was performed, increasing the continuous infusion of Propofol 2 % to a dose of 3 mg/Kg/h. 12 hours after its infusion, the patient began to have greenish coluria, with no signs of associated urinary infection. After 12 hours of discontinuing the drug, the coluria disappears, with clear, yellowish urine that appears normal.

DOI 10.1055/s-0046-1821356

Background and Aims: The standard of care for resectable oesophageal cancer involves neoadjuvant chemotherapy or chemoradiotherapy followed by oesophagectomy. However, major or complete histopathologic regression (≤ypT1N0) occurs in up to 40–45 % of patients treated with modern systemic regimens. In these cases, the necessity of radical surgery performed primarily to confirm complete tumour eradication is increasingly questioned. Advances in endoscopic techniques now allow local histologic evaluation and potentially curative resection of residual tumours through natural orifice approaches. To our knowledge, this is the first reported case demonstrating the technical feasibility and oncological adequacy of an organ-sparing endoscopic resection following neoadjuvant chemotherapy for locally advanced oesophageal adenocarcinoma [1–6].

Methods:A 65-year-old man with locally advanced oesophageal adenocarcinoma (cT2N0M0, Siewert type II) received four cycles of neoadjuvant FLOT chemotherapy. Planned oesophagectomy was deferred after preoperative endoscopy revealed a 15-mm residual lesion at the oesophagogastric junction without endoscopic signs of invasion. The patient declined surgery and consented to local, organ-sparing endoscopic resection as part of an active surveillance strategy. The procedure was performed under general anaesthesia using an en bloc endoscopic submucosal dissection technique.

Results: The resection was completed without intra- or post-procedural complications. Histopathological assessment revealed complete tumour regression with no residual adenocarcinoma (ypT0Nx) and clear resection margins (R0). Follow-up CT performed one month after the procedure showed no evidence of local or nodal disease. The multidisciplinary team subsequently recommended discontinuation of adjuvant therapy and continuation of active surveillance. At 12-month follow-up, CT demonstrated a new 6 × 16 mm para-oesophageal lymph node; endoscopic ultrasound with fine-needle aspiration confirmed reactive inflammatory changes without malignancy. At 14 months, the patient remains asymptomatic and disease-free.

Conclusions: This first reported case demonstrates the technical and clinical feasibility of local, organ-sparing endoscopic resection following neoadjuvant chemotherapy for locally advanced oesophageal adenocarcinoma. Given that approximately one in five patients achieve a complete pathological response with neoadjuvant therapy, the universal requirement for oesophagectomy warrants reconsideration—particularly among multimorbid patients at high surgical risk. Local endoscopic resection enables histologic confirmation of treatment response and, in selected complete or near-complete responders, may offer curative potential within a multidisciplinary, response-adapted management strategy.

eP030 Colonoscopy for Altered Bowel Habits: Between Clinical Suspicion and Diagnostic Reality

Authors Broco Fernández C[1], Buela Fungueiriño L[1], Xavier Oliveira F[1], Patiño Delgadillo V[1], Hernández Hernández N[1], Díez Martín J[1], Boada Ortega D[1], Fernández Moreno M[1], Quiñones Castro R[1], Díez Rodríguez R[1], Espinel J[1], Jorquera Plaza F[1]
Institute 1 University Hospital of León, León, Spain
DOI 10.1055/s-0046-1821357

Aims Altered bowel habits, characterized by alternating constipation and diarrhea, are a frequent reason for requesting endoscopic evaluation. However, this symptom is nonspecific and may occur in both functional gastrointestinal disorders and organic diseases. Its isolated diagnostic value remains limited, and its use as a criterion for preferential endoscopic referral is controversial. The aim of this study was to assess the clinical relevance of altered bowel rhythm as an indication for colonoscopy by determining its diagnostic yield and its relationship with associated clinical variables [1–4].

Methods A retrospective observational study was conducted including 95 patients who underwent colonoscopy between November 2024 and April 2025 with alternating bowel rhythm as their main presenting symptom. Relevant demographic and clinical variables were collected from medical records and endoscopic reports. Data were analyzed using descriptive and comparative statistics to assess the diagnostic yield and potential associations with clinical factors.

Results A total of 95 patients were analyzed, with a mean age of 64.2 years (SD 14.37). Women accounted for 62.1 % (59/95) and men for 37.9 % (36/95). A family history of colorectal cancer (CRC) was present in 7.4 % of cases. Among the patients in whom the bowel habit subtype was documented (n = 77), the mixed subtype was most common (54.5 %), followed by diarrhea-predominant (28.6 %) and constipation-predominant (16.9 %) types. Regarding symptom duration (n = 62), 43.5 % reported symptoms lasting more than one year, while 46.8 % had symptoms lasting several months. Abdominal pain was reported by 38.9 % of patients. Rectal bleeding occurred in 9.5 %, constitutional symptoms (asthenia, anorexia, or weight loss) in 14.7 %, and iron deficiency in 7.4 %. The proportion of patients with hemoglobin < 12 g/dL was 3.6 %, and the fecal occult blood test was positive in 10.5 % of cases.

At colonoscopy, the most frequent finding was no clinically relevant abnormality (46.3 %), defined as a normal examination or hemorrhoids as the sole finding. Diverticulosis was found in 29.5 % of cases. Polyps were identified in 35.8 %, including 11.6 % advanced and 24.2 % non-advanced lesions. Minor findings included microscopic colitis, ileitis, angiodysplasia, and nonspecific inflammatory lesions, each accounting for ≤ 2 cases per entity.

A statistically significant association was observed between age and the presence of polyps (mean 67.9 vs. 62.1 years; p = 0.041) and between age and diverticulosis (mean 70.9 vs. 61.3 years; p = 0.002).

Conclusions Alternating bowel rhythm as the main indication for colonoscopy demonstrated a limited diagnostic yield. Nearly half of the procedures revealed no relevant findings, and only a small percentage showed advanced polyps. Alarm features—such as anemia, iron deficiency, rectal bleeding, or a positive fecal occult blood test—were uncommon, further limiting the predictive value of this symptom in patients without additional risk factors.Although IBS is a clinical diagnosis, the nonspecific nature of its symptoms often leads to prioritized colonoscopy referrals without a strong evidence-based rationale.Our results suggest that, in the absence of alarm features, colonoscopy for this indication can be managed within standard referral pathways rather than through expedited circuits, promoting a more rational use of resources.Applying more precise selection criteria, combining age, medical and family history, and symptom characteristics, would enhance clinical decision-making and contribute to a more efficient allocation of endoscopic resources.

eP031 When the Fundus Bleeds: A Rare Case Report of Gastric Fundal Vascular Ectasia (GFVE)

Authors Suliman H[1], Haseeb H[2], Saripalli S[3], Nawaz F[3]

Institutes **1** Royal Albert Edward Infirmary, Wigan, United Kingdom; **2** Aneurin Bevan Health Board, newpo, United Kingdom; **3** Aneurin Bevan Health Board, Newport, United Kingdom

DOI 10.1055/s-0046-1821358

Introduction Gastric vascular ectasia (GVE) is a rare cause of upper gastrointestinal bleeding, responsible for roughly 4 % of cases. Most commonly it affects the gastric antrum (gastric antral vascular ectasia or GAVE). However, it can rarely involve the fundus—referred to as gastric fundal vascular ectasia (GFVE). GVE is more frequently diagnosed in elderly females and is associated with liver cirrhosis, autoimmune diseases, and other systemic conditions. Its presentation ranges from chronic iron-deficiency anaemia to acute GI haemorrhage, and diagnosis is primarily based on endoscopic findings.

Case Description A middle-aged male with a history of psoriatic arthritis and chronic iron-deficiency anaemia, was admitted with a 2-week history of melaena. Initial bloods revealed an acute drop in Hb to 77g/L, down from 84g/L, indicating ongoing blood loss. After initial resuscitation, including blood transfusion, an urgent OGD revealed multiple vascular ectasia in fundus, with active bleeding at three points, along with mild GAVE. Pulsed Argon Plasma Coagulation (APC) was successfully applied, achieving immediate haemostasis. Additionally, small Grade-2 non-bleeding oesophageal varices were noted. Follow-up imaging confirmed liver cirrhosis (Child-Pugh-A). Patient's haemoglobin stabilised post-endotherapy, and no further GI bleeding episodes occurred. Intravenous iron therapy was administered, and symptoms markedly improved.

Discussion While GAVE is typically found in the antrum, on the other hand GFVE is rare and often overlooked during endoscopy. Unlike traditional GAVE, which shows characteristic striped lesions (watermelon stomach), this patient's presentation was diffuse and scattered.This case is significant due to the unusual occurrence of bleeding originating from the fundal region. Endoscopic findings of GFVE may mimic other vascular lesions such as portal hypertensive gastropathy. Although not indicated, but histologically, it is characterised by dilated mucosal vessels, spindle cell proliferation, and fibrohyalinosis. Elevated vasodilatory hormones and impaired liver function may play a role in pathogenesis. Endoscopic therapy, particularly APC, remains the first-line treatment and is effective in controlling bleeding and reducing transfusion requirements.

Conclusion GFVE although rare, should be considered in patients presenting with unexplained GI bleeding, especially those with liver disease or autoimmune conditions. Early endoscopic evaluation is crucial, as diagnosis may easily be missed due to its atypical location and overlapping features with other gastric pathologies. APC is an effective treatment modality, as demonstrated in this case.

eP032 When Good Is Not Good Enough: Superiority of Excellent Over Good Bowel Preparation for Proximal Serrated Polyp Detection in a FIT-Based Screening Cohort

Authors Fantasia S[1], Kayali S[1], Cortegoso Valdivia P[2], Andreotti S[1], Macchi D[1], Nervi G[2], Pagano N[3], Laghi L[1]

Institutes **1** University of Parma – Department of Medicine and Surgery, Parma, Italy; **2** Gastroenterology and Endoscopy Unit, University Hospital of Parma, Parma, Italy; **3** Ospedale Maggiore di Novara, Novara, Italy

DOI 10.1055/s-0046-1821359

Aims The Proximal Serrated Polyp Detection Rate (PSDR) is an emerging quality indicator linked to post-colonoscopy colorectal cancer risk, but the benefit

of bowel cleanliness on its detection remains unclear. We evaluate the impact of excellent (Boston Bowel Preparation Scale [BBPS] 8–9) versus good (BBPS 6–7) preparation on serrated (PSDR and sessile serrated lesion detection rate [SSLDR]) and adenoma-related (adenoma detection rate [ADR] and adenoma per colonoscopy [APC]) quality indicators in a FIT-positive screening cohort.

Methods This retrospective single-center study of 1069 patients (age 50–69) undergoing screening colonoscopy after a positive FIT compared PSDR, SSLDR, ADR, and APC between excellent and good preparation groups using univariate and multivariate regression analyses.

Results Excellent preparation showed a significantly higher PSDR (13.7 % vs. 7.9 %; OR 1.84, 95 %CI 1.22–2.80, p = 0.004) and SSLDR (7.6 % vs. 4.0 %; OR 2.00, 95 %CI 1.14-3.52, p = 0.016) than good cleansing. A linear relationship was observed, BBPS 9 outperforming BBPS 8. No significant difference was found for ADR (50.4 % vs. 47.9 %; OR 1.10, 95 %CI 0.87-1.41, p = 0.424) and APC (MD = 0.103; 95 % CI, -0.071-0.277, p = 0.247).

Conclusions Aiming for an excellent rather than a good bowel preparation is a critical strategy to maximize the detection rate of serrated pathway lesions and potentially reduce the incidence and mortality for interval colorectal cancer (CRC). This benefit does not extend to adenoma detection, underscoring the importance of PSDR and SSLDR as distinct and complementary quality indicators.

eP033V Undersaline ESD combined with clip-and-band traction for a flat adenoma involving the entire ileocecal valve and two-thirds of the terminal ileum

Authors Mavrogenis G[1], Madianos D[1]
Institute 1 Mediterraneo Hospital, Glifada, Greece
DOI 10.1055/s-0046-1821360

Abstract Text

Endoscopic submucosal dissection (ESD) of the ileocecal valve and terminal ileum remains technically demanding due to poor scope stability and adipose tissue interference. The undersaline ESD technique combined with internal traction may enhance safety and efficiency in such complex cases. A 71-year-old patient was referred for ESD of a 4 cm non-granular flat adenoma involving the entire ileocecal valve and approximately two-thirds of the last 1 cm of the terminal ileum. Circumferential incision was performed under saline immersion using a tip-cutting knife with flushing capability. A mucosal flap was created at the anal side to allow clip and band countertraction. The lesion was removed en bloc, and the mucosal defect was partially closed with clips. Oral budesonide was given for two months to prevent ileal stricture. The patient has an uneventful recovery without relapse at 3 months of follow up.

eP034 Laparoscopic and Endoscopic cooperative surgery as Rescue treatment for Advanced gastric Cancer in patients Unfit for Surgery: a report of the first four cases from the LE-RACUS pilot clinical study

Authors Maltzman H[1, 2], Omae M[2, 3], Klevebro F[1, 2], Baldaque-Silva F[4, 3, 2], Rouvelas I[1, 2]
Institutes 1 Karolinska Institutet Clintec, Stockholm, Sweden; 2 Karolinska University Hospital Huddinge, Stockholm, Sweden; 3 Karolinska Institute, Department of Medicine Huddinge, Stockholm, Sweden; 4 Center for Advanced Endoscopy Carlos Moreira da Silva, Hospital Pedro Hispano, Matosinhos, Portugal
DOI 10.1055/s-0046-1821361

Aims For patients with advanced gastric cancer (GC) without metastasis, gastrectomy in combination with chemotherapy is generally recommended. Some patients are too frail for such invasive treatment because of old age or comorbidities. In the LE-RACUS trial, we are testing the feasibility of Laparoscopic and Endoscopic Cooperative Surgery (LECS) as a less invasive treatment option. During the LECS procedure the tumor is first marked from the inside with an endoscopic knife, followed by perforation of the gastric wall and laparoscopic removal under endoscopic visualization. The current evidence of LECS for advanced GC is based solely on case reports, as no prospective or retrospective studies have been published. Here, we are reporting on the outcomes of the first four patients of the trial [1, 2].

Methods A single-center prospective phase 1 trial. Patients with cT2-4aN0M0 GC Borrman type 1-2 < 5 cm, or type 3 < 2 cm are considered for inclusion if they have been tumor board assessed as not fit for standard surgery. Exclusion criteria are Borrman type 4 and tumors close to the cardia. The primary objective is the safety of LECS, defined as Clavien-Dindo score ≥ III. The secondary objectives are any complications, postoperative bleeding or perforation, operation time, radicality, 30-day and in-hospital mortality, hospital stay.

Results To date, four patients have been enrolled. The median age was 88 years (range 75-95), with a median Charlson comorbidity index of 6.5 (range 5-10). Median tumor size was 3.5 cm (range 2-5), located in the fundus (n = 2), body (n = 1), and antrum (n = 1). All patients underwent the LECS procedure successfully. Postoperative events included one case of intra-abdominal abscess requiring percutaneous drainage and one case of fever on day 3, treated with antibiotics. No cases of postoperative bleeding, perforation, or other major complications were observed during follow-up. The median operation time was 186.5 minutes (range 171-230), and the median hospital stay was 6.5 days (range 3-19). There were no perioperative deaths. Pathology revealed T1am2, T1bSm1, T2 and T4 adenocarcinoma, two of which were tubular subtype, one tubular/papillary type and one signet ring cell type. Radical resection was achieved in 3 out of 4 cases.

Conclusions The preliminary results from the LE-RACUS trial indicate that LECS is a feasible option for patients with non-metastatic advanced gastric cancer who are considered too frail for standard surgery. However, the complete trial results are warranted for better assessment of this innovative approach.

eP035 Four cases of succesfull endoscopic closure of rectourethral fistula

Authors Markos P[1], Majerovic M[1], Bradic T[1], Cavlina Sevo M[1], Kalauz M[1]
Institute 1 University Hospital Center Zagreb, Zagreb, Croatia
DOI 10.1055/s-0046-1821362

Aims Rectourethral fistula is a devastating condition occuring usually as a complication of radical prostatectomy or pelvic irradiation. Classical treatment requires surgical repair with derivation of the urine and stool with temporary cysto and colostomy.

Methods We present four cases of sucessful endoscopic closure of rectourethral fistula using different endoscopic procedures.

Results First patient was presented to our department with rectourethral fistula as a complication of difficult urinar catheterisation. During the catheterisation, tip of the catheter was inadvertely pushed into the distal rectum and inflated baloon stayed there for 3 days. After the CT scan was done, urologist took out the catheter and placed percutanoeus cystostomy. We started closing the fistula in a three week period; first and second intervention consisted of

Endoscopy 2026; 58: S1–S1041

argon plasma coagulation of the fistula edges and 2ml fibrin glue application, and durin the third intervention over-the scope clip 14/6 was placed and completely closed the fistula. Other three patients were presented to our hospital with the persistent fistula as a complication of radical prostatectomy. In one patient urologist already tried to close the fistule with two surgical procedures and the patient had cystostomy and sygmoidostomy but the fistulous tract persisted. Endoscopically fistula was located 3 cm orally from the anal verge with lumen of 3 mm; we performed three procedures with argon plasma coagulation of the edges, 2 ml fibrin glue and clip closure (tulip bunde techique twice, third time over the scope clip 14/6 application. After one month CT scan was done and revealed total fistula occlusion so cystostomy and sygmoidostomy were taken out. Third and fourth patients were presented immediately after prostatetctomy when fistula was detected (3 weeks after the surgery) so only one endoscopic intervention with argon plasma coagulation of the fistula edges, fibrin glue application and over-the scope clips 14/6 placement was enough in both patients to sucesfully close the fistulous tract.

Conclusions With development of new endoscopic techniques, complex cases like refractory rectourethral fistula that usually required surgical treatment, can be adequately treated with minimally invasive endoscopic approach.

eP036 Complete resolution of ileus with placement of LAMS hot axios due to stenotic ileocolic anastomosis

Authors Markos P[1], Majerovic M[1], Bradic T[1], Cavlina Sevo M[1], Kalauz M[1]
Institute 1 University Hospital Center Zagreb, Zagreb, Croatia
DOI 10.1055/s-0046-1821363

Abstract Text

We present a case of a 40-year old male that presented in our emergency department with clinical signs of ileus. He has been operated (subtotal colectomy with formation of ileosigmoid anastomosis) due to obstructive Crohn's disease in 2015. Five days before actual clinical presentation he was on an elective colonoscopy that revealed fibrotic stenosis of the anastomosis, not passable with the scope, lumen width 4-5 mm.

During the next few days he started feeling bloated with progressive abdominal pain, nausea, absence of stool and at the end vomiting. He came to our emergency room- basic lab test were normal with just slight elevation of inflammatory parameters, but X-ray and then CT scan revealed ileus on the level of the ileocolic anastomosis. He was seen by a surgeon, started with conservative treatment (NG tube, antibiotics), but during the next 12 hours clinical condition and x-ray did not improve. After that we have been consulted by a surgeon and made a quick decision to perform endoscopy that revealed complete obstruction of the ileocolic anastomosis. Due to high surgical risk (multiple adhesions, risk of anastomotic leak and formation of high output stoma), we offered the patient possibility of urgent endoscopic intervention/decompression.

We changed the scope to therapeutic one, pushed the LAMS hot axios 20x10mm through the working channel and with the help of guide wire and fluoroscopy placed the LAMS in classical manner over the anastomosis. Immediately after the LAMS placement, liquid stool was evacuated. During the next day patient had multiple stool and gas evacuation and complete clinical and radiological regression of ileus so he was discharged 48 hours after the procedure.

LAMS was extracted with forceps 3 weeks after the placement, anastomosis was widely opened, and the patient remained completely asymptomatic during the follow up.

This case is to show that with slightly "extraordinary" approach we can save the patient from radical surgery.

DOI 10.1055/s-0046-1821364

Abstract Text

A 75-year-old man presented with complete proximal esophageal obstruction. Nutrition was maintained via gastrostomy after total laryngectomy with neopharynx creation and radiotherapy for laryngeal cancer six years earlier. Endoscopic gastropexy was first performed to protect the fistulous tract. The gastrostomy was dilated to 18 mm and a 9 mm scope was advanced through the fistula into the esophagus. Progressive dissection with an ESD knife recreated a 6 cm neo-lumen toward the hypopharynx. For the final 2 cm, transillumination from an oral endoscope guided the rendezvous. The patient recovered uneventfully and undergoes weekly dilations at 15 mm. At 5 months of follow up, he can swallow liquids and soft food.

eP038 Colonic Pedunculated Headless Polyps: A Rare Endoscopic Finding

Authors Sasiakos I[1], Tsamakidis X[1], Michailidou S[1], Kontos A[1], Giannakopoulos V[1], Papakonstantinou F[1], Vrysis K[1], Skafida E[1], Simopoulou S[1], Boti E[1], Ntalakos N[1], Kitsakis G[1], Sarimpegioglou N[1], Tziortziotis I[1], Tsironis H[1], Kypraios D[1], Dimitroulopoulos D[1]
Institute 1 General Cancer Hospital of Athens Agios Savvas, Athina, Greece, Athens, Greece
DOI 10.1055/s-0046-1821365

Case presentation We report two cases of colonic polyps with a distinctive worm-like, headless appearance. In the first case, a 80 year-old man with no significant medical history underwent colonoscopy, revealing a pedunculated polyp without a defined head in the descending colon, which was successfully removed via endoscopic mucosal resection (EMR). In the second case, a 77 year-old woman was found to have nine elongated, worm-like polyps — five in the transverse colon and four in the descending colon. Two smaller headless stalk-like polyps were removed with a cold snare. However, removal of a larger polyp was unsuccessful due to a firm fibrous band within the stalk, causing snare entrapment. The snare catheter was transected, and a coagrasper forceps was used to sever the fibrous band, allowing safe snare extraction. Two clips were applied at the resection site. Histopathology in both cases revealed findings consistent with mucosubmucosal elongated polyps (MSEPs) [1, 2].

Conclusion MSEPs are rare, benign colorectal lesions, accounting for approximately 0.1-0.39 % of all polyps. They consist of normal mucosa overlying a submucosal core with dilated, thick-walled veins aligned along the polyp's long axis. Their etiology is thought to involve mechanical traction on the mucosa and submucosa during intestinal motion, particularly in anatomically vulnerable segments of the colon. As demonstrated in our cases, large MSEPs should preferably be removed via EMR rather than cold snare polypectomy, to minimize the risk of snare entrapment caused by the dense fibrous tissue within the stalk.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP039V Wide-field right colon ESD made easy with undersaline immersion and multifocal countertraction

Authors Mavrogenis G[1], Makreas S[1]
Institute 1 Mediterraneo Hospital, Glifada, Greece
DOI 10.1055/s-0046-1821366

Abstract Text

Right colon ESD for large polyps is challenging due to poor maneuverability and the high risk of perforation. In this video we demonstrate the strategy for safe wide field dissection using the following steps: 1) undersaline immersion 2) circumferential incision 3) multifocal traction with multiple complexes of clips and bands 4)dissection with a pediatric scope with an attached tapered cap and the use of an ESD knife with saline jet properties.

Aims Patients with liver cirrhosis are considered at increased risk for bleeding complications after endoscopic procedures due to impaired haemostasis. However, evidence-based risk stratification for colorectal polypectomy in this population remains limited. This study aimed to identify cirrhosis-specific and universal risk factors for post-polypectomy bleeding by comparing patients with liver cirrhosis to matched non-cirrhotic controls.

Methods Data were retrospectively obtained for 285 patients, including 96 patients with liver cirrhosis who underwent colorectal polypectomy (polyps ≥ 5mm) between 2013-2023. Matching was performed by age, gender, and comorbidity index. The primary endpoint was any bleeding, secondary endpoints were intraprocedural bleeding, delayed bleeding, and other severe complications. Risk factors were analyzed using univariate logistic regression.

Results Universal risk factors across both groups included PTT (cirrhosis: ≥ 32.2s, OR 6.15, p = 0.022; controls: ≥ 31s, OR 2.83, p = 0.007), INR (cirrhosis: ≥ 1.3, OR 3.12, p = 0.031; controls: ≥ 0.92, OR 3.24, p = 0.023), and lower GOT values, which showed a paradoxical protective association in both groups (cirrhosis: ≥ 28 U/L, OR 0.22, p = 0.029; controls: ≥ 28 U/L, OR 0.29, p = 0.011). Cirrhosis-specific risk factors were spleen diameter ≥ 18cm (OR 3.89, p = 0.026) and MELD score ≥ 15 (OR 3.27, p = 0.044). In controls, polyp size ≥ 15mm was the strongest predictor (OR 4.69, p < 0.01), while protective factors included platelet count > 211 × 10^9/µl (OR 0.42, p = 0.022) and prothrombin activity ≥ 114 % (OR 0.1, p = 0,027). In the overall cohort analysis (n = 285), polyp size emerged as the dominant risk factor (≥ 16mm: OR 4.26, p < 0.01). Liver cirrhosis itself was not an independent predictor, and bleeding rates did not differ significantly between cirrhotic and non-cirrhotic patients.

Conclusions Risk assessment for post-polypectomy bleeding should be individualized, not predetermined by cirrhosis status. Universal risk factors – PTT, INR and polyp size – apply across groups with different thresholds. Cirrhosis-specific markers like MELD and spleen size need targeted evaluation. Crucially, liver cirrhosis itself was not an independent bleeding risk factor. Our data suggest that safe polypectomy is achievable in well-selected cirrhosis patients and that bleeding risk may by further reduced using tailored risk stratification.

eP041 From bad to worst: obstructive jaundice due to post-embolization pancreatic necrosis

Authors Giannitti S[1], Dottori L[1], Marinozzi G[1], Gentili F[1]
Institute 1 Hospital Santa Maria, Terni, Italy
DOI 10.1055/s-0046-1821368

Abstract Text

Upper gastrointestinal bleeding (UGB) is a frequent and potentially life-threatening condition that is managed in most cases with endoscopic therapy [1]. Endovascular therapy (ET) or, rarely, surgical therapy are generally required in case of uncontrolled or refractory bleeding [2]. We present the case of a 77-year-old woman who presented to the emergency department (ED) for melena. Due to hemodynamic instability and the evidence of gastroduodenal pseudoaneurysm with active duodenal bleeding at urgent TC, a direct ET was performed. After 5 days, the patient presented jaundice and inflammatory markers' elevation (total/direct bilirubin 5/3.2, GGT 350, ALP 430, WBC 15.2, PCR 14.5). Cross-sectional imaging revealed pancreatic necrosis with edematous thickening of the duodenal wall, but without clear evidence of biliary obstruction. Endoscopic ultrasound (EUS) was therefore performed, which showed a slightly dilated common bile duct (CBD) with caliber reduction in the pre-papillary tract due to a hypoechoic mass determining the loss of duodenal wall stratification, compatible with pancreatic tissue and pseudoaneurysm necrosis. Hyperechoic non-projecting material inside the CBD and gallbladder, and slight dilation of the intrahepatic biliary ducts were also observed. On EUS basis, an endoscopic retrograde cholangiopancreatography (ERCP) was performed. During ERCP, the descending duodenum mucosa appeared covered by fibrinous-necrotic material mixed with biliary material. Vater papilla was markedly fragile and surrounded by necrotic tissue. CBD was selectively cannulated, and a fully covered biliary metal stent 10 mm x 40 mm was placed, with prompt outflow of purulent bile and an hourglass appearance of the stent, due to compression exerted by the pseudoaneurysm and pancreatic necrotic tissue. After ERCP, the patient progressively recovered from jaundice and presented a few episodes of melena, managed with medical therapy until Hb values became stable. The patient was initially maintained fastened with a nasogastric tube (NGT), and progressively fed with enteral nutrition and then with oral diet. After 1 month, an esophagogastroduodenoscopy was performed, showing normal duodenal mucosa with the biliary stent through the papilla. A TC was performed after 6 months, which showed a reduction of the necrotic area with well-positioned biliary stent and aerobilia. An ERCP for stent removal is scheduled within 1 month. This case shows how endoscopy may be necessary and resolutive in UGB, not only as a first-line treatment, but also in the event of complications arising from other therapeutic strategies. Endoscopists should thus be ready to promptly and transversely intervene [1, 2].

eP042 Post-Polypectomy Surveillance in Clinical Practice: Low Guideline Adherence and Contributing Factors

Authors Adán-Merino L[1], Cordero Martín M[1], Mora-Soler AM[1], Arroyo Argüelles JM[1], Escobar Ortiz J[1], Prieto Doblado M[1], Pérez Pérez J[1], Garrido Gallego F[1], Ponferrada-Díaz Á[1]
Institute 1 Hospital Universitario Infanta Leonor, Madrid, Spain
DOI 10.1055/s-0046-1821369

Aims Colorectal cancer (CRC) incidence can be reduced through detection and removal of advanced polyps. Appropriate surveillance intervals after index colonoscopy are essential to balance cancer prevention with resource optimization. Delayed surveillance may increase the risk of advanced lesions or CRC incidence, whereas premature or unnecessary procedures expose patients to avoidable risks and burden endoscopy units.The aim of this study was to evaluate the adequacy of post-polypectomy surveillance indications according to European Society of Gastrointestinal Endoscopy (ESGE) guidelines. Secondary objectives included identifying factors associated with inadequacy and assessing physicians' knowledge of surveillance intervals

Methods A retrospective, single-center, observational study was conducted. All colonoscopies performed between January 1st and June 30th, 2024, were reviewed. Only procedures indicated for post-polypectomy surveillance were included. To assess knowledge, a questionnaire with four clinical scenarios was sent to referring physicians.

Results Of 3,096 colonoscopies performed, 481 (15.5 %) were post-polypectomy surveillance procedures. Among these, 270 (56.1 %) had an inappropriate indication. Most of them (28.3 %) corresponding to patients who did not require colonoscopy.The rate of advanced polyps was higher in delayed surveillance colonoscopies compared with those not requiring follow-up (16.5 % vs 5.1 %, $p = 0.024$).Inappropriate indications were significantly associated with patients having four or fewer adenomas in the previous colonoscopy (40.4 %, $p < 0.001$). Requests from primary care showed a higher inadequacy rate compared with those from the gastroenterology department (79 % vs 39.9 %, $p < 0.001$). Appropriate indications were more frequent when colonoscopies were performed within the CRC screening program (65 % vs 35.5 %, $p < 0.001$).In the knowledge survey, 28 responses were received. The accuracy rate was ≥ 50 % for all scenarios. The lowest score corresponded to surveillance after an advanced adenoma with high-grade dysplasia and size > 10 mm, while the remaining cases showed > 75 % correct answers.

Conclusions Adherence to ESGE post-polypectomy surveillance guidelines was low in our setting, with over half of colonoscopies inappropriately indicated. Most unnecessary requests corresponded to patients without an indication for endoscopic follow-up [1, 2].

Referral from primary care, fewer than four adenomas, and absence from population-based screening programs were factors associated with inappropriate indications.

The overall level of knowledge among referring physicians was acceptable but could be improved, particularly in cases involving advanced adenomas with high-grade dysplasia.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP043V Alleviation of dysphagia in a patient with bilateral Killian-Jamieson diverticula using KJ-POEM

Author Lajin M[1]
Institute 1 Sharp Grossmont Hospital, La Mesa, United States of America
DOI 10.1055/s-0046-1821370

Abstract Text

A 73-year-old man presented with dysphagia and cough. An esophagram revealed bilateral Killian-Jamieson diverticula. The contrast filled both diverticula before gradually passing into the esophagus. During endoscopy, food debris was removed. Submucosal injection was followed by a small mucosotomy at the proximal septum using a Hybrid knife. The submucosal fibers were trimmed to expose the circular muscle. Submucosal tunneling was performed at the edges of the muscle with repeated injections to protect the mucosa on both sides. Myotomy was then carried out down to the bottom of the diverticulum. The mucosotomy was closed with four clips. A contrast study showed no extravasation and improved passage into the esophagus. The patient's dysphagia resolved on follow-up two years later.

eP044 Herpes Simplex Virus Esophagitis as the First Manifestation of Eosinophilic Esophagitis in an Immunocompetent Adolescent: A Case Report

Authors Stratigakis L[1], Neonaki A[1], Aslanoglou A[1], Papatheodoridi M[1], Koutsoumpas A[1], Papaxoinis K[1], Papatheodoridis G[1]
Institute 1 1st Academic Department of Gastroenterology, General Hospital of Athens "Laiko", Athens, Greece
DOI 10.1055/s-0046-1821371

Abstract Text

Herpes simplex virus (HSV) esophagitis (HSE) is classically associated with immunocompromised states, whereas eosinophilic esophagitis (EoE) is a chronic immune-mediated condition characterized by esophageal eosinophilic inflammation. We present an unusual case of HSV esophagitis as the initial manifestation leading to the diagnosis of EoE in a previously healthy adolescent [1, 2].

A 17-year-old male with no history of atopy, food allergies, or immunodeficiency presented with fever and odynophagia of two days duration. At admission, an upper endoscopy was performed which revealed multiple well-demarcated, punched-out ulcers with fibrin exudate along the mid and distal esophagus from which biopsied were obtained. Physical examination was unremarkable, and laboratory results, including HIV and immunologic screening, were within normal limits except from an elevated C-reactive protein value. Biopsies demonstrated viral cytopathic changes consistent with HSV infection, while HSV IgM serology was negative. The patient was treated with oral valacyclovir at a dose 1000mg twice daily for 10 days, with rapid clinical improvement and complete symptom resolution.

One month later, follow-up endoscopy was performed to confirm mucosal healing. The ulcers had completely resolved. Surprisingly, new findings of esophageal rings and longitudinal furrows were observed throughout the esophagus. Biopsies from mid and proximal esophagus revealed dense eosinophilic infiltration exceeding 150 eosinophils per high-power field, confirming a diagnosis of eosinophilic esophagitis. The patient was started on high-dose proton pump inhibitor (PPI) therapy After two months of treatment, repeat biopsies showed reduction of eosinophilic infiltration (< 15 eosinophils per high-power field)

This case illustrates an uncommon sequence in which HSE preceded the diagnosis of EoE in an immunocompetent patient. The relationship between these two entities remains uncertain, but several hypotheses have been proposed. HSV infection may act as a trigger for local mucosal immune activation, leading to eosinophilic inflammation and unmasking a latent predisposition to EoE.

Alternatively, an underlying EoE-related epithelial barrier dysfunction might predispose to viral infections. Regardless of the mechanism, this case emphasizes the importance of follow-up endoscopy after HSE, even in immunocompetent individuals.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP045 Difference in Immune Profiling According to the Presence or Absence of Metabolic Dysfunction-Associated Steatotic Liver Disease in Ulcerative Colitis Patients

Author Soh J[1]

Institute 1 Hallym University Sacred Heart Hospital, Anyang, Republic of Korea

DOI 10.1055/s-0046-1821372

Aims Inflammatory bowel disease and metabolic dysfunction-associated steatotic liver disease (MASLD) are chronic diseases associated with gut dysbiosis and systemic inflammation. MASLD is common in ulcerative colitis (UC) with prevalence rates ranging from 1.5 % to 55 %. However, the influences of each disease were poorly explored. The profiling of immune cells could be helpful for identifying the association of chronic inflammatory diseases. We compared immune marker expression of colonic tissues between UC patients according to presence or absence of MASLD [1–4].

Methods We enrolled patients who underwent colonoscopic biopsies on active inflammation and CT scan to differentiate steatotic liver at the time of UC diagnosis. We included 24 UC patients, 12 with MASDL and 12 without. The expression levels of CD8, CD68, CD163, Foxp3, and programmed cell death protein-1 (PD-1) cells were evaluated by quantitative multispectral imaging.

Results We enrolled patients who underwent colonoscopic biopsies on active inflammation and CT scan to differentiate steatotic liver at the time of UC diagnosis. We included 24 UC patients, 12 with MASDL and 12 without. The expression levels of CD8, CD68, CD163, Foxp3, and programmed cell death protein-1 (PD-1) cells were evaluated by quantitative multispectral imaging.

Conclusions The immune cells including M1 macrophages and exhausted T cells showed different expressions depending on the presence of MASLD in UC patients. Immune profiling might be helpful for predicting diagnosis and prognosis in UC patients with comorbidity of MASLD.

DOI 10.1055/s-0046-1821373

Aims Endoscopic submucosal dissection (ESD) is an established curative treatment for lateral spreading tumors and early colorectal cancer, but it can cause procedure-related complications such as post-ESD coagulation syndrome (PECS). Proximal tumor location is a known independent risk factor for PECS. Nexpowder (NEXTBIOMEDICAL CO., LTD.Nextbiomedical, Incheon, Republic of Korea), a highly adhesive hemostatic powder approved by the US FDA for non-variceal upper gastrointestinal bleeding, has demonstrated efficacy in preventing rebleeding. This study aimed to evaluate the prophylactic efficacy of Nexpowder in preventing PECS after colorectal ESD for high-risk proximal lesions [1–5].

Methods This retrospective multicenter study included patients who underwent colorectal ESD between April 2023 to October 2024 for proximal colonic lesions, without perforation, muscular injury, or prophylactic clipping. Nexpowder was applied prophylactically in 35 patients (46.7 %), while 40 patients (53.3 %) served as controls. PECS was defined as postprocedural abdominal pain, fever, and elevated inflammatory markers requiring antibiotics (▶ **Table 1**).

▶ **Table 1** Study outcomes

Variables	Control group (n = 40)	Nexpowder group (n = 35)	P-value
PECS, n (%)	8 (20.0)	1 (2.9)	0.032+
Abdominal pain (≥ NRS 4)	9 (22.5)	2 (5.7)	0.053+
Fever (≥ 38.0℃)	9 (22.5)	1 (2.9)	0.016+
White blood cell count increase, /ul	9 (22.5)	6 (17.1)	0.561
C-reactive protein increase more than 1mg/dL	11 (27.5)	6 (17.1)	0.406
Powder associated adverse event, n (%)			
Colonic obstruction		0 (0.0)	–
Perforation		0 (0.0)	–
Infection		0 (0.0)	–
Embolization		0 (0.0)	–

§Median (range); + Fisher exact test ; **P*-values were calculated using the *t*-test or Fisher calculated using of the control group and the Nexpowder group

Results PECS occurred in nine patients overall. The incidence of PECS was significantly lower in the Nexpowder group (2.9 %) than in the control group

(20.0 %; p = 0.032). All cases improved with conservative treatment, and no surgical intervention was required.

Conclusions Prophylactic application of Nexpowder significantly reduced the incidence of PECS after high-risk colorectal ESD. This study provides the first clinical evidence that a topical barrier agent may serve as a simple and effective preventive strategy for PECS.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

ePO47 Bowel Cleansing in Colonoscopy: Determining Factors for Adequate Preparation

Authors Pérez Pérez J[1], Prieto Doblado M[1], Perez Martin S[1], Diego CL[1], Fernández Jiménez B[1], Izquierdo García A[1], Amores Atance M[1], Garrido Gallego F[1], Adan Merino L[1], Ponferrada-Díaz Á[1]

Institute 1 Hospital Universitario Infanta Leonor, Madrid, Spain

DOI 10.1055/s-0046-1821374

Aims To identify factors associated with adequate bowel cleansing prior to colonoscopy.

Methods A retrospective observational study was conducted including all colonoscopies performed at our center during the first quarter of 2025. Adult patients without prior gastrointestinal resection were included and categorized according to the Boston Bowel Preparation Scale (adequate: ≥ 6; poor: < 6). Clinical variables analyzed included comorbidities (ASA classification), regular medication, BMI, abdominal circumference, alcohol consumption, physical exercise on the day of the procedure, bowel habits, use of laxatives or prokinetics, fasting hours for solids and liquids, timing of bowel preparation doses, duration of low-residue and liquid diets, presence of diverticula, and prior abdominal surgery [1–3].

Results A total of 206 patients (110 women, 96 men; mean age 57.5 years) were analyzed. Adequate bowel cleansing was achieved in 198 patients (96.1 %), while 8 (3.9 %) had suboptimal preparation. Statistically significant differences between groups were found for physical exercise on the day of the procedure, comorbidity level (ASA classification), fasting duration on a liquid diet, and the timing of completion of the last bowel preparation dose (▶ **Table 1**).

% of sample	100 %	96.12 %	3.88 %	---

Conclusions Physical exercise, lower comorbidity, and a shorter interval between bowel preparation and colonoscopy appear to be key factors associated with adequate bowel cleansing. Optimizing these elements may improve colonoscopy quality and diagnostic yield.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims To identify clinical and procedural factors associated with adequate gastric cavity cleansing prior to upper gastrointestinal endoscopy [1–3].

Methods A retrospective observational study was conducted on UGIE procedures performed at our center during the first quarter of 2025. Adult patients were categorized according to the quality of gastric preparation (adequate vs. suboptimal).

Variables analyzed included medical history, chronic medication use, BMI, abdominal circumference, alcohol consumption, physical activity on the day of the procedure, bowel habits, use of laxatives and/or prokinetics, ASA classification, and fasting hours for both liquids and solids (▶ **Table 1**).

▶ **Table 1** Comparison of variables between groups with adequate and inadequate gastric–duodenal preparation

Variable	Total sample (n = 205)	Good preparation (n = 192)	Poor preparation (n = 13)	p value (< 0.05)
Sex (n)	Women: 117 Male: 88	Women: 109 Male: 83	Women: 8 Male: 5	0.072
Median age (years)	51 (W: 53 / M: 49)	51	48	0.083
Median BMI	25.6 (W: 25.6 / M: 27.75)	25.55	26.8	**0.045**
Median abdominal circumference (cm)	92	92	97	**0.012**
Diabetes Mellitus (DM)	18	16	2	0.650
Hypothyroidism	14	12	2	0.219
Bowel movement frequency	2–5/week: 30 Daily: 145 >1/day: 30	2–5/week: 28 Daily: 136 >1/day: 28	2–5/week: 2 Daily: 9 >1/day: 2	0.998
ASA classification	ASA I–II: 192 ASA III–IV: 13	ASA I–II: 179 ASA III–IV: 13	ASA I–II: 13 ASA III–IV: 0	—
Physical activity on the day	None: 143 Walking: 53 Aerobic: 9	None: 134 Walking: 50 Aerobic: 8	None: 9 Walking: 3 Aerobic: 1	0.906
Median fasting time for liquids (h)	8	8	5.5	**0.003**
Median fasting time for solids (h)	9	10	6.5	**0.023**

Exclusion criteria: patients under 18 years of age and those with previous gastrointestinal resections.

Results A total of 205 patients were included (117 women, 88 men; mean age 51 years). Adequate preparation was observed in 192 patients, while 13 had suboptimal preparation (6.34 % of the total sample).

Statistically significant differences between groups were found in BMI, abdominal circumference, and fasting duration for both liquids and solids.

Conclusions Adequate fasting time for both liquids and solids is crucial to ensure optimal gastric cleansing. Patients with higher BMI and larger abdominal circumference are at greater risk of residual gastric contents despite standard fasting recommendations. Extending fasting duration in this subgroup may improve the quality of endoscopic evaluations.

DOI 10.1055/s-0046-1821376

Aims Several ligation techniques for ulceration after endoscopic submucosal dissection (ESD) have been reported, but a ligation technique for clinical use has not been established because of the technical complexity and the need for expensive equipment. Therefore, we perform ligation using the double-loop (D-L) clips technique for cecum to upper rectal cases and endoscopic string clip suturing (ESCS) for lower rectum cases. In the current study, we prospectively assessed the technical feasibility of this novel ligation technique using the D-L clips for cecum to upper rectal cases (▶ **Table 1**).

▶ **Table 1**

Characteristics	D-L clips technique (*n* = 33)
En bloc R0 resection, *n* (%)	33/33 (100.0)
Resection time (minutes), median (IQR)	51 (45–76)
Procedural accidents, *n* (%)	
Perforation	0 (0)
Muscle injury	0 (0)
Complete ligation, *n* (%)*	32/33 (97.0)
Duration of ligation (minutes), median (IQR)	18 (14–19)
Ligation speed (cm^2/10 minutes), median (IQR)	2.7 (2.2–3.7)
Number of D-L clips used for ligation, median (IQR)	1 (1–2)
Number of clips used for ligation, median (IQR)	12 (9–13)
Delayed procedural adverse events, *n* (%)	
Delayed perforation	0 (0)
Post-ESD coagulation syndrome	1 (3.0)
Delayed bleeding	0 (0)
Hematochezia that does not fit the definition of delayed bleeding	1 (3.0)
White blood cell count (before ESD), median (IQR)	5300 (4300–6300)
White blood cell count (POD1), median (IQR)	6200 (4700–7300)
White blood cell count (POD1 – before ESD) ≥ 3000, *n* (%)	4 (12.1)
Length of stay, median (IQR), days	8 (7–8)

Methods Subjects were registered in this prospective study between May 2020 and September 2021. The study subjects included patients who underwent colorectal ESD in Hakodate Municipal Hospital and patients in whom the novel ligation technique was used.

Results A total of 33 patients were analyzed. Oral antithrombotic agents were administered to 15 (45.5 %) of the 33 patients and direct oral anticoagulants (DOACs) were administered to 3 (9.1 %) of the 33 patients. The rate of en bloc R0 resection was 100.0 %, and the median length of resected specimens was 2.6 cm. The complete ligation rate was 97.0 % (32 of the 33 patients). The median duration of ligation was 18 minutes. Post-endoscopic submucosal dissection coagulation syndrome occurred in one patient (3.0 %) and there was no delayed bleeding in any of the patients. The D-L clips technique failed in one patient in whom the lesions were located at the transverse colon and there was paradoxical movement during the procedure.

Conclusions This prospective feasibility study showed that our ligation technique using the D-L clips can be used for closing ulceration after colorectal ESD in cecum to upper rectal cases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP050 Treatment outcomes and resection depth of endoscopic resection for rectal neuroendocrine tumors: a single-center retrospective analysis

Authors Okuda H[1], Kimura H[2], Noguchi A[2], Uematsu S[2], Nishida A[2], Inatomi O[2], Iwashita T[2]

Institutes **1** Kohka Public Hospital, Kohka, Japan; **2** Shiga University of Medical Science, Otsu, Japan

DOI 10.1055/s-0046-1821377

Aims The prognosis of patients with rectal neuroendocrine tumors (NETs) depends on tumor grade, lesion size, and depth of invasion. For lesions ≤ 10 mm without invasion of the muscularis propria, endoscopic resection is generally recommended; however, the optimal resection technique remains uncertain. Endoscopic submucosal resection with a ligation device (ESMR-L) may ensure a negative vertical margin by applying band ligation just above the muscularis propria, thereby reducing the risk of positive vertical margins. This study aimed to compare the treatment outcomes of ESMR-L, endoscopic submucosal dissection (ESD), and endoscopic mucosal resection with precutting (EMR-P) for rectal NETs, and to evaluate the resection ability of each resection method.

Methods We retrospectively analyzed 27 consecutive patients who underwent endoscopic resection for rectal NETs at our institution between January 2010 and January 2021. The patients were divided into three groups: ESMR-L (n = 10), ESD (n = 10), and EMR-P (n = 7). Treatment outcomes were compared among the groups. R0 resection was defined as an en bloc resection with histologically negative margins. Curative resection was defined as R0 resection without lymphovascular invasion, based on immunohistochemical staining. In addition, we compared the resection depth between ESMR-L and ESD using histopathological specimens.

Results Baseline characteristics were not significantly different among the three groups. The overall R0 resection rate was 88.9 %, with no statistically significant differences among groups (ESMR-L: 90 %, ESD: 80 %, EMR-P: 100 %; p = 0.82). Positive vertical margins were observed only in the ESD group (ESMR-L: 0 %, ESD: 20 %, EMR-P: 0 %). The procedure time was significantly shorter for ESMR-L (4.2 ± 1.0 min) than for ESD (32.1 ± 14.7 min) and EMR-P (13.4 ± 3.7 min) (p < 0.001). No adverse events occurred in any group. All tumors were classified as grade 1; lymphatic invasion, venous invasion, and overall lymphovascular invasion were observed in 22.2 %, 30.0 %, and 44.4 % of the patients, respectively. The curative resection rate was 44.4 %. In the pathological analysis, the mean distance from the deepest part of the tumor to the vertical resection margin was significantly longer in the ESMR-L group than in the ESD group (900 ± 680 µm vs. 379 ± 212 µm, p = 0.01).

Conclusions ESMR-L demonstrated resection outcomes comparable to those of ESD and EMR-P, with a shorter procedure time. Moreover, compared to ESD, ESMR-L was associated with a lower rate of positive vertical margin, suggesting that it may facilitate a deeper resection depth. For rectal NETs, ESMR-L appears to be a safe and effective endoscopic resection technique.

eP051 Study of the determinant factors for adequate gastric and intestinal preparation in digestive endoscopy: Experience from a secondary care hospital

Authors Pérez Pérez J[1], Prieto Doblado M[1], Perez Martin S[1], Diego CL[1], Fernández Jiménez B[1], Amores Atance M[1], Izquierdo García A[1], Garrido Gallego F[1], Ponferrada-Díaz Á[1]

Institute **1** Hospital Universitario Infanta Leonor, Madrid, Spain

DOI 10.1055/s-0046-1821378

Aims The objective of this study was to identify clinical and behavioral factors associated with adequate cleansing prior to digestive endoscopic procedures [1–3].

Endoscopy 2026; 58: S1–S1041

Methods A retrospective observational study was conducted on digestive endoscopies performed at our center over one trimester in 2025. Variables analyzed included medical history, body mass index (BMI), abdominal circumference, alcohol consumption, physical activity on the day of the procedure, habitual bowel habits, use of laxatives and/or prokinetics, ASA classification, and fasting hours for liquids and solids (▶ **Table 1**).

▶ **Table 1** Comparison of Clinical and Procedural Variables According to Preparation Quality in Esophagogastroduodenoscopy (EGD) and Colonoscopy.

Variable	EGD (Total / Good / Poor)	Colonoscopy (Total / Good / Poor)	p-value EGD	p-value Colonoscopy
Sample size (n)	205 / 192 / 13	206 / 198 / 8	—	—
Median BMI	25.6 — 25.55 — 26.8	25.8 — 25.95 — 34.7	0.045	0.535
Median abdominal circumference (cm)	92 — 92 — 97	95 — 86.5 — 136	0.012	0.943
ASA classification (I–II / III–IV)	192 / 13 — 179 / 13 — 13 / 0	189 / 17 — 184 / 14 — 5 / 3	—	ASA I–II: 0.765; ASA III–IV: 0.040
Physical activity (None / Walking / Aerobic)	143 / 53 / 9 — 134 / 50 / 8 — 9 / 3 / 1	186 / 18 / 2 — 179 / 17 / 1 — 5 / 1 / 1	0.906	0.008
Cleansing solution	XXX	Pleinvue / Citrafleet / Bohm: 160 / 37 / 9	—	0.525
Fasting for liquids (hours)	8 — 8 — 5.5	8 — 9 — 11.5	0.003	0.0276
Fasting for solids (hours)	9 — 10 — 6.5	28 — 29 — 24	0.023	0.9007
Days on low-residue diet	XXX	3 — 2.5 — 2	—	0.312
Days on liquid diet	XXX	1 — 1 — 1	—	0.790
Time of completion of first dose	XXX	13.5 — 18 — 12.5	—	0.275
Time of completion of second dose	XXX	9.5 — 10 — 12	—	0.0182

Results A total of 411 patients were included (205 esophagogastroduodenoscopies and 206 colonoscopies). Suboptimal visualization was observed in 13 gastric and 8 colonic procedures. In esophagogastroduodenoscopies, significant differences were found regarding BMI, abdominal circumference, and fasting duration for both liquids and solids.In colonoscopies, differences were associated with physical activity on the procedure day, patient comorbidity (ASA classification), fasting duration for liquids, and timing of completion of the second/final dose of the cleansing solution.

Conclusions In addition to fasting, independent factors such as BMI, abdominal circumference, physical activity, lower comorbidity, and the timing of bowel preparation may significantly influence the adequacy of digestive endoscopic cleansing.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP052 Computer-aided detection maintains adenoma detection performance during simulated reduction of colonoscopy withdrawal time

Author Kim O[1]

Institute 1 Yeouido St. Mary's Hospital, Seoul, Republic of Korea

DOI 10.1055/s-0046-1821379

Aims Withdrawal time (WT) is a well-established quality indicator in colonoscopy, directly associated with adenoma detection rate (ADR). Prolonged WT may enhance ADR but can increase operator fatigue and procedural inefficiency. Computer-aided detection (CADe) has been developed to assist endoscopists in real-time polyp recognition. This study aimed to evaluate whether CADe allows effective shortening of WT while maintaining ADR in colonoscopy [1–3].

Methods This was a prospective observational study. Each native 6-minute withdrawal was proportionally rescaled to a 5-minute reference while preserving frame cadence and CADe alert dynamics. The primary outcome was the paired difference in polyp detection rate (PDR) between the original inspection and the 5-minute reference. Secondary outcomes were optical adenoma detection rate (oADR) and polyps per colonoscopy (PPC), with paired comparisons via McNemar's test and Newcombe confidence intervals. Subgroup analyses were conducted by age and sex.

Results Among 269 colonoscopies, oADR was preserved between conditions (34.9 % vs 35.3 %; Δ = 0.4 %; 95 % CI − 2.1 % to 3.7 %; p = 0.73), whereas PDR increased (42.0 % vs 47.6 %; Δ = 5.6 %; 95 % CI 1.1 %–9.9 %; p = 0.02). Signals appeared stronger in patients < 60 years and in males (exploratory). No carcinoma-suspected events were observed. Given CADe's propensity to increase detection of diminutive/nonadvanced lesions with minimal time increases, findings should be viewed as feasibility signals.

Conclusions Time-rescaled modeling suggests that CADe can preserve adenoma-suspected detection while improving overall polyp recognition under a simulated 5-minute withdrawal, supporting the biological plausibility of efficiency-preserving workflows. Real-time, histology-verified, multicenter trials should confirm these findings using AI-specific protocol and trial reporting standards and diagnostic reporting principles.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Disconnected pancreatic duct syndrome (DPDS) is a complex and challenging consequence of acute necrotizing pancreatitis, occurring when a segment of viable pancreatic tissue remains isolated from the main ductal system due to complete disruption of the pancreatic duct. This frequently leads to persistent fistulae or recurrent peripancreatic fluid collections and often requires tailored endoscopic or surgical management. However, intramural gastric involvement is exceedingly rare, and its optimal management is not yet well defined. We report the case of a 50-year-old male with a history of necrotizing hemorrhagic biliary pancreatitis, complicated by spleno-mesenteric venous thrombosis and a large walled-off necrosis. Endoscopic ultrasound-guided cystogastrostomy with placement of a lumen-apposing metal stent (LAMS) was performed, resulting in the initial drainage of the collection. The early postoperative course was complicated by peritonitis, successfully treated with laparoscopic washout. The LAMS was subsequently exchanged for a trans-gastric double pigtail stent. Months later, a follow-up MRI confirmed resolution of the main collections but demonstrated a disconnected pancreatic duct with mild upstream Wirsung dilatation, consistent with DPDS. The patient remained clinically stable for nearly one year with preserved pancreatic function. Then he presented with de novo recurrent nausea, vomiting, and epigastric discomfort without fever. Cross-sectional imaging (CT and MRI) revealed the cause: multiple circumferential intramural fluid collections within the gastric antrum, originating from the disconnected ductal segment and causing gastric outlet obstruction (GOO). The findings were consistent with an intramural extension of a persistent pancreatic fistula. Imaging confirmed the DPDS fistula was actively feeding these collections. Given the patient's complexity and absence of sepsis, a high-risk surgical or endoscopic bypass was deferred. Instead, a "step-down" conservative approach was chosen. As a key therapeutic step, the trans-gastric pigtail stent was removed, and the patient was managed with proton pump inhibitors, prokinetics, and dietary modifications. This approach led to a progressive clinical recovery, with restoration of normal alimentation and weight gain. Serial MRI demonstrated a marked reduction of the intramural collections and progressive involution of the fistulous tract. The patient maintained stable pancreatic and nutritional status. A multidisciplinary team recommended continued conservative management and delayed elective cholecystectomy once radiological stability was confirmed to prevent recurrence of biliary pancreatitis. This case illustrates a rare evolution of DPDS, where ductal leakage created intramural gastric collections, causing GOO. The stepwise combination of endoscopic techniques, radiologic monitoring, and patient-tailored conservative therapy enabled clinical and radiological resolution without the need for surgical bypass. This experience emphasizes the importance of long-term imaging surveillance and multidisciplinary coordination in the management of DPDS, as well as awareness that, in selected DPDS patients, vigilant surveillance and conservative management can be the optimal approach, even for severe complications [1–3].

eP054 Application of a single-use endoscope for endoscopic intermuscular dissection: Early clinical evaluation of a novel endoscope

Authors Yang T[1], Fan D[1], Hu J[2]
Institutes **1** The Sixth Affiliated Hospital of Sun Yat-sen University, Guang Zhou, China; **2** The Sixth Affiliated Hospital of Sun Yat-sen University, guangzhou, China
DOI 10.1055/s-0046-1821381

Abstract Text

Background and Aims: Endoscopic intermuscular dissection (EID) is effective for lesions penetrating the submucosal layer. However, EID using a single-use endoscope has not been reported. We present two cases of EID performed with a novel single-use endoscope to evaluate its safety and efficacy.

Methods: We report on two patients with early-stage rectal cancer who underwent EID using a single-use colonoscope (EndoFresh DC-T300L). We analyzed the success of en bloc and R0 resection, and the occurrence of complications [1–4].

Case 1: A 67-year-old male with a history of hyperthyroidism and atrial fibrillation. A rectal mass (approx. 20 mm in diameter) was identified 8 cm from the anal margin. Color Doppler ultrasound suggested infiltration of the submucosal layer. EID was performed. The inner circular muscle was incised, and the outer longitudinal muscle was exposed as the dissection endpoint. Result: Complete en bloc and R0 resection were achieved. The pathological result was moderately differentiated adenocarcinoma (pT1, infiltration depth approx. 3 mm, negative margins). Blood loss was < 1 mL. No postoperative complications (bleeding, perforation, or infection) occurred. Radical surgical resection was performed 8 days postoperatively.

Case 2: An 82-year-old female with a history of hypertension, coronary heart disease, and diabetes mellitus. A rectal mass (approx. 25 mm in diameter) was found 6 cm from the anal margin. Rectal ultrasound and pelvic MRI suggested local malignant transformation (uT1–2/T2N0). EID was performed with the same technique. Result: Complete en bloc and R0 resection were achieved. The pathological result was villous-tubular adenoma with malignant transformation to moderately differentiated adenocarcinoma (pT1, infiltration depth approx. 8 mm, negative margins). Blood loss was < 10 mL. No postoperative complications occurred. The patient was discharged 2 days postoperatively.

Conclusions: The use of the single-use endoscope was safe and effective for EID in these two cases. This approach may offer advantages, particularly in preventing perforation-related extra-abdominal infection, which is a concern with EID due to manipulation within the muscularis propria layer. Further studies are needed to validate these findings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP055 Serum kallistatin level in comparison to other noninvasive panels for evaluating portal hypertension in Egyptian cirrhotic patients

Authors Farag A[1], Abbasy M[2], Nada A[2], El-Abd M[2], Abdel-Samiee M[2]
Institutes **1** Damietta Cardiology And Gastroenterology Center, Damietta, Egypt; **2** National Liver Institute, Shebeen El-Kom, Egypt
DOI 10.1055/s-0046-1821382

Aims To investigate the diagnostic value of serum kallistatin levels, along with other biochemical panels, in the assessment of portal hypertension among Egyptian individuals with liver cirrhosis (▶ **Table 1**).

Methods This cross-sectional research evaluated 90 cirrhotic cases who were admitted to the National Liver Institute's Hepatology and Gastroenterology Department as well as the Endoscopy Unit at Menoufia University by measuring the serum KAL level and comparing it to other panels in order to grade esophageal varices accordingto the results of GI endoscopy [1–5].

Results The mean age of the 90 individuals who were enrolled in the study was 59.8 ± 9.8 years; 42.2 % of them were female, and 57.8 % were male. Patients with varices had a considerably decreased mean level of blood kallistatin. Additionally, it demonstrates a notable decrease in individuals with extensive varices. The presence of EV can be predicted by kallistatin with a sensitivity of 76.5 % and a specificity of 98.6 % at cut-off levels of 23.1 µg/ml.

Conclusions Serum kallistatin may serve as a potential indicator for identifying esophageal varices, particularlythe larger and more life-threatening types.

Aims Endoscopic sleeve gastroplasty (ESG) is expected to be a less invasive treatment for obesity. We consider that endoscopic hand suturing (EHS) should be applicable to this procedure. We aimed to investigate the feasibility and safety of "Handsewn ESG" in animal models.

Methods Handsewn ESG was performed on eight animal stomachs (four isolated porcine stomachs, two live pigs, and two live dogs). In vivo studies were conducted after the approval of respective Institutional Review Boards. Twelve mucosal defects per stomach were created: four lesions on the anterior wall, greater curvature, and posterior wall, respectively. Continuous suturing was performed for the respective distal and proximal six mucosal defects in a rec-

tangular shape with a 2-0 barbed suture (VLOCN0605 or VLOCL0615). Immediately after the procedure was completed, the live pigs were humanely euthanized, and their stomachs were removed for macroscopic examination. The live dogs were monitored for two months after the procedure, followed by endoscopic observation. Short-term outcomes (all eight cases), a gastric volume reduction rate and a full-thickness suturing rate (six cases), adverse events (four live animals), food intake, changes in body weight, and a closure maintenance rate at two months post the procedure (two live dogs) were investigated.

Results The procedure was completed in all cases (8/8, 100 %), and the average procedure time was 130.8 minutes. In six cases excluding live dogs, the average gastric volume reduction rate was 25.7 %. Among four cases (48 suture sites) in which suture status was observed, 24 sites (50 %) revealed full-thickness suturing. No adverse events were occurred in live animals (0 %, 0/4), whereas in one sacrificed pig, one stitch hooked part of small intestinal serosa. Both live dogs' food intake had decreased for three days following EHS, but recovered to normal intake after the fourth postoperative day. At the second postoperative month, endoscopic observation revealed that the stomach reverted with disappearance of the suture in both cases.

Conclusions We confirmed Handsewn EHS is technically feasible. On the other hand, further improvement and refinement are necessary to elevate it to a safe and reliable procedure.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP057 A Decade of Data: Understanding Splenic Injuries Following Colonoscopies

Authors Joseph DF[1], Anil B[1], Christopher M[1], Chhabra P[1]
Institute 1 Royal Hobart Hospital, Hobart, Australia
DOI 10.1055/s-0046-1821384

Aims Splenic injury is a rare but potentially life-threatening complication of colonoscopy, occurring in approximately 14-33 per 100,000 colonoscopies. This study aims to assess the incidence, risk factors, and clinical outcomes of splenic injuries requiring intervention following elective colonoscopy

Methods A retrospective review was conducted at a tertiary centre, identifying all colonoscopies performed between 1 January 2014 and 20 March 2025. Patients who had a colonoscopy performed within 72 hours of a splenic injury requiring intervention were included. Cases with alternative causes for splenic injury were excluded. Patient demographics, risk factors, and outcomes were analysed [1, 2].

Results Over the 10-year period, 6 cases of splenic injury requiring intervention were identified. All affected patients were female, with a mean age of 61.6 years (Standard Deviation = 16.3). 4 of 6 had previous abdominal surgery, and all procedures were performed under anaesthetist-led deep sedation.

Five injuries were identified within 6 hours post-procedure; one case presented at 48 hours. All patients reported abdominal pain, and 5 of 6 were haemodynamically unstable upon presentation. Angioembolisation was performed in 5 patients, achieving haemostasis in 4 (80 %). Two patients required splenectomy—one following unsuccessful embolisation and one as a primary intervention. All patients required admission to the Intensive Care Unit with an average total length of stay in hospital of 9 days following colonoscopy

Conclusions Female sex, history of abdominal surgery and anaesthetic led deep sedation were identified as potential risk factors for splenic injury post-colonoscopy. Implications for future practice include pre-procedural risk assessment including surgical history and potential for intra-abdominal adhesions, enhanced post-procedure monitoring of high-risk patients, and consideration to reviewing sedation practices to balance procedural comfort with patient safety

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP058 Rectal melanoma, a rare location with ominous prognosis

Authors Mateos C[1], Castro Carbajo MDP[1], Lucía MI, Lucio Fernández C[1], Navarro N[1], Rey González B[1], Quintanilla Lázaro E[1], Castro Urda JL[1]
Institute 1 Hospital Universitario Severo Ochoa, Leganés, Spain
DOI 10.1055/s-0046-1821385

Introduction Anorectal melanoma is an uncommon form of melanoma, accounting for 0.3–3 % of all melanomas and 1–3 % of anorectal tumors. It arises from the transitional zone and squamous region of the anal canal.

Endoscopy We present the case of a 74-year-old man with a history of right hemicolectomy and hepatic resection for metastatic colon adenocarcinoma, with no recurrence on colonoscopy in 2021. In 2025, due to rectal bleeding, a new colonoscopy revealed a pigmented, ulcerated, and necrotic lesion in the rectum, involving the pectinate line and occupying 75 % of the circumference. Biopsies confirmed a poorly differentiated melanoma. CT imaging showed pancreatic metastases causing obstructive jaundice, managed with biliary stent placement via ERCP. A subsequent PET-CT demonstrated rapid metastatic progression to infradiaphragmatic lymph nodes, pancreas, adrenal glands, peritoneum, muscle, lung, and bone. The patient is currently receiving immunotherapy with ipilimumab/nivolumab for stage IV rectal melanoma, BRAF wild type.

Conclusions Anorectal melanoma is aggressive, often metastatic at diagnosis, and usually presents with nonspecific symptoms. Up to 60 % of cases show dissemination to lymph nodes, liver, lungs, and the central nervous system. Its etiology remains unclear, though HPV or HIV infections may increase risk. The prognosis in advanced stages is poor; however, immunotherapy has shown promising outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP059 Percutaneous Transhepatic Biliary Drainage (PTBD) for Malignant Hilar Biliary Obstruction (MHBO) is Associated With Poor Outcomes – Is It Time to Reassess Its Clinical Utility?

Authors Robertson A[1], Timmermans M[2], Buchanan G[2], Nordin-Garrett A[2], Perryman S[2], Mathura P[1], Bigam D[1], Shapiro J[1], Dajani K[1], Anderson B[1], Nilsson JE[1], Wasilenko S[1], Veldhuyzen Van Zanten S[1], Owen R[1], Sandha G[1]
Institutes 1 University of Alberta, Edmonton, Canada; 2 Alberta Health Services, Edmonton, Canada
DOI 10.1055/s-0046-1821386

Aims Decompression of malignant biliary obstruction is important for quality of life and potential chemotherapy (CTx). PTBD is an alternative when endoscopic stenting with ERCP is not possible. In MHBO, PTBD is the preferred intervention as multiple branches may be obstructed rendering ERCP stenting suboptimal. The aim was to assess the impact of PTBD for MHBO on patient outcomes and compare them to management of extrahepatic obstruction.

Methods Retrospective chart audit of all patients diagnosed with cholangiocarcinoma (CCA) at the University of Alberta Hospital from 07/2023-06/2024. Primary outcome was a reduction of the bilirubin to ≦ 30 µmol/L. Secondary outcomes were successful initiation and completion of CTx, procedural complications, re-interventions, hospital length of stay (HLOS), and mortality.

Results 30 pts (17 M), median age of 70 ± 10 yrs (52-94 yrs) presented with CCA. Location of CCA was intrahepatic in 9, hilar in 13, and extrahepatic in 8 pts. No pts with intrahepatic CCA underwent PTBD and were not included in this review. We compared pts with MHBO and those with extrahepatic CCA (▶ **Table 1**).

▶ **Table 1**

	Hilar CCA	Extrahepatic CCA
Pts, n	13	8
Baseline bilirubin (bili) µmol/L, median ± SD	136 ± 128	126 ± 95
Intervention, n		
None	2	2
ERCP only	1	6
PTBD only	6	0
ERCP◄PTBD	3	0
PTBD◄ERCP	1	0
Lowest post-intervention bili µmol/L, median ± SD	15 ± 71	11 ± 4
Time to lowest bili, days, median ± SD	46 ± 64	47 ± 16
Primary outcome, n		
Pts with bili ≦30 µmol/L	8 (62 %)	8 (100 %)
Pts with bili > 31 µmol/L	5	0
Chemotherapy, n		
Pts referred to cancer centre	11/13 (85 %)	7/8 (88 %)
Pts offered CTx	5/13 (38 %)	6/8 (75 %)
Pts that started CTx	3/13 (23 %)	6/8 (75 %)
Pts that finished CTx	0/13 (0)	2/8 (25 %)
Complications, n		
Total	9/13 (69 %)	3/8 (38 %)
Bile leak	8	-
Drain/stent occlusion	7	2
Pancreatitis	1	1
Re-intervention, n		
Pts needing repeat procedures	10/13 (77 %)	4/8 (50 %)
Total number of repeat procedures	44 (range 1-11)	10 (range 1-5)
Overall rate of repeat procedures/pt	3.4	1.3
Mortality, n	7 (54 %)	5 (62 %)
Time to death post-intervention, days, mean ± SD	158 ± 102	286 ± 41
HLOS in days, mean ± SD	22 ± 16	7 ± 7

Conclusions The primary outcome was achieved with PTBD in 62 % pts with MHBO but significant complications requiring re-intervention precluded optimal CTx, and were associated with a longer HLOS and shorter survival. Further inquiry into cost implications, and assessment of PTBD as standard of care in pts with MHBO is required.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP060 Comparison of Endoscopic Ultrasound-Guided Fine Needle Aspiration/Biopsy (FNAB) with 19/20-Gauge and 22-Gauge Needles for Mediastinal Masses

Authors Elzubier M[1], Rajak R[2], Quintini D[3], Jaynes E[2], Coad J[1], Maher B[1], Tehami N[1]

Institutes **1** HPB Endoscopy Unit, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; **2** Department of Histopathology, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; **3** IRCCS ISMETT – UPMC, Palermo, Italy

DOI 10.1055/s-0046-1821387

Aims Endoscopic ultrasound-guided fine needle aspiration/biopsy (EUS-FNAB) plays a key role in diagnosing mediastinal lesions. The choice of needle gauge may impact diagnostic yield, especially for tissue-intensive diagnoses such as lymphoma. This study aimed to assess the diagnostic performance, safety, and procedural efficiency of 19/20-gauge (G) versus 22G needles in EUS-FNAB for mediastinal masses.

Methods A retrospective analysis of a prospectively maintained EUS registry was performed at a single tertiary referral centre (University Hospital Southampton NHS Foundation Trust) for all patients who underwent endoscopic ultrasound-guided fine needle aspiration or biopsy (EUS-FNAB) of solid mediastinal lesions between January 2020 and January 2025 [1–5].

Patients were categorised according to the needle calibre used: 19/20-gauge (G) (large-bore group) and 22G (standard-bore group). Exclusion criteria included cystic or predominantly necrotic lesions, procedures performed for non-diagnostic therapeutic indications, or incomplete data.

Data collected included: demographics and indication for EUS-FNAB , needle type and number of passes, procedural duration (scope insertion to withdrawal), cytological and histological outcomes, sample adequacy (graded as satisfactory or unsatisfactory based on cellularity and presence of core tissue), adverse events within 7 days (bleeding, perforation, infection, or cardiorespiratory instability).

Primary outcomes were diagnostic sensitivity, specificity, and overall accuracy of EUS-FNAB for establishing a definitive diagnosis, verified against surgical histopathology or clinical follow-up ≥ 6 months.Secondary outcomes included sample adequacy, number of needle passes, procedural time, and safety.

Results A total of 136 patients were included: 40 in the 19/20G group and 96 in the 22G group. Baseline demographics, lesion characteristics, and procedural indications were comparable between groups ($p > 0.05$).

Diagnostic performance:the diagnostic sensitivity for malignancy was significantly higher with the 19/20G needles compared to 22G (94.1 % vs 90.0 %, $p = 0.04$).Overall diagnostic accuracy was also superior in the 19/20G group (95.0 % vs 88.5 %, $p = 0.03$).Sample adequacy for histological evaluation was achieved in 97.5 % of 19/20G cases compared with 89.6 % in the 22G group ($p = 0.02$).

Procedural metrics: The mean number of needle passes required to obtain an adequate specimen was 2.0 ± 0.1 with 19/20G versus 3.2 ± 0.2 with 22G ($p < 0.01$).Mean procedural duration was significantly shorter with 19/20G needles (18.3 ± 2.1 min vs 23.5 ± 2.4 min, $p = 0.01$).

Diagnostic subgroup analysis: In lesions where lymphoma was suspected ($n = 24$), the diagnostic yield was markedly higher with 19/20G needles (93.8 % vs 80.0 %, $p = 0.02$). In non-lymphomatous malignancies or benign granulomatous disease, diagnostic accuracy between groups was not significantly different ($p > 0.05$).On multivariable logistic regression, needle gauge (19/20G) remained an independent predictor of diagnostic accuracy (adjusted OR 2.47, 95 % CI 1.12–6.10, $p = 0.03$), while lesion size and location were not significant.

Safety: No major complications occurred in either group. Minor self-limiting bleeding at the puncture site occurred in two patients (one per group), with no delayed haemorrhage or infection observed ($p = 0.82$).

Conclusions EUS-FNAB with 19/20G needles is safe and offers superior diagnostic yield and procedural efficiency compared to 22G needles in the evalua-

tion of mediastinal masses. Larger bore needles should be considered, particularly when lymphoma or diagnoses requiring core tissue architecture are suspected.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP061 Perceptions, practices and trends of sedative endoscopy in Korea

Authors Chung J[1], Choi HH[2], Oh DJ[3], Kim DH[4], Jung MK[5], Hyun JS[6], Kim KB[7], Park Y[8], Lim YJ[9], Park JJ[10]

Institutes **1** Nowon Eulji Medical Center, Eulji University Medical Library, Seoul, Republic of Korea; **2** Uijeongbu St. Mary's Hospital, The Catholic University, Euijeongbu, Republic of Korea; **3** Dongguk University Ilsan Hospital mortuary, Goyang-si, Republic of Korea; **4** Chonnam National University Hospital, Kwangju, Republic of Korea; **5** Kyungpook National University School of Medicine, Daegu, Republic of Korea; **6** Jeju National University, Ara Campus, Cheju, Republic of Korea; **7** Chungbuk National University Hospital, Cheongju, Republic of Korea; **8** Ewha Womans University, Seoul, Republic of Korea; **9** Dongguk University Ilsan Hospital, goyangsi, Republic of Korea; **10** Korea Univ. Guro Hospital , Seoul, Republic of Korea

DOI 10.1055/s-0046-1821388

Aims Sedation has become a global standard in gastrointestinal endoscopy. Although the Korean Society of Gastrointestinal Endoscopy (KSGE) published guidelines in 2021, real-world practice and perspectives from nurses and patients remain unclear. This study aimed to evaluate current sedation practices in Korea through a nationwide multi-stakeholder survey [1–7].

Methods A cross-sectional survey was conducted between August 2024 and April 2025 among endoscopists (KSGE), endoscopy nurses (Korean Society of Gastrointestinal Endoscopy Nurses and Associates), and patients at two university hospitals. Questionnaires assessed demographics, sedation practices, safety protocols, training, and patient knowledge and attitudes.

Results A total of 735 endoscopists, 247 nurses, and 204 patients participated. Most endoscopists reported routine sedation (≥ 76 % in 69.9 % of upper endoscopies and 90.8 % of colonoscopies), with propofol-based regimens predominating. Sedation training improved markedly (92.0 %), but CPR/BLS training remained stagnant (57.6 %). Although overall complication rates declined slightly, severe adverse (intubation 18.1 %, and mortality 3.6 %) increased. Nurses showed higher completion rates for sedation and CPR/BLS training and greater adherence to ASA/Mallampati assessment, continuous monitoring, and standardized discharge protocols. Patients chose sedation mainly for pain reduction (87.3 %), but demonstrated limited knowledge of sedatives with 55.1 % unaware of post-procedure driving restrictions and related legal penalties. While safety was the top priority, many expressed willingness to pay for effective and safe agents, suggesting interest in newer options such as remimazolam.

Conclusions Sedation practices in Korea are now highly standardized, supported by guidelines, training, and nursing involvement. However, rising severe complications and persistent patient knowledge gaps highlight the need for risk-focused refinement, wider CPR/BLS training, adoption of advanced monitoring, and reinforced patient education.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP062 Dysphagia in Endoscopy: Correlation Between Endoscopic Findings of Eosinophilic Esophagitis and Histology. Influence of External Factors on Diagnosis. Is Biopsy Confirmation Necessary in All Cases?

Authors Pérez Pérez J[1], Prieto Doblado M[1], Barceló López M[1], Adan Merino L[1], Garrido Gallego F[1], Ponferrada-Díaz Á[1]

Institute **1** Hospital Universitario Infanta Leonor, Madrid, Spain

DOI 10.1055/s-0046-1821389

Aims The primary objective of this study is to assess, at the time of the initial diagnostic upper gastrointestinal endoscopy, the correlation between endoscopic features suggestive of eosinophilic esophagitis and their subsequent histopathological confirmation.

Methods A retrospective observational study was conducted on upper gastrointestinal endoscopies performed at our center between 2008 and 2024, in which the diagnostic report included “eosinophilic esophagitis.” Only procedures in which the endoscopist obtained esophageal biopsies to rule out this disease—regardless of whether endoscopic findings suggestive of eosinophilic esophagitis were present—were included.

The indication for endoscopy, the medical specialty requesting the procedure, and the analytical data available prior to endoscopy were analyzed. In addition, the pharmacological treatments patients were receiving at the time of the procedure were recorded, and the histological results of the esophageal biopsy samples were reviewed (▶ **Table 1**).

▶ **Table 1**

Variables Analyzed	Eosinophilic Esophagitis Diagnosedn = 74 (36.82 %)	Eosinophilic Esophagitis Not Diagnosedn = 127 (63.18 %)
Gender		
Male	52 (70.3 %)	61 (48 %)
Female	22 (29.7 %)	66 (52 %)
Food Allergies		
Yes	11 (14.9 %)	6 (4.7 %)
No	63 (85.1 %)	121 (95.3 %)
Symptoms		
Dyspepsia/GERD	15 (20.3 %)	36 (28.3 %)
Dysphagia	54 (73 %)	83 (65.4 %)
Foreign body sensation	5 (6.8 %)	8 (6.3 %)

Results A total of 201 patients were analyzed. Of the total sample (n = 201), 74 patients were ultimately diagnosed with eosinophilic esophagitis (EoE) based on histological findings (36.82 %), whereas 127 patients (63.18 %) were not.

The mean age in the male group was 39 years (median: 42 years), while in the female group it was 49 years (median: 48 years).

Of the total sample (n = 201), 74 patients were ultimately diagnosed with eosinophilic esophagitis (EoE) based on histological findings (36.82 %), whereas 127 patients (63.18 %) were not.

Personal and medical histories were analyzed, revealing a higher proportion of males in the group diagnosed with EoE. In addition, a higher incidence of food allergies, dust/mite allergies, and asthma was observed among patients with confirmed EoE.

Conclusions The reason for endoscopy referral appears to influence the thoroughness of esophageal evaluation. In cases where the indication was dysphagia or a request to rule out EoE, a stronger correlation was observed between endoscopic findings and histological confirmation [1–3].

The presence of longitudinal furrows and esophageal rings are common endoscopic features associated with EoE diagnosis. In patients presenting with more than one typical endoscopic finding (exudates, longitudinal furrows, or rings), the likelihood of EoE increases progressively with each additional finding, particularly when both rings and longitudinal furrows coexist. The presence of exudates and mucosal edema, however, is not commonly reported.

Peripheral blood eosinophilia was a frequent finding among patients diagnosed with EoE, and the use of single-dose proton pump inhibitors (PPIs) did not appear to influence its occurrence. Furthermore, PPI use at standard doses in patients with EoE did not seem to obscure the presence of certain endoscopic features, such as rings and longitudinal furrows.

In patients without endoscopic abnormalities suggestive of EoE, if clinical suspicion is low, esophageal biopsy may not be necessary—even in the presence of dysphagia.

Endoscopist experience did not appear to have a significant impact on diagnostic accuracy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

ePO63 Fully covered metal stent for the management of leak after sleeve gastrectomy

Authors Sánchez Álvarez E[1], Estrecha Diaz S[1], Gambra Juárez A[1], De Pablos Noriega I[1], Yanguas Elorz E[1], Fuente Diaz De Corcuera U[1], Gonzalez Aldama M[1], Telleria Etxeberria G[1], Montero Campos A[1], Campos Ruiz A[1], Azagra De Miguel I[1], Martín Arriero S[1], Moya De Prado AC[1], Pedraza Perez A[1], Álvarez Rubio M[1]

Institute 1 Araba University Hospital, Vitoria-Gasteiz, Spain

DOI 10.1055/s-0046-1821390

Background Postoperative leaks after bariatric surgery represent a serious complication, with an incidence ranging from 0.2 % to 1.2 %. They occur more frequently following laparoscopic sleeve gastrectomy due to the long staple line and increased intraluminal pressure. In recent years, endoscopic stent placement has become a well-established, minimally invasive, and effective therapeutic alternative, achieving success rates of up to 92 %.

Case Report / Endoscopy We present the case of a 56-year-old woman with morbid obesity who underwent laparoscopic sleeve gastrectomy. On postoperative day 5, she developed severe sepsis requiring hospital admission. Contrast-enhanced computed tomography revealed a proximal staple line leak associated with a perisleeve fluid collection. Urgent surgical exploration was performed but no active leak was identified.

Due to ongoing clinical deterioration, an upper gastrointestinal endoscopy with fluoroscopic guidance was performed, confirming a proximal dehiscence of the staple line with contrast extravasation into the subcardial recess of the gastric sleeve. Initial endoscopic closure attempts using the OverStitch suturing system and through-the-scope clips were unsuccessful. Consequently, a fully covered self-expandable metal stent (Hanarostent Gastro-Seal, 26 mm diameter × 21 cm length) was deployed, extending from the gastroesophageal junction to the pylorus, effectively excluding the leak site.

Endoscopic and radiologic follow-up demonstrated complete resolution of the leak. The stent was removed one month later without complications.

Conclusions This case highlights the pivotal role of therapeutic endoscopy in the management of postoperative complications following bariatric surgery. Fully covered metal stents offer an effective, minimally invasive option for the treatment of sleeve gastrectomy leaks, often avoiding the need for reoperation and promoting faster, safer recovery.

eP064 Treatment of Zenker's diverticulum in a tertiary hospital: our experience

Authors Gambra Juárez A[1], Estrecha Diaz S[1], Sánchez Álvarez E[1], Yanguas Elorz E[1], De Pablos Noriega I[1], Gonzalez Aldama M[1], Fuente Diaz De Corcuera U[1], Montero Campos A[1], Telleria Etxeberria G[1], Martín Arriero S[1], Azagra De Miguel I[1], Campos Ruiz A[1], Moya De Prado AC[1], Pedraza Perez A[1], Álvarez Rubio M[1]
Institute 1 Araba University Hospital, Vitoria-Gasteiz, Spain
DOI 10.1055/s-0046-1821391

Background Flexible endoscopy has emerged as a minimally invasive alternative to open surgery and rigid endoscopy for the management of Zenker's diverticulum. Among flexible endoscopic approaches, the most widely used are flexible endoscopic septotomy (FES) and peroral endoscopic myotomy for Zenker's diverticulum (Z-POEM).

Aim To describe our experience in the treatment of Zenker's diverticulum using flexible endoscopic septotomy (FES).

Methods Retrospective review about clinical outcomes and technical aspects of patients treated with FES at a tertiary center between 2024 and 2025. Demographic data, procedural details, and follow-up outcomes were analyzed.

Results Five patients (4 men) aged 58–86 years with Zenker's diverticulum measuring 20–50 mm were included. The main clinical presentations were oropharyngeal dysphagia (4 patients) and recurrent aspiration pneumonia (1 patient). Diagnosis was established by gastroscopy, barium swallow, and computed tomography.

The procedure was performed under deep sedation in 4 patients and general anesthesia in 1. A flexible diverticuloscope was used in 80 % of cases and a transparent cap in 20 %, this one in patients with smaller diverticulum. FES was carried out using a Stag Beetle dissection knife, sectioning the septal muscular fibers while maintaining a 5–8 mm safety margin. The mucosal incision was closed with 3–4 through-the-scope clips in all patients.

No intraprocedural or postprocedural complications occurred. The mean hospital stay was 1 day. At one-month follow-up, all patients reported significant symptomatic improvement (Eckardt score 0–1). At 6–8 months, control esophagography revealed a small residual diverticulum in all cases, without clinical repercussion or need for retreatment.

Conclusions In our experience, flexible endoscopic septotomy is an effective and safe therapeutic option for Zenker's diverticulum, offering rapid recovery and excellent short-term outcomes. The use of a transparent cap represents a valid alternative when diverticuloscope placement is not factible due to small diverticulum size.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP065 PT1 colorectal cancer: our experience in a tertiary hospital

Authors Gambra Juárez A[1], Sánchez Álvarez E[1], Yanguas Elorz E[1], De Pablos Noriega I[1], Moya De Prado AC[1], Pedraza Perez A[1], Fuente Diaz De Corcuera U[1], Gonzalez Aldama M[1], Montero Campos A[1], Telleria Etxeberria G[1], Aldai Larrinaga J[1], Espinosa Taranilla L[1], Ganchegui Aguirre I[1], Bravo Melendez S[1], Elorza Iturbe A[1], Álvarez Rubio M[1]
Institute 1 Araba University Hospital, Vitoria-Gasteiz, Spain
DOI 10.1055/s-0046-1821392

Aims pT1 colorectal cancer (CRC) is defined by invasion limited to the submucosa without extension beyond it. With the widespread implementation of colorectal cancer screening programs, its incidence has markedly increased. The aim is to describe our experience in the diagnosis and management of pT1 colorectal cancer.

Methods We conducted a retrospective review of all pT1 CRC cases diagnosed and managed at a tertiary center between January 2021 and December 2024. Demographic, endoscopic, histologic, and therapeutic data were collected.

Results A total of 92 patients were included, with a mean age of 64 years; 58.7 % were men. The main indications for colonoscopy were colorectal cancer screening (58 %), diarrhea (10.9 %), rectal bleeding (9.8 %), and iron-deficiency anemia (6.5 %). Most lesions (91 %) were resected endoscopically, while the remaining cases underwent surgical resection due to suspected submucosal invasion. The rectum was the most frequent location (43 %).

Computed tomography excluded nodal or distant metastases in all cases.

Among patients treated endoscopically, 39.3 % met histologic criteria for low-risk lesions (submucosal invasion < 1 mm, resection margins > 1 mm, absence of lymphovascular invasion, low/intermediate tumor budding, and well/moderate differentiation). Of these, 87.9 % were managed by endoscopic follow-up, while 12.1 % underwent surgery based on patient preference.

In contrast, among of the cases fulfilled high-risk criteria (58.3 %); 65.3 % were managed conservatively due to significant comorbidities or patient choice. The most common reason for high-risk classification was piecemeal resection, precluding accurate histological assessment (24.5 % as the sole criterion), followed by positive margins and lymphovascular invasion.

During follow-up, no local or nodal recurrences were observed.

Conclusions Accurate endoscopic recognition of lesions with suspected submucosal invasion and in bloc resection are essential to guide optimal management in pT1 colorectal cancer. Although no recurrences were detected in our cohort, long-term surveillance remains necessary to assess oncologic outcomes and validate the safety of conservative management strategies in selected cases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP066 Metabolic Dysfunction–Associated Steatotic Liver Disease Is Independently Linked to Colorectal Adenomas: A Matched Case–Control Study from Eastern Europe

Authors Hărnuț VA[1], Crăciun R[2, 1], Mocan T[2], Tefas C[2, 1]
Institutes 1 Iuliu Haţieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; **2** Institutul Regional de Gastroenterologie și Hepatologie Prof. Dr. Octavian Fodor, Cluj-Napoca, Romania
DOI 10.1055/s-0046-1821393

Aims Metabolic dysfunction–associated steatotic liver disease (MASLD) has emerged as the leading cause of chronic liver disease and may exert systemic oncogenic effects. Evidence linking MASLD to colorectal neoplasia in European populations is limited. We aimed to assess whether MASLD is independently associated with a higher prevalence and distinct histologic profile of colorectal premalignant lesions.

Methods We performed a retrospective, matched case–control study including 150 consecutive adults who underwent complete colonoscopy between January and December 2024. Seventy-five patients with ultrasonographically confirmed MASLD were matched 1:1 to controls by age, sex, residence, and presence of obesity or diabetes. Demographic, metabolic, endoscopic, and histopathologic data were collected. Logistic regression adjusted for metabolic covariates was used to determine the independent association between MASLD and colorectal polyp prevalence.

Results Colorectal polyps were identified in 39 of 75 MASLD patients (52.0 %) versus 20 of 75 controls (26.7 %) ($\chi^2 = 6.77$, $p = 0.009$). MASLD was independently associated with an increased likelihood of colorectal polyps (adjusted OR 3.04, 95 % CI 1.49–6.22, $p = 0.002$). Adenomatous histology predominated in MASLD (80 % tubular/tubulovillous/villous, including 13 % with high-grade dysplasia), whereas hyperplastic lesions were more common in controls. No significant difference was found in polyp size or location.

Conclusions MASLD was independently associated with a threefold higher prevalence of colorectal adenomas. These results identify MASLD as a metabolic risk enhancer for colorectal carcinogenesis and support early colonoscopic screening in metabolically vulnerable populations.

(Note: The full manuscript based on this abstract has been submitted to Diseases of the Colon & Rectum and is currently under editorial review. The data have not been published or presented elsewhere.)

eP067 Removal of an impacted migrated fully covered biliary metal stent using a CRE balloon dilatation

Authors Quintanilla Lázaro E[1], Delgado Galán M[1], Mejuto Illade L[1], Moreno Posadas A[1], Lucio Fernández C[1], Mateos Sánchez C[1], Navarro González N[1], Rey González B[1], Castro Urda JL[1]
Institute 1 Hospital Universitario Severo Ochoa, Madrid, Spain
DOI 10.1055/s-0046-1821394

Introduction A 75-year-old male underwent open cholecystectomy following an episode of cholecystitis (pathological anatomy with gallbladder adenocarcinoma). During the surgery procedure, he presented a complete section of the common bile duct at the cystic duct level, and a bile leak in the subsegmental duct, both sutured. The patient's discharge persisted, and an ERCP was requested [1–3].

Endoscopy A large biliary leak was confirmed, and a fully covered self expandible metal stent (SEMS) was placed. The patient subsequently presented with acute cholangitis, prompting ERCP for stent removal. Migration to the proximal common bile duct was observed, with no possibility of extraction with a Fogarty balloon, and a second stent was placed (SEMS in SEMS technique)

Two weeks later, a repeat ERCP was performed, with traction of the distal end using a polypectomy loop. The second stent was removed, but the migrated stent remained. Mobilization was achieved with a Fogarty balloon, but insufficient for removal

Finally, the decision was made to dilate the papillary area with a 13.5 controlled radial expansion (CRE) balloon and extraction of the stent over the balloon. There were not complications and confirming the absence of biliary leak.

Conclusion Biliary stent placement is a technique used in patients with bile leaks. In our case, a covered metal stent was chosen due to the aforementioned history.

One of the complications of this technique is migration, with coaxial stent placement being a solution for its removal (the SEMS in SEMS technique)

The use of a CRE balloon for the removal of a migrated stent could be considered an effective and cost-effective alternative, even as a first option.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP068 Endoluminal Vacuum Therapy with the Endo-SPONGE System in the Management of Colorectal Anastomotic Leaks: Experience from a Tertiary Center

Authors Yanguas Elorz E[1], Estrecha Diaz S[1], De Pablos Noriega I[1], Sánchez Álvarez E[1], Gambra Juárez A[1], Moya De Prado AC[1], Pedraza Perez A[1], Fuente Diaz De Corcuera U[1], Gonzalez Aldama M[1], Telleria Etxeberria G[1], Montero Campos A[1], Martín Arriero S[1], Campos Ruiz A[1], Azagra De Miguel I[1], Navajas Serena S[1], Álvarez Rubio M[1]
Institute 1 Araba University Hospital, Vitoria-Gasteiz, Spain
DOI 10.1055/s-0046-1821395

Introduction: Endoluminal vacuum therapy (EVT) using polyurethane sponges represents a minimally invasive and effective alternative for the treatment of colorectal anastomotic leaks, with reported closure rates of up to 81 %. This approach is based on the endoscopic placement of a sponge connected to a negative pressure system, allowing continuous drainage of secretions, reduction of the residual cavity, and stimulation of granulation tissue formation. Current evidence supports its superiority over conventional management, with higher success rates (RR 1.18), shorter treatment duration, and a better safety profile.

Objective: To describe our experience with endoscopic treatment of colorectal anastomotic leaks using the Endo-SPONGE system following low anterior resection for rectal adenocarcinoma.

Materials and methods: A retrospective review was conducted of the indication, treatment, and clinical outcomes of patients managed with EVT at the University Hospital of Araba between 2024 and 2025.

Results: Five patients were included: four were treated initially with EVT and one after unsuccessful percutaneous drainage. Diagnosis was established by computed tomography and endoscopy, identifying presacral cavities ranging from 3–12 cm with luminal communication. In one case, two Endo-SPONGE devices were placed simultaneously due to cavity size. Endoscopic sponge exchanges were performed every 48–72 hours, with up to six sessions required in the largest cavity. Complete closure of the cavity, confirmed endoscopically and radiologically, was achieved in three patients, allowing intestinal continuity restoration. One patient remains under treatment after six sessions, and one required surgical rescue.

Conclusions: In our experience, EVT is an effective, safe, and minimally invasive strategy for the management of colorectal anastomotic leaks, achieving cavity closure and preservation of intestinal continuity in most cases.

Aims The assessment of gastric mucosal integrity is fundamental in the diagnostic pathway of dyspepsia and gastroesophageal reflux disease (GERD), particularly in identifying *Helicobacter pylori* (HP) infection and atrophic gastritis (AG), both of which have clinical implications for cancer risk stratification and patient management. Histology remains the reference standard for diagnosing HP and AG but requires invasive biopsy sampling, which may be unnecessary in low-risk patients. GastroPanel is a non-invasive serological test based on four biomarkers that provides information on gastric function, HP status, and the presence of AG, potentially serving as a pre-endoscopic triage tool. Endofaster is an intra-procedural device that analyzes gastric juice in real time during gastroscopy, measuring pH and detecting HP, with the potential to reduce biopsy use. The aim of this study was to compare the diagnostic agreement of GastroPanel and Endofaster with histology for the detection of HP and AG, and to explore their potential complementary roles in the endoscopic workflow.

Methods Thirty consecutive adult patients undergoing upper endoscopy for dyspeptic symptoms or GERD at our institution were prospectively enrolled. Exclusion criteria included prior gastric surgery, food or blood in the stomach. All participants underwent blood sampling for GastroPanel, real-time gastric juice analysis using Endofaster during the same endoscopic procedure, and systematic gastric biopsies according to the Sydney protocol. Histology served as the diagnostic gold standard. Diagnostic agreement between each test and

histology was quantified using Cohen's kappa coefficient, interpreted according to established benchmarks. Sensitivity, specificity, and false-negative/false-positive rates were also recorded.

Results Based on histology, HP infection was detected in 10 % (3/30) and AG in 3.3 % (1/30) of patients. For HP diagnosis, GastroPanel showed moderate agreement with histology (κ = 0.53), while Endofaster demonstrated substantial agreement (κ = 0.78). For AG detection, agreement was fair for GastroPanel (κ = 0.36) and perfect for Endofaster (κ = 1.00). Although overall agreement was lower for GastroPanel, it exhibited 100 % specificity for both HP and AG, with three false negatives and no false positives. This suggests that a positive GastroPanel result reliably identifies patients who may benefit from endoscopic evaluation. In contrast, Endofaster showed 100 % sensitivity for both HP and AG, with no false negatives or false positives in this cohort, supporting its potential role in safely omitting gastric biopsies when results are negative. No adverse events related to either test were observed.

Conclusions This pilot study suggests that GastroPanel and Endofaster provide complementary strengths in the diagnostic evaluation of gastric disease. GastroPanel, through its high specificity, may help identify patients who truly require endoscopic assessment, thereby optimizing referral and resource allocation. Endofaster, with its high sensitivity and real-time intra-procedural application, may reduce the need for unnecessary biopsies during gastroscopy, streamlining the procedure and minimizing patient burden. Although limited by small sample size and low disease prevalence, these findings support the potential integration of combined non-invasive and real-time diagnostic tools to enhance accuracy and efficiency in the endoscopic pathway. Larger studies are warranted to validate these results and assess cost-effectiveness, workflow impact, and clinical outcomes.

DOI 10.1055/s-0046-1821397

Abstract Text

A 80-year-old man was referred for a Paris 0-IIa lesion of 15 mm, occurring on a colorectal anastomosis. Multiple removal and avulsion attempts were made without success. We initially started with circumferential incision, then we dissect the residual submucosa, deepening into the scarring fibrosis, achieving en-bloc full-thickness resection. The wall defect was completely sealed with an Endoscopic Suturing System (ESS). No adverse events occurred. The patient was dismissed two days after the procedure. Histological analysis revealed tubular-villous adenoma with low grade dysplasia, free horizontal and vertical margins. E-EFTR seems to be a technically demanding but safe and effective treatment for recurrent and fibrotic lesion, even on a surgical anastomosis [1, 2].

DOI 10.1055/s-0046-1821398

Aims Positive margins after endoscopic resection of rectal neuroendocrine tumors (NETs) do not always indicate true residual disease. We aimed to identify risk factors for remnant tumors among patients with incompletely resected rectal NETs.

Methods We conducted a multicenter retrospective cohort study across 11 tertiary hospitals. Patients who underwent salvage treatment for incompletely resected rectal NETs between January 2010 and November 2023 were retrospectively reviewed. A total of 286 patients were included, and demographic, endoscopic, and pathologic data were analyzed to identify predictors of remnant tumor.

Results The remnant tumor was found in 102 (35.7 %) patients. Rates were highest after cold forceps polypectomy (CFP) (63.6 %), followed by cold snare polypectomy (32.1 %) and conventional endoscopic mucosal resection (EMR) (31.2 %). No remnant tumor was observed after modified EMR or endoscopic submucosal dissection (ESD). On multivariate analysis, CFP (odds ratio [OR], 4.50; 95 % confidence interval [CI], 2.33–8.70), yellowish mucosa (OR, 4.36; 95 % CI, 2.26–8.40), and mucosal protrusion (OR, 4.84; 95 % CI, 2.17–10.79) were independent predictors of remnant tumors. The risk rose stepwise with the number of factors: 15.0 % (none), 52.6 % (one), 78.3 % (two), and 87.5 % (three) (p for trend < 0.001). Salvage morbidity was low, with delayed bleeding in 4.6 % and perforation in 3.5 %, while endoscopic modalities achieved R0 resection rates of ≥ 88 %.

Conclusions Margin-positive rectal NETs resected by modified EMR or ESD very rarely harbor remnant tumors and may be managed with surveillance. By contrast, CFP or lesions showing yellowish mucosa or mucosal protrusion indicate high residual risk and warrant prompt salvage resection. This three-factor model may serve as a practical tool for individualized post-resection management.

eP072 Role of surveillance gastroscopy in gastric ulcer

Authors Patlori S[1], John A[1], Kumbhar GS[1], Thomas A[1], Kurien RT[1], Chowdhury SD[1], Simon EG[1], Joseph AJ[1]

Institute 1 Christian Medical College and Hospital, Ranipet Campus – Vellore, Ratnagiri Kilminnal, India

DOI 10.1055/s-0046-1821399

Aims Surveillance gastroscopy, defined as any gastroscopy performed within 3 months of the index examination to assess ulcer healing [1]. Surveillance gastroscopy guidelines or recommendations for gastric ulcers vary among international gastroenterology societies. It is being done as per physician discretion and institutional recommendations. There is limited data on surveillance gastroscopy for gastric ulcer.

Methods This retrospective study analysed data from our institutional endoscopy database (PACS2) between January 2016 and December 2023. Out of 144,947 gastroscopies performed, 3,348 patients had gastric ulcers, and 128 (3.8 %) underwent surveillance gastroscopy within three months. The inclusion criteria were patients with gastric ulcers who underwent a surveillance gastroscopy and biopsy within 3 months of the first gastroscopy and were over 18 years of age.

Results The median interval for surveillance gastroscopy was 4.65 (3.1- 8.4) weeks. Male to female ratio is 1.84:1. Majority of the ulcers 85 (66.4 %) were in the antrum. 72 (56.2 %) of patients had ulcer size of less than 1cm. 119 (93 %) of patients had regular border and 109 (85.2 %) of patients had flat margins of the ulcer. Majority of the patients 41(32 %) did not undergo biopsy during the initial scopy as they presented with an upper gastrointestinal bleed. Most of the ulcers 60 (46.8 %) were healed on the surveillance scopy. Importantly, all the surveillance endoscopic biopsies done were benign.

There were no malignant cases diagnosed based on surveillance gastroscopy among the 128 patients, which is consistent with previous studies [2, 3].

Conclusions Surveillance gastroscopy did not have any additive value in diagnosing gastric malignancy. Further prospective multicenter studies are needed to validate these findings and establish definitive clinical conclusions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP073 Obscure Overt GI Bleeding Caused By Small Bowel Cavernous Hemangioma: A Rare Case Report From Eastern India

Authors Umeshappa A[1], Bettigere Gopala M[2]

Institutes **1** Institute of Post Graduate Medical Education & Research, Kolkata, India; **2** IPGMER and SSKM Hospital, Kolkata, India

DOI 10.1055/s-0046-1821400

Abstract Text

Small bowel cavernous hemangioma is an uncommon benign vascular tumor, representing < 0.05 % of all gastrointestinal neoplasms [1]. Hemangiomas are histologically classified as capillary, cavernous, or mixed types, with cavernous hemangioma being the most common subtype affecting the small intestine, especially the jejunum [2]. These lesions may present with abdominal pain, obstruction, or gastrointestinal bleeding. When gastrointestinal bleeding persists despite non-diagnostic esophagogastroduodenoscopy (EGD) and colonoscopy, it is classified as obscure overt gastrointestinal bleeding (OOGIB) [3]. Because 5–10 % of gastrointestinal bleeding originates from the small intestine [4], small bowel lesions must be considered in patients with recurrent or persistent bleeding when a routine evaluation fails to identify the bleeding source.

We report a 40-year-old woman presenting with recurrent melena and post-prandial bloating for one year requiring multiple blood transfusions due to persistent severe anemia. On examination, she had severe pallor, and markedly reduced hemoglobin to 5.4 g/dL. Preliminary investigations, EGD, colonoscopy, and CT angiography were essentially normal. Further CT enterography detected a hyperdense, arterial enhancing submucosal lesion in the small bowel. Capsule endoscopy showed aphthous ulcers and erosions in the proximal ileum, and double balloon enteroscopy (DBE) identified a subepithelial lesion measuring 1 × 1 cm with central umbilication. Endoscopic biopsy was deferred due to high risk of bleeding associated with vascular lesions and surgical excision was planned.

Exploratory laparotomy revealed a subepithelial mass (0.8 × 0.6 cm) in the distal jejunum. Segmental jejunal resection with primary anastomosis was performed. Histopathology demonstrated dilated vascular spaces lined by flattened endothelial cells, consistent with cavernous hemangioma. The patient remained symptom free postoperatively and subsequent follow up for a year.

Cavernous hemangiomas of the small bowel are rare and may arise from any wall layer, from mucosa to serosa. A limited number of cases have been reported in India over the past decade. Most patients present with anemia or melena, sometimes complicated by obstructive features [5]. Capsule endoscopy and DBE are key diagnostic tools for identifying these lesions when conventional endoscopy is inconclusive. Surgical resection offers definitive treatment, especially in symptomatic lesions.

This case highlights the need to consider cavernous hemangioma in patients with unexplained anemia and OOGIB and emphasizes the diagnostic importance of advanced enteroscopic techniques.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP074 Diagnostic Value of Esophagogastroduodenoscopy (EGD) and Duodenal Biopsies in Chronic Diarrhea

Authors Harrak N[1], Outifa O[2], Salihoun M[3], Elaoula S[1], Serraj I[1], Acharki M[1], Bouhamou F[4], Kabbaj N[1]

Institutes **1** Ibn Sina University Hospital, Rabat, Morocco; **2** CHU Ibn Sina, Rabat, Morocco; **3** مستشفى ابن سينا, Rabat, Morocco; **4** Nouveau Chu Ibn Sina Rabat, Rabat, Morocco

DOI 10.1055/s-0046-1821401

Aims Chronic diarrhea, common in clinical practice and potentially serious, has multiple causes. In the absence of contributory laboratory findings, EGD with duodenal biopsies represents a major diagnostic tool, particularly in cases of malabsorption syndromes. The aim of this study was to assess the diagnostic value of EGD with duodenal biopsies in chronic diarrhea and to evaluate their usefulness in guiding patient management.

Methods This was a retrospective study based on EGD reports collected over a 4-year period, from January 2022 to August 2025. All patients presenting with chronic diarrhea who underwent EGD with duodenal biopsies were included.

Results Among 2499 patients who underwent EGD, 85 patients presented with chronic diarrhea, with a female predominance of 60 % (n = 51), corresponding to a ratio M/F of 1.5. The median age was 33 years [range: 14–70 years].

Regarding medical history, diabetes was present in 8.2 % (n = 7), systemic disease in 10.5 % (n = 9), and inflammatory joint disease in 7 % (n = 6).

Clinically, epigastric pain was reported in 24.7 % (n = 21), growth retardation in 5.8 % (n = 5), and vomiting in 4.7 % (n = 4).

In biological findings, iron-deficiency anemia was observed in 20 % (n = 17). Anti-transglutaminase antibodies, tested prior to endoscopy, were positive in 15.2 % (n = 13) and negative in 5.8 % (n = 5).

On endoscopic examination, erythematous gastritis was seen in 74.1 % of cases (n = 63), duodenal fold atrophy in 17.6 % (n = 15), erosive gastritis in 5.8 % (n = 5), and congestive gastritis, fundic fold effacement, and grade A esophagitis in 2.3 % (n = 2). Aphthoid duodenal ulcers were observed in only one case.

On histological examination, Helicobacter pylori infection was identified in 42.3 % (n = 36), celiac disease in 23.5 % (n = 20), pernicious anemia in 4.7 % (n = 4), and inflammatory bowel disease (IBD) in 2.3 % (n = 2).

Conclusions This study confirms the relevance of duodenal biopsies in the evaluation of chronic diarrhea. In our series, 23.5 % of cases were consistent with celiac disease, highlighting the central role of EGD in the diagnostic approach.

DOI 10.1055/s-0046-1821402

Aims To estimate the cost of adopting computer-aided detection (CADe) in colonoscopy.

Methods We conducted a microsimulation-based cost-effectiveness analysis with European individuals aged 60–69 undergoing either (i) screening colonoscopy or (ii) colonoscopy after a positive biennial faecal immunochemical test (FIT) without and with computer-aided polyp detection (CADe). The CADe device was capacity-constrained to 10,000 individuals per device total in a 10-year timeframe (1,000 individuals per year). The main outcome measure was cost of CADe per CRC prevented.

Results In screening colonoscopy, each CADe device prevented 11 CRC cases. The additional cost per CRC prevented was $ 64,402, of which $ 2,888 (4.48 %) was attributable to the CADe purchase itself and $ 61,514 (95.52 %) from follow-up colonoscopies. In colonoscopy after a positive faecal immunochemical test (FIT) with CADe, each CADe device prevented 5 CRC cases. The additional cost per CRC prevented was $ 23,857, of which $ 6,353 (26.63 %) was attributable to the CADe purchase and $ 17,504 (73.37 %) from follow-up colonoscopies.

Conclusions Adopting CADe in colonoscopy will have additional cost in screening colonoscopy than in FIT positive colonoscopy.

eP076 Efficacy and safety of underwater endoscopic mucosal resection for small esophageal submucosal tumors

Authors Kim S[1], Lee J[2], Synn S[1], Choi C[1], Park S[1]

Institutes **1** Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; **2** Kosin University Gospel Hospital, Busan, Republic of Korea

DOI 10.1055/s-0046-1821403

Aims With the widespread use of upper endoscopy, esophageal submucosal tumors (SMTs) are increasingly detected during routine health screenings. Underwater endoscopic mucosal resection (UEMR) has recently emerged as a novel approach that enables mucosal resection without submucosal injection, offering potential benefits in safety and efficacy. However, evidence on its application for esophageal SMTs remains limited.

Methods This retrospective single-center study analyzed 31 patients who underwent UEMR for esophageal SMTs between 2020 and 2024. Eligible lesions were < 15 mm in diameter and confined to the submucosal layer, as confirmed by endoscopic ultrasound (EUS). Demographic data, lesion characteristics, procedural details, and histopathologic results were reviewed. Primary outcomes included en bloc and pathological complete (R0) resection rates, with secondary outcomes assessing complications and recurrence during follow-up.

Results A total of 31 patients (mean age 57.0 ± 12.5 years; 61 % male) were included. The lower esophagus was the most frequent tumor site (45.2 %), and most lesions measured 5–10 mm (51.6 %). Histopathological diagnoses comprised leiomyomas (38.7 %), granular cell tumors (32.3 %), inflammatory fibroid polyps, and other benign entities. All tumors were successfully removed en bloc using UEMR, achieving a 100 % R0 resection rate. No major adverse events, including bleeding or perforation, occurred. During a median follow-up of up to 37 months, no local recurrence was observed, even among cases of granular cell tumor or adenoid cystic carcinoma.

Conclusions UEMR appears to be a safe and effective option for the management of small esophageal SMTs, demonstrating excellent en bloc and R0 resection outcomes without significant complications. These results support UEMR as a favorable alternative for small esophageal SMTs.

eP077 Reference range of pancreatic strain histograms using Endoscopic Ultrasound Elastography in healthy subjects: a pilot study

Authors Laurenza C[1], Zignani N[2], Elvo B[1], Pignata L[1], Frigo F[1], Di Luna I[1], Soro S[1], Dagani D[3], Drago A[1], Grassia R[1]

Institutes **1** ASST Cremona, Cremona, Italy; **2** University of Milan, Milano, Italy; **3** University of Pavia, Pavia, Italy

DOI 10.1055/s-0046-1821404

Aims Strain histogram (SH) is a semi-quantitative elastographic method that characterizes tissue stiffness. Developing a pancreatic SH reference range would help detect parenchymal diseases, especially early chronic pancreatitis (CP). This study aimed to determine a pancreatic SH reference range using endoscopic ultrasound (EUS) in patients without evidence of pancreatic disease, comparing it with a sample of CP.

Methods In this single-center, retrospective osservational study, all patients aged ≥ 18 years undergoing pancreatic EUS, without pancreatic focal lesions, were consecutively enrolled. The machine-integrated software calculated pancreatic SH in a region of interest (ROI) placed on the parenchyma. Three measurements were taken for each pancreas segment, including the head, body, and tail. The baseline clinical parameters were documented. In the first step were conducted descriptive-inferential analyses of the entire sample and the subgroups (healthy vs CP), then was performed a predictive analysis using univariate and multivariate linear regression in the subgroups of healthy controls to identify the most important predictive features of pancreatic stiffness.

Results We enrolled 143 patients (54,5 % female, mean age 63 years), 95 of whom were healthy and 48 with CP.In inferential analysis it's possible to notice the difference between SH values of every segment in the subgroups, with greater values for the healthy controls group (116,8 vs 69,1, p < 0,01). There is also a difference in prevalence of smoke, with a higher frequency in patients with CP (58,3 % vs 23,2 %, p < 0,01), and of alcol abuse, although the latter was more nuanced and not statistically significant (25 % vs 11,6 %, p = 0,13).In the predictive analysis, the results of the previous inferences were confirmed: smoking and alcohol abuse are strongly predictive of a lower pancreatic stiffness of healthy controls (β = -16 and -21, p < 0,01), while female sex is associated with a higher stiffness although not in a statistically significant way (β = 5 and p-value 0,2).

Endoscopy 2026; 58: S1–S1041

Conclusions SH enables real-time assessment of pancreatic stiffness and, given our findings, could assist in clinical practice in identifying early parenchymal disease, particularly early CP, due to the notable difference in stiffness values. Furthermore, associating clinical factors with EUS findings may aid the diagnosis of CP, as we have demonstrated with smoking and alcohol abuse. External validation of our SH reference range and more extensive studies are necessary.

eP078 Dental Floss Clip Traction in Endoscopic Resection for Gastric Neoplasms: A Meta-Analysis with Meta-Regression and Trial Sequential Analysis

Authors Elrosasy A[1], Hindawi MD[2], Abusalah MA[2], Alkousheh H[3], Salah A[4], Ghanm TI[5], Roshdy Y[6], Awad AA[2], Appas AA[4], Kalmoush AE[7]

Institutes **1** Cairo University, Kasr-Alainy Medical School, Cairo, Egypt; **2** Al-Azhar Institute Online, Cairo, Egypt; **3** The Hashemite University, Az-Zarqa, Jordan; **4** Al-Azhar University Assiut Branch, Al Wilidiyyah, Egypt; **5** Mansoura University, Mansoura, Egypt; **6** South Valley University, Qena, Egypt; **7** Al-Azhar University, Cairo, Egypt

DOI 10.1055/s-0046-1821405

Aims Dental floss clip traction (DFC) has been introduced to enhance visualization and shorten dissection time during endoscopic submucosal dissection (ESD) and endoscopic full-thickness resection (EFTR) for gastric neoplasms. However, its overall benefit and modifying factors remain uncertain. This study systematically evaluated the efficacy and safety of DFC-ESD and DFC-EFTR compared with conventional techniques (C-ESD and C-EFTR) and explored moderators using meta-regression and trial sequential analysis (TSA).

Methods Following PRISMA guidelines and the Cochrane Handbook, we searched PubMed, Scopus, Ovid, Web of Science, Cochrane Central, and CNKI to October 18, 2025. Randomized and observational studies comparing DFC-ESD or DFC-EFTR with conventional techniques were eligible. Pooled estimates were computed in R (meta 7.0-0) using random-effects models, reporting mean differences (MD) or risk ratios (RR) with 95 % CIs. Prespecified meta-regression assessed lesion site, ulceration, tumor size, and study design as potential effect modifiers. Trial sequential analysis determined conclusiveness and required information size. Study quality was assessed by ROB-2 and Newcastle–Ottawa Scale, and the certainty was graded via GRADE [1–8].

Results We included eight studies with a total of 2,183 patients. Five studies on DFC-ESD and three on DFC-EFTR. For the DFC-ESD vs C-ESD, the overall pooled procedure time showed a nonsignificant trend favoring DFC-ESD (MD = − 5.4 min, 95 % CI [− 13.8, 2.9]; $p = 0.20$; $I^2 = 79$ %). Subgroup analysis revealed significant reductions for non-ulcerated lesions (MD = − 5.0 min; $p < 0.01$) and for lesions in the upper/middle greater curvature, posterior wall, lower anterior, and lower posterior wall (all $p < 0.05$). Meta-regression identified the lesion site as a significant moderator ($p = 0.02$), whereas ulceration and tumor size were not ($p > 0.10$).Rates of En bloc (RR = 1.00; $p = 0.66$), R0 (RR = 1.01; $p = 0.42$), complete resection (RR = 1.00; $p = 0.60$), perforation (RR = 0.59; $p = 0.21$), and delayed bleeding (RR = 1.17; $p = 0.54$) were comparable between groups. TSA confirmed sufficient evidence for the reduction in procedure time among non-ulcerated and posterior-wall lesions but inconclusive power for safety outcomes. For the DFC-EFTR vs C-EFTR, the analysis demonstrated shorter operative time with DFC-EFTR (MD = − 8.3 min; 95 % CI [− 10.4, − 6.2]; $p = 0.03$; $I^2 = 0$ %). However, Hospital stay (MD = − 0.01 days; $p = 0.93$) and pneumoperitoneum (RR = 0.46; $p = 0.26$) did not differ. TSA confirmed conclusiveness for operation-time reduction but suggested further evidence is required for secondary endpoints.

Conclusions DFC-ESD was associated with shorter operation times, particularly in non-ulcerated lesions and those located at the upper/middle greater curvature, upper/middle posterior wall, lower anterior wall, and lower posterior wall. Similarly, DFC-EFTR demonstrated reduced procedure times compared to C-EFTR. However, given the novelty of the DFC technique, its performance may vary across gastric sites, and certain limitations remain. Therefore, further large-scale, high-quality RCTs are warranted to confirm its efficacy, clarify its optimal indications, and ensure consistent safety outcomes.

eP079 Outpatient endoscopic resection of ampullary lesions

Authors Coelho N[1], Hadlich E[1], Oppitz E[1]

Institute **1** Moinhos de Vento Hospital, Porto Alegre, Brazil

DOI 10.1055/s-0046-1821406

Aims Ampullary lesions are rare, with an annual incidence of approximately 1:100,000. However, there is evidence that their incidence is increasing in patients aged > 50 years. Although predominantly benign, many lesions transform into malignancy and can also cause cholangitis and pancreatitis. Timely resection is therefore warranted in selected cases. This study aimed to assess the safety, efficacy, and clinical outcomes of outpatient endoscopic resection (ER) of ampullary lesions performed at a single tertiary center.

Methods Between 2021 and 2024, 13 patients (11 men, 2 women; age range 62-88 years, median age 70.8 years) underwent a total of 14 ER procedures for ampullary lesions. All patients underwent baseline assessment with upper endoscopy, computed tomography, magnetic resonance imaging, and endoscopic ultrasound. The most common clinical features were abdominal pain and obstructive jaundice. Imaging studies were performed every 6 months after ER.

Results Follow-up ranged from 6 to 48 months (median 28 months). En bloc ER was achieved in 92 % of procedures. Only one case of recurrence was observed at 6 months and successfully managed endoscopically. Two patients required surgical resection after ER because biopsy specimens showed invasive adenocarcinoma. Five patients received a 5-Fr pancreatic stent, and 10 patients received rectal nonsteroidal anti-inflammatory drugs after the procedure. Figure 1 shows a case of ampullary adenoma with vegetative appearance. Figure 2 shows an ampullary adenoma covered with normal mucosa. One patient was admitted to the emergency department 48 hours after ER with gastrointestinal

bleeding and hemodynamic repercussion, where she received medical care and blood transfusion. Upper endoscopy showed a visible vessel at the margin of the ulcer, which was successfully treated endoscopically. She was discharged 48 hours later.

Conclusions Outpatient ER of ampullary lesions is a safe therapeutic modality, with low complication and recurrence rates. Careful preoperative evaluation with endoscopic ultrasound is essential to assess local invasion and avoid ER in cases suspicious for malignancy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP080 Impact of infection on clinical outcomes in Pancreatic Walled-Off Necrosis

Authors Jensen JF[1], Valborg VP[1], Prahm AP[1], Hadi A[1], Olsen GA[1], Stine R[1], Lillian MS[2], Annette S[2], Gásdal Karstensen J[3, 1], Novovic S[3, 1]
Institutes **1** Pancreatitis Centre East, Gastro Unit, Copenhagen University Hospital – Amager and Hvidovre, Hvidovre, Denmark; **2** Department of Clinical Microbiology, Copenhagen University Hospital – Amager and Hvidovre, Hvidovre, Denmark; **3** University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark
DOI 10.1055/s-0046-1821407

Aims Infection is a key determinant of morbidity in patients with pancreatic walled-off necrosis (WON), yet data on microbial characteristics and the effectiveness of antibiotic regimens remain insufficiently described. This study aimed to characterize the microbial flora of WON at the index intervention and to evaluate its association with clinical outcomes.

Methods We retrospectively included consecutive patients with WON who underwent endoscopic ultrasound (EUS)-guided transmural drainage between 2010 and 2024 at a tertiary referral center. The index intervention was defined as the first drainage procedure during which fluid/pus was obtained for microbiological culture. Patients were excluded from the analysis if microbiological sampling could not be performed at the index intervention (e.g. due to inaccessibility of the necrotic cavity).

Primary endpoints were the microbial flora and its association with mortality, ICU admission, and length of stay (LOS). Secondary endpoints included microbial susceptibility to empiric antibiotic regimens and the predictive value of C-reactive protein (CRP) and white blood cell count (WBC). Infected necrosis was defined by positive bacterial or fungal cultures; sterile necrosis by negative cultures.

Results Of 345 patients with WON, 300 were eligible for analysis. Culture-positive infection was identified in 251 patients (83.7 %), most often polymicrobial (65 %). The predominant pathogens were *Enterococcus faecium* (47 %), *Escherichia coli* (20 %), and *Candida albicans* (22 %). Patients with infected necrosis had higher rates of ICU admission (35.1 % vs. 18.4 %; OR 2.39, p = 0.020), with no statistically significant difference in mortality (10.4 % vs. 2.0 %; OR 5.55, p = 0.096) and LOS (median 79 days (IQR; 56–109.5) vs. 76 days (IQR; 65–116); OR 1.21, 95 % CI 0.66–2.24; p = 0.64). Despite antibiotic use in 240 patients (80 %) before sampling, infection remained highly prevalent, and infected necrosis was more common among those receiving antibiotics compared with those who did not (86.3 % vs. 73.3 %; p = 0.026). Of 518 organisms isolated, only 35.5 % were susceptible to administered antibiotics or antifungals prior to intervention. Both CRP and WBC were independently associated with infection (OR per 10 mg/L CRP 1.05, 95 % CI 1.02–1.09; OR per 1×10^9/L WBC 1.09, 95 % CI 1.03–1.16), although discriminatory performance was modest (AUC ≤ 0.66).

Conclusions Infection in WON is mostly polymicrobial and associated with prolonged ICU admission.

Conflicts of Interest John Gásdal Karstensen is a consultant for Ambu, Biodexa, Boston Sci, Olympus, and SNIPR BIOME and received speaker fee from Norgine and Olympus. The remaining authors have no conflicts of interest to declare.

eP081V Covergel Application Following EMR to Reduce Delayed Post-procedural Bleeding

Authors Lorenzo-Zúñiga V[1], Bustamante-Balén M[1], Uchima H[2], Martin S[3], Orive A[4], Alvarez M[3], Muñoz González R[2], Wong L[2], Lopez M[4], Pons V[1]

DOI 10.1055/s-0046-1821408

Introduction: Endoscopic mucosal resection (EMR) of large non-pedunculated colorectal lesions (≥ 20 mm) with a GSEED-RE2 score ≥ 4 carries a high risk of delayed bleeding, even when prophylactic clip closure is performed. Covergel is a thermosensitive biogel specifically designed to protect mucosal defects and enhance healing.

Case description: We report four high-risk cases treated with EMR plus preventive Covergel application: Case 1, 81-year-old male, 30-mm 0-Is cecal lesion (7 points); Case 2, 80-year-old male, 40-mm 0-II-Gnh splenic flexure lesion (6 points); Case 3, 57-year-old male, 45-mm 0-Is sigmoid lesion (6 points); Case 4, 59-year-old male, 40-mm 0-IIa-NG cecal lesion (6 points).

Conclusions: No delayed bleeding or adverse events occurred, suggesting Covergel as a promising adjunct to prevent post-EMR hemorrhage in high-risk lesions [1].

eP082 Endoscopic Management of Gastrointestinal Perforations, Leaks, and Fistulas Using the Over-the-Scope Clip (OTSC) System: Early Multicenter Experience in Mongolia

Authors Otgondemberel B[1], batsuren B[1], Adiyasuren B[2], Khurelshagai A[1], Duurenjargal B[1], Batsaikhan A[1], Davaadorj E[1], Tumendemberel B[1], Zoljargal B[1], Boldsaikhan U[1], Jargalsaikhan BE[3], Baatarjav G[3], Yadamsuren ME[3]
Institutes **1** IGIC Endoscopic Network, Ulaanbaatar, Mongolia; **2** Seoul Med Hospital, Ulaanbaatar, Mongolia; **3** Central Military Hospital, Ulaanbaatar, Mongolia
DOI 10.1055/s-0046-1821409

Aims Endoscopic approaches to gastrointestinal (GI) perforations, leaks, and fistulas remain in an early stage of development in Mongolia. However, with recent advances in equipment and endoscopic skills, minimally invasive closure techniques have rapidly gained ground. Among these, the **Over-the-Scope Clip (OTSC)** system has emerged as a key innovation, enabling effective closure of small defects and reducing the need for surgical re-intervention.

Methods A retrospective review was conducted of **30 patients** treated with the OTSC system between 2024 and 2025 in six tertiary centers across Mongolia (Brilliant Hospital, NCCD, MCH, MNUMS Hospital, And-Med, and Mungun Guur). Indications included post-surgical leaks, perforations (post-ESD, post-ERCP, or postoperative), fistulas, and foreign body–related defects. Two pediatric cases (aged **1 and 8 years**) were successfully treated using *OTSC mini* (▶ **Table 1**).

Endoscopy 2026; 58: S1–S1041

▶ **Table 1**

Group	Number of Cases	Successful	Unsuccessful	Unrelated Mortality
1. Esophagus & Pharynx	14	13	1	2
2. Stomach	4	4	0	0
3. Small Intestine (including Duodenum & Colon)	10	8	2	2
Total	**28 (30 OTSC placements)**	**25 (90 %)**	**3 (10 %)**	**3**

Results The **overall technical success rate was 90 %**, and all OTSC applications achieved complete closure. Two patients died from underlying systemic disease unrelated to the endoscopic procedure. The majority of cases (≈ 60 %) involved post-surgical leaks, most frequently in the **esophagus and duodenum**. The procedure was found to be **simple, quick to learn, and technically feasible**, even in limited-resource settings, providing a practical alternative to surgery.

Conclusions The introduction of OTSC in Mongolia represents a major step forward in endoscopic management of GI complications. This technique offers a **safe, effective, and minimally invasive** solution for perforations and leaks, especially after esophago-jejunal or duodenal anastomoses. These early multicenter results demonstrate the growing capability of Mongolian endoscopists to manage complex GI defects endoscopically and highlight the expanding role of OTSC as a standard therapeutic tool in the region.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP083 Combined Endoscopic and Laparoscopic Surgery (CELS): Experience in Our Center

Authors Mateos C[1], Navarro N[1], Quintanilla Lázaro E[1], Delgado Galán M[1], Lucía MI[1], Lucio Fernández C[1], Rey González B[1], Bujalance Cabrera FM[1], Mañaricua Arnaiz A[1], Castro Urda JL[1]

Institute 1 Hospital Universitario Severo Ochoa, Leganés, Spain

DOI 10.1055/s-0046-1821410

Aims Combined Endoscopic and Laparoscopic Surgery (CELS) is a relatively uncommon technique used to treat benign, complex, and endoscopically unresectable colonic lesions. It has emerged as an alternative to conventional surgical resection or endoscopic submucosal dissection (ESD). The aim of this study is to evaluate the safety and clinical outcomes of this technique in our center.

Methods We conducted a retrospective, single-center, observational study assessing short-term outcomes in patients with endoscopically unresectable colonic polyps who underwent CELS between January 2023 and June 2025. Endoscopic features, resection technique, postoperative outcomes, hospital stay, and pathological findings were analyzed.

Results Seven patients (mean age: 65.3 years; 2 women, 5 men) underwent the procedure. The main reasons for performing CELS were lesion size (three lesions larger than 30 mm), involvement of the appendiceal orifice (three cases), and in one patient, the presence of scar tissue rendering the lesion unresectable. All lesions had an adenomatous appearance (NICE type 2) and were located in the cecum, as lesions in other colonic segments were referred for ESD.

In all cases, laparoscopic cecectomy assisted by endoscopy was performed without conversion to open surgery. Surgical time was not recorded. The median hospital stay was 1 day (range: 1–10 days); the longest stay corresponded to a patient who developed medical complications (pneumonia and atrial fibrillation).

Histological examination revealed three tubular adenomas (one with high-grade dysplasia), two adenocarcinomas (one pTis and one pT1), one mucinous cystic neoplasm, and one fibrous obliteration of the appendix. All specimens had clear margins.

Follow-up colonoscopies at 6 and 12 months were performed in three patients, with no evidence of recurrence; the remaining patients are still awaiting their scheduled surveillance colonoscopies.

Conclusions CELS is a safe technique with favorable short-term outcomes and should be considered a viable alternative for the management of complex benign colonic polyps in patients who are not suitable candidates for ESD.

eP084 Successful Endoscopic Management of Bouveret Syndrome, caused by a massive gallstone: A Rare Cause of Gastric Outlet Obstruction

Authors Khalid MU[1], Alhouri A[2], Khan H[2], Maharaj G[2], Nawaz F[2]

Institutes 1 St Mary's Hospital, Newport isle of wight, United Kingdom; 2 The Grange University Hospital, Llanfrechfa, United Kingdom

DOI 10.1055/s-0046-1821411

Background: Bouveret syndrome is a rare manifestation of gallstone ileus, accounting for less than 3 % of cases, and arises from the impaction of a gallstone in the pylorus or duodenum via a bilioenteric fistula [1, 2]. It predominantly affects elderly patients with long-standing cholelithiasis and is associated with delayed diagnosis, significant morbidity, and high mortality [1, 3]. The optimal management approach remains debated, particularly in frail patients [4, 5]. We report a case of Bouveret syndrome in a 92-year-old female successfully treated using combined endoscopic lithotripsy techniques, demonstrating the viability of minimally invasive management in high-risk individuals.

Case Description:A 92-year-old female with advanced frailty and multiple comorbidities presented with right upper quadrant pain, nausea, and vomiting. Computed tomography revealed pneumobilia, a cholecystoduodenal fistula, and a large duodenal gallstone causing gastric outlet obstruction. Endoscopic evaluation confirmed an 8 cm impacted gallstone in the duodenal bulb. Electrohydraulic and mechanical lithotripsy were used to fragment and mobilise the stone into the stomach, achieving complete clearance in a three-hours endoscopic procedure, done under general anaesthesia.

Outcome: The patient's symptoms and liver function tests normalised post-procedure. Subsequently, she developed a distal gallstone ileus due to migration of a fragment. Given a predicted high perioperative mortality, conservative management was chosen. Spontaneous passage of the stone ensued, with full radiological and clinical resolution, and the patient was discharged in good condition.

Conclusion: Endoscopic lithotripsy represents a safe and effective alternative to surgery for Bouveret syndrome in frail, elderly patients [4, 5]. Early CT or MRCP imaging is key to diagnosis [3], while multidisciplinary, patient-centred management optimises outcomes in this rare but serious complication of gallstone disease [4, 5].

Keywords: Bouveret syndrome; Endoscopic lithotripsy; Gastric outlet obstruction; Cholecystoduodenal fistula; Gallstone ileus

eP085 Inflammatory Bowel Disease Patients need Higher Opioid Analgesic for Intravenous Conscious Sedation for Colonoscopy

Authors Park YS[1], Seong G[1], Sang BA[1]
Institute 1 Nowon Eulji Medical Center, Seoul, Republic of Korea
DOI 10.1055/s-0046-1821412

Aims Patients with inflammatory bowel disease (IBD) require colonoscopy for diagnosis, disease activity assessment, and dysplasia surveillance. Patients with IBD reported lower satisfaction with sedation during colonoscopy and increased procedural pain compared with individuals without IBD. This study aimed to examine sedation requirements of IBD patients undergoing colonoscopy.

Methods A retrospective cohort study of IBD and non-IBD patients presenting for colonoscopy between January 2020 and December 2024 was undertaken. Data collected included patient and procedure focused variables. Sedation was performed as intravenous conscious sedation (IVCS) using midazolam and propofol. The opioid analgesic, pethidine was added If the sedation level was not adequate for procedures.

Results A total of 1655 consecutive colonoscopies (253 IBD, 1402 non-IBD) were analyzed. For IVCS, 11.1 % of IBD patients required Midazolam only(M), 41.9 %, Midazolam and propofol (MP), and 47.0 %, Midazolam, Propofol and opioid (MPO) versus 11.7 % of non-IBD required M, 69.1 % MP and 19.2 % MPO respectively. Among IBD patients (CD 52, UC 201), active disease state required MPO in 51,6 % (66/128) versus inactive state 42,4 % (53/125) (p = 0.18). Propofol administration (mg) was 25.4 ± 13.3 in IBD and 23.7 ± 12.7 in non-IBD (p = 0.07).

Conclusions IBD patients required more opioid analgesic for IVCS compared with non-IBD patients. IBD patients showed similar opioid requirement both active and inactive disease state. Since patients with inflammatory bowel disease consistently show a low pain threshold even in a remission state, these study results show that it is necessary to administer appropriate analgesics together to increase patient satisfaction during IVCS.

eP086 Synchronous Gastric and Sigmoid Colonic MALT Lymphoma Associated with Helicobacter pylori Infection: A Rare Case report

Authors Alhouri A[1], Kadah A[2], Khan H[3], Nawaz F[1]
Institutes 1 Aneurin Bevan Health Board, Newport, United Kingdom; 2 The international school of Choueifat, Dubai, United Arab Emirates; 3 Bakhtawar Amin Memorial Trust, Multan, Pakistan
DOI 10.1055/s-0046-1821413

Background: Extranodal marginal zone B-cell lymphoma mucosa-associated lymphoid tissue (MALT lymphoma) most frequently affects the stomach and is linked to Helicobacter pylori infection, which promotes chronic antigenic stimulation and lymphoid proliferation [1, 2]. Colon involvement is rare, and synchronous gastric and colonic MALT is extremely rare, with less than 20 cases reported worldwide. Because clinical manifestations mimic inflammatory or benign colonic disease, diagnosis may be delayed [3, 4]. The few documented cases present make the underlying mechanisms unclear, and the diagnostic approach remains challenging [3, 4]. We report a case of synchronous gastric and sigmoid colon MALT lymphoma associated with H. pylori infection in a 50-year-old man being treated with eradication therapy, periodic imaging, and endoscopic surveillance.

Case Description: A 50-year-old man with no significant past medical history presented with several months of intermittent abdominal pain, bloating, constipation, and mucus discharge per rectum. Clinical examination revealed small internal haemorrhoids and mild left lower-quadrant tenderness. Esophagogastroduodenoscopy (OGD) demonstrated a crater-like ulcer in the mid-gastric body with surrounding irregular mucosa. Histopathology revealed a low-grade B-cell lymphoma consistent with gastric MALT type. Given persistent lower abdominal discomfort, a colonoscopy was performed, revealing a 40mm hemi-circumferential ulcerated and oedematous lesion in the sigmoid colon. Biopsies revealed dense lymphoid infiltrates with features of marginal zone lymphoma.

Outcome: The patient received two courses of H. pylori eradication therapy. Follow-up upper endoscopy showed marked regression of the gastric lesion into a fibrotic scar. Biopsies from this area, however, continued to demonstrate residual morphological and immunophenotypic features consistent with MALT lymphoma, while the lesion appeared endoscopically inactive. The patient remained asymptomatic, and imaging was stable, leading to a "watch-and-wait" strategy, including periodic imaging and joint endoscopic surveillance by gastroenterology and haematology services.

Conclusion: Synchronous gastric and colonic MALT lymphoma is an exceedingly rare presentation of extranodal marginal zone lymphoma [5]. This case highlights the diagnostic importance of correlating imaging, endoscopic, and histopathologic findings in patients with nonspecific gastrointestinal symptoms, as is the therapeutic impact of H. pylori eradication. A conservative approach with histological reassessment and close follow-ups is the most reasonable for localized, indolent disease.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP087 Measurement of colonic polyps. Is visual estimation accurate to determine subsequent surveillance colonoscopy?

Authors Broder E[1], Besherdas K[2]
Institutes 1 Royal Free Hospital, London, United Kingdom; 2 Royal Free Hospital, London, United Kingdom, United Kingdom
DOI 10.1055/s-0046-1821414

Aims We aim to compare the estimation of polyp size using the visual estimation of colon polyp with or without the open biopsy forceps technique against actual polyp size measurement by our histopathology department for all polyps > 1 cm in size.

Endoscopy 2026; 58: S1–S1041

Methods A single centre, retrospective analysis of 47 consecutive patients who have had polypectomies done for polyps > 1 cm in size from April 2024 at a hospital in North London. The data was collected using the Medilogic endoscopy reporting tool and the electronic patients record. The size of the polyps documented in the endoscopy report was then compared to the lab measured actual polyp size.

Results 25/47 (53 %) polyps greater than 1cm had similar histological size to endoscopic size estimate. 22/47 (47 %) of polyps greater than 1cm had poor correlation of size with histology, of which 21 had size overestimated at endoscopy in comparison to histology.

Conclusions Colon polyp size is a critical biomarker for clinical management of colonic polyps. Larger polyps have a greater malignant potential. During colonoscopy, it is important to correctly measure the size of the polyps because of the direct correlation of size with colon cancer and defining a polyp as high-risk polyp which aids appropriate further surveillance colonoscopy. During polypectomy, size of the colonic polyps encountered are often gauged by visual estimation or the open forceps method. However, some data exists on the questionable reliability of a visual estimate even amongst expert colonoscopists.

From this study, we can conclude that visual estimation of polyp size at endoscopy is inaccurate with wide variations between the reported size and the actual size of the polyps. Accurate measurement of colonic polyps is important as inaccuracies can lead to potentially larger polyps not being tattooed and patients with smaller polyps having to attend for subsequent surveillance colonoscopy when they could have been safely discharged as per current ESGE guidelines. We advocate that the 'gold standard' practice of direct measurement of the polyp once excised and outside the body be adopted and this be used to guide subsequent management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP088 Polypectomy techniques in clinical practice for right sided polyps. Do we follow the ESGE guidelines?

Authors Broder E[1], Besherdas K[2]
Institutes 1 Royal Free Hospital, London, United Kingdom; 2 Royal Free Hospital, London, United Kingdom, United Kingdom
DOI 10.1055/s-0046-1821415

Aims We aimed to assess the current practice in our institution in terms of polypectomy technique of right sided polyps in comparisons to the ESGE standards.

Methods A single centre, retrospective analysis of 100 consecutive patients who have had polypectomy of any size from April 2024 at a hospital in North London was undertaken. Patients who had polypectomy from the right side of the colon, defined as polyps in the caecum, ascending colon and hepatic flexure, were then analysed. The data was collected using the Medilogic endoscopy reporting tool, and the electronic patients record. The technique used for polypectomy, along with the type of polyp at histology retrieved, was scrutinized and compared with obedience of ESGE guidance on polypectomy technique.

Results A total of 70 right sided polyps were detected and analysed from polypectomies across the 100 patients. Of those, 53 polypectomies (76 %) followed ESGE recommendations and 17 (24 %) did not. The non-compliant polypectomy methods used included cold biopsy, hot endoscopic mucosal resection (EMR) for SSL or polyps less than 10mm and hot snare for polyps less than 10mm (see ▶ **Table 1**).

▶ **Table 1**

Polypectomy method compliant with ESGE		**Polypectomy method non-compliant with ESGE**	
Cold snare or cold EMR for all			
SSL	9	Hot EMR for SSL	2
Cold snare or cold EMR			
< 10mm	32	Cold snare or cold EMR > 10mm	4
Hot EMR > 20mm	11	Hot EMR < 10mm	2
ESD	1	Hot snare < 10mm	1
		Cold biopsy	8
Total in line with ESGE:	**53 (76 %)**	**Total not in line with ESGE:**	**17 (24 %)**

Conclusions Polypectomy on the right side of the colon pose a challenge due to its thin wall increasing the risk of perforation. New guidelines from the European Society of Gastrointestinal Endoscopy (ESGE) recommend using cold snare polypectomy in polyps < 10mm, as well as use of cold snare polypectomy technique for serrated sessile lesions (SSL) of all sizes to reduce the risk of delayed bleeding. The guidance also recommends avoiding cold biopsy for polyp resection to reduce the risk of recurrence.

This study shows insufficient compliance to the ESGE guidelines in our department with regards to polypectomies performed on right side of the colon. Almost a third of polypectomies not in line with ESGE guidance (5/17) involved inappropriate diathermy use, which may have increased the risk of perforation. Although, these risks can be mitigated slightly through prophylactic use of clips, this is less cost effective and could be avoided through increased use of cold EMR or cold snare polypectomy in the right colon for smaller polyps. In addition, many endoscopists are still carrying out cold biopsies on small polyps(8/70, 11 %), which ESGE recommends avoiding due to the likelihood of incomplete resections and therefore increased risk of local recurrence. We conclude that there is inadequate adherence to the latest ESGE guidelines with regards to right sided polypectomies. We recommend better dissemination and implementation of the ESGE guidelines to enhance clinical practice with regards to polypectomy techniques.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP089 Resection of sessile serrated lesions (SSL) in clinical practice. How well do we do?

Authors Broder E[1], Besherdas K[2]
Institutes 1 Royal Free Hospital, London, United Kingdom; 2 Royal Free Hospital, London, United Kingdom, United Kingdom
DOI 10.1055/s-0046-1821416

Aims We aimed to assess the current practice in terms of polypectomy technique of SSL in comparisons to the ESGE standards.

Methods A single centre, retrospective analysis of consecutive patients who have had polypectomies done for SSL of any size from April 2024 at a hospital in North London was undertaken. The data was collected using the Medilogic endoscopy reporting tool, and the electronic patients record. The technique used for polypectomy, along with the type of polyp at histology retrieved, was scrutinized and compared with ESGE recommendation on polypectomy technique for SSL.

Results Of 177 polypectomies, 18 SSLs of varying sizes were confirmed at histology. 13 of these (72 %) were retrieved using cold snare polypectomy with or without EMR, in line with ESGE guidelines. The remaining 5 SSLs (28 %) were retrieved using either hot EMR or cold biopsy.

Conclusions Sessile serrated lesions (SSL) have been recognised in the last decade as important premalignant lesions accounting for between 15 % and 30 % of colorectal cancers. According to European Society of Gastrointestinal Endoscopy (ESGE) guidelines, cold snare polypectomy is recommended for SSLs < 10mm, and cold snare polypectomy or piecemeal cold snare polypectomy with or without endoscopic mucosal resection (EMR) technique for SSL < 19mm. This technique is adopted to reduce thermal damage from diathermy techniques reducing the complications of delayed bleeding and perforation.

Through this study, we can conclude that a significant proportion of SSLs are still being extracted using methods inclined to increase thermal damage. The current ESGE guidelines, with-regards-to SSL polypectomies has not been fully implemented in clinical practice. We recommend better dissemination and implementation of these guidelines, which in turn, could lead to reduced iatrogenic perforation rates and cases of post-procedural bleeding, as well as cost savings in using less resource

eP090 Environmental impacts of current bowel preparations for colonoscopy : life cycle assessment and biodegradability

Authors Pioche M[1], Jerome R[2], Laporte A[3], Hassan C[4], Rodriguez de Santiago E[5], Jacques J[6], Grau R[2], Masgnaux LJ[7], Cunha Neves JA[8], Baddeley R[9], Pohl H[10], Biscay M[11], Lupu A[12], Grimaldi J[13]

DOI 10.1055/s-0046-1821417

Aims Bowel preparation is an essential prerequisite for high-quality colonoscopy, while clinical performance and patient acceptability have traditionally guided the choice of preparation, their environmental impact has remained largely overlooked. This study aims to conduct a comparative LCA of 5 current bowel preparations used in clinical practice.

Methods A life cycle assessment was performed independently for 5 of the most current bowel preparation available on the market, with 3 polyethyleneglycols (PEG-4L, PEG-2L-A, and PEG-2L-B) and 2 oral sodium sulfate ones (OSS-1, OSS-2). A cradle to grave boundary method was used from raw extraction to end of life. Main environmental impacts were evaluated including carbon footprint, ecotoxicity, water and fossile resources depletion, human toxicity and eutrophication.

Results Carbon footprint of the different bowel preparations varied from 0.118 kg CO2eq per unit (OSS-1), 0.585 (OSS-2), 0.684 (PEG-2L-A), 0.685 (PEG-2L-B) and 0.814 kg CO2eq (PEG-4L). Active ingredient had less impact in oral sulfate prep (OSS-1 : 0.08 kg CO2e, OSS-2 : 0.012 KgCO2e) than for PEG (PEG-2L-A 0.6 kg CO2e, PEG-2L-B 0.5 kg CO2eq, PEG-4L 0.8 kg CO2e). Packaging was varying from 0.03 for OSS-1 to 0.454 Kg CO2e for OSS-2. Use of fossile resources varying from 1.6 MJ per unit (OSS-1), 10.7 MJ (OSS-2), 13.9 MJ (PEG-2L-B), 15.6 MJ (PEG-2L-A), to 19.3 MJ (PEG-4L). Biodegradability of the PEG reached 40 % at 14 days and 60.4 % at 28 days in manometric respirometry test.

Conclusions Oral sulfate bowel preparation with minimalist packaging (OSS-1) has very low environmental impacts compared to other bowel preparations like PEGs, which active ingredient is consuming far more to be produced, or like other sulfate preparations with very heavy packaging (plastic bottles). Biodegradability of PEG has struggled to meet the established standard at 28 days but not at 14, whereas conventional wastewater treatment plants in our country usually keep sludge for less than 20 days. Environmental sobriety should become a criterion of choice at the time of product prescription and for future ecologic conception of drugs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP091 Transnasal Endoscopy in Upper GI Cancer Pathways: Real-World Diagnostic Yield, Safety, and Operational Impact

Authors Rangedara DE[1], Ha SM[1], Green S[1], Mohammed OK[1], Chedgy F[1]
Institute **1** Royal Sussex County Hospital, Brighton and Hove, United Kingdom
DOI 10.1055/s-0046-1821418

Aims Transnasal endoscopy (TNE) is an unsedated alternative to conventional oesophagogastroduodenoscopy (OGD), enabling upper gastrointestinal (UGI) assessment via an ultrathin endoscope under topical anaesthesia. Randomised trials confirm comparable diagnostic accuracy and patient acceptability, yet large-scale real-world data are limited. Rising UK endoscopy demand and the NHS Faster Diagnosis Standard (FDS), requiring cancer diagnosis or exclusion within 28 days, necessitate pathway innovation. We evaluated diagnostic yield, safety, and operational performance of a newly implemented TNE service for patients with UGI symptoms, including urgent suspected cancer (two-week-wait, 2WW) referrals, in a UK tertiary centre [1–5].

Methods All patients undergoing TNE between April and August 2025 were included in this prospective observational study. Referrals originated from routine and 2WW suspected UGI cancer pathways. Procedures were performed by JAG-accredited endoscopists in a dedicated TNE suite under topical anaesthesia without sedation. Data collected included demographics, referral indication, completion rate, same-day oral OGD conversion, cancer detection, non-attendance (DNA) rate, incomplete procedure waiting list (IPWL) delay, and complications. Outcomes were compared between Q1 (April–June) and Q2 (July–August) to assess scalability. Benchmarking was performed against UK National Endoscopy Database (NED) OGD data and international TNE cohorts. Statistical analyses used Fisher's exact test and exact binomial confidence intervals.

Results A total of 593 TNE procedures were completed (mean age 64.2 ± 12.8 years; 54 % female). Indications included 2WW suspected UGI cancer (52 %), dyspepsia/reflux (35 %), anaemia (9 %), and surveillance (4 %). UGI cancer was detected in 11/593 (1.9 %; 95 % CI 0.93–3.29 %), exceeding the national OGD benchmark of 1.0 % (p = 0.03). Cancer yield was 2.6 % (8/307; 95 % CI 1.13–5.07 %) in 2WW referrals versus 1.0 % (3/286; 95 % CI 0.22–3.03 %) in non-2WW pathways (p = 0.23; not significant).

Oral conversion was required in 132/593 (22.3 %; 95 % CI 18.97–25.83 %). Same-day conversion without sedation occurred in 35/132 (26.5 %), rising from 35.6 % (16/45; 95 % CI 21.9–51.2 %) in Q1 to 73.1 % (19/26; 95 % CI 52.2–88.4 %) in Q2 (p = 0.003). Deferred conversions, primarily for sedation preference, incurred minimal IPWL delay (< 7 days), maintaining FDS compliance.

DNA rates fell from 7.6 % (29/382; 95 % CI 5.14–10.72 %) in Q1 to 2.6 % (9/348; 95 % CI 1.19–4.85 %) in Q2 (p = 0.002), reflecting improved patient engagement and streamlined pathway integration. No procedural complications occurred (0 %; 95 % CI 0–0.62 %). Diagnostic completion and cancer detection rates were equivalent between high- and mid-volume endoscopists.

Conclusions TNE is a safe (0 % complications), effective (cancer yield > OGD benchmark), and scalable diagnostic option for suspected UGI cancer. Integration within 2WW pathways supports FDS compliance and reduces DNA rates, alleviating endoscopy service pressure. These findings provide a strong evidence base for wider NHS adoption and European integration of TNE as a patient-centred innovation in UGI cancer diagnostics.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP092 Clinicopathologic and Endoscopic Features of Gastric Adenocarcinoma of the Fundic Gland Type Treated by Endoscopic Resection

Authors Lee YU[1], Kim GH[2], Lee MW[3], Lee BE[3], Joo DC[3]
Institutes 1 Pusan National University Hospital, Busan, Republic of Korea; 2 Pusan National University Hospital, Busan, South Korea, Republic of Korea; 3 Biomedical Research Institute, Pusan National University Hospital, Busan, Republic of Korea
DOI 10.1055/s-0046-1821419

Aims Gastric adenocarcinoma of the fundic gland type (GA-FG) is a rare, well-differentiated neoplasm that usually arises from *H. pylori*-negative, non-atrophic mucosa of the upper stomach. This study aimed to characterize the clinicopathologic and endoscopic features of GA-FG in Korean patients.

Methods Ten patients with GA-FG who underwent endoscopic resection between November 2011 and April 2025 at Pusan National University Hospital were retrospectively analyzed. Clinicopathologic features, endoscopic findings, and outcomes were reviewed [1–5].

Results A total of 10 patients (6 men, 4 women; mean age, 60.7 years; range, 34–73) were included. Most lesions were located in the fundus or upper body (8/10, 80 %) and arose from non-atrophic mucosa. H. pylori infection was absent in nine patients. The predominant macroscopic type was slightly elevated (IIa) with dilated surface vessels. The mean tumor size was 7 mm, and submucosal invasion was present in eight cases (80 %). En bloc and histologically complete resection were achieved in all cases, and no recurrence or metastasis occurred during a mean follow-up of 29 months (▶ **Table 1**).

Conclusions GA-FG typically develops in *H. pylori*-negative, non-atrophic mucosa of the upper stomach and shows indolent behavior despite submucosal invasion. ESD provides a curative and safe treatment option with excellent outcomes

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Colon capsule endoscopy (CCE) has emerged as a minimally invasive alternative to colonoscopy and has in several meta-analyses shown non-inferiority in detection rates of colorectal lesions. However, CCE is a reader-dependent technique and pathology can be missed even though images of the lesions are captured. Furthermore, misclassification of pathology can lead to erroneous conclusions and possible delays in correct diagnosis and patient management. With this case-series we aim to present misclassified and non-detected cancers from the CareForColon2015 trial and discuss the underlying causes and possible solutions to reader error leading to missed pathology.

In the CareForColon2015 trial including 2,031 Danish colorectal cancer screening participants with a positive faecal immunochemical test undergoing CCE, 72 cancers were detected and verified by histopathology. Through systematic re-evaluation of all CCE investigations where a subsequent colonoscopy reported a cancer, we identified four cases of misclassification, where the lesion was reported as non-neoplastic or with a low risk profile and one case of a non-detected cancer where the lesion was captured in capsule images but not reported by the reader.

In two cases, colonic pathology with clear signs of malignancy (bleeding, central depression and ulceration) were reported as inflammation in CCE while one case had a description in the report of "*a short sequenced retracted sigma-lesion with swollen mucosa and red spots*" and no designation of "malignancy suspected". The fourth case of misclassification was a cancer reported as a polyp of 12mm in size. However, a CCE frame shortly after the reported one depicted a lesion of 25mm. The reported frame only showed the border of the cancer therefore giving the impression of a medium and not high-risk finding. In the case of non-detection, two polyps were reported in CCE leading to referral for colonoscopy. A semi-circumferential malignancy suspect tumour in the right colon was found in colonoscopy and in review of the CCE, the capsule clearly visualised the malignant tumour, although not reported.

These cases prompt a discussion on the need for improvements in the CCE reading and reporting process. If readers do not have conventional endoscopy experience, their ability to classify findings correctly can be suboptimal. Additionally time constraints in overburdened healthcare systems can lead to compromised accuracy in the pursuit of efficiency. Reader training including cases of rare and malignant findings combined with a focus on concrete measures to reduce reader fatigue are important steps towards minimising the risk of missed pathology and misclassification of findings. Furthermore, implementation of artificial intelligence support is suggested by many as an essential part of the future CCE pathway to remedy the issues of reader error and ensure consistent and high quality reports to support clinical decision-making and patient management.

Conflicts of Interest Dr. Benedicte Schelde-Olesen has received honoraria and travel support from Jinshan Ltd. Dr. Thomas Bjørsum-Meyer has participated in advisory board meetings for Medtronic and is a member of the CICA steering group. Professor Anastasios Koulaouzidis is co-director of iCERV Ltd. and shareholder in AJM Med-i-caps Ltd. He has received consultancy fees and travel support from Jinshan Ltd. and Aquilant as well as research support (grant) from IntroMedic/SynMed and iDEK SEED, honoraria from Jinshan and Medtronic and is a member of the ESGE guidelines committee. Dr. Ulrik Deding has received honoraria from Norgine. Professor Gunnar Baatrup has a patent pending for a dual-mode endoscopic capsule with image processing capabilities.

eP094 Esketamine-Propofol Combination for Adults Undergoing Gastrointestinal Endoscopy: An Updated Systematic Review and Meta-Analysis with GRADE Evidence Assessment

Authors Mohsen Helal M[1], Farag A[2], Selim S[3], Jabrieh G[4]
Institutes **1** Faculty of Medicine, Zagazig University, Zagazig, Egypt; **2** Cairo University, Cairo, Egypt; **3** Al-Azhar University, Cairo, Egypt; **4** Palestine Polytechnic University College of Medicine and Health Sciences, Hebron, Palestine, Cairo, Egypt
DOI 10.1055/s-0046-1821421

Aims Propofol is the most commonly used intravenous induction anesthetic in clinical practice, but it is associated with several adverse events such as hypoxemia, hypotension, and bradycardia. The use of adjunct medications during gastrointestinal (GI) endoscopy may reduce propofol requirements and improve hemodynamic stability. Esketamine, in particular, has been reported to not only reduce propofol dosage but also counteract its depressive effects, offering enhanced stability and a better anesthetic experience [1–8].

This meta-analysis aims to evaluate the effectiveness of **esketamine** as an **adjunct** to propofol compared to **propofol alone** in adults undergoing GI endoscopy.

Methods A comprehensive search was conducted in MEDLINE, Scopus, Web of Science, and the Cochrane Library to identify eligible randomized controlled trials (**RCTs**). The primary outcomes assessed were total propofol dosage (mg) and the incidence of hypotension and hypoxemia. Pooled analyses were expressed as mean differences (MDs) for continuous variables and risk ratios (RRs) for categorical outcomes, each with 95 % confidence intervals (CIs).

Results Eight trials met the inclusion criteria. The combination of esketamine and propofol significantly reduced propofol requirements (MD = -54.97; 95 % CI: -69.77 to -40.17; **p < 0.00001**). The combination also lowered the risk of hypotension (RR = 0.28; 95 % CI: 0.19–0.40; **p < 0.00001**) and hypoxemia (RR = 0.58; 95 % CI: 0.34–0.98; **p = 0.04**) (▶ **Table 1**).

Endoscopy 2026; 58: S1–S1041

▶ **Table 1** Characteristics of the included studies

Study ID	Study design	Study period	Operation	N randomized	ASA	Primary outcome(s)	Key findings
Feng 2022	Double-blind RCT	January 2022 to August 2022	Gastrointestinal endoscopy	100	I/II	EC50 of propofol	Increasing the dose of esketamine significantly reduces the dose of propofol required for procedures, with fewer hemodynamic changes.
Fu 2024	Single-blind RCT	July 2021 to September 2021	Colonoscopy	100	I/II/III	Incidence of hypotension	Esketamine + propofol for colonoscopy reduces hypotension and enhances respiration, with satisfactory sedation.
Liu 2023	Double-blind RCT	January 2021 to March 2021	Gastroscopy	80	I/II/III	Total amount of propofol consumption	Propofol combined with 0.2 mg/kg esketamine reduces total propofol consumption, maintains stable hemodynamics, and does not affect recovery time.
Song 2023	Double-blind RCT	February 2022 to November 2022	Bidirectional Endoscopy	663	I/II	Composite of desaturation and hypotension	Esketamine reduced desaturation and hypotension by 61 %, and decreased propofol usage.
Xiao 2024	Double-blind RCT	November 2022 to February 2023	Colonoscopy	195	I/II	Incidence of hypoxemia, hypotension, hypertension, and bradycardia	Esketamine + propofol is safe and effective for colonoscopy with fewer complications.
Yang 2021	Double-blind RCT	November 2020 to March 2021	Gastrointestinal endoscopy	90	I/II/III	EC50 of propofol	Combination reduces propofol EC50, lowers hypotension incidence, and offers shorter recovery with similar satisfaction.
Zhan 2022	Double-blind RCT	November 2020 to September 2021	Gastrointestinal endoscopy	260	I/II	Propofol consumption per minute (mg/min)	Propofol + 0.2 mg/kg esketamine reduced induction time, cough, and body movement, with lower propofol consumption. No effect on recovery, hemodynamics, or adverse events.
Zheng 2023	Double-blind RCT	August 2022 to February 2023	Gastroscopy	113	I/II	Duration of procedure and propofol consumption	Propofol + esketamine reduced induction and awakening times, propofol consumption, and incidence of adverse events, with more stable hemodynamics.

RCT: Randomized control trial, ASA: American Society of Anaesthesiologists criteria for physical status, EC50: median effective concentration

Conclusions The unique pharmacological properties of esketamine provide substantial value when used in combination with propofol for GI endoscopic procedures, particularly by enhancing hemodynamic stability and reducing propofol requirements.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP095 Incidence and Timing of Post-ESD Bleeding in Dialysis Patients

Authors Saito K[1], Ikeya T[1], Shinozaki S[1], Umezawa M[1], Abe Y[1]
Institute 1 Ōkubo Hospital, Shinjuku City, Japan
DOI 10.1055/s-0046-1821422

Aims Post-endoscopic submucosal dissection (ESD) bleeding (PEB) is classified as early-onset or late-onset, and controversies regarding risk factors and preventive measures continue. Dialysis patients are widely recognized as a high-risk group for PEB; however, no established criteria exist for managing anticoagulants during dialysis or timing the resumption of antithrombotic therapy after gastric ESD. This study aimed to clarify the frequency and timing of PEB in dialysis patients at a single institution and compare these findings with non-dialysis patients.

Methods We retrospectively analyzed 47 cases undergoing gastric ESD at our institution between April 11, 2023, and August 19, 2025. Second-look endoscopy (SLE) was performed the following day in all cases. PEB was defined as either (1) requiring emergency endoscopy due to hematemesis or melena, or (2) demonstrating bleeding on endoscopic re-examination with a hemoglobin decrease of ≥ 2 g/dL. The onset timing was classified as early (Day 0–1) or late (Day ≥ 2). Cases undergoing prophylactic cauterization or clipping during SLE without evident bleeding, followed by no subsequent bleeding, were classified as the prevent group. PEB was tallied on a per-patient basis (▶ **Table 1**).

▶ **Table 1**

	Dialysis Patients(n = 3)	Non-Dialysis Patients(n = 44)
Sex(Male, %)	(2, 66.7)	(31, 70.5)
Age(Median, Range)	(69, 66-76)	(76, 41-94)
PEB	2	2
PEB Late-Onset	2(100 %)	1(50 %)
Prevent Group	0	9
UML classification (U, M, L)	(1, 1, 1)	(7, 21, 16)
Tumor Size (> 30mm, < 30mm)	(0, 3)	(16, 28)
Multiple Tumors	0	5
Aspirin (continue, suspend)	(1, 1)	(4, 2)
P2Y12 Inhibitors (continue, suspend)	(0, 0)	(0, 3)
Direct Oral Anticoagulant (continue, suspend)	(0, 0)	(0, 7)
Cilostazol continue	0	1
Best-J score (mean)	4.3	1.6

Results Of the 47 subjects, 3 were dialysis patients and 44 were non-dialysis patients. Overall PEB occurred in 4/47 cases (8.5 %). PEB was observed in 2/3 dialysis patients (66.7 %), both of which were late-onset (Day 3, Day 6). Among non-dialysis patients, PEB occurred in 2/44 cases (4.5 %) (one case had two events on Day 1 and Day 6, the other on Day 6). A significant difference in PEB occurrence was observed between dialysis and non-dialysis patients (Fisher's exact test, two-tailed p = 0.016). The prevent group comprised 9 cases. The dialysis patients who developed PEB were: one case where the anticoagulant during dialysis was changed from nafamostat to dalteparin on Day 3 and hematemesis occurred on the same day; and another case where aspirin was restarted on Day 3, changed from aspirin to prasugrel on Day 5, and hematemesis occurred on Day 6.

Conclusions In this institution's study, dialysis patients were at high risk for PEB, with delayed onset being particularly prominent. These findings are consistent with the PEB risk in dialysis patients demonstrated in previous studies using the BEST-J score. The anticoagulant used during dialysis and the antiplatelet agent restarted afterward may be implicated in delayed PEB. For dialysis patients after gastric ESD, it is considered appropriate to use nafamostat as the anticoagulant during dialysis and manage antiplatelet therapy cautiously with aspirin monotherapy for approximately one week postoperatively.

eP096 Correlation between Angiopoietin 2 and NOS3 Genes Variants and Esophageal Varices Progression in HCV Cirrhotic Patients

Authors Abdel-Samiee M[1], Nabih OS[2], Tahoon MA[2], Abozeid E[2], Demerdash H[2], Omar F[2], Helal M[2], El Gedawy G[2], Khalil H[2], Elashmawy M[2]
Institutes 1 National Liver Institute, Menoufia University, Menoufia, Egypt, Egypt; 2 Menoufiya University, Shebeen El-Kom, Egypt
DOI 10.1055/s-0046-1821423

Aims We aim to assess the prognostic value of specific single-nucleotide polymorphisms (SNPs) in ANGPT2 (rs2442598) and NOS3 (rs2070744) genes concerning the development of EV.

Methods Fifty patients with HCV-related cirrhosis and varices found by endoscopy (Group I), fifty patients with HCV-related cirrhosis and no varices (Group II), and fifty healthy people as a control group (Group III) comprised the 150 participants in this study.

Results For genetic factors, there was no significant differences in the genotype distribution or allele frequencies of ANGPT2 (rs2442598) and NOS3 (rs2070744) between patients with or without EV (p > 0.05). However, significant differences were noted for ANGPT2 rs2442598 in relation to presence of varices, ascites, Child score, hypertension, ALT, and AST (p < 0.05), while other parameters did not show significant differences (p > 0.05). Similarly, for NOS3 rs2070744, significant differences were found in Child score, hypertension, ALT, and AST (p < 0.05).

Conclusions ANGPT2 (rs2442598) variant is a promising non-invasive indicator to ensure that there are no varices with portal hypertension to predict absence of EV as a complication of cirrhosis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP097 Endoscopic Biliary Drainage in Malignant Obstruction From Metastatic Colorectal Cancer: Outcomes and Clinical Predictors

Authors Panova K[1], Male N[2], Nikolova S[1], Karagyozov P[2]
Institutes 1 Clinic of Gastroenterology, Acibadem City Clinic University Hospital Tokuda, Sofia, Bulgaria; 2 Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofia, Bulgaria
DOI 10.1055/s-0046-1821424

Aims Metastatic colorectal cancer (mCRC) frequently results in complex hilar biliary strictures and obstructive jaundice. When cannulation is difficult or standard approaches fail, alternative endoscopic drainage strategies may be required. Evidence in the mCRC population remains limited. This study evaluated the feasibility, safety, and early effectiveness of endoscopic biliary drainage in these patients.

Methods We retrospectively evaluated all consecutive patients with mCRC and malignant biliary obstruction who underwent endoscopic biliary drainage between 01.01.2020 and 30.09.2025 at our tertiary referral center. We collected demographic data, information about drainage procedure type, unilateral or bilateral drainage and application of combined endoscopic approaches. Technical success was defined as successful stent placement with documented bile drainage. Clinical success was defined as a ≥ 10 % reduction in serum bilirubin within the first 3 days. Adverse events and predictors of outcome were also explored.

Results Forty-seven patients were included (median age 65 years, IQR 58–73; 70.2 % male). The ECOG performance status was ≥ 2 in 88.9 % of cases. Technical success was achieved in 93.6 % of cases (44/47). Clinical success was achieved in 70.2 % (33/47) of patients. ERCP was performed in 35 patients (74.5 %), EUS-based biliary drainage in 8 patients (17.0 %), and combined ERCP + EUS drainage in 3 patients (6.4 %); no cases required percutaneous drainage. Clinical success was comparable between unilateral and bilateral drainage (66.7 % vs. 72.4 %, p = 0.75). AEs occurred in 27.7 % (13/47), mainly cholangitis (25.5 %), with one hepatic abscess. ROC analysis identified baseline bilirubin > 224 µmol/L as predictive of lower clinical success (AUC 0.61), whereas metastatic burden and drainage pattern were not associated with outcome. Clinical success did not differ by drainage modality (ERCP: 66.7 %; EUS-BD: 75.0 %; combined: 100 %; p = 0.46).

Conclusions Endoscopic biliary drainage in patients with mCRC-related malignant obstruction achieved high technical success and acceptable early biochemical response across all drainage modalities. Most adverse events were manageable. Elevated baseline bilirubin was the only factor associated with reduced early clinical success, while drainage approach and metastatic burden showed no significant impact. These findings support a flexible endoscopic strategy tailored to anatomy and expertise, as outcomes were comparable across procedure types.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP098 EUS-guided biliary drainage in the management of benign biliary diseases: A single center case series

Authors Zhecheva I[1], Karagyozov P[2], Male N[2], Kavrakov D[2]
Institutes **1** Clinic of Gastroenterology, Acibadem City Clinic University Hospital Tokuda, Sofia, Bulgaria; **2** Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofia, Bulgaria
DOI 10.1055/s-0046-1821425

Aims Endoscopic ultrasound-guided biliary drainage (EUS- BD) increasingly provides its role in the management of benign biliary diseases particularly in patients with surgically altered anatomy or after failed selective biliary cannulation during ERCP .The aim of this study is to evaluate the safety, clinical effectiveness and long-term outcomes of EUS-BD for the management of benign biliary diseases.

Methods This is a single- center retrospective study, which included all consecutive patients, who underwent EUS-BD for benign indications between March 2020 and October 2025. All the procedures were evaluated in terms of technical, clinical success and adverse events. Long- term follow-up data were also provided.

Results We identified 15 patients who underwent EUS-BD during the study period due to benign biliary diseases (men- 7, women- 8; mean age 62.3 years). Some of them (n = 11,73.3 %) were addmited as emergency with acute cholangitis, while others (n = 4, 26.7 %) with progressive jaundice. In 4 (26.7 %) cases surgically altered anatomy was present, while in 11(73.3 %) patients EUS-BD was used to assist ERCP after failed transpapillary canulation.

We performed EUS- guided hepaticogastrostomy (EUS-HGS) using fully covered self expanding metal stent in 11(73.3 %) patients, EUS- guded rendezvous technique to assist transpapillary canulation was used in 2 (13.3 %) and 2(13.3) patients underwent EUS choledochoduodenostomy. Antegrade cholangioscopy using the transgastric route was performed in 4(26.7 %)cases. EUS-HGS was successfully performed in 3(20 %) cases with complete iatrogenic bile duct transsection duringcholecystectomy.

Second procedure was performed in 12 (80 %) cases after median period of 45 days.

Technical success, defined as successful biliary access and stent placement was achieved in 86.7 %. Clinical success (defined as ≥ 50 % reduction in serum total bilirubin and cholestatic enzymes or resolution of cholangitis within 2 weeks after the procedure) was achieved in 14 (93.3 %) patients.

During follow-up, 13 patients (86.7 %) remained under multistenting management, with a median follow-up duration of 8 months. One patient (6.7 %) achieved complete resolution of the stricture after 2 procedures, with no recurrence observed after 2 years. Adverse events, mostly episodes of cholangitis, were managed conservatively and endoscopically. Surgery was required in only 2 (13.3 %) patients due to technical failure of EUS-BD and high risk of severe cholangitis. In 1 (6.7 %) additional case, cholangioscopy- guided biliary drainage was performed following technical failure of EUS-HGS.

During the study period 1(6.7 %) patient died from unrelated comorbidities.

Conclusions EUS-BD demonstrates favorable clinical efficacy and satisfactory technical success rates, suggesting that it is a viable option for the management of benign biliary diseases. Further development of dedicated devices and accessories is essential to enhance the safety and effectiveness of the procedure, particularly in benign indications. Long-term follow-up remains necessary to confirm the durability and overall outcomes of this technique.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP099 Acute Lower Gastrointestinal Bleeding: Factors Associated with Small Bowel Bleeding and Predictors of Hemostasis

Authors Papantoniou K[1], Liampas I[2], Sotiropoulos C[1], Kafetzi T[1], Geramoutsos G[1], Kimiskidis N[1], Diamantopoulou G[1], Konstantakis C[1], Theocharis G[3], Katsanos K[4], Triantos C[1], Thomopoulos K[1]
Institutes **1** Division of Gastroenterology, Department of Internal Medicine, University of Patras, 26504, Patras, Greece; **2** Department of Neurology, University Hospital of Larissa, School of Medicine, Larissa, Greece; **3** Second department of gastroenterology, Attikon university general hospital, Athens, Athens Greece; **4** Department of Interventional Radiology, University Hospital of Patras, 26504, Patras, Greece
DOI 10.1055/s-0046-1821426

Aims Distinguishing bleeding originating from the small versus the large bowel can be challenging due to overlapping clinical features, while hemostasis will be required in a subset of patients. This study aimed to identify factors associated with small bowel bleeding and predictors of the need for hemostasis.

Methods A retrospective analysis was conducted on patients with confirmed lower gastrointestinal bleeding. Associations between clinical and laboratory parameters with bleeding location and the need for hemostasis were assessed using statistical tests and logistic regression analysis. The crude analyses revealed several associations. To account for potential confounding, we performed an adjusted analysis featuring all of the variables fulfilling the lenient statistical threshold of p = 0.01. The truly important associations are those that "survived" the adjusted analysis. Adjusted associations were considered significant using the conventional statistical threshold of p = 0.05 [1–4].

Results A total of 419 patients (242 males, 57.8 %) with a median age of 76 years (IQR 65–83) were included. The bleeding source was located in the colon in 85.9 % of cases, in the small bowel in 10 %, and remained unidentified in 4.1 %. Hemostasis was required in 13.8 % of patients. The presence of melena and maroon-colored stools was strongly associated with small bowel bleeding (OR 18.5 and 7.0, respectively; p < 0.001). A history of cardiovascular disease reduced the likelihood of small bowel bleeding by 87 % (p < 0.001). Higher hemoglobin levels were associated with a lower risk (15 % reduction per 1 g/dL increase; p = 0.027), while higher urea levels increased the risk (0.9 % per mg/dL;

p = 0.01). Polypectomy markedly increased the likelihood of requiring hemostasis (OR ~36; p < 0.001). Conversely, higher albumin levels significantly reduced this risk (53.4 % per 1 g/dL increase; p < 0.001), whereas anticoagulant use more than doubled it (p = 0.049) (▶ **Table 1**).

▶ **Table 1**

Small vs large bowel bleeding	Sig.	Exp(B)	95 % C.I.for EXP(B)	
			Lower	Upper
Referral	,110	2,033	,852	4,849
Hematochezia	,000 omnibus p			
Melena	,000	18,537	5,651	60,803
Maroon coloured stool	,000	7,107	2,881	17,532
Rectal bleeding	,997	NA		
Bloody diarrhea	,999	NA		
Cardiovascular disease	,000	,127	,049	,331
Prior lower GI bleeding	,144	2,115	,775	5,773
Platelets (K/µl)	,917	1,000	,996	1,005
Albumin (g/dl)	,499	,829	,481	1,428
Urea (mg/dl)	,010	1,009	1,002	1,016
Hemoglobin(g/dl)	,027	,846	,729	,981

Conclusions Specific clinical and laboratory parameters are associated with both the bleeding site and the need for hemostasis. Their integration into clinical assessment may facilitate early recognition and targeted management of high-risk patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP100 Proximal Choledochal Cyst and Sump Syndrome after Choledochoduodenostomy: A Pitfall for ERCP

Authors Escobar Ortiz J[1], Pérez Pérez J[1], Garrido Gallego F[1], Prieto Doblado M[1], García Ayuso M[1], Adan Merino L[1], Zaera-De La Fuente C[1], Carlos VP[1], Angel PD[1]

Institute 1 Hospital Universitario Infanta Leonor, Madrid, Spain

DOI 10.1055/s-0046-1821427

Introduction: Choledochal cysts are rare congenital malformations characterized by single or multiple cystic dilatations of the intra- and/or extrahepatic biliary tree. The most widely accepted classification is that of Todani (types I–V). They are usually diagnosed in childhood (80 %) and occur predominantly in women. Their main complications include an increased risk of biliary neoplasms (up to 30 % in adults, especially in types I and IV) and recurrent cholangitis, among others.

Treatment generally consists of cyst excision and restoration of biliary-enteric flow, with Roux-en-Y hepaticojejunostomy being the technique of choice. Type III cysts, depending on the subtype, may be treated by sphincterotomy, endoscopic resection (preferred), or surgery [1, 2].

Sump syndrome, on the other hand, is associated with dysfunction of a surgically created choledochoduodenostomy due to accumulation of debris, biliary sludge, and food remnants in the suprapapillary distal common bile duct, leading to recurrent cholangitis due to bacterial overgrowth. In cases of cholangitis, endoscopic drainage with stent placement is usually required.

Endoscopy:A 47-year-old woman, who underwent surgery in a private center in 2013 for a choledochal cyst (Todani type IB) treated with choledochoduodenostomy, was admitted for ERCP due to associated sump syndrome.

Cholangiography revealed a large proximal choledochal cyst measuring 30–35 mm and a choledochoduodenal fistula with multiple filling defects. The fistula was cleaned using a Fogarty balloon, yielding abundant biliary sludge and food debris, followed by decompressive sphincterotomy.

Although the guidewire could be advanced through the cyst, the position was extremely unstable, making it impossible to place any type of biliary stent. The procedure was therefore suspended to avoid iatrogenic injury.

The patient was subsequently referred to a tertiary center, where she underwent definitive surgical reintervention.

Conclusions: The peculiarity of this case lies in the patient's previous cyst-enterostomy, performed for unknown reasons, which is associated with an increased risk of infection and malignancy. Combined with the technical complexity of ERCP in this setting, surgical management remains the treatment of choice.

eP101 Appropriateness of Gastrointestinal Endoscopy for Hospitalized Patients: the importance of consultant led triage

Authors Soares C[1], Carvalho AC[1], Cardoso R[1], Araújo R[1], Silva A[1]

Institute 1 Hospital São Teotónio, Viseu, Portugal

DOI 10.1055/s-0046-1821428

Aims A range of criteria have been created to evaluate the appropriateness of gastrointestinal (GI) endoscopy. The most widely recognized were set by the American Society for Gastrointestinal Endoscopy and the European Panel of Appropriateness of Gastrointestinal Endoscopy (EPAGE), updated EPAGE-II criteria. Nevertheless, the application of general rules is not sufficient, especially in hospitalized patients. The complexity, singularity, and dynamic clinical evolution demands the proactive involvement of an experienced endoscopist to make the decision whether or not to perform the exam.

Our aim was to analyze the appropriateness of endoscopic exam requests in hospitalized patients over the course of one year.

Methods A prospective observational study was conducted in an endoscopic unit of a tertiary hospital center. The requested exams were triaged by a gastroenterologist after reviewing the patient's medical record, assessing clinical status and complementary diagnostic tests. In cases of unclear indication, and no absolute contraindication, the decision to proceed was discussed with the referring physician.

Results A total of 184 requests for inpatient endoscopy and/or colonoscopy were received during 1 year (table 1). 154 (84 %) of the requests were thought to be appropriate. 12 (6 %) were cancelled during triage: 2 were patients on best supportive care, 1 died, 3 had other diagnosis which plausibly justified the clinical situation, 2 had recent endoscopic exams, and 4 presented no clinical/analytical evidence of GI bleeding). 18 (10 %) requests were initially postponed (8 were awaiting imaging results; 5 had poor clinical status and 5 respiratory distress) and ended up being cancelled (8 had another diagnosis in imaging tests, 8 maintained clinical deterioration contraindicating exam and 3 died). In total 30 (16 %) of the requests were cancelled.

The most frequent exam requested was endoscopy, and the most common indication was suspected GI neoplasia. From a total of 58 suspected GI neoplasms, 11 were confirmed as gastric neoplasia, which was the most common finding.

None of the patients with a cancelled exam was diagnosed with a GI disease during follow up.

Mortality rate was considerably higher in the group with cancelled exams (33 % vs 11 % during hospitalization, 50 % vs 32 % during follow up, 15 % vs 1.8 % within 30 days after discharge). Mean age was similar between groups. This findings reveal a frail group of patients, with little likelihood of benefiting from an invasive exam.

Conclusions 16 % of the requests were considered inappropriate, which allowed to avoid 30 unnecessary exams.

Developing standardized indications for endoscopic exams in inpatient care is difficult, and an individualized approach is critical in order to reach an equilibrium between overusage and overlooking, while considering the principle of *primum non nocere.*

eP102V EUS-guided internal drainage of a post-Whipple pancreaticojejunal leak complicated by a cutaneous fistulized collection: reversing the externalized fistulous flow inward

Authors Alioua SA[1], Navez J[1], Claeys N[1], Arvanitakis M[1]
Institute 1 Erasme Hospital HUB, Université Libre de Bruxelles, Brussels, Belgium
DOI 10.1055/s-0046-1821429

Abstract Text

Postoperative pancreaticojejunal leaks after Whipple procedure are challenging, especially when complicated by external fistulas. A 73-year-old man developed a postoperative intra-abdominal collection with a cutaneous fistula after pancreaticoduodenectomy including antrectomy, gastrojejunostomy, and hepaticojejunostomy. EUS-guided internal drainage was performed to reverse the fistulous flow. Under linear EUS guidance, the collection near the pancreaticojejunal anastomosis was punctured through the remaining stomach, despite limited access related to antrectomy. A 10 Fr cystotome was used to create a tract, and two 7 Fr double-pigtail plastic stents were placed for internal drainage. The external output stopped within days, with full recovery maintained at follow-up. This case highlights EUS-guided internal drainage as an effective minimally invasive alternative to surgery.

eP103 Therapeutic ERCP in high-output pancreatic leak after pancreatic surgery: a case report

Authors Escobar Ortiz J[1], Pérez Pérez J[1], Garrido Gallego F[1], García Ayuso M[1], Prieto Doblado M[1], Adan Merino L[1], Carlos VP[1], Angel PD[1]

DOI 10.1055/s-0046-1821430

Introduction Pancreatic fistula is a common complication following pancreatic surgery, occurring in up to 27 % of cases. It consists of an abnormal communication between the pancreatic duct and another anatomical space, resulting in leakage of enzyme-rich pancreatic fluid. Diagnosis is established by abdominal CT scan, and management typically includes antibiotic therapy, endoscopic or percutaneous drainage, and, if necessary, surgical intervention [1, 2].

We present the case of a 65-year-old man who had recently undergone distal pancreatectomy with splenectomy for pancreatic adenocarcinoma and was admitted with septic shock. CT imaging revealed multiple collections in the splenectomy and pancreatic tail region. Several surgical drains were placed without success, as the collections persisted after a few days. A high-output pancreatic fistula was suspected, and an Endoscopic Retrograde Cholangiopancreatography (ERCP) was requested to facilitate drainage of the collections.

Endoscopy During ERCP, selective cannulation of the Wirsung duct was achieved using a reverse double-guidewire technique. The duct appeared shortened (5–6 cm) and displaced as a result of the prior surgery. Contrast injection demonstrated leakage from the remnant of the Wirsung duct and its branches, likely communicating with the described collections. A 5 cm × 5 Fr plastic pancreatic stent was placed, with abundant pancreatic juice observed flowing through the papilla. A follow-up CT scan one week later showed a marked reduction in the size of the surgical bed collections, with the stent in good position and no ductal dilatation.

The patient remains stable, showing good clinical progress, pending complete resolution of the collections.

Conclusion Endoscopic drainage of collections secondary to pancreatic leaks via ERCP may represent an effective therapeutic option, potentially reducing the need for repeat surgical interventions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP104 Clinical & Procedural Predictors of ERCP Technical Success & Adverse Events in Adults

Authors Mehra V[1], Khalaf K[1], Youssef M[1], Bucheeri MAGA[2], Li H[1], May G[1], Mosko J[3], Calo N[1]
Institutes 1 St. Michael's Hospital, Toronto, Canada; 2 University of Toronto, Toronto, Canada; 3 Division of Gastroenterology, St. Michael's Hospital, Toronto, Canada
DOI 10.1055/s-0046-1821431

Aims According to the WHO, by 2050 the global population aged 60 years & older is projected to double, reaching ~2.1 billion people. This demographic shift is expected to increase the demand for invasive medical procedures among older adults. Endoscopic retrograde cholangiopancreatography (ERCP) remains a cornerstone intervention in the management of pancreaticobiliary disorders & age-associated outcome data is scarce. We aimed to identify determinants of ERCP technical success & adverse events among patients < 60 & ≥ 60 years, as per WHO definition of older adults.

Methods Data from consecutive patients' (> 18 years) index ERCP at Saint Michael's Hospital, a large tertiary centre in Toronto, Canada from 2010-2020

were retrospectively analysed. The primary outcome was ERCP's technical success & the secondary outcome was the occurrence of adverse events (post-ERCP pancreatitis, bleeding, perforation, or abdominal pain). Patients were stratified by age into 2 subgroups: < 60 years & ≥ 60 years. To facilitate interpretation, a continuous age term scaled per 10-year increase was created. To identify independent predictors, univariable & multivariable logistic regression were constructed for the primary outcome. Firth penalized logistic regression was applied for adverse events due to their rarity. ORs & 95 % CIs were reported.

Results Among patients aged ≥ 60 years, altered anatomy (OR 0.17, 95 % CI 0.11-0.25), use of non-duodenoscope instruments (OR 0.42, 95 % CI 0.22-0.83), history of cancer (OR 0.69, 95 % CI 0.54-0.90), & liver-related conditions (OR 0.60, 95 % CI 0.38-0.99) were independently associated with reduced odds of technical success. Among patients aged < 60 years, altered anatomy (OR 0.16, 95 % CI 0.07-0.36), use of non-duodenoscope instruments (OR 0.35, 95 % CI 0.14-0.90), but also presence of pancreatic disease (OR 0.56, 95 % CI 0.34-0.95) was associated with lower odds of success and female sex was associated with higher odds of success as compared to males (OR 1.52, 95 % CI 1.10-2.09). Among patients aged < 60, 5.8 % experienced adverse events as compared to 6.1 % among those aged ≥ 60. Increasing age (OR 1.26, 95 % CI 1.04–1.54) & pancreatic ductal indication (OR 2.54, 95 % CI 1.33–4.60) were associated with increased odds of adverse events in patients aged < 60 years. Among those aged ≥ 60 years, general anaesthesia (OR 4.93, 95 % CI 1.20–16.23) predicted higher adverse events.

Conclusions These findings highlight that both patient-related comorbidities and procedure-related factors influence ERCP success and safety differently across age strata. Recognition of these may help guide procedural planning, patient counselling and operator allocation.

Conflicts of Interest Dr. Jeffrey Mosko received research support from Boston Scientific and ERBE, and speaker honouraria and consulting fees from Boston Scientific, ERBE, Fuji, Medtronic, Pendopharm, and Steris.

eP105 Bleeding during and after ERCP? A real world study evaluating clinical practice guidelines for anticoagulant and antiplatelet drugs

Authors Voulgaris T[1], Tribonias G[2], Karamanolis G[1], Papanikolaou I[1], Polydorou A[1], Vezakis A[1]

Institutes **1** B Surgical Unit of National and Kapodistrian University, Areteion Hospital, Endoscopy department, Athens, Greece; **2** Gastroenterology Department, Korgialeneio-Benakeio Hellenic Red Cross Hospital, Athens, Greece

DOI 10.1055/s-0046-1821432

Aims Anticoagulants according to guidelines play a role in the development of bleeding during and following Endoscopic Retrograde Cholangiopancreatography (ERCP). At the same time it is recommended that antiplatelets with the exception of aspirin should be also discontinued before ERCP. Aim of our study was to evaluate the impact of following these guidelines in a real world setting.

Methods We analysed prospectively documented clinical, epidemiological and ERCP data from consecutive patients (n = 3147, mean age:68 ± 16, Females:51 %), with an intact papilla who were submitted to an ERCP during a 20 years-period. Data analysis and collection was executed on 2025. In patients submitted to ERCP from 2000 until 2011 (period A n = 1521,) all anticoagulants and antiplatelet drugs were arrested before ERCP while in patients submitted to ERCP from 2012 until 2020 (period B, n = 1626) aspirin was not arrested before ERCP.

Results Antiplatelet use did not differ between the two periods (7.7 % respectively, p = 1.000) while anticoagulants were used numerically but not statistically significantly more often in the period B (6.5 % vs 5 %, p = 0.096, συνολικά 5.8 %). Bleeding during ERCP was observed in total in 33.3 % and was observed more commonly in period B B (40.9 % vs 25.9 %, p < 0.001), upon periampullary diverticulum existence (37.9 %), when antiplatelet (if yes 43.4 % vs 32.5 % if not used, p < 0.001) or anticoagulant drugs were used (if yes 42.0 % vs 32.8 % if not used, p = 0.012) and if needle knife (NK) was used (if yes 41.5 % vs 28.6 % if not used, p < 0.001). All the above mentioned factors were independently correlated with intraprocedural bleeding during ERCP. (PAD: OR:1.354, p = 0.002, antiplatelet use: OR:1.323, p = 0.005, anticoagulant use: OR:1.275, p = 0.049, NK use: OR:1.610, p < 0.001) The rate of clinical significant bleeding post ERCP was in total 1.2 % without difference between the two periods (B:1.2 % vs A:1.3 %, p = 0.749), while it was observed more commonly if intraprocedural bleeding occurred (if yes 2.7 % vs 0.5 % if not used, p < 0.001) as also upon anticoagulant use (if yes 6.7 % vs 0.9 % if not used, p < 0.001) but not antiplatelet use (if yes 1.7 % vs 1.2 % if not used, p = 0.544), needle knife use (if yes 1.5 % vs 1.1 % if not used, p = 0.320) or the existence of a periampullary diverticulum (if yes 1.3 % vs 1.2 % if not used, p = 0.998). Both intraprocedural bleeding and anticoagulant usage were independent factors correlated with clinical significant bleeding post ERCP (OR:4.842, p < 0.001 and OR:1.855, p < 0.001 respectively).

Conclusions The policy of not arresting aspirin before ERCP is correlated with increased rate of intraprocedural bleeding but is not a factor predisposing patients to clinical significant bleeding. Anticoagulant use is both correlated with intraprocedural and clinical significant bleeding.

Abstract Text

Appendiceal mucocele is a rare condition characterized by the obstructive enlargement of the appendix due to accumulation of mucin within its lumen [1–7]. A 65-year-old patient following a positive fecal occult blood test underwent a colonoscopy that revealed a appendix's subepithelial tumor. A first CT scan confirmed the endoscopic suspicion.Subsequently, he was referred to our unit to perform ESD.The new colonoscopy showed a 2 cm subepithelial tumor, covered by normal mucosa with a single whitish erosion.Initially, the evaluation of the lesion's consistency was performed using foreign forceps, and when we pressed a large amount of mucus came out, with complete disappearance of the mass. Five weeks later, a second CT scan confirmed the disappearance of the mucocele.

eP107 ERCP: Does Patient Position Count?

Authors Aouroud H[1], Aouroud M[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1821434

Aims Endoscopic retrograde cholangiopancreatography (ERCP) is conventionally performed in the prone or left lateral position (PP/LLP), providing optimal anatomical alignment and easier biliary cannulation. However, the supine position (SP) may facilitate airway management and anaesthetic safety, particularly in patients with obesity, respiratory compromise, or recent abdominal surgery. This study aimed to compare the efficacy, safety, and procedural outcomes of ERCP according to patient positioning in a tertiary Moroccan centre.

Methods A retrospective observational study was conducted at the Hepato-Gastroenterology Department, Mohammed VI University Hospital, Marrakech, from January 2021 to October 2025. A total of 738 consecutive ERCPs were analysed. Positions used: prone/lateral (PP/LLP, *n = 671*, 91 %) and supine (SP, *n = 67*, 9 %). Data collected included demographics, indication, cannulation success, procedure duration, and adverse events (cardiopulmonary events, post-ERCP pancreatitis [PEP], bleeding, perforation). Statistical analysis was performed using SPSS 26.0, with $p < 0.05$ considered significant.

Results Mean age was 58 ± 13 years, with 56 % females. Main indications were choledocholithiasis (62 %), malignant obstruction (24 %), benign strictures (9 %), and others (5 %). Cannulation success was significantly higher in the prone/lateral group (93.1 % vs 88.0 %; *p = 0.04*). Mean procedure time was comparable (32 ± 10 min vs 34 ± 12 min; *p = 0.27*). Cardiopulmonary events occurred in 2.6 % overall (PP/LLP = 2.4 %, SP = 2.9 %; *p = 0.71*). PEP occurred in 4.6 % (PP/LLP = 4.5 %, SP = 5.2 %; *p = 0.56*). Bleeding occurred in 1.8 % (1.7 % vs 2.3 %; *p = 0.63*), and perforation in 0.5 % (0.4 % vs 0.8 %; *p = 0.48*). No procedure-related mortality was recorded.

Conclusions Over this four-year experience, the prone/lateral position provided a higher ERCP success rate without prolonging procedure time or increasing complications. The supine position remains a safe and comfortable alternative for selected high-risk patients when prone positioning is not feasible. A patient-tailored strategy is recommended to optimise both technical performance and anaesthetic safety.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP108 Acute ectopic pancreatitis following EUS-guided fine needle biopsy of a duodenal subepithelial lesion: An exceedingly rare iatrogenic complication

Authors Wang R[1], Harkirat S[1]
Institute 1 UPMC Mercy, Pittsburgh, United States of America
DOI 10.1055/s-0046-1821435

Background and Aims Ectopic pancreas is an uncommon subepithelial lesion typically located in the duodenum or gastric antrum. Although EUS-guided tissue acquisition can assist in differentiating these lesions from gastrointestinal stromal tumors or neuroendocrine neoplasms, biopsy of ectopic pancreatic tissue may, in rare instances, precipitate acute inflammation. We report a unique case of acute ectopic pancreatitis triggered by EUS-guided fine needle biopsy (EUS-FNB) of a duodenal lesion, underscoring the importance of procedural awareness and post-biopsy monitoring [1–6].

Case Description A 55-year-old man with a history of coronary artery disease and GERD presented with right upper quadrant pain. Cross-sectional imaging revealed a 1.9 cm ovoid lesion in the distal duodenum, initially suspected to be a gastrointestinal stromal tumor. EUS demonstrated a 19 mm well-defined hypoechoic submucosal lesion arising from the muscularis propria, containing small anechoic foci suggestive of ductal elements. Under Doppler guidance, four passes were made using a 22-gauge SharkCore FNB needle. No immediate complication occurred. Within 6 hours post-procedure, the patient developed worsening abdominal pain and low-grade fever. Laboratory testing showed mild lipase elevation (59 U/L). CT abdomen revealed duodenal wall thickening and perilesional fat stranding, consistent with localized pancreatitis. The patient was managed conservatively with bowel rest, intravenous fluids, and analgesia, with full recovery within 72 hours. Histopathology confirmed benign pancreatic acinar and ductal tissue, diagnostic of ectopic pancreas.

Results The clinical, imaging, and histologic correlation established the diagnosis of acute ectopic pancreatitis secondary to EUS-FNB. At two-month follow-up, the patient remained asymptomatic without recurrence.

Conclusions Ectopic pancreatitis following EUS-guided biopsy is exceptionally rare, with only isolated cases reported in the literature. This case illustrates how needle-induced ductal injury within ectopic pancreatic tissue can provoke acute inflammation. Awareness of EUS features characteristic of ectopic pancreas should guide procedural decision-making and may prevent unnecessary tissue acquisition.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP109 Endoscopic Ultrasound-Guided Diagnosis and Molecular Characterization of Pancreatic Perivascular Epithelioid Cell Tumor (PEComa) Harboring TSC2 Mutation: Expanding the Diagnostic and Therapeutic Spectrum

Authors Wang R[1], Harkirat S[1]
Institute 1 UPMC Mercy, Pittsburgh, United States of America
DOI 10.1055/s-0046-1821436

Background: Perivascular epithelioid cell tumors (PEComas) are rare mesenchymal neoplasms characterized by epithelioid or spindle cells co-expressing melanocytic and smooth muscle markers. Pancreatic PEComas are exceedingly uncommon, with limited data guiding diagnosis and management. Mutations in TSC1/TSC2 lead to mTOR pathway activation, identifying a potential target for mTOR inhibitors such as everolimus and temsirolimus. Accurate endoscopic ultrasound (EUS) evaluation and molecular profiling are critical for diagnosis and therapeutic planning.

Case Presentation: A 37-year-old woman undergoing pelvic MRI for chronic pelvic pain was found to have a 4.1 cm enhancing mass at the inferolateral aspect of the pancreatic head. Cross-sectional imaging and ^68Ga-DOTATATE

PET were indeterminate for neuroendocrine tumor. EUS revealed a well-defined, hypoechoic lesion without vascular invasion or ductal dilation. EUS-guided fine-needle biopsy (FNB) demonstrated epithelioid cells with eosinophilic cytoplasm and absent atypia, mitoses, or necrosis. Immunohistochemistry showed strong positivity for HMB-45, Melan-A, MITF, and SMA, with patchy desmin, consistent with PEComa. Next-generation sequencing identified a pathogenic TSC2 frameshift mutation (p.R1355Wfs*60), microsatellite stability, and low tumor mutational burden (4.4 mut/Mb). The presence of a concurrent left renal angiomyolipoma suggested possible syndromic association with tuberous sclerosis complex (TSC). The patient underwent robotic-assisted enucleation, and final histopathology confirmed PEComa. A minor postoperative pancreatic leak resolved with conservative management [1–4].

Discussion: EUS-FNB plays a pivotal role in the minimally invasive diagnosis of pancreatic PEComa, enabling both histologic and molecular characterization. The identified TSC2 mutation confirms mTOR pathway dysregulation, supporting the rationale for targeted therapy with mTOR inhibitors in unresectable or recurrent disease. Prior reports demonstrate durable responses to everolimus and temsirolimus, highlighting their emerging role in the management of PEComas. In this case, complete resection achieved curative outcome, but the genomic findings underscore the importance of precision oncology in follow-up planning.

Conclusion: This case illustrates the diagnostic utility of EUS-guided biopsy coupled with molecular profiling in identifying pancreatic PEComa with actionable TSC2 mutation. Integration of EUS pathology and genomic testing not only establishes definitive diagnosis but also guides potential targeted therapy. Recognition of TSC-related features is essential for comprehensive evaluation and multidisciplinary management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP110V Efficacy of Thermofusion Technique in the Management of Grade IV Internal Hemorrhoids

Authors Harrak N[1], Acharki M[2], Salihoun M[3], Kabbaj N[2]

Institutes 1 Ibn Sina Hospital, Mohammed V University in Rabat, Rabat, Morocco; 2 Ibn Sina University Hospital, Rabat, Morocco; 3 Rabat, Morocco

DOI 10.1055/s-0046-1821437

Abstract Text

Hemorrhoids represent a common proctologic condition often requiring surgical management, particularly Grade IV. Thermofusion using the Ligasure device has emerged as an effective, minimally invasive technique ensuring precise hemostasis with limited thermal spread. We report the case of a 34-year-old male presenting rectal bleeding andanemia. Examination confirmed three internal Grade IV hemorrhoids. Thermofusion hemorrhoidectomy was performed under spinal anesthesia. The procedure achieved complete hemostasis, preserved sphincter integrity, and required no sutures. Postoperative recovery was uneventful, with same-day discharge and satisfactory healing at 3 weeks. Complete mucosal recovery occurred by 6 weeks. Thermofusion demonstrates a safe, efficient, and tissue-sparing alternative to conventional hemorrhoidectomy.

eP111 The effectiveness of the MAP(ASH) score in predicting clinical outcomes in patients with acute variceal bleeding

Author Eruzun H[1]

Institute 1 Samsun Training and Research Hospital, Department of Gastroenterology, Samsun, Türkiye

DOI 10.1055/s-0046-1821438

Aims Acute variceal bleeding is one of the most fatal complications of cirrhosis. Accurate risk stratification is crucial to guide management and predict prognosis. Most existing scoring systems have limitations due to subjective variables and difficulties in practical application. The aim of this study was to evaluate the prognostic performance of the MAP(ASH) score, a novel and bedside applicable system previously validated in nonvariceal upper gastrointestinal bleeding, in patients with acute variceal bleeding [1].

Methods Between January 2019 and December 2024, 681 patients admitted with suspected upper gastrointestinal bleeding were retrospectively screened. Active variceal bleeding was confirmed in 162 patients, of whom 66 with complete data were included. The MAP(ASH) score was calculated by assigning 2 points for hemoglobin < 10 g/dL, systolic blood pressure < 90 mmHg, and albumin < 2.5 g/dL, and 1 point each for Glasgow Coma Scale < 15, ASA score ≥ 2, and pulse > 100/min (range 0–9). Demographics, endoscopic findings, variceal characteristics, MELD-Na, CTP, and MAP(ASH) scores were recorded. Outcomes included in hospital and 6 week mortality and rebleeding.

Results Of the patients, 60 % were male with a mean age of 63 years. The most common etiology of cirrhosis was steatotic liver disease (43.9 %), followed by hepatitis B (27.3 %). Endoscopic band ligation was performed in 93 %. Patients who died or rebled during hospitalization or within 6 weeks had significantly higher MAP(ASH), CTP, and MELD-Na scores. A MAP(ASH) score ≥ 3.5 predicted in hospital and 6 week mortality as well as rebleeding with sensitivity and specificity exceeding 70 %.

Conclusions MAP(ASH) is a simple and practical scoring system that does not rely on subjective parameters and can be easily applied at the bedside. Our findings suggest that it performs comparably to established prognostic models in cirrhosis. Validation in larger cohorts may further support its use in routine clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

[1] Redondo-Cerezo E, Vadillo-Calles F, Stanley AJ et al. MAP(ASH): A new scoring system for the prediction of intervention and mortality in upper gastrointestinal bleeding. J Gastroenterol Hepatol 2020; 35 (1): 82–89. doi:10.1111/jgh.14811

eP112 Biliary Stent Migration Resulting in Colonic Perforation

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Mustacchia P[1]

Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1821439

Introduction Endoscopic biliary stents are placed to relieve obstruction secondary to CBD stones, strictures and malignant obstruction. Common complications include stent occlusion and migrations. Perforation due to dislodged stent is a rare complication. The most common site of a migrated biliary stent is the duodenum, whereas complications in the rest of the small intestine or colon are rare. Routine prosthesis removal is done in 3 months but can be extended to 6 months.

Case Description/Methods 87F with history of diverticulosis initially presented with gallstone pancreatitis for which she underwent ERCP with sphincterotomy, balloon sweep with stone extraction and biliary stent placement[A 10 Fr x 7 cm biliary stent]. Patient tolerated the procedure without any complications. Two months later ERCP was repeated for stent removal, however old stent was not found in place. Extended sphincterotomy, s/p lithotripsy and balloon sweeps were performed. Some residual stones remained in the distal CBD. A 10 Fr x 7 cm biliary stent was placed. CT Abdomen with contrast was done revealing dislodged biliary stent in the sigmoid with intraluminal remnants in the sigmoid colon. Endoscopic retrieval was performed and the defect was closed with a 16mm Hemoclip.

Discussion Stent migration occurs in 6-8 % of the cases, only 1 % of the migration leads to bowel injury. The risk of migration is higher if a biliary sphincterotomy is performed while placing the stent. A review of literature revealed that the risk of migration is the highest with straight plastic stents and low stent migration in uncovered self-expanding metallic stents. Patients usually present with abdominal pain, with/without cholestatic disease. A CT abdomen or abdominal radiograph can aid in diagnosis of stent migration. A repeat ERCP would confirm the diagnosis of migration. Endoscopic retrieval sooner is recommended regardless of the presence of complications. In complicated cases surgical intervention is mandated as early as possible. In patients with biliary stent, abdominal pain, obstruction and abscess should raise a suspicion for stent migration.

eP113 Nationwide Trends in Colon Cancer: Exploring Racial and Gender Disparities, 2019–2022

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Mustacchia P[1]
Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America
DOI 10.1055/s-0046-1821440

Aims Colon cancer incidence demonstrates notable disparities across racial and gender groups. Certain populations, such as Black individuals, experience significantly higher risks, while gender differences further influence the likelihood of diagnosis. These disparities highlight the need for targeted interventions to address inequities and improve prevention and treatment strategies.

Methods Data from the Nationwide Admission Database (HCUP) for 2019–2022 were analyzed, encompassing 1,748,576 adult hospital admissions. Patients included in the study had a principal diagnosis of colon cancer. Logistic regression was used to assess the relationships between race, gender, and the likelihood of colon cancer diagnosis. To address multicollinearity, Variance Inflation Factor (VIF) analysis was performed, and highly collinear variables were excluded. Race categories were encoded using one-hot encoding, and gender was incorporated as a predictor. The logistic regression model, developed with Statsmodels, evaluated the significance of predictors using z-values and p-values, quantifying the independent effects of race and gender while controlling for other variables.

Results Analysis revealed significant associations between race, gender, and colon cancer incidence. Black individuals had higher odds of being diagnosed with colon cancer, whereas other racial groups exhibited lower odds. Gender differences were also evident, with females demonstrating an increased likelihood of colon cancer diagnosis. These findings provide robust evidence of demographic disparities in colon cancer risk.

Conclusions This study highlights the substantial influence of race and gender on colon cancer incidence. The elevated risk observed among African Americans underscores the need for targeted preventive measures, while the increased risk among females points to gender-specific factors requiring further investigation. These results stress the importance of incorporating race and gender considerations into strategies to reduce disparities in colon cancer burden and improve health equity

eP114 Beta-Blocker Therapy With Carvedilol Is Linked to Lower Bleeding and Readmission Rates in Cirrhosis: A Nationwide Analysis

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Mustacchia P[1]
Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America
DOI 10.1055/s-0046-1821441

Aims Carvedilol, a non-selective beta-blocker, is widely prescribed for hypertension and heart failure. Recently, its potential in preventing variceal bleeding, a severe complication in cirrhosis patients, has been investigated. With the high rates of hospital readmissions among these patients, evaluating interventions to reduce these occurrences is vital. This study uses a large-scale national dataset to assess the effects of carvedilol on variceal bleeding incidence and subsequent hospital readmissions in cirrhosis patients.

Methods We analyzed data from the Nationwide Inpatient Sample (HCUP) covering 2,858,576 adults between 2019 and 2024. The study focused on patients prescribed carvedilol, assessing its impact on variceal bleeding and readmission rates. Chi-square tests were used for categorical variables, examining carvedilol's effects on outcomes. Risk reduction was quantified using odds ratios (OR) with 95 % confidence intervals (CI). Contingency tables evaluated bleeding and readmission rates at 30 and 60 days. Statistical significance was set at $p < 0.05$.

Results Among 43,668 cirrhosis patients, those on Carvedilol (n = 19,766) had significantly lower variceal bleeding (18.3 % vs. 61.6 %) and 30-day readmissions (0.3 % vs. 51.8 %) compared to non-users (n = 23,902). At 60 days, readmissions were also reduced (1.0 % vs. 44.7 %). Carvedilol use was associated with lower odds of bleeding ($p < 0.001$), 30-day readmission (OR = 0.001, 95 % CI: 0.0008–0.0013; $p < 0.001$), and 60-day readmission (OR = 0.37, 95 % CI: 0.32–0.44; $p < 0.001$).

Conclusions This study demonstrates that carvedilol significantly reduces variceal bleeding and hospital readmission rates in cirrhosis patients. The decrease in 30-day and 60-day readmission rates suggests carvedilol provides both immediate and sustained benefits after discharge. These findings highlight carvedilol's potential as a preventive strategy for cirrhosis complications, improving patient outcomes and reducing healthcare utilization. Further research is needed to explore the mechanisms behind these effects and assess the long-term benefits of carvedilol therapy in diverse populations.

eP115 Syphilitic Colonic Involvement Mimicking Lymphoid Aggregates: Diagnostic Considerations

Authors Ram mohan RM[1], Natt D[1], Achal P[1], Magam R[2], Mustacchia P[1]
Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America
DOI 10.1055/s-0046-1821442

Introduction Syphilis is a sexually or vertically transmitted disease caused by the spirochete T. pallidum. The liver involvement is very uncommon (< 1 % of cases) and can occur in the 2º or 3º phase of the disease due to the multiplication and hematogenous spread of the spirochete to the liver. In the 2º syphilis phase, cholestasis occurs, with a typical elevation of alkaline phosphatase. Signs include pyrexia, the typical generalized rash involving the palms and the soles, and even nephrotic syndrome, not all required. In the tertiary phase, the characteristic lesions are syphilitic gummas, most commonly in the right lobe of the liver, and generally asymptomatic, but can cause compression leading to Budd–Chiari syndrome. Diagnosis includes blood tests like CBC, LFTs, blood cultures, and imaging such as sonography, CT scan, MRCP, ERCP, and percutaneous transhepatic cholangiography. Treatment includes IV antibiotics, ERCP, or surgery to open the duct and drain bile to reduce the build-up of fluid. This

case study highlights the importance of detection of early syphilitic involvement of the bile duct and liver.

Case Description/Methods A 53-year-old female with right-sided abdominal lower abdominal pain and occasional epigastric pain with bloating. She presented with maculopapular rash involving palms and soles with vague right-sided abdominal pain and left quadrant abdominal pain for 2 weeks duration associated with nausea. Treponema pallidum was found to be reactive. Colonoscopy revealed hyperplastic changes with focal lymphoid aggregate. As the patient was allergic to penicillin, doxycycline was started for 14 days.

Discussion This case was unique as it shows the importance of keeping 2°/3° syphilis on the differential diagnosis of a patient presenting with cholestatic hepatitis. Treatment for syphilis results in the resolution of biochemical abnormalities. Syphilis as a cause of hepatitis was suspected based on the characteristic liver enzyme pattern, with more prominent elevation in the alkaline phosphatase level, negative serology for hepatotropic viruses, and the rapid resolution of symptoms and biochemical abnormalities with therapy. Given liver biopsy findings in syphilitic hepatitis, such as portal and lobular inflammatory cell infiltrates, hepatocellular necrosis, cholestasis, and non-caseating granulomas are non-specific and the identification of spirochetes is challenging, a liver biopsy is not crucial for diagnosing syphilitic hepatitis or cholangitis when therapy elicits a positive response.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP116 Gastric Ulcer Healing Disparities Across Race and Language Groups: Evidence From a National Database

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Mustacchia P[1]
Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America
DOI 10.1055/s-0046-1821443

Aims This retrospective study examines the effects of race and language on the healing rates of gastric ulcers from 2021 to 2024, utilizing inpatient hospital data. By excluding patients who received endoscopic therapy, and using propensity score matching for baseline characteristic alignment, the focus shifts to the role of Proton Pump Inhibitors and sociodemographic factors in treatment outcomes. This analysis is essential for identifying disparities and improving targeted healthcare approaches.

Methods We conducted a retrospective analysis of inpatient hospital data from 2021 to 2024, focusing on patients diagnosed with gastric ulcers via endoscopy. Those who received endoscopic therapy were excluded. We utilized propensity score matching to align baseline characteristics of the cohort. All participants received 40mg of Proton Pump Inhibitors daily for 8 weeks, followed by a repeat endoscopy. The research specifically investigated the influence of race and language on ulcer healing rates, incorporating patient demographics (gender, race, language) and post-treatment outcomes. Descriptive statistics were used to evaluate healing rates across demographic groups, and logistic regression analyzed the impact of gender and race on healing, including coefficients and p-values to determine statistical significance.

Results This study included 350 patients who underwent pre- and post-endoscopy for gastric ulcer management, exploring the impact of race and language on healing outcomes. Race significantly influenced healing rates, with Hispanics experiencing the lowest rates ($P = 0.012$). Patients with English as a second language also showed lower healing rates compared to native speakers ($P = 0.035$). The regression analysis revealed a strong positive association between having English as a first language and healing likelihood (Coefficient = 3.59).

Conclusions The significant differences in ulcer healing rates among racial groups and between English-speaking and non-English-speaking patients highlight systemic disparities in healthcare outcomes. The notably lower healing rates in Hispanics and those for whom English is a second language suggest that sociolinguistic barriers contribute to treatment inequity. These results underscore the necessity for culturally competent care and language-specific interventions to enhance treatment effectiveness and equity in healthcare services, aiming to mitigate the observed disparities in gastric ulcer management.

eP117 AI-Driven Innovation in Gastroenterology: Insights From ChatGPT-4.0 and GLASS AI

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Mustacchia P[1]
Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America
DOI 10.1055/s-0046-1821444

Aims In the rapidly evolving field of Gastroenterology, AI tools such as GLASS AI and ChatGPT 4.0 are becoming increasingly vital. This study contrasts these technologies, exploring their effects on diagnostic accuracy, patient care, and educational initiatives. GLASS AI excels in image-based diagnostics and procedural support, whereas ChatGPT 4.0 efficiently processes vast amounts of medical literature and patient information, enhancing decision-making. Grasping their unique capabilities is key to integrating AI into gastroenterological practices effectively, thus improving patient outcomes and healthcare delivery.

Methods Our research conducted an in-depth comparative analysis of ChatGPT 4.0 and GLASS AI, focusing on critical factors like "Ease of Use," "Reliability," "Response Time," and "Overall Experience." We employed a Likert scale ranging from 1 (low performance) to 5 (high performance) to assess their effectiveness. The evaluation covered 50 different clinical scenarios in Gastroenterology and Hepatology. Five seasoned reviewers thoroughly assessed the outcomes, followed by paired t-tests for each category to perform a detailed and systematic analysis of the results, providing insightful findings on the comparative performance of these AI technologies.

Results Our data analysis revealed statistically significant differences between ChatGPT 4.0 and Glass AI in several categories. The paired t-tests results for "Ease of Use (T-test: 4.41, $P < 0.01$)," "Reliability (T-test: 4.425, $P < 0.01$)," "Response Time (T-test: 4.091, $P < 0.01$)," and "Overall Experience (T-test: 3.12, $P < 0.01$)" indicate significant discrepancies in performance ratings between the two systems, which are unlikely to occur by chance.

Conclusions The comparative analysis between GLASS AI and ChatGPT 4.0 in Gastroenterology highlights each AI tool's unique strengths and efficiencies. Significant statistical differences in ease of use, reliability, response time, and overall user experience demonstrate ChatGPT 4.0's superiority over GLASS AI. Adopting a hybrid approach that combines the advantages of both technologies could offer the greatest benefits in advancing Gastroenterology. This study underscores the importance of understanding the specific capabilities of various AI tools to maximize their potential in healthcare.

eP118 Digital Platforms Driving Change: The Role of YouTube and TikTok in Colon Cancer Education

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Mustacchia P[1]
Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America
DOI 10.1055/s-0046-1821445

Aims Social media platforms like YouTube and TikTok have become significant conduits for health information dissemination, impacting public awareness of critical issues such as colon cancer screening. This study examines how these platforms influence colon cancer awareness, comparing the quality and reliability of the content presented. By evaluating videos based on their educational value and trustworthiness, we aim to discern the potential of each platform

Endoscopy 2026; 58: S1–S1041

to effectively educate and guide patients concerning colon cancer prevention and screening practices.

Methods Our study at Nassau University Medical Center, New York, analyzed "colon cancer screening awareness" videos on YouTube and TikTok. We selected English-language videos with relevant audio, assessing quantitative aspects like views, likes, and subscriber counts, and qualitative aspects, classifying content as scholarly or personal. We used DISCERN, GQS, and PEMAT to evaluate credibility and quality, with intraclass correlation among seven researchers ensuring consistency. Statistical analyses were conducted using Microsoft Excel and IBM SPSS, highlighting differences in content quality between YouTube and TikTok.

Results Our analysis of 220 videos on colon cancer awareness (110 from YouTube and 110 from TikTok) revealed significant differences in quality and reliability. YouTube videos scored higher in DISCERN (45.27 ± 17.10 vs. 31.09 ± 13.42, $p < 0.012$), PEMAT (3.89 ± 0.70 vs. 2.48 ± 0.85, $p < 0.022$), and GQS (3.98 ± 0.55 vs. 2.58 ± 0.74, $p < 0.041$) compared to TikTok. These results suggest that YouTube provides more dependable and higher-quality information for patients seeking knowledge about colon cancer.

Conclusions Our findings underscore significant discrepancies in the educational quality of colon cancer awareness videos on YouTube and TikTok. YouTube's superior scores in DISCERN, PEMAT, and GQS reflect its higher reliability and quality as an educational resource. This suggests that viewers seeking information about colon cancer screening will likely find more accurate and actionable content on YouTube. The results advocate for healthcare professionals to guide patients toward more reliable sources on social media for health information.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP119 Obesity as a Risk Factor for Diverticulitis: Insights From a Nationwide HCUP Database Analysis

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Mustacchia P[1]
Institutes **1** Nassau University Medical Center, East Meadow, United States of America; **2** Nassau University Medical Center, East Meadow, NY, USA, United States of America
DOI 10.1055/s-0046-1821446

Aims This study analyzes data from 2,858,576 adults using the Nationwide Admission Database (HCUP) from 2019 to 2024, focusing on the incidence and readmission rates of diverticulitis within 30 and 60 days. It explores the impact of obesity—a known risk factor—alongside demographic influences like race and gender. Employing chi-square tests, logistic regression, and ROC curve analysis, the research examines how these factors correlate with diverticulitis outcomes, shedding light on their interplay in hospital readmissions.

Methods Data were collected from the HCUP database, reflecting hospital admissions spanning 2019 to 2024 for 2,858,576 adults. The study primarily investigates the incidence of diverticulitis and subsequent readmission rates at 30 and 60 days, while analyzing the effects of obesity, race, and gender on these outcomes. Chi-square tests were used to compare incidence and readmission rates between obese and non-obese groups across different demographics. Logistic regression assessed the influence of gender and race on the probability of readmissions at specified intervals, integrating coefficients for these variables.

Results Between 2019 and 2024, HCUP's Nationwide Admission Database was used to analyze 2.8 million adult hospital admissions, identifying 234,024 diverticulitis cases, with 112,014 classified as obese (BMI > 30). Chi-square tests showed significant differences in 30- and 60-day readmission rates between obese and non-obese patients ($p < 0.001$). Diverticulitis incidence also varied by obesity ($p = 0.025$). Logistic regression revealed gender and race influenced readmissions, with higher odds in females and African Americans across both 30- and 60-day intervals.

Conclusions The study confirms a strong correlation between obesity and increased readmission rates for diverticulitis, highlighting obesity's significant impact on the condition's recurrence. It also reveals gender and racial disparities in readmission rates, with females and African Americans experiencing higher rates, especially at 60 days. The ROC curves demonstrate the predictive accuracy of the models, particularly for 30-day readmissions. These findings are crucial for crafting targeted interventions that address the specific needs of these vulnerable groups, aiming to enhance outcomes and reduce healthcare costs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP120V "A Rare Case of Gastroscope Trapped inside an EUS-Hepaticogastrostomy Stent Rescued by Dual-Scope Technique"

Authors Nguyen Trong N[1], Duong P[2]
Institutes **1** BỆNH VIỆN K CƠ SỞ TÂN TRIỀU, Hanoi, Vietnam; **2** K National Cancer Hospital, Hanoi, Vietnam
DOI 10.1055/s-0046-1821447

Abstract Text

EUS-HGS stent related adverse events occur in approximately 3 % of procedures, mainly due to stent migration or dysfunction. We report the first documented case of a gastroscopy becoming trapped inside an HGS stent. A 46-year-old woman with stage IIIC ovarian cancer underwent EUS-HGS after failing ERCP. During check-up, the gastroscopy stuck inside stent lumen due to radial force and misalignment. Initial forceps retrieval failed. Another gastroscope was introduced simultaneously (dual-scope technique) to grasp the stent mesh and gently release the trapped scope without complication. This case highlights a rare complication and demonstrates the effectiveness of the dual-scope technique as a rescue approach in this situation [1–6].

DOI 10.1055/s-0046-1821448

Aims Gastrointestinal endoscopy is resource-intensive and contributes substantially to healthcare's environmental footprint. While the ESGE position statement on green endoscopy highlights the need for a more sustainable practice, concrete guidance on implementation remains limited[1]. This study explored sustainability efforts in endoscopy departments in the south-west of the Netherlands and examined barriers and facilitators influencing their adoption.

Methods Semi-structured interviews were conducted with green team members from eight endoscopy departments. Transcripts were thematically analyzed to map sustainability initiatives and implementation factors. A second interview round validated the initiative list, and sustainability coordinators provided additional hospital-wide information [1].

Results Across the eight hospitals, 73 distinct sustainability initiatives were identified, with departments having implemented a mean of 42 initiatives (range: 38–49). Frequently reported measures included reducing suction tubing and canisters (n = 8), oxygen catheters (n = 8), sterile water bottles (n = 7), and absorption pads (n = 6). All departments used strict triage protocols to prevent unnecessary procedures and addressed patient and staff travel through telemedicine and cycling incentive programs. In general, three interrelated themes affected implementation:

a. Institutional and organizational factors: barriers included conflicting policies from other disciplines (n = 6), limited time (n = 5), cost constraints (n = 4), and restrictive hospital rules (n = 4); enablers included hospital-wide alignment (n = 7), supportive leadership (n = 6), and structural resources (n = 4).

b. Behavioral and cultural factors: barriers included staff resistance (n = 7), lack of evidence (n = 6), and low prioritization (n = 5); enablers included active green teams (n = 7), visualized before-and-after results (n = 6), and protected time (n = 5).

c. System-level factors: barriers included limited influence on industry (n = 3) and national and international regulations (n = 2); enablers included collaboration across endoscopy departments regionally (n = 6), across departments within the hospital (n = 5), and the availability of empirical evidence (n = 5).

Conclusions Endoscopy departments in the south-west of the Netherlands have adopted a wide range of sustainability initiatives, primarily targeting reductions in single-use items, unnecessary procedures, and travel emissions. Despite this progress, substantial institutional, cultural, and system-level barriers persist. Advancing sustainable endoscopy will require coordinated organizational support, engaged leadership, robust evidence, and strong cross-departmental and inter-hospital collaboration.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821449

Aims Quantify patient-reported barriers relevant to **diagnostic colonoscopy** and describe recognition of colonoscopy as a CRC screening test to inform endoscopy service improvement.

Methods Cross-sectional bilingual survey (community and hospital). Adults ≥ 18 years. Analysis restricted a-priori to respondents who **had heard of CRC**. Outcomes: (1) **recognition of colonoscopy** as a screening method (Yes/No/Don't know); (2) prevalence of barrier domains (pain/bleeding concerns, embarrassment, bowel-prep aversion, anaesthesia concerns, access/distance, **cost**, information gaps, "unnecessary if asymptomatic," no doctor advice, time constraints, personal/psychological factors). Likert items dichotomised (Agree/Strongly agree = barrier present). Descriptives and exploratory comparisons (▶ **Table 1**).

▶ **Table 1** Cohort characteristics, primary outcome, and barrier prevalence

Variable	Value
Age, median (IQR), years	58 (53–62)
Male	51 %
Health insurance	53 %
Recognises colonoscopy as a CRC screening method	62.5 %

Analysis set: respondents who had heard of colorectal cancer (n = 208).

Results N = 304; analysis set **n = 208** (heard of CRC). Median age **58** (IQR 53–62); **51 %** male; health-insurance **53 %**. **Recognition of colonoscopy** as a screening method: **62.5 %**. Most prevalent barriers: **doctor did not advise screening 73 %**, **unaware of benefits 72 %**, **screening expensive 61 %**, **unnecessary if asymptomatic 59 %**, **fear of diagnosis 46 %**, **pain/bleeding concerns 45 %**, **distance/unavailability 42 %**, **embarrassment 30 %**, **time constraints 30 %**. Exploratory comparisons showed lower recognition among those endorsing "I do not deserve screening" (52 % vs 64 %) (▶ **Table 2**).

▶ **Table 2** Barrier domains (Agree/Strongly agree)

Barrier domain	Prevalence
Doctor did not advise screening	73 %
Unaware of benefits of screening	72 %
Screening is expensive / unaffordable	61 %
Screening unnecessary if asymptomatic	59 %
Fear of diagnosis	46 %
Pain / bleeding concerns	45 %
Distance / unavailability of services	42 %
Embarrassment	30 %
Time constraints / too busy	30 %

Note: Barrier items measured on a 5-point Likert scale; Agree/ Strongly agree treated as barrier present.

Conclusions Fewer than two-thirds recognise colonoscopy as a screening test; **information, access, and cost** barriers dominate. Endoscopy services should implement standardised pre-assessment education, referrer prompts, cost/ transport pathways, and targeted counselling on pain/anaesthesia to improve booking conversion and reduce DNAs for diagnostic colonoscopy [1–4].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP123 Ectopic Peri-anastomotic Gastric Variceal Bleeding due to Segmental Portal Hypertension after Roux-en-Y Reconstruction: A Case Report

Authors Barros Santos P[1], Serrano M[1], Currais P[1], Rosa I[1]

Institute 1 Oncology Institute Francisco Gentil, Lisboa, Portugal

DOI 10.1055/s-0046-1821450

Background Segmental (sinistral) portal hypertension is a rare and often under-recognized cause of upper gastrointestinal bleeding, usually secondary to splenic or portal branch obstruction. We describe a unique case of ectopic peri-anastomotic gastric variceal bleeding after subtotal gastrectomy and Roux-en-Y reconstruction, successfully managed with endoscopic band ligation.

Case Presentation A 76-year-old man, with no relevant medical history, underwent subtotal gastrectomy for gastric adenocarcinoma in July 2024. The patient remained asymptomatic until October 2024, when he developed postprandial fullness, nausea and weight loss. In April 2025, he underwent conversion from Billroth II procedure to a Roux-en-Y due to symptomatic gastric stump gastritis. Pre-surgical CT scan was unremarkableIn September 2025, a routine postoperative surveillance endoscopy was performed. The examination revealed large esophageal and gastric varices (GOV2), as well as peri-anastomotic ectopic gastric varices (IGV2). During the procedure, one of the IGV2 developed sudden spurting bleeding. Hemostasis was achieved with a single band ligation, as cyanoacrylate was unavailable. The patient completed a 5-day continuous infusion of octreotide and received prophylactic ceftriaxone. No rebleeding occurred nor transfusion was required. CT angiography demonstrated a patent portal vein with a markedly thinned left portal branch and atrophy of hepatic segments II–III, consistent with localized (sinistral) portal hypertension. The spleen and the splenic vein were unremarkable. He was discharged on carvedilol 3.125 mg twice daily, adjusted due to bradycardia [1, 2].

At one-month follow-up, the patient remained asymptomatic and free of recurrent bleeding. Transient elastography (FibroScan) confirmed the absence of chronic liver disease (F0).

Discussion Ectopic gastric varices secondary to segmental portal hypertension are extremely uncommon, particularly after gastric surgery. In this case, focal obstruction of the left portal branch likely resulted in localized venous hypertension and collateral veins formation at the gastrojejunal anastomosis. The absence of cirrhosis and normal spleen size supported a diagnosis of left-sided (segmental) portal hypertension probably due to the surgical procedure. Endoscopic band ligation, though less commonly used for ectopic varices, proved to be an effective alternative when cyanoacrylate was unavailable.

Conclusion This case highlights a rare cause of variceal bleeding following Roux-en-Y reconstruction, secondary to segmental portal hypertension. Endoscopic band ligation provided effective hemostasis and may represent a valuable therapeutic option in similar challenging scenarios.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP124 Endoscopic prediction of Helicobacter pylori infection: time to Biopsy-sparing Diagnostic Model

Authors Capasso M[1], Romeo S[1], Bertè R[1], Metelli F[1], Alicante S[1], Cerrone A[1], Bertolazzi S[1], Londoni C[1], Manfredi G[1]

Institute 1 Gastroenterology and Digestive Endoscopy Department, Maggiore Hospital, Crema (CR), Italy

DOI 10.1055/s-0046-1821451

Aims*Helicobacter pylori* (*H. pylori*) infection is one of the most prevalent chronic bacterial infections worldwide [1]. The literature describes several endoscopic signs may predict *H. pylori* status [2, 3]. However, random biopsies according to Sydney system are still widely used for its determination. Aim is to evaluate the diagnostic performance of endoscopic characteristics in predicting *H. pylori* infection.

Methods This was a monocentric prospective study including all consecutive patients who underwent upper-GI endoscopy in one-year timeframe. Every procedure was performed by trained endoscopists in order to describe regular arrangement collecting venules (RAC), fundic gland polyps (FGPs), linear streaks, hematin spots and diffuse redness. *H. pylori* infection was histologically investigated.

Results A total of 421 patients were enrolled, according to inclusion criteria (F: 222, 52.7 %, median age 54.1 y.o.). The presence of RAC both in greater curvature and in lesser curvature, FGPs and diffuse redness were significantly associated with higher prevalence of *H. pylori* infection ($p < 0.0001$). Considering the interaction effect by the optical evidence of intestinal metaplasia, RAC and FGPs maintained their significance with an OR of 0.05 (0.02-0.13) and 0.11 (0.03-0.53), respectively. All the characteristics described showed a high negative predictive value (> 90 %). Lastly, according to a probabilistic model, a ROC curve was built with AUROC 0.893 (95 % CI: 0.854–0.932).

Conclusions The proposed endoscopic assessment has a high predictive capability for *H. pylori* infection, whereas the presence of RAC and FGPs are the most important and reliable indicators of H. pylori status. Our findings may represent a first step toward avoiding unnecessary random biopsies, promoting a more accurate endoscopic examination focused on the careful assessment of the gastric mucosa.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP125 Cricopharyngeal Peroral Endoscopic Myotomy (CP-POEM) As A New Emerging Minimally Invasive Treatment for Cricopharyngeal Bar – Experience of a Tertiary Centre of a South European Country

Authors Borges Chaves C[1], Vidal Lima F[1], Ribeiro H[1], Elisa GS[2, 1], Gravito-Soares M[2, 1], Amaro P[1], Souto P[1], Narra Figueiredo P[2, 1]
Institutes **1** Gastroenterology Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; **2** Faculty of Medicine, University of Coimbra, Coimbra, Portugal
DOI 10.1055/s-0046-1821452

Introduction Cricopharyngeal bars represent an uncommon and frequently underrecognized cause of oropharyngeal dysphagia, resulting from dysfunction or fibrosis of the cricopharyngeal muscle. Conventional management options include open surgical myotomy or endoscopic dilation. Cricopharyngeal peroral endoscopic myotomy (CP-POEM) has emerged as a minimally invasive technique [1].

Case Report We report two cases of symptomatic cricopharyngeal bar successfully treated with CP-POEM, with mean age of 76 ± 11.3 years-old and Eckardt score of 5.5 ± 3.5. One patient was under anticoagulation with apixaban due to history of ischemic stroke and atrial fibrillation. One of the cases underwent botulinum toxin therapy prior to CP-POEM with temporary symptomatic response. All procedures were performed using a triangle-tip(TT)-knife (Olympus) with SprayCoag 2.5 mode for submucosal tunnelling and Endocut Q 2.0 for cricopharyngeal miotomy (Vio3, ERBE). Hypopharyngeal mucosotomy was closed using through-the-scope clips. Mean procedure time was 103.5 ± 26.2 minutes. In one case, due to space conflict and significant crycopharingeal bar hypertonia, it was necessary to remove the cap trapped in the distal portion of the tunnel with foreign body forceps. In both cases, a temporary subcutaneous emphysema was recorded with capnoperitoneum requiring percutaneous drainage in one case. A single-dose of intravenous corticosteroids after the procedure facilitated extubation of patients due to a significant edema of the hypopharynx and arytenoids. There were no complications after the procedure. At 3.5 ± 3.5 months follow-up, both patients were completely asymptomatic (Eckardt score of 0) with improvement of overall quality of life. We present endoscopic and imaging iconography.

Conclusion CP-POEM is a minimally invasive endoscopic option that appears to be effective and safe for patients with symptomatic cricopharyngeal bars. In both cases, CP-POEM resulted in rapid and sustained symptom resolution, without major complications. This technique should be considered as first-line approach with improvement in symptom control and lower morbidity than conventional techniques. Larger studies with longer follow-up are warranted to confirm long-term outcomes in broader clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP126 Diagnostic yield of bile cultures during ERCP in patients with acute cholangitis

Authors Fernandez Martos R[1], Martin Arranz E[1], Amiama Roig C[1], Larrea E[1], Diaz-Pollan B[1], Pineda-Pampliega J[2], Martin-Arranz MD[3]
Institutes **1** La Paz University Hospital, Madrid, Spain; **2** Universidad Complutense de Madrid, Madrid, Spain; **3** IdiPAZ, Inmune-mediated gastrointestinal disorders and other digestive diseases, Madrid, Spain
DOI 10.1055/s-0046-1821453

Aims Acute cholangitis is a potentially life-threatening condition that requires early empirical antibiotic therapy. In a context of increasing antimicrobial resistance, systematic bile culture sampling during ERCP could optimize antibiotic treatment. The aim of this study is to describe the microbiological profile of acute cholangitis in our setting and to evaluate the clinical impact of bile cultures on therapeutic decision-making.

Methods A prospective, descriptive, observational study was conducted at a tertiary center between 2022 and 2025. Patients diagnosed with acute cholangitis according to the Tokyo Guidelines who underwent ERCP with bile culture were included. Demographic, etiological, microbiological, and antimicrobial treatment variables were collected.

Results A total of 151 patients were included (57 % male). According to the Tokyo classification, 29 (19 %) presented with severe, 100 (66 %) with moderate, and 17 (13 %) with mild cholangitis. Fifty-five percent (55 %) had a naïve papilla, 20 % had prior ERCP without a stent, and 25 % had prior ERCP with a biliary stent. The most frequent etiology was lithiasis (82 patients, 54 %), followed by malignant stricture (46 patients, 31 %).

Bile cultures were positive in 129 cases (85 %); of these, 20 % were severe, 67 % moderate, and 13 % mild cholangitis. Conversely, in patients with severe cholangitis 90 % had positive cultures ,in 86 % of the moderate, and 77 % of the mild. Most positive cultures were polymicrobial (59 %), with a predominance of Gram-negatives (57 %), mainly Enterobacteriaceae and enterococci. Other relevant microorganisms were bacteria of the SPICE group found in 32 patients (25 %) and Candida in 12 (9 %).

The proportion of polymicrobial cultures did not differ significantly among patients with naïve papilla, prior ERCP without stent, and prior ERCP with stent ($p > 0.05$).

Among patients with positive cultures, 92 % (119 patients) had received prior antibiotics. Following microbiological results, treatment was modified in 58 % of cases (primarily via de-escalation or targeted therapy) and in 42 % via escalation or broadening of antibiotic coverage. Blood cultures were obtained in 76 patients with positive bile cultures, resulting positive in 45 (60 %) and concordant with bile culture in only 43 cases (57 %).

Conclusions Systematic bile culture collection during ERCP is a simple and efficient procedure, with a high diagnostic yield (85 %) and greater sensitivity than blood cultures. Polymicrobial infection is frequent, particularly in patients with prior ERCP, although no significant differences were observed between groups. Bile cultures allow for antibiotic therapy adjustment in a considerable number of patients, both allowing de-escalation and contributing to reduce risk of resistance development and also adjusting therapy in case of resistant or atypical microorganisms.

eP127 Diagnostic performance of a deep learning-based tool for the detection and staging of rectal cancers on endoscopic ultrasound examinations: a pilot study

Authors Montale A[1], Valvano M[1], Ghezzi A[1], Pavini N[1], Magliocco M[2], Fantazzini A[3], Rutigliani M[4], Oppezzi M[1], Stefanelli G[1], Campanale MC[1], Molini L[4], Paparo F[4]

Institutes **1** Galliera Hospital, Genova, Italy; **2** University of Genoa, Genova, Italy; **3** Camelot Biomedical, Genoa, Italy; **4** Galliera, Genoa, Italy

DOI 10.1055/s-0046-1821454

Aims Colorectal cancer is the third most common cancer in men and the second in women. Accurate loco-regional staging, primarily based on magnetic resonance imaging (MRI) and rectal endoscopic ultrasound (R-EUS), is essential for treatment planning and relies on assessing tumor depth (T) and regional lymph nodes (N) according to the TNM system. In situ (Tis) and submucosal (T1) tumors may be suitable for minimally invasive endoscopic resection, whereas up to one-third of T2 tumors present mesorectal lymph node metastases, requiring MRI for more accurate staging. Only a few studies have explored artificial intelligence, particularly deep learning (DL), for EUS-based detection and staging of rectal tumors.

Methods This prospective, single-center pilot study evaluated the diagnostic performance of a DL-based tool for detecting and staging rectal tumors on R-EUS images. The model used a convolutional neural network (CNN) with a ResNet backbone pretrained on ImageNet for image classification and segmentation. Performance was assessed using accuracy, precision, recall, F1-score, and spatial agreement metrics between model and expert segmentations (Dice similarity coefficient, DSC). The model was tested for its ability to distinguish Tis–T1 from T2–T3 tumors, and separately, Tis from all other stages.

Results Fifty patients were prospectively enrolled from May 2023 to December 2024. Tumor segmentation showed a median DSC of 0.65 (IQR 0.17). Pathological tissue detection achieved an accuracy of 0.77 (precision 0.85, recall 0.77, F1-score 0.81). For classifying Tis–T1 vs. T2–T3, accuracy was 0.64 (precision 0.88, recall 0.64, F1-score 0.74). For distinguishing Tis from other stages, accuracy reached 0.80 (precision 0.83, recall 0.89, F1-score 0.86). Mesorectal lymph node segmentation yielded a median DSC of 0.62 (IQR 0.17).

Conclusions The DL-based tool may assist less-experienced operators in identifying candidates for minimally invasive endoscopic resection. The semi-supervised training produced diagnostic performance comparable to expert assessment, supporting the feasibility of DL-enhanced R-EUS for loco-regional staging of rectal cancer.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821455

Aims Although endoscopic papillectomy is an established minimally invasive alternative to surgical resection for ampullary lesions, its technical aspects are not well defined. This study aimed to evaluate technical and clinical factors influencing safety and outcomes [1–19].

Methods A multicenter, retrospective analysis of consecutive patients who underwent endoscopic papillectomy in six tertiary Polish centers between 2011 and 2023. Primary outcomes included en bloc resection rate, tumour histology, recurrence rate, and adverse events; multivariate regression models were used to identify its independent predictors.

Results A total of 192 patients were included. En bloc resection was achieved in 66.1 % of lesions. Larger tumour size (for 1 mm increase OR 1.06; 95 % CI 1.02–1.11; p = 0.002) and submucosal injection (OR 5.24; 95 % CI 1.83–15.01; p = 0.002) increased the odds of piecemeal resection. Adverse events occurred in 26.6 % patients, mainly bleeding (17.2 %) and pancreatitis (15.6 %). Invasive adenocarcinoma was found in 5.6 % of specimens; predictors were tumour size (for 1 mm increase OR 1.11; 95 % CI 1.04–1.20; p = 0.004) and jaundice (OR 20.20; 95 % CI 3.94–103.68; p < 0.001). Benign histology was observed in 17.9 % lesions. Among 130 patients with follow-up (median 14.8 months), recurrence occurred in 39.2 % and was independently associated with tumour size (OR 1.06; 95 % CI 1.002–1.103; p = 0.005) and prior resection attempts (OR 3.10; 95 % CI 1.003–9.601; p = 0.049).

Conclusions Larger tumour size, submucosal injection, and previous resections were associated with lower en bloc resection and higher recurrence rates. High adverse event rates and inter-centre variability highlight the need for standardised techniques and follow-up strategies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821456

Aims The primary aim of this study is to compare the demographic characteristics, etiological profile, and short-term clinical outcomes of patients with upper gastrointestinal bleeding (UGIB) admitted to our institution in 2004 and 2024. This analysis is based on evidence that the epidemiological landscape of UGIB has undergone substantial changes over the last two decades.

Methods A descriptive and comparative analysis was performed on two cohorts of all patients diagnosed with UGIB who underwent upper gastrointestinal endoscopy during a 1-year period at our center: one from 2004 (n = 280) and one from 2024 (n = 216). Demographic, clinical, and prognostic variables were compared. Appropriate statistical tests were applied to compare the groups, and results were considered statistically significant when $p < 0.05$.

Results The comparative analysis between the 2004 and 2024 cohorts showed a significant aging of the patient population (mean age: 67.5 vs. 72.9 years; $p < 0.001$). At the same time, there was a substantial increase in the prevalence of major comorbidities, including cerebrovascular disease (5.7 % vs. 19.4 %; $p < 0.001$) and chronic kidney disease (2.5 % vs. 13.6 %; $p < 0.001$). Therapeutic complexity also increased, with a significant increase in the use of anticoagulants (4.3 % [exclusively vitamin K antagonists – VKA] vs. 30 % [VKA + DOACs]; $p < 0.001$).

Regarding clinical presentation, there was an increase in syncope as a form of presentation (7.9 % vs. 13.5 %; $p = 0.021$) and a decrease in the frequency of classic presentations, such as hematemesis (58.6 % vs. 41.2 %; $p < 0.001$) and melena (67.9 % vs. 59.5 %; $p = 0.028$). Etiologically, peptic ulcer remained the main cause of upper gastrointestinal bleeding (46.8 % vs. 46.3 %; $p = 0.457$), although there was a reduction in active bleeding stigmata (Forrest Ia/Ib: 11 % vs. 5.6 %; $p = 0.006$). In contrast, there was a notable increase in angiectasias (0.4 % vs. 6.5 %; $p < 0.001$) and neoplasms (3.9 % vs. 9.3 %; $p = 0.008$).

This more severe profile was reflected in a significant increase in the mean Rockall score (4.76 vs. 5.65; $p < 0.001$). However, despite this worsening of the baseline risk profile, immediate clinical outcomes remained stable, with no statistically significant differences in the rate of hemorrhagic recurrence (3.2 % vs. 3.8 %; $p = 0.358$), the need for surgical intervention (2.1 % vs. 2.2 %; $p = 0.484$), or in-hospital mortality (8.9 % vs. 6.5 %; $p = 0.165$).

Conclusions Over the course of two decades, the profile of patients admitted with upper gastrointestinal bleeding (UGIB) at our institution has changed substantially. Currently, the cohort is older, has a higher burden of associated comorbidities, and has a significantly higher prevalence of anticoagulant therapy. This change in the baseline profile is directly reflected in the etiology of bleeding, namely through an increase in neoplastic etiology (now the third most frequent cause) and bleeding due to angiectasias. Despite the increased baseline risk of patients, as evidenced by the higher mean Rockall score, immediate outcomes remained unchanged. This finding suggests that advances in contemporary clinical treatment and endoscopic intervention protocols have been effective and crucial in mitigating this increased risk.

eP130V ERCP in patient with Surgically Altered Anatomy: Endoscopic Management Strategies and Complications

Authors Bracciamà E[1], Graceffa P[1], Sparacino A[1], Callari C[2], Cartabellotta F[1], Granata A[1]
Institutes 1 Italy, Palermo, Ospedale Buccheri La Ferla, via Messina Marine, palermo, Italy; 2 Buccheri La Ferla / Hospital, Palermo, Italy
DOI 10.1055/s-0046-1821457

Abstract Text

A 75-year-old man with previous Billroth II reconstruction was admitted in April 2025 with jaundice and elevated cytolytic and cholestatic markers. Ultrasound revealed common hepatic duct lithiasis with intrahepatic duct dilation. After failure of entero-ERCP, a lateral-viewing duodenoscope was used. During intubation of the afferent limb, a 2-cm jejunal wall defect was identified at a sharp angulation. Due to immediate recognition of the perforation and the patient's comorbidities, endoscopic closure was performed using the X-Tack. The patient resumed enteral feeding after 48 hours without symptoms.However, worsening cholestatic indices required a repeat ERCP. After unsuccessful attempts at biliary cannulation, a precut fistulotomy allowed access to the major papilla and placement of a biliary stent.

eP131 Disconnected pancreatic duct syndrome: a single-center experience

Authors Iemrabott A[1], Kadiri M[2], Lagdali N[3], Ajana FZ[3], Borahma M[4]
Institutes 1 Ibn Sina University Hospital, Rabat, Morocco; 2 Hospital Ibn Sina, Rabat, Morocco; 3 Mohammed V University, Rabat, Morocco; 4 Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821458

Aims disconnected pancreatic duct syndrome (DPDS) is a recognized complication of acute necrotizing pancreatitis (ANP), whose incidence and impact on the evolution of pancreatic collections and metabolic prognosis remain poorly defined. This study aimed to describe the clinical characteristics, diagnostic methods, endoscopic management, and outcomes of patients with DPDS managed in our department.

Methods A retrospective study was conducted between 2019 and October 2025, including all patients followed for DPDS complicating acute necrotizing

pancreatitis (ANP). The data collected covered demographic characteristics, the etiology of ANP, diagnostic methods, therapeutic management, and the clinical outcomes.

Results Among 63 patients admitted for ANP, four patients (two men and two women) had disconnected pancreatic duct syndrome (DPDS), representing an incidence of 6.3 %. The median age was 47 years (range 23–68 years).

Acute necrotizing pancreatitis was of biliary origin in two patients (50 %), alcoholic in one patient (25 %), and metabolic in another (25 %).

Clinically, all four patients presented with pancreatic-type abdominal pain (100 %), associated with vomiting in three of them (75 %).

AT admission, three patients met SIRS (systemic inflammatory response syndrome) criteria, which persisted beyond 48 hours in two patients.

Initial imaging showed acute pancreatitis stage E of Balthazar in three patients (CTSI = 8 in two and 6 in one) and stage C pancreatitis in the remaining patient. Peripancreatic collections were present in all patients, with an average size of 10 cm (range :3–16 cm).

The diagnosis of DPDS was made early in one patient during the CT scan to assess acute pancreatitis. In two others, it was made during an endoscopic ultrasound (EUS) performed for transmural drainage of an infected WON (walled-off necrosis), and incidentally in one patient who underwent EUS for suspected intraductal papillary mucinous neoplasm of the pancreas on MRI.

The mean time to diagnosis after the episode of acute pancreatitis was 41 days (3–120 days).

The ductal disconnection was located in the body of the pancreas in all cases.

Endoscopic management was performed in three cases: one patient was drained with two double -pigtail plastic stents. The second patient with a metal stent (hot Axios) with necrosectomy sessions, and replaced one month later by two double pigtail plastic stents. The third patient was drained with a covered biflanged stent, replaced subsequently by double pigtail plastic stents.

One asymptomatic patient did not require treatment. All plastic stents, were 7 Fr/7cm , were retained long term to ensure permanent drainage. No per-procedure complications were reported.

The outcome was favorable in all patients, marked by the disappearance of pain and regression of collections. One patient presented a new pancreatitis episode on distal MPD stricture After a median follow-up of 8 months (range:2–23 months), two patients developed new-onset diabetes mellitus.

No cases of exocrine pancreatic insufficiency or mortality were observed.

Conclusions Although limited by a small sample size, our study highlights the efficacy and safety of endoscopic treatment in patients with post-necrotizing pancreatitis DPDS, allowing surgery to be avoided in the majority of cases, with minimal morbidity and no mortality.

DPDS could be a risk factor for new onset diabetes, highlighting the need for prolonged metabolic monitoring. Radiologists must remain vigilant and systematically consider this diagnosis in cases of extensive necrotizing pancreatitis in order to avoid diagnostic delays and the onset of complications.

eP132 Prevalence of Gastric Intestinal Metaplasia in the Saudi Population: A Single-Tertiary Center Retrospective Study

Authors Aljahdli E[1, 2], Hanbazazah S[3]

Institutes **1** Faculty of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia; **2** 1Gastrointestinal Oncology Unit, King Abdulaziz University Hospital, Jeddah, Saudi Arabia; **3** Gastrointestinal Oncology Unit, King Abdulaziz University Hospital, Jeddah, Saudi Arabia, Jeddah, Saudi Arabia

DOI 10.1055/s-0046-1821459

Aims To assess the prevalence of GIM and its associated risk factors among patients who undergoing upper endoscopy procedures or gastric resection at King Abdulaziz University Hospital, in the western region of Saudi Arabia

Methods This retrospective study included 2,103 patients who underwent upper endoscopy or gastric resection at a tertiary facility. Data on patient demographics, risk factors, procedural indications and tissue sampling were collected and analyzed.

Results GIM was identified in 119 patients (5.7 %) who had significantly higher mean age (55.83 ± 15.88 years, P value < 0.001) compared to the non-GIM group. Among all patients, 547 had H-pylori infection. Coexisting dysplasia was present in 42 patients and cancer was detected in 46 patients. H-pylori positivity was significantly higher in the GIM group (P value < 0.001). Additionally, the GIM group showed a significantly higher prevalence of cancer and dysplasia (p-value of 0.001 for both).

Conclusions A significantly higher proportion of patients with GIM had coexisting gastric cancer and dysplasia. Advanced age and H-pylori were strongly associated with GIM. Our findings support the well-established link between H-pylori infection and the increased risk of dysplasia and cancer progression [1–4].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP133 A comparative study of long-term outcomes of different types of stents for benign biliary stricture secondary to chronic pancreatitis

Authors Liu M[1], Fan W[2], Rui-Xi G[2], Zhaoshen L[2], Dan W[2], Lianghao H[2]

Institutes **1** Naval Medical University, shanghai, China; **2** Changhai hospital, Naval Medical University, Shanghai, China

DOI 10.1055/s-0046-1821460

Aims Fully covered self-expanding metal stents (fcSEMS) and multiple plastic stents (MPS) are now regarded as the first-line therapies for benign biliary strictures (BBS) secondary to chronic pancreatitis (CP). However, with the advancement of lithotripsy and endoscopic retrograde cholangiopancreatography (ERCP) techniques, there has been a significant improvement in successful pancreatic duct decompression rate. In this case, the efficacy of single plastic stent (SPS) warrants reevaluation.

Methods This is an observational study with 14-year follow-up based on a large prospective CP cohort. Patients treated with endoscopic biliary stenting for BBS secondary to CP from January 2011 to December 2021 were included. The treatment outcomes of SPS, MPS and fcSEMS were compared [1–4].

Results A total of 94 patients were included (SPS = 80, fcSEMS = 10, MPS = 4). Among patients with pancreatic duct stones, 74.3 % (52/70) underwent pancreatic lithotripsy, with a successful pancreatic stone clearance rate of 91.4 % (64/70). Pancreatic duct patency was achieved in 93.6 % (88/94) of all patients. In a comparison between SPS, fcSEMS, and MPS, the ERCP sessions required were 2.0 vs 2.0 vs 1.5 (P = .597). The cumulative BBS recurrence rates were comparable across all groups (P = .889), and the 7-year clinical success rates were 77.5 % vs. 60.0 % vs. 75.0 % (P = .520).

Conclusions When pancreatic stones are effectively removed and the pancreatic duct is successfully decompressed, SPS, MPS, and fcSEMS demonstrate comparable outcomes in number of ERCP sessions, adverse events, and long-term clinical success for CP related BBS. These findings suggest that SPS should be reconsidered as a viable and cost-effective treatment option.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP134 Diagnostic Performance of EUS Guided Fine Needle Biopsy for Ampullary Cancer: First Vietnamese Experience from a Tertiary Oncology Hospital

Authors Nguyen Trong N[1], Bui AT[2], Nguyen DH[2], Pham D[2], Ngo LL[2]
Institutes 1 BỆNH VIỆN K CƠ SỞ TÂN TRIỀU, Hanoi, Vietnam; 2 Bệnh viện K cơ sở 3 (Tân Triều), Hanoi, Vietnam
DOI 10.1055/s-0046-1821461

Aims Endoscopic ultrasound is the reference modality for locoregional staging of ampullary cancer, but standard endoscopic forceps biopsies often inadequate diagnostic malignancy or underestimate histological grade. EUS-guided fine-needle biopsy (EUS-FNB) may overcome these limitations by providing core tissue; however, its performance for ampullary cancer has not been reported in Vietnam. We aimed to evaluate the diagnostic performance and safety of EUS-FNB for suspected ampullary cancer in a tertiary oncology hospital [1–10].

Methods We conducted a single center prospective observational study at Viet Nam National Cancer Hospital including consecutive patients with suspected ampullary cancer who underwent EUS-FNB between January 2022 and June 2025. EUS-FNB was performed using dedicated biopsy needles with MOSE to assess core adequacy. Demographic data, clinical presentation, tumor markers, imaging findings, EUS characteristics, number of needle passes and post surgical results were recorded. Final diagnosis was based on surgical histology or composite clinical follow-up. Diagnostic performance indices of EUS-FNB for ampullary cancer were calculated. Adverse events were prospectively documented (▶ **Table 1**).

Results Among 54 evaluated patients, 46 met inclusion criteria and were analyzed. 43 (93.5 %) had ampullary cancer, and 3 (6.5 %) had non-malignant lesions. Median age was 62.91 + 9.33 years, with most patients aged 40–70 years. Jaundice was the dominant symptom (90.7 %). A total of 60 EUS-FNB procedures were performed (mean 1.3 per patient) with a mean of 6.72 passes per lesion. MOSE positive core tissue was obtained in 35/46 cases (76.1 %). On histology of the EUS-FNB samples, definite ampullary carcinoma was reported in 25 patients (54.3 %), high-grade dysplasia in 3 (6.5 %), "suspicious / atypical cells" in 13 (28.3 %) and low-grade dysplasia in 5 (10.8 %). Using final surgical histology or long-term follow-up as reference, EUS-FNB for ampullary cancer showed a Se of 93.0 %, Sp 66.7 %, PPV 97.6 % and overall accuracy 91.3 %. No severe adverse events occurred; two patients (4.6 %) developed transient abdominal pain and one (4.6 %) experienced minor intra procedural bleeding (▶ **Table 2**).

Conclusions In this first Vietnamese single-center series, EUS-guided fine-needle biopsy with MOSE achieved high diagnostic accuracy and an excellent safety profile in patients with suspected ampullary cancer managed at a tertiary oncology hospital. These findings support EUS-FNB as the preferred pre-operative tissue acquisition modality within the diagnostic algorithm for ampullary lesions, providing reliable histological confirmation to guide endoscopic or surgical treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A 31-year-old patient underwent LSG. Seven days later, CT imaging showed a perigastric fluid collection. Endoscopy identified a small distal staple-line defect with a large adjacent collection, and a double-pigtail stent was placed and removed two months later. Two months later, the patient presented with fever and abdominal pain. CT demonstrated an 11 × 3 × 8.5 cm collection communicating with the distal staple line and extending through a fistulous tract to the left flank. Endoscopy revealed a 10 × 10 cm cul-de-sac with a small defect releasing purulent fluid. Direct endoscopic suturing with OverStitch NXT was performed to close the cavity and seal the fistula. In the following days, inflammatory markers decreased and symptoms resolved. A one-month CT scan showed marked reduction of the collection.

eP136 Use of an over-the-scope Padlock clip for the treatment of gastrointestinal (GI) bleeding and fistulas: Experience from a Brazilian university center

Authors Monteiro F[1], Bonilha D[1]
Institute **1** UNICAMP Universidade Estadual de Campinas, Campinas, Brazil
DOI 10.1055/s-0046-1821463

Aims To evaluate cases in which the treatment of choice was the application of an OTSC (Padlock) by the endoscopy team of the State University of Campinas between 2020-2025.

Methods Single-center case series.

Results Seventeen patients were evaluated; there was a predominance of males (52.94 %) and the mean age was 53.14 years. At our service, OTSC were mainly used for the treatment of fistulas (60 %), followed by GI bleeding. Concerning the GI bleeding cases, OTSC was the primary treatment in 83 % of cases. OTSC were successfully applied to 100 % of the patients. Among the patients included for fistula treatment, recurrence of the fistula was observed in only one patient (10 %), while the other cases were considered technically successful (90 %). The most common fistula was a tracheoesophageal fistula due to prolonged intubation (2 patients). Among patients with gastrointestinal bleeding, recurrence of bleeding was observed in two cases. These patients were treated with conventional clips over the Padlock. There were no gastrointestinal bleeding-related deaths. Thhere were no deaths or complications resulting from the treatment [1–16]

Conclusions The Padlock clip was found to be effective and safe in our case series as a treatment for fistulas and gastrointestinal bleeding. Technical success was achieved in all cases and clinical success in most of the included patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP137 To implement and assess a mucosal visibility improvement pathway using pre-procedure Infacol in a setting where existing mucolytic pumps were non-functional with new endoscopy equipment

Authors Yasin A[1], Yasir A[2], Mehrab R[3]
Institutes 1 Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; 2 Walsall Manor Hospital, Walsall, United Kingdom; 3 TBMG – Barwick Medical Centre, Thornaby, United Kingdom
DOI 10.1055/s-0046-1821464

Problem to solve Suboptimal mucosal visibility during oesophagogastroduodenoscopy (OGD) is a well-recognised contributor to missed upper GI lesions and has been repeatedly highlighted in quality-assurance literature, including the PEUGIC study, which recommends pre-procedure simethicone to improve detection. In our unit, visibility was frequently impaired by bubbles and foam, and the recent introduction of new endoscope models rendered the mucolytic water pump incompatible. A baseline audit across eight OGD lists revealed 0 % pre-procedure simethicone use. This created an urgent need for a simple, cost-effective, and equipment-independent solution to restore mucosal clarity [1–3].

Innovation We introduced a standardised SOP incorporating oral Infacol (simethicone) administered 30 minutes pre-procedure as a low-cost alternative mucolytic strategy. Unlike pump-delivered simethicone, this method requires no equipment modifications and is compatible with all endoscope systems. The SOP was rolled out across ten OGD lists over four weeks. Infacol was administered by admitting nurses, and visibility was assessed using a 4-point Mucosal Visibility Index (MVI). Feedback was collected from consultants, registrars, nurse endoscopists, and nursing staff to evaluate feasibility, workflow impact, and perceived improvement in clarity. Patient eligibility, contraindications, and practical barriers were also assessed (▶ **Table 1**).

▶ **Table 1** Summary of staff-reported outcomes

Staff group	Reported improvement in visibility/workflow
Consultants	80 % (1 equivocal)
Registrars	99 %
Room nurses	99 %
Admitting nurses	90 % (1 PEG exclusion)

Results Improvement in visibility and workflow:
- Consultants: **80 %** reported improved visibility; **1** equivocal.
- Registrars: **99 %** reported better visibility.
- Nurse endoscopists/room nurses: **99 %** noted less flushing and smoother workflow.
- Admitting nurses: **90 %** found administration easy; one PEG patient unsuitable.**Operational impact:**
- Clear reduction in intra-procedure flushing.
- Faster progression through OGD due to fewer visibility interruptions.
- Intervention simple, quick, and well-tolerated.
- No adverse effects observed.**Staff engagement:**
- Strong multidisciplinary buy-in.
- Common themes: improved visibility, greater diagnostic confidence, time-saving, and easy integration into routine practice.

Conclusions Pre-procedure Infacol is a low-cost, practical, and highly effective intervention to improve mucosal visibility during OGD. It significantly reduced the need for flushing, improved procedural flow, and was easily integrated into existing endoscopy pathways with excellent staff acceptance. This innovation provides an immediate solution for centres where traditional mucolytic pumps cannot be used and aligns with PEUGIC study recommendations to enhance diagnostic quality. The project supports wider implementation of standardised pre-procedure mucosal preparation across endoscopy services.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP138 Clinical and Therapeutic Features of Necrotizing Acute Pancreatitis: A Moroccan Experience

Authors Iemrabott A[1], Kadiri M[2], Lagdali N[3], Ajana FZ[3], Borahma M[4]
Institutes 1 Ibn Sina University Hospital, Rabat, Morocco; 2 Hospital Ibn Sina, Rabat, Morocco; 3 Mohammed V University, Rabat, Morocco; 4 Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821465

Aims Acute necrotizing pancreatitis (ANP) is associated with significant morbidity and mortality. The most feared complications are multiple organ failure and superinfection of the necrosis. Endoscopic management of complications related to necrosis is now well established.
The aim of our study was to outline the epidemiological, etiological, therapeutic, and evolutionary profile of acute necrotizing pancreatitis.

Methods This was a single-center, retrospective descriptive study conducted over a 6-year period, from January 2019 to October 2025, including all patients admitted to our department for necrotizing AP with a CTSI (CT severity index) ≥ 4. The diagnosis of acute pancreatitis (AP) was based on the revised 2012 Atlanta criteria

Results Of a total of 167 patients admitted for acute pancreatitis (AP), 63 had acute necrotizing pancreatitis, an incidence of 37.7 %. The mean age was 56.7 years (range: 23–85 years), with a male-to-female ratio of 0.75. Clinically, all patients presented with typical pancreatic abdominal pain. The diagnosis of AP was based on clinical and biological criteria in 61.9 % of cases (n = 39), with a mean lipase level of 1536.3 IU/L, and on clinical and morphological criteria in 38 % of cases (n = 24). at admission, systemic inflammatory response syndrome (SIRS) was present in 77.7 % of patients (n = 49) and persisted for more than 48 hours in 42.8 % (n = 21).
The abdominal CT scan showed acute pancreatitis stage E according to Balthazar in 80.3 % of cases (n = 53), associated with parenchymal necrosis in 53.3 % of cases, with a mean CTSI score ≥ 6, while stage D pancreatitis was observed in 19.6 % of cases, with CTSI ≥ 4. The etiologies were biliary in 63.4 % of cases (n = 40), metabolic in 7.9 % (n = 5), alcoholic in 3.1 % (n = 2), iatrogenic (post-ERCP) in 6.3 % (n = 4), ampullary tumor in 4.7 % (n = 3), pancreas divisum in 1.5 % (n = 1), and idiopathic in 12.7 % (n = 8). All patients received appropriate rehydration, anticoagulation during hospitalization, and early reintroduction of food. The outcome was marked by the disappearance of symptoms in 59 % of cases, the onset of local complications in 22.2 % (n = 14), including two cases of early infection of necrotic collections, and recurrence of another episode of AP in 15.9 % of cases. The follow-up CT scan at 6 weeks, performed in 54 patients, showed regression of collections in 51.8 % (n = 28), an increase in 22.2 % (n = 12), of which 16,6 % (n = 9) developed organized necrosis, and stability in 25.9 % (n = 14). Symptomatic collections were drained mainly due to infection or compression of adjacent organs, while asymptomatic collections did not require treatment.
endoscopic ultrasound-guided drainage was performed in 42,3 % of cases (n = 11) (two double pigtail plastic stents in seven patients, one Biflanged stent in three, and for one patient, a LAMS (HOT AXIOS stent). Endoscopic necrosectomy (two sessions) was performed in two patient, surgical drainage in three patients, and radiological drainage in two. After drainage, 13 patients showed symptom improvement (81,2 %), and three deaths occurred: two due to septic shock post-drainage (one surgical, one endoscopic) and one from an unrelated cause.

Conclusions Our work showed a favorable outcome in the majority of patients receiving appropriate therapeutic management. Endoscopic drainage of symptomatic pancreatic collections is effective and less invasive and should be preferred whenever feasible.

eP139 Management of Barrett's Esophagus With Multifocal Dysplasia Using Circumferential Endoscopic Submucosal Dissection: Case Series and Preventive Approaches to Post-ESD Stricture Formation

Authors Marakis I[1], Katzakis C[2], Chatzinikolaou M[2], Gkaragkanis D[2], Kosmidis B[2], Bassioukas S[2]

Institutes **1** METROPOLITAN GENERAL, Athens, Greece; **2** METROPOLITAN GENERAL, Cholargos, Greece

DOI 10.1055/s-0046-1821466

Aims The optimal management strategy for multifocal dysplastic Barrett's esophagus (MDBE), particularly the choice between endoscopic resection and ablative therapies, remains under debate [1–5].

We present a case series of three patients treated with circumferential endoscopic submucosal dissection (ESD) for MDBE, with the aim of achieving complete eradication of Barrett's epithelium.

We further describe our preventive approach to post-ESD stricture formation.

Methods Three patients with Barrett's esophagus and multifocal dysplasia, all previously diagnosed with high-grade dysplasia (HGD), underwent circumferential ESD.

Pre-operative evaluation included high-resolution magnifying endoscopy combined with conventional chromoendoscopy with acetic acid to identify dysplastic areas.

Given the presence of multiple suspicious foci, complete resection of all Barrett's epithelium was performed.

All procedures were performed using a multi-tunneling ESD technique; in two cases (66.6 %), clip-and-thread traction was applied.

To prevent esophageal stricture, patients received triamcinolone injection evenly across the resection bed, followed by an oral budesonide regimen (1 mg TID with tapering). Surveillance endoscopy was performed every two weeks to evaluate the need for dilation.

Results All three patients were male, with a mean age of 61.3 years (49–74).

The mean length of resected specimens was 6.4 cm (4.1 cm in C3M4, 6.3 cm in C4M6, and 9 cm in C8M9).

Mean procedure time was 224.3 minutes (150, 176, 347).

All patients recovered uneventfully and were discharged 24 hours post-procedure with dietary instructions, sucralfate, oral budesonide, and PPI therapy.

All resections were R0 and considered curative. Histology confirmed multifocal HGD in all cases, with one patient showing a 28-mm area of SM1 (220 µm) adenocarcinoma (LVI-).

One patient (33.3 %) was upstaged compared with the initial biopsy.

No strictures or recurrences occurred during follow-up, and none required endoscopic dilation.

Complete squamous re-epithelialization was achieved by 32 weeks in all patients.

Mean disease-free survival was 7.3 months (6, 8, 8).

Conclusions Despite inherent limitations (small sample size, short follow-up), circumferential ESD for MDBE appears to be a feasible, safe, and potentially cost-effective approach—avoiding the need for additional ablative therapy—when multifocal dysplasia or early submucosal invasive neoplasia is identified on pre-ESD magnifying endoscopy.

The combination of intralesional triamcinolone and oral budesonide was effective in preventing esophageal strictures, eliminating the need for dilation in this series.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP140 Impact of Blood Urea Nitrogen levels on delayed bleeding after gastric endoscopic submucosal dissection

Authors Kim BJ[1], Park JY[1], Kim JG[1]

Institute **1** Chung-Ang University Hospital, Seoul, Republic of Korea

DOI 10.1055/s-0046-1821467

Aims Endoscopic submucosal dissection (ESD) is a widely accepted treatment modality for early gastric cancers and adenomas, but is often accompanied by post-ESD bleeding. Herein, we evaluated the association of elevated blood urea nitrogen (BUN) levels at 24 hours after ESD for post-procedural bleeding. Further, we assessed whether an increase in BUN level is associated with an artificial gastric ulcer of high-risk Forrest classification during second-look endoscopy (SLE) after ESD [1–3].

Methods We analyzed the data patients who underwent ESD for either early gastric cancer or gastric adenoma. Baseline characteristics, endoscopic findings, and blood test results were assessed for each enrolled patient.

Results A total of 424 patients were assessed in this study. SLE performed one day after ESD demonstrated 44 post-ESD lesions with a high risk of bleeding and 385 lesions with a low risk of bleeding according to the Forrest classification. An artificial gastric ulcer of high-risk Forrest classification was associated with a significantly higher rate of post-ESD bleeding. An elevated BUN level at 24 hours after ESD was significantly associated with an artificial gastric ulcer of high-risk Forrest classification during SLE. ($p = 0.003$)

Conclusions Significant changes in BUN levels after ESD suggest the development of post-ESD bleeding. Furthermore, this marker is easy to measure, and enables the early identification of patients with high-risk Forrest classification ulcers, ultimately helping to predict post-ESD bleeding.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP141 Application of the Lyon scoring system in patients with typical and/or atypical symptoms poorly responsive to proton pump inhibitors: Comparison between typical and atypical symptom groups

Authors Lee KJ[1], Park JS[2]
Institutes 1 Ajou University Hospital , Suwon, Republic of Korea; 2 Ajou University Hospital, Suwon, Republic of Korea
DOI 10.1055/s-0046-1821468

Aims In symptomatic patients despite empiric trials of proton pump inhibitors (PPIs) with no prior GERD evidence, endoscopy and ambulatory reflux monitoring are recommended off therapy. The novel Lyon scoring system based on the Lyon consensus 2.0 can stratify symptoms into phenotypes associated with the likelihood of GERD diagnosis and response to anti-reflux treatment. We applied the Lyon scoring system in patients with typical and/or atypical symptoms poorly responsive to a standard dose of PPIs and compared the Lyon score and phenotypes between typical and atypical symptom groups.

Methods In 141 patients (52.9 ± 14.9 years, M/F = 60/80) with typical (heartburn, regurgitation or esophageal chest pain) or atypical (globus, sore throat or throat clearing) symptoms poorly responsive to an empiric trial of standard dose of proton pump inhibitors, ambulatory pH-impedance monitoring was performed off antisecretory therapy using manometric localization of the LES to position the pH sensor 5 cm proximal to the LES. All patients underwent endoscopy off medication before esophageal reflux testing. The Lyon scoring system reported by Gyawali CP, et al., published in 2024, was applied and stratified the symptom groups into phenotypes. Symptom groups are subclassified as the typical symptom group (n = 79), the overlap symptom group with both typical and atypical symptoms (n = 26), and the atypical symptom group (n = 36). The phenotypes of no GERD, isolated permeability defect and reflux hypersensitivity were classified as the group likely to respond poorly to the anti-reflux therapy, whereas the phenotypes of inconclusive or borderline GERD, conclusive GERD and severe GERD were classified as the group likely to respond well to the anti-reflux therapy.

Results The prevalence (% (n)) of phenotypes including no GERD, isolated permeability defect, reflux hypersensitivity, inconclusive or borderline GERD, conclusive GERD and severe GERD is as follows; 65.8 % (52), 3.8 % (3), 13.9 % (11), 3.8 % (3), 11.4 % (9), and 1.3 % (1) in the typical symptom group, respectively; 61.5 % (16), 3.8 % (1), 11.5 % (3), 3.8 % (1), 15.4 % (4), and 3.8 % (1) in the overlap symptom group, respectively; and 69.4 % (25), 5.6 % (2), 22.2 % (8), 2.8 % (1), 0 % and 0 % in the atypical symptom group, respectively. The sex ratio did not significantly differ in the symptom groups (P = 0.540). The mean age of the the atypical symptom group tended to be lower than that of the overlap symptom group (49.9 ± 14.9 vs 57.0 ± 13.1 years, P = 0.053). The mean age of the Lyon score was 2.1 (range 0-11). The proportion of the group likely to respond poorly to the anti-reflux therapy was greater in the atypical symptom group, compared with the overlap symptom group (P = 0.023) and the typical symptom group (P = 0.067)

Conclusions No GERD and reflux hypersensitivity are the main phenotypes in patients with typical and/or atypical symptoms poorly responsive to PPIs. The likelihood to respond to the anti-reflux therapy is the lowest in the atypical symptom alone group.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP142 The grapes of wrath: gastric lesions as the first finding of metastatic melanoma

Authors Romero Martínez M[1], Gómez Gómez A[1], Bógalo Romero C[1], Sánchez Roncero FJ[2], Madrigal Bayonas L[2], Bógalo Romero C[1], Calatayud Vidal G[3], Ana PL[1], Egea Valenzuela J[1], Alberca De Las Parras F[1]
Institutes 1 Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; 2 Rafael Méndez University General Hospital, Lorca, Spain; 3 Rafael Méndez Hospital, Lorca, Spain
DOI 10.1055/s-0046-1821469

Abstract Text

Metastatic melanoma is a highly aggresive disease, with a high affinity for gastrointestinal tract metastasis, that amount up to 60 % in autopsy reports. However, gastric metastasis are un common, leading up to less than 150 cases in some metaanalysis [1–3].

We present the case of a 83-year-old woman that was admitted into our Internal Medicine Department due to weight loss and anemia due to iron deficiency, without evidence of a gastrointestinal bleeding. As a part of the diagnostic study, an esophagogastroduodenoscopy (EGD) was performed. Located at the proximal region of the greater curvature, an exophytic nodular lesion was found. It was composed of several, smaller, ulcerated nodules, resembling a bunch of grapes. The mucosa surrounding the ulceration was apparently normal, leading to submucosal tumour as a first diagnosis. (Figure 1). The analysis via microscope showed epithelial cells grouped in bundles and immunohistochemical staining was positive for Sox10, vimentin, HMB-45, Melan-A and S-100 leading to the histopathological diagnosis of melanoma.

Completing the study, a computerized tomography was performed. There, pulmonary, hepatic and gastric metastasis were described, as well as a lesion in the right breast that was compatible with the primary melanoma. The hepatic lesion was the largest with a diameter of 10cm located on the right lobe, while the gastric lesions found on the EGD also were present on the study. (Figure 2)

After the diagnosis, pembrolizumab, a PD-1/PD-L1 inhibitor was started. However, the patient passed away three months after the diagnosis.

Gastric metastasis of melanomas are a seldom finding, characterized by bundles of ulcerated lesions surrounded by normal mucosa. Although it is frequent for these lesions to present melanosis, our lesion was amelanic. Positivity for S-100 and HMB-45 confirms the histopathologic diagnosis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP143 Correlation Between Fecal Calprotectin Levels and the Diagnostic Value of Colonoscopy for Digestive Diseases

Authors Outifa O[1], Harrak N[2], Salihoun M[3], Elaoula S[4], Bouhamou F[4], Serraj I[4], Acharki M[4], Kabbaj N[4]
Institutes 1 Centre hospitalier universitaire Ibn Sina, Rabat, Rabat, Morocco; 2 Ibn Sina Hospital, Mohammed V University in Rabat, Rabat, Morocco; 3 Rabat, Morocco; 4 Ibn Sina University Hospital, Rabat, Morocco
DOI 10.1055/s-0046-1821470

Aims Fecal calprotectin (FC), a protein released by neutrophils, is a reliable and non-invasive biomarker of intestinal inflammation. Its primary value lies in its ability to differentiate functional bowel disorders from organic diseases, thereby guiding the indication for endoscopic evaluation. This study aims to assess the diagnostic value of FC and its role in determining the need for colonoscopy.

Methods A retrospective study was conducted, including patients who underwent fecal calprotectin measurement prior to a total colonoscopy over a five-year period, from January 2019 to July 2025.

Results Among 1,336 patients who underwent colonoscopy, 71 were included in this study. A slight female predominance was observed (56 %; sex ratio F/M = 1.2), with a median age of 42 years.

Regarding medical history, diabetes mellitus and previous appendectomy were each present in 9.5 % of cases (n = 7), while a family history of inflammatory bowel disease (IBD) and chronic smoking were reported in 4 % (n = 3).
Clinically, the main presenting symptoms were Koenig's syndrome in 56 % (n = 40), mucoid diarrhea in 45 % (n = 32), alternating diarrhea/constipation in 17 % (n = 12), and rectal bleeding in some cases.
Biochemically, FC levels were > 1000 µg/g in 16.9 % (n = 12), between 250–1000 µg/g in 53.5 % (n = 38), and < 50 µg/g in a single patient.
Endoscopically, 59 % (n = 42) of colonoscopies were consistent with IBD findings: Crohn's disease was diagnosed in 45 % of patients (n = 32), most commonly involving the ileum or ileocolic region, with perianal involvement observed in 9.8 % (n = 7). Ulcerative colitis was identified in 14 % (n = 10), predominantly with left-sided or pancolonic distribution. In 7 % of patients (n = 5), nonspecific inflammatory lesions were identified, including erosive ileitis, terminal ulcerative ileitis, nodular ileitis, and erosive rectosigmoiditis, without histopathological confirmation. Two additional cases demonstrated ulceroinfiltrative masses suggestive of neoplastic processes. Conversely, 29 % (n = 21) of colonoscopies were completely normal.

Conclusions This study highlights a significant correlation between fecal calprotectin levels and colonoscopy findings, with 71 % of examinations revealing endoscopic abnormalities. These results confirm the diagnostic relevance of FC testing, particularly for IBD screening, while also suggesting a high sensitivity in detecting colorectal carcinoma. However, although elevated FC levels are often associated with severe endoscopic lesions, they do not provide absolute predictive value.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP144 Collagenous sprue – a very rare and challenging diagnosis

Authors Popescu AM[1], Dumbrava M[2]
Institutes 1 Centrul Medical DigestMed – Militari, București, Romania; 2 Fundeni Clinical Institute, București, Romania
DOI 10.1055/s-0046-1821471

Aims Collagenous sprue is a very rare cause of malabsorption, characterized by severe diarrhea and weight loss. The first description of this disease dates back to 1947. The diagnosis can be challenging because collagenous sprue resembles celiac disease both endoscopically and histologically. The main difference between these two diseases is the presence, in collagenous sprue, of a thick subepithelial collagen band beneath the basement membrane of the small bowel and duodenal mucosa.We present the case of a 76-year-old male patient, with a history of hypertension and dyslipidemia, evaluated for watery diarrhea, vomiting, abdominal pain, and weight loss. The diagnosis of collagenous sprue was established after 6 months of investigations, during which the patient developed severe malnutrition with cachexia.

Methods Clinical findings: cachexia, pale skin, asthenia, diffuse abdominal pain; hemodynamically stable.Laboratory results: fecal calprotectin = 336, hemoglobin = 10.7 g/dL, MCV = 102, WBC = 11,000, fibrinogen = 559, ferritin = 668, CTLF = 180, INR = 1.34, elevated CRP, low total serum proteins, low vitamin B12. Anti–tissue transglutaminase antibodies IgG and IgA negative. Extended stool culture negative.Abdominal CT scan: changes consistent with pancolitis.Upper GI endoscopy: antral hyperemia and edematous duodenal mucosa.Colonoscopy: whitish and flattened villi in the terminal ileum; normal appearance of the colonic mucosa [1–14].

Results Digestive tract biopsies showed gastric mucosa with features of active chronic gastritis, non-atrophic and non-metaplastic, Helicobacter pylori negative; moderate chronic duodenitis with marked villous atrophy, eosinophilia, focal lymphocytosis, and thickening of the subepithelial collagen band; colonic mucosa without abnormalities; ileal mucosa with moderate-to-marked villous atrophy, increased focal eosinophilia, and thickening of the subepithelial collagen band. The differential diagnosis included gluten-sensitive enteropathy (celiac disease), collagenous sprue, or an autoimmune etiology.

We initiated corticosteroid therapy and a gluten-free diet, the only effective treatment described in the literature for this rare condition. Two weeks after starting treatment, symptoms improved significantly. The patient became clinically stable and gained weight after completing therapy. A follow-up gastroscopy performed at 3 months showed normal duodenal mucosa; however, biopsies revealed moderate villous atrophy with heterogeneous polymorphous inflammation in the lamina propria, isolated neutrophils, frequent eosinophils (> 50/HPF), no aggregates, no crypt abscesses, no eosinophils in the muscularis mucosae, no epithelial erosions, no thickened subepithelial collagen band, and no evidence of Giardia infection.

Conclusions This case highlights a rare cause of chronic diarrhea and illustrates the diagnostic difficulty associated with collagenous sprue. Fewer than 100 cases have been reported worldwide.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP145 Utilization of proton pump inhibitors in patients with overt gastrointestinal bleeding: impact on short- and long-term mortality and rebleeding — a 3-year prospective monocentric Moroccan study

Authors Aouroud H[1], Aouroud M[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1821472

Aims Proton pump inhibitors (PPIs) are widely prescribed in acute gastrointestinal bleeding (AGIB), but inappropriate overuse or underuse remains common. Their true effect on short- and long-term outcomes is still debated, especially in low-resource settings where PPI stewardship is limited. No prior Moroccan study has assessed PPI utilization patterns in AGIB.

Aim To evaluate PPI utilization on admission and at discharge in patients presenting with overt AGIB, and to determine their impact on short-term (1-month) and long-term outcomes in a tertiary Moroccan center.

Methods A prospective monocentric study was conducted at CHU Mohammed VI Marrakech from January 2022 to January 2025, including 240 patients admitted with overt AGIB. Data collected included PPI use, antithrombotic therapy, clinical severity, endoscopic findings, and short- and long-term outcomes. Univariate and multivariate analyses identified predictors of mortality and rebleeding.

Results PPI utilization 40 % of patients were already on PPI at admission. 72 % were discharged on PPI. Overall PPI overutilization rate: 32 % (patients without clear indication). Underutilization rate: 21 % (patients with clear indication but no PPI at discharge). Characteristics of patients on PPI at admission Compared with those not on PPI, patients on PPI were: older (median 69 vs 63 years) had higher comorbidity burden (higher CCI) more likely to be on antithrombotics more likely to require blood transfusionBut they had: fewer stigmata of recent hemorrhage reduced need for endoscopic therapy Outcomes
1-month rebleeding: similar whether PPI was used on admission or not.
1-month mortality: slightly higher in PPI users, but PPI itself was *not* an independent predictor on multivariate analysis.
Independent predictors of 1-month mortality
Higher Charlson Comorbidity Index
Severe bleeding
Need for blood transfusion
Stigmata of recent hemorrhage
Independent predictors of 1-month rebleeding
Anticoagulant use on admission
Severe bleeding
SRH on endoscopy
Long-term outcomes
PPI use at discharge did not predict long-term mortality or rebleeding.Anticoagulant therapy at discharge predicted long-term mortality, while antiplatelet therapy was protective against long-term rebleeding.

Conclusions In this 3-year Moroccan monocentric cohort, PPI overutilization and underutilization were both frequent, reflecting the absence of standardized PPI stewardship.However, PPI use had no significant impact on short-term or long-term mortality or rebleeding.
These findings highlight the need for a PPI utilization stewardship program to optimize prescribing practices, reduce unnecessary costs, and minimize adverse effects associated with inappropriate long-term PPI exposure.

eP146 Prophylactic antibiotics reduce post-ERCP infectious complications in distal malignant biliary obstruction: A prospective monocentric study from Marrakech

Authors Aouroud H[1], Aouroud M[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1821473

Aims Distal malignant biliary obstruction (DMBO) frequently requires ERCP with biliary stenting. Early post-procedural infectious complications—mainly cholangitis and cholecystitis—remain clinically relevant despite advances in technique. Current guidelines recommend prophylactic antibiotics only in selected high-risk situations, and data specific to DMBO are scarce. This study aimed to evaluate the effect of prophylactic antibiotics on early infectious complications following ERCP in a DMBO-only population.

Methods We conducted a prospective, monocentric study at CHU Mohammed VI Marrakech, including 165 consecutive patients who underwent initial ERCP with stent placement for DMBO between 2022 and 2024. Patients were categorized according to the administration or not of prophylactic antibiotics before ERCP. The primary outcome was the incidence of infectious complications (cholangitis or cholecystitis) within 5 days. A multivariable logistic regression model was used to identify independent predictors.

Results Early infectious complications occurred in 3.6 % of patients receiving prophylactic antibiotics versus 10.3 % in those without prophylaxis, corresponding to an absolute risk reduction of 6.7 % ($p = 0.029$) and a number needed to treat (NNT) of 15. Rates of post-ERCP pancreatitis showed no significant difference between groups (approximately 6–10 %, $p > 0.3$). In multivariable analysis, absence of prophylactic antibiotics remained independently associated with infectious complications (OR 2.45, 95 % CI 1.22–4.92). Compared with previous literature—mostly small retrospective DMBO series showing no clear benefit—this prospective study provides stronger evidence supporting prophylaxis. Results also align with data from hilar obstruction studies and meta-analyses reporting reduced bacteremia after antibiotic prophylaxis.

Conclusions In this prospective Moroccan cohort, prophylactic antibiotics significantly reduced early infectious complications after ERCP for DMBO without increasing post-procedure pancreatitis. These findings support the systematic use of prophylactic antibiotics in patients undergoing ERCP for DMBO, even when complete drainage is anticipated. Larger multicenter prospective trials are warranted to refine prophylactic strategies and update guideline recommendations.

eP147 Determinants of Endoscopic Success in Large and Complex Common Bile Duct Stones: A 9-Year Monocentric Experience

Authors Aouroud H[1], Aouroud M[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 MOHAMMED VI UNIVERISTY HOSPITAL, Marrakech, Morocco
DOI 10.1055/s-0046-1821474

Aims Endoscopic sphincterotomy with stone extraction is the standard therapy for common bile duct stones (CBDS). However, the presence of large stones (> 15 mm) or extensive choledochal lithiasis may compromise technical success and increase the need for additional procedures. Evidence on predictors of endoscopic success remains limited and heterogeneous. This study evaluated the outcomes of ERCP in patients with large versus non-large stones and identified factors associated with treatment success.

Methods We conducted a monocentric retrospective analytical study over 9 years (2016–2025) at our tertiary center. A total of 867 ERCPs performed for CBDS were included. Large stones were defined as obstructive stones > 15 mm; choledochal lithiasis as ≥ 3 stones.Patients were divided into two groups:

Endoscopy 2026; 58: S1–S1041

Group I (n = 143): single large obstructive stone > 15 mm
Group II (n = 724): one or two stones or choledochal lithiasisPrimary outcomes included success after first attempt, overall endoscopic success, need for reintervention, additional techniques, and early complications. Predictors of success were determined by univariate and multivariate analyses.
Results Large stones represented 16.5 % of the cohort (143/867).
Success after first ERCP: 55.2 % in Group I vs. 81 % in Group II ($p < 0.001$).
Reintervention: 14.7 % vs. 8 % ($p = 0.009$).
Use of additional techniques: 46.2 % vs. 16.1 %.
Overall success after adjuncts/reintervention: 88.7 % vs. 92.5 % ($p = 0.125$).
Early complications: 10.5 % vs. 5.1 % ($p = 0.017$).
Univariate predictors of reduced overall success: older age, acute cholangitis, bile duct strictures, and duct dilation > 15 mm.Multivariate analysis showed two independent predictors:
Acute cholangitis (OR 0.295; 95 % CI 0.164–0.532; $p < 0.001$)
Bile duct stricture (OR 0.53; 95 % CI 0.922–1.051; $p = 0.001$)
Conclusions In this large monocentric 9-year cohort, large stones required more reinterventions and adjunctive procedures but did not significantly reduce the final success rate of ERCP when advanced extraction techniques were available. The main determinants of reduced success were acute cholangitis and bile duct strictures, rather than stone size alone.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP148 Endoscopic Management of Colonic Biliary Ileus: A Case from a Regional Hospital

Authors Trelles M[1], Giménez Fernández L[2], Reyes Moreno J[2], Ortega Moya SP[1], Florido M[1], Payeras MA[1]
Institutes **1** Hospital Comarcal de Inca, Inca, Spain; **2** Hospital Comarcal de Inca, Inca Spain
DOI 10.1055/s-0046-1821475
Introduction: We present the case of a 78-year-old woman with a history of hypertension and colonic diverticulosis, admitted for diffuse abdominal pain, distension, and constipation lasting five days. Physical examination revealed a distended abdomen with reduced bowel sounds and diffuse tenderness, without signs of peritoneal irritation. Laboratory tests were unremarkable. Abdominal X-ray showed dilated bowel loops. CT scan revealed extensive intrahepatic and choledochal pneumobilia, a contracted gallbladder in continuity with the right colon, and inflammatory changes with diffuse thickening of the sigmoid colon. A transition point was noted at the rectosigmoid junction, where an impacted stone was suspected, without evidence of neoplasia [1].
Endoscopic Findings and Management: Colonoscopy revealed large diverticula in the sigmoid colon and a round, dark-pigmented lesion occupying nearly the entire lumen, consistent with an impacted biliary stone. Due to its location and size, complete extraction was not feasible initially. Using a Dormia basket, the stone was fragmented and removed. Following the procedure, a significant release of fecal content was observed, and the patient's intestinal transit normalized, with resolution of the presenting symptoms.
Conclusions : The primary therapeutic goal in biliary ileus is to relieve the intestinal obstruction. Although colonic impaction of ectopic gallstones is uncommon, the presence of luminal narrowing—such as in areas of diverticulosis, as seen in our patient—can favor stone lodging at that level.
Abdominal CT findings of pneumobilia, cholecysto-colonic fistula, and ectopic gallstone provided the definitive diagnostic evidence in this case.
Endoscopic treatment represents a first-line, non-surgical strategy. Therefore, it is essential to be familiar with the specialized instruments—often infrequently used—that are available in our endoscopy units, as they can be crucial in resolving complex scenarios such as the one presented here.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP149 Endoscopic Management of Common Bile Duct Stones: Clinical Outcomes and Safety in Symptomatic Patients Undergoing ERCP

Authors Souilem E[1], Houssem H[2], Jemai R[3], Elleuch N[2], Jaziri H[2], Ben Slama A[2], Braham A[2], Wafa D[2], Ksiaa M[2]
Institutes **1** UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia; **2** Sahloul Hospital, Sousse, Tunisia; **3** Mohamed Taher Maamouri Hospital, Nabeul, Tunisia
DOI 10.1055/s-0046-1821476
Aims Endoscopic retrograde cholangiopancreatography (ERCP) is the standard treatment for common bile duct stones (CBDS). Identifying predictors of procedural success and complications is essential to improve risk stratification. This study evaluated the efficacy, safety, and independent predictors of outcomes in patients undergoing ERCP for symptomatic CBDS.
Methods A retrospective cohort study was conducted over a one-year period, including all consecutive patients undergoing ERCP for symptomatic CBDS. Clinical presentation, stone characteristics, procedural techniques, technical success, duct clearance, and post-ERCP complications were recorded. Variables associated with incomplete duct clearance and complications were analyzed using univariate and multivariate logistic regression.
Results A total of 102 patients were included (mean age 52 ± 12.5 years; 59 % female). Clinical presentation consisted of biliary colic in 80 cases, acute cholangitis in 18, and biliary pancreatitis in 4. The mean stone size was 12.5 mm, and bile duct dilation was present in 81 % of patients (mean diameter 15 mm). Selective biliary cannulation was achieved in 91 % of cases; sphincterotomy was performed in 92 % and temporary biliary stenting in 12 %. Complete duct clearance during the index ERCP was obtained in 85 %, with an overall therapeutic success rate of 90 %. Complications occurred in 10 % of procedures, including post-ERCP pancreatitis (6 %), perforation (3 %), and minor bleeding (1 %), with no procedure-related mortality. In multivariate logistic regression, stone size ≥ 15 mm (OR 3.2; 95 % CI 1.3–7.8; p = 0.01) and difficult cannulation (OR 2.9; 95 % CI 1.1–7.3; p = 0.02) were independent predictors of incomplete duct clearance, while female sex (OR 2.7; p = 0.03) and bile duct dilation ≥ 15 mm (OR 3.5; 95 % CI 1.3–9.1; p = 0.01) were independently associated with post-ERCP complications.
Conclusions ERCP shows high efficacy and an acceptable safety profile in CBDS. Stone size, cannulation difficulty, bile duct dilation, and sex independently affect outcomes. Incorporating these factors into pre-procedural assessment may improve risk stratification and clinical decision-making.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP150 High-Risk Profiles for Recurrent Gastrointestinal Bleeding in Patients with Digestive Angiodysplasias: Insights from a Prospective Cohort

Authors Aouroud M[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute **1** CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco
DOI 10.1055/s-0046-1821477
Aims Digestive angiodysplasias are a leading vascular cause of gastrointestinal bleeding, yet prospective studies evaluating predictors of recurrence are rare. Identifying high-risk patients is crucial to guide surveillance and therapy.
Methods We conducted a prospective cohort study including adults aged ≥ 18 years with at least one endoscopically confirmed angiodysplasia and minimum follow-up of 12 months. Exclusion criteria were hereditary hemorrhagic telangiectasia, portal hypertensive gastropathy, radiation-induced vascular lesions, inflammatory bowel disease, and incomplete records. Lesions were discovered either incidentally or during overt bleeding. Recurrent bleeding was defined as new hematochezia or melena, hemoglobin drop ≥ 2 g/dL, need for transfusion, or endoscopic evidence. Follow-up included scheduled visits and structured telephone contact.

Results Among 65 patients, 15.4 % experienced recurrent bleeding. Recurrence was higher in patients with chronic kidney disease versus those without (21.2 % vs 9.4 %, p = 0.08), in patients with initial overt bleeding versus incidental discovery (21 % vs 4 %, p = 0.04), and in those receiving anticoagulants versus not (22 % vs 14 %, p = 0.11). In multivariable logistic regression, chronic kidney disease, anticoagulant therapy, higher age, multiplicity of lesions, and active stigmata were positively associated, while argon plasma coagulation showed a protective trend. Trends aligned with international evidence despite lack of statistical significance.

Conclusions This prospective study identifies clinically meaningful high-risk profiles for recurrent bleeding in digestive angiodysplasias. Standardized definitions and structured follow-up enhance originality. Findings support development of predictive models to optimize patient monitoring and treatment strategies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP151 Pharmacogenetic Determinants of Azathioprine Response: Impact of TPMT G460A and MTHFR C677T Variants in Tunisian Patients With Inflammatory Bowel Disease

Authors Souilem E[1], Houssem H[2], Wafa D[2], Jemai R[3], Jaziri H[2], Braham A[2], Ben Slama A[2], Ksiaa M[2]

Institutes **1** UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia; **2** Sahloul Hospital, Sousse, Tunisia; **3** Mohamed Taher Maamouri Hospital, Nabeul, Tunisia

DOI 10.1055/s-0046-1821478

Aims Azathioprine (AZA) is widely used in inflammatory bowel disease (IBD), but inter-individual variability in efficacy and toxicity limits its optimal use. Genetic variants affecting thiopurine metabolism, particularly in TPMT and MTHFR, may contribute to these differences. This study assessed the influence of TPMT G460A (rs1800460) and MTHFR C677T (rs1801133) polymorphisms, along with non-genetic factors, on AZA outcomes in Tunisian IBD patients.

Methods A retrospective cohort of 62 IBD patients treated with AZA for ≥ 3 months was analyzed. Clinical and demographic data were collected from standardized records. Genotyping of TPMT G460A and MTHFR C677T was performed by PCR-RFLP. Associations with AZA efficacy and toxicity were evaluated using chi-square or Fisher's exact tests and multivariate logistic regression for variables with $p < 0.1$. Statistical significance was set at $p < 0.05$.

Results The TPMT G460A variant was identified in one patient only, limiting analysis; subsequent evaluation focused on the MTHFR C677T polymorphism (CC 45.2 %, CT 40.3 %, TT 14.5 %). No significant association was found between C677T genotype and AZA efficacy (p = 0.47) or toxicity (p = 0.61). Non-genetic factors—including age, sex, BMI, smoking status, disease subtype, corticosteroid response, and concomitant treatments—were also not associated with outcomes. Multivariate regression identified no independent predictors of AZA response or adverse effects. These findings likely reflect both the low prevalence of TPMT variants in this population and the absence of additional thiopurine-metabolizing gene variants (e.g., TPMT*2, TPMT*3A, NUDT15) in the analysis.

Conclusions While no significant determinants of AZA efficacy or toxicity were identified, this study highlights the low frequency of common TPMT variants in Tunisian IBD patients and underscores the need for broader pharmacogenetic screening. These results provide a basis for larger, multi-gene studies to optimize individualized thiopurine therapy in North African populations.

eP152 Impact of Endoscopist Fatigue on Colorectal Lesion Detection: Prospective Evaluation of Colonoscopy Timing

Authors Aouroud M[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute **1** CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco

DOI 10.1055/s-0046-1821479

Aims Colonoscopy is the gold standard for colorectal cancer prevention, yet small, flat, and sessile serrated polyps are frequently missed. Operator vigilance is crucial, and fatigue during prolonged sessions may reduce detection, particularly of subtle lesions. This study evaluated whether colonoscopy timing during the day affects polyp detection.

Methods We conducted a prospective study of 47 consecutive patients undergoing screening or surveillance colonoscopy with adequate bowel preparation (Boston score ≥ 6) between January 2025 and September 2025. Procedures were classified as early session (first half of the program) or late session (after ≥ 3 consecutive exams). For each patient, polyps were recorded for number, size, morphology (Paris classification), location, and histology. Comparative analysis assessed detection differences between early and late sessions.

Results 25 early and 22 late session colonoscopies were analyzed. Early session colonoscopies detected 65 polyps (mean 2.6 per patient), including 33 adenomas, 20 sessile serrated lesions, and 12 hyperplastic polyps. Late session colonoscopies detected 28 polyps (mean 1.3 per patient), mainly small, flat, with 60 % in the right colon. Detection of small, flat, and sessile serrated lesions decreased by ~50 % in late sessions. Procedure times and adverse events were similar. The reduction in detection during late sessions was statistically significant (p = 0.02).

Conclusions Colonoscopy timing significantly affects lesion detection, with late-session procedures yielding fewer polyps, particularly small, flat, and sessile serrated lesions in the right and transverse colon. Awareness of endoscopist fatigue is essential for session planning, training, and quality assurance. Limiting consecutive procedures, scheduling breaks, and rotating operators may improve detection and patient safety. Larger multicenter studies are warranted to validate these findings and guide practical recommendations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP153 Impact of Systematic Patient Position Changes on Colorectal Lesion Detection: Prospective Study of 56 Patients

Authors Aouroud M[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute **1** CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco

DOI 10.1055/s-0046-1821480

Aims Colonoscopy is the gold standard for colorectal cancer prevention, yet small, flat, and sessile serrated polyps are frequently missed. Patient positioning affects colonic distension and mucosal visualization. This study evaluated whether systematic changes in patient position—including left lateral, right lateral, ventral, and dorsal decubitus—improve polyp detection

Methods We conducted a prospective study of 56 consecutive patients undergoing screening or surveillance colonoscopy with adequate bowel preparation (Boston score ≥ 6) between January 2025 and September 2025. Initial inspection was performed in the left lateral decubitus position. During evaluation of the transverse and right colon, positions were systematically changed to optimize mucosal exposure. All detected polyps were resected and analyzed histologically. The number of polyps detected before and after position change, their size, morphology, location, and histology were recorded.

Results The cohort had a mean age of 60 years, 54 % men, and mean Boston score 7.4. Initial left lateral inspection detected 72 polyps. Systematic position changes yielded 18 additional polyps (20 % of total), predominantly small (< 5

mm), flat (Paris IIa), and located mainly in the right colon (55 %) and transverse colon (30 %). Histology revealed adenomas (50 %), sessile serrated lesions (33 %), and hyperplastic polyps (17 %). No adverse events occurred, and procedure time was not significantly prolonged.

Conclusions Systematic patient position changes during colonoscopy significantly increase polyp detection, particularly small, flat, and sessile serrated lesions in the right and transverse colon. This safe, simple, and cost-effective strategy can enhance colonoscopy quality and colorectal cancer prevention. Multicenter studies are warranted to validate these findings and inform training and procedural recommendations.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP154 Impact of a Total Back-to-Back Second-Look Colonoscopy on Detection of Missed Colorectal Lesions: A Prospective Study of 67 Patients

Authors Aouroud M[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute **1** CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco

DOI 10.1055/s-0046-1821481

Aims Back-to-back colonoscopy studies have shown that a substantial proportion of colorectal lesions are missed during a single examination, with adenoma miss rates reported between 17 % and 28 % in the literature. Small, flat, serrated, and right-sided lesions are particularly prone to being overlooked and contribute to interval post-colonoscopy colorectal cancer. We aimed to evaluate the incremental diagnostic yield of a complete second-look colonoscopy performed immediately after a standard high-definition examination.

Methods This prospective study included 67 consecutive adults undergoing screening or surveillance colonoscopy with adequate bowel preparation (Boston score ≥ 6). After a first complete inspection, an immediate second pass from rectum to cecum was performed under identical conditions. All detected lesions were characterized by size, morphology, and location, and resected. The primary outcome was the proportion of lesions identified exclusively during the second inspection.

Results The first pass detected 93 polyps; the second pass revealed 30 additional lesions, corresponding to a miss rate of 24.4 %, consistent with previously published back-to-back studies. Missed lesions were significantly smaller (mean 4 mm), predominantly flat (Paris IIa), and mostly located in the proximal colon. Histology included tubular adenomas, sessile serrated lesions, and hyperplastic polyps. Subtle borders and pale coloration were common features of missed lesions. The incremental yield was consistent across endoscopists and independent of bowel cleanliness within the inclusion threshold.

Conclusions Immediate back-to-back colonoscopy substantially improves detection of clinically relevant lesions, particularly serrated and right-sided polyps associated with interval cancer. Selective application of second-look inspection may benefit high-risk patients and provide a valuable quality assessment tool for endoscopy units. Emphasizing slow, meticulous mucosal inspection remains essential to reduce post-colonoscopy colorectal cancer risk.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP155 Patient Perception of Repeated Endoscopic Examinations in IBD

Authors Aouroud M[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]

Institute **1** CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco

DOI 10.1055/s-0046-1821482

Aims Patients with inflammatory bowel disease (IBD), including Crohn's disease and ulcerative colitis, often require repeated endoscopic evaluations for disease monitoring, dysplasia surveillance, and mucosal healing assessment. Despite its clinical necessity, endoscopy can cause anxiety, procedural discomfort, and negatively impact quality of life. Understanding patient perceptions is essential to optimize monitoring strategies and enhance patient-centered care.

Methods This prospective multicenter study included 200 consecutive IBD patients undergoing colonoscopy or sigmoidoscopy at tertiary centers between January 2023 and December 2025. Eligible patients were adults with confirmed IBD and at least one prior endoscopy. Patients with cognitive impairment, language barriers, or recent major surgery were excluded. Following each procedure, patients completed a validated questionnaire assessing anxiety, procedural discomfort, burden of bowel preparation, perceived necessity of the procedure, and willingness for future endoscopies. Data on disease type, activity (CDAI or partial Mayo score), prior endoscopies, age, sex, sedation, and complications were collected.

Results Among participants, 108 (54 %) had Crohn's disease and 92 (46 %) ulcerative colitis; mean age was 38.7 years, 52 % female. Prior endoscopies ranged from 1 to 10 (median 3). Moderate-to-high pre-procedure anxiety was reported by 64 %, higher in patients with active disease (VAS 7.2 vs 4.5, $p < 0.01$), females, and younger patients. Anxiety slightly decreased in patients with > 3 prior endoscopies. Bowel preparation was the most burdensome step for 52 % of patients, especially during active disease (VAS 6.9 vs 5.1, $p = 0.02$). Procedural discomfort was moderate in 65 % and high in 14 %, with sedation reducing discomfort significantly (VAS 4.3 vs 6.6, $p < 0.01$).

Despite discomfort, 81 % expressed willingness to adhere to future endoscopic monitoring if adequately informed. No significant differences were observed between Crohn's disease and ulcerative colitis in perceptions or tolerance.

Conclusions In conclusion, repeated endoscopies are perceived as necessary but are associated with anxiety and discomfort, particularly due to bowel preparation and anticipation. This multicenter study identifies high-risk patient profiles and highlights the importance of tailored strategies—optimized preparation, sedation, structured education, and patient-centered scheduling—to improve adherence, satisfaction, and overall quality of care. Incorporating patient perspectives into monitoring protocols supports shared decision-making and long-term treatment engagement.

eP156 EPAGE Criteria in Real-World Practice: Are We Missing Significant Upper GI Pathology?

Authors Souilem E[1], Jemai R[2], Houssem H[3], Jaziri H[3], Elleuch N[3], Braham A[3], Ben Slama A[3], Wafa D[3], Ksiaa M[3]

Institutes **1** UNIVERSITY HOSPITAL SAHLOUL, sousse, Tunisia, Sousse, Tunisia; **2** Mohamed Taher Maamouri Hospital, Nabeul, Tunisia; **3** Sahloul Hospital, Sousse, Tunisia

DOI 10.1055/s-0046-1821483

Aims The use of upper gastrointestinal endoscopy (UGIE) continues to rise, often beyond evidence-based indications. The EPAGE criteria were developed to standardize and rationalize endoscopy indications, but their real-world performance remains uncertain. This study evaluated the applicability of EPAGE criteria in daily practice and assessed the association between indication appropriateness and clinically significant endoscopic findings.

Methods We conducted a retrospective study including all UGIE procedures performed at Sahloul University Hospital (Sousse, Tunisia) from May to July 2023. Indications were classified according to EPAGE categories ("necessary and appropriate," "appropriate," "uncertain," "inappropriate," or "non-applicable") using the official EPAGE software. Exams with indications not covered by EPAGE were excluded. Significant endoscopic lesions were recorded, and their association with EPAGE categories was statistically analyzed.

Results Among 290 UGIE procedures, 42 (14.5 %) were excluded; **248 examinations** were analyzed (mean age 59.2 years; sex ratio M/F = 0.7). The most frequent indications were upper GI bleeding (28.3 %), dyspepsia (24.2 %), and iron-deficiency anemia (15.3 %). EPAGE classification rated indications as **necessary/appropriate in 60.5 %**, **appropriate in 23.4 %**, **uncertain in 3.9 %**,

inappropriate in 12.9 %, and **non-applicable in 15.5 %**.Clinically significant lesions were found in **79 %** of cases with necessary/appropriate indications. A significant association was observed between EPAGE appropriateness and endoscopic yield (**p = 0.02**). However, even in **inappropriate or uncertain indications**, significant lesions were detected in **40 %** of examinations, including 5 peptic ulcers and 3 neoplastic lesions.

Conclusions While most UGIE indications met EPAGE criteria, the substantial proportion of significant findings among procedures deemed inappropriate or uncertain suggests that current EPAGE recommendations may lack sensitivity in real-world clinical settings. These results support the need for **updating and refining EPAGE criteria** to better match contemporary diagnostic practices.

eP157 Optimization of Endoscopy Training: Strategies to Improve the Practical and Theoretical Teaching of Endoscopic Techniques

Authors Aouroud M[1], Bouhdoud N[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute 1 CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco
DOI 10.1055/s-0046-1821484

Aims Digestive endoscopy is a rapidly expanding specialty, essential for the diagnosis and treatment of gastrointestinal diseases. It occupies a central place in the daily practice of gastroenterologists. The need for high-quality training has increased due to the growing complexity of techniques and the volume of patients requiring endoscopic interventions. Therefore, the need to standardize and improve digestive endoscopy training is crucial to meet increasing clinical demands. A simulation center represents an opportunity to provide structured and progressive training for young gastroenterologists.

The main challenges include the absence of animal models and reliance on simulators for practical training, heterogeneous exposure of residents to clinical cases during intensive rotations, and difficulty for residents to acquire standardized practical skills in a structured setting.

The objectives were to evaluate the effectiveness of an optimized educational program on residents' skills, identify weaknesses and opportunities for improvement in the current curriculum, and propose recommendations to strengthen the quality of training.

Methods This is a prospective single-center study including 18 residents in training who underwent two evaluations three months apart using a competency assessment grid based on direct observation with immediate feedback. The assessment grid was developed based on previously validated grids created by experts in digestive endoscopy. It is composed of five parts subdivided into multiple items allowing evaluation of cognitive, integrative, and technical skills.

The educational program included theoretical training with interactive courses, video analysis of diagnostic and interventional endoscopy, endoscopy staff meetings on various topics such as tumors, inflammatory diseases, polypectomy, hemostasis, APC, and foreign body extraction, and case studies focused on multiple pathologies. Practical training in the simulation center used high-fidelity simulators to learn basic techniques and manage simulated complications, with realistic scenarios for colonoscopy and upper endoscopy and real-time feedback from instructors. Intensive supervised clinical rotations allowed participation in real procedures to reinforce skills acquired in simulation, with post-procedure feedback sessions using the assessment grid.

Evaluation included an initial test to assess baseline competence, practical simulator tests after each session to measure progression, and satisfaction surveys among residents and instructors.

Results Results showed improvement in all evaluated items. Residents in the first year progressed from maximal to significant supervision, while third- and fourth-year residents progressed from significant supervision to minimal supervision and competence. Improvement was less marked in integrative skills. Technical skills showed a 35 % average increase in practical scores after simulation training, with significant improvement in recognizing anomalies and manipulating endoscopic equipment. Resident satisfaction was high: 50 % found simulators effective for learning basic techniques, 90 % considered intensive rotations essential, and 80 % emphasized the need to introduce animal-model simulation. Instructors observed that residents were more confident and precise in their technical skills and highlighted the need to expand simulator access for advanced scenarios and to integrate animal-model simulation into training.

Conclusions In conclusion, a training program combining simulation and intensive supervised clinical rotations significantly improves technical and theoretical skills in young endoscopists. This single-center model can serve as a reference for other training centers.

eP158 Diagnostic performance of FIB-4 and APRI for non-invasive detection of advanced fibrosis in chronic hepatitis B: a FibroScan-based study

Authors Jemai R[1], Souilem E[2], Harbi R[3], Mrabet S[4], Akkari I[4], Ben JE[4]
Institutes 1 Mohamed Taher Maamouri Hospital, Nabeul, Tunisia; 2 Hôpital Sahloul, Sousse, Tunisia; 3 Hospital Farhat Hached, Sousse, Tunisia; 4 Hospital Farhat Hached, Sousse, Tunisia
DOI 10.1055/s-0046-1821485

Aims Non-invasive tools are increasingly used to stratify fibrosis in chronic hepatitis B (CHB). Liver stiffness measurement (LSM) by transient elastography (FibroScan) is widely adopted, while blood-based scores such as FIB-4 and APRI are simple and inexpensive. We aimed to evaluate the diagnostic performance of FIB-4 and APRI for the detection of advanced fibrosis in CHB, using FibroScan as the reference.

Methods We retrospectively included CHB patients who underwent FibroScan examination at F.Hached University Hospital (Sousse, Tunisia). Demographic, clinical and laboratory data were collected. Fibrosis stages were classified as F0–F1, F2, F3 and F4 based on LSM; advanced fibrosis was defined as F3–F4. FIB-4 and APRI scores were calculated from routine blood tests. Receiver operating characteristic (ROC) curves were constructed to assess the ability of FIB-4 and APRI to detect advanced fibrosis. Area under the ROC curve (AUC), optimal cut-offs , and diagnostic performance at classical thresholds were reported.

Results Eighty CHB patients were analyzed; **advanced fibrosis (F3–F4)** was present in **22/80 (27.5 %)** and absent in 58/80 (72.5 %). Mean FIB-4 and APRI values were significantly higher in patients with advanced fibrosis compared with those without (FIB-4: **4.86 vs 1.88**, APRI: **1.50 vs 0.46**).

For the detection of advanced fibrosis, AUC was **0.91** for FIB-4 and **0.94** for APRI. The optimal cut-off for FIB-4 was **2.57**, yielding a sensitivity of **100 %** and a specificity of **85.5 %**. The optimal APRI cut-off was **0.65**, also providing a sensitivity of **100 %** and a specificity of **85.5 %**.

At classical thresholds, FIB-4 ≥ 1.45 showed **100 % sensitivity** and **60.0 % specificity** (PPV 50.0 %, NPV 100 %) for advanced fibrosis, whereas FIB-4 ≥ 3.25 provided **59.1 % sensitivity** and **85.5 % specificity** (PPV 61.9 %, NPV 83.9 %). An APRI ≥ 1.0 yielded **59.1 % sensitivity**, **90.9 % specificity** (PPV 72.2 %, NPV 84.7 %).

Conclusions Both FIB-4 and APRI demonstrated excellent diagnostic performance for the detection of advanced fibrosis, with AUCs above 0.90 and high accuracy at optimized cut-offs. Classical rule-in thresholds (FIB-4 ≥ 3.25 and APRI ≥ 1.0) provided good specificity, whereas lower cut-offs offered very high sensitivity and NPV. These findings support the use of FIB-4 and APRI as simple triage tools to identify CHB patients who warrant confirmatory assessment by transient elastography.

eP159 Evaluation of Accessibility to Diagnostic and Interventional Digestive Endoscopy in the Southern Region in a Low-Resource Setting: Experience from a Reference Center

Authors Aouroud M[1], Bouhdoud N[1], Aouroud H[1], Nacir O[1], Lairani FE[1], Ait Errami A[1], Oubaha S[1], Samlani Z[1], Krati K[1]
Institute **1** CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Marrakech, Morocco
DOI 10.1055/s-0046-1821486

Aims Digestive endoscopy is essential for the diagnosis and treatment of gastrointestinal diseases. However, regions in the southern part of the country, characterized by predominantly rural populations and geographic challenges, face significant barriers in accessing specialized care. The reference center plays a crucial role in providing this care. This descriptive study analyzes patient characteristics, indications for endoscopic procedures, and obstacles encountered, with the aim of proposing adapted solutions.

Methods This is a cross-sectional descriptive study conducted over six months, from September 2024 to March 2025, including 512 patients who underwent endoscopic procedures at the center, originating from both urban and rural areas of the southern region in a low-resource setting. Collected data included demographic information (age, sex, urban/rural origin), health coverage (social security schemes, private insurance, uninsured patients), type of procedures performed (colonoscopy, upper endoscopy, endoscopic ultrasound, ERCP, capsule endoscopy), indications (diagnostic or interventional), and delays and obstacles (average waiting time for an appointment, distance traveled, and financial costs). Data sources included medical records, hospital registries, patient questionnaires, and interviews with healthcare professionals.

Results The study included 512 patients, with a mean age of 51 years (range 19–85), with a predominance of males (58 %). Most patients (68 %) came from rural areas, mainly from Ouarzazate (20 %), Zagora (18 %), Taroudant (15 %), Al Haouz (10 %), and El Kelaâ des Sraghna (5 %), while 32 % came from urban areas such as Agadir, Ida-Outanane, Marrakech, and Guelmim. Colonoscopy accounted for 45 % of procedures, mainly indicated for rectal bleeding (40 %), colorectal cancer screening (25 %), chronic diarrhea (15 %), and polypectomies (10 %). Upper endoscopy represented 35 % of procedures, mainly for epigastric pain (30 %), upper gastrointestinal bleeding (50 %), suspected gastritis or ulcer (10 %), and foreign body management (5 %). Endoscopic ultrasound was performed in 10 % of cases, primarily for pancreatic or biliary tumors (40 %), cysts (30 %), and suspected submucosal tumors (20 %). ERCP accounted for 7 % of interventions, mainly for bile duct stones (60 %), cholangitis (20 %), and biliary stent placement (20 %). Capsule endoscopy, performed in 3 % of cases, was mainly used for unexplained iron-deficiency anemia (60 %) and obscure gastrointestinal bleeding (30 %).

Regarding health coverage, 60 % of patients were affiliated with social security schemes, 20 % with other national programs, 10 % had private insurance, and 10 % were uninsured. Average waiting times varied by procedure, with four weeks for colonoscopy, six weeks for endoscopic ultrasound, and one to two weeks for ERCP. The average distance traveled to access care was 210 km, ranging from 30 to 950 km. Seventy-five percent of patients reported financial difficulties related to indirect costs, including transportation and accommodation.

Conclusions In conclusion, the center serves as a major reference point for patients from the southern region in a low-resource setting, with most patients originating from rural areas. The study highlights major challenges in accessing digestive endoscopy due to geographic, financial, and organizational barriers. These findings align with international data from other low-resource and developing countries and underscore the urgent need to improve service delivery. Solutions such as mobile endoscopy units, strengthening local hospitals, and improving subsidies for indirect care costs could significantly transform access to digestive endoscopy in the region.

eP160 Refining endoscopic screening: non-invasive prediction of esophageal varices and high-risk varices in chronic hepatitis B

Authors Jemai R[1], Souilem E[2], Harbi R[3], Akkari I[4], Mrabet S[4], Ben JE[4]
Institutes **1** Mohamed Taher Maamouri Hospital, Nabeul, Tunisia; **2** Hôpital Sahloul, Sousse, Tunisia; **3** Hospital Farhat Hached, سوسة, Tunisia; **4** Hospital Farhat Hached, Sousse, Tunisia
DOI 10.1055/s-0046-1821487

Aims Endoscopic screening for esophageal varices is recommended in patients with advanced chronic liver disease, but many patients have no or only low-risk varices. Simple non-invasive markers could help to better select candidates for endoscopy. We aimed to assess the prevalence of esophageal varices and to evaluate the performance of liver stiffness measurement (LSM), platelet count, FIB-4 and APRI for predicting esophageal varices and high-risk varices in chronic hepatitis B (CHB).

Methods We conducted a retrospective study including adult CHB patients who underwent both FibroScan and upper gastrointestinal endoscopy at F. Hached University Hospital. LSM (kPa), platelet count and routine laboratory parameters were collected. FIB-4 and APRI were calculated. Esophageal varices were graded (1–3). High-risk varices were defined as grade ≥ 2 and/or the presence of red wale signs. Advanced fibrosis was defined as F3–F4 by LSM. Receiver operating characteristic (ROC) curves were used to evaluate the ability of LSM, platelets, FIB-4 and APRI to predict any varices and high-risk varices.

Results Eighty CHB patients were analyzed. Esophageal varices of any grade were found in **18/80 (22.5 %)** patients, and **high-risk varices** in **5/80 (6.3 %)**, all in patients with advanced fibrosis. Compared with patients without varices, those with varices had lower platelet counts (mean **103 vs 180 × 10⁹/L**, $p < 0.001$), higher FIB-4 scores (**5.38 vs 1.93**, $p < 0.001$) and higher APRI values (**1.52 vs 0.53**, $p < 0.001$). LSM tended to be higher in patients with varices (**16.5 vs 9.9 kPa**, $p = 0.10$).

For the prediction of **any varices**, the area under the ROC curve (AUC) was **0.73** for LSM, **0.87** for FIB-4, **0.83** for APRI and **0.84** for platelet count. Optimal cut-offs for detecting any varices were approximately **4.9 for FIB-4** (sensitivity 68.8 %, specificity 96.4 %), **0.65 for APRI** (sensitivity 87.5 %, specificity 74.5 %) and **7.3 kPa for LSM** (sensitivity 87.5 %, specificity 67.3 %).

For **high-risk varices**, discrimination was very good, with AUCs of **0.96** for FIB-4, **1.00** for APRI and **0.75** for LSM, although based on a small number of events (n = 5). In this setting, thresholds around **7.0 for FIB-4**, **2.7 for APRI** and **12 kPa for LSM** all achieved 100 % sensitivity and high specificity.

Conclusions In this cohort of CHB patients, esophageal varices were present in about one quarter and high-risk varices in a small but clinically relevant proportion. Non-invasive markers, particularly FIB-4, APRI and platelet count, showed good to excellent performance for predicting esophageal varices and high-risk varices, and may help refine the selection of patients requiring screening endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP161 Diagnostic yield of colonoscopy in isolated constipation compared with other lower gastrointestinal indications

Authors Jemai R[1], Souilem E[2], Dahmeni W[3], Elleuch N[3], Jaziri H[3], Braham A[3], Ben Slama A[3], Ksiaa M[3]
Institutes **1** Mohamed Taher Maamouri Hospital, Nabeul, Tunisia; **2** Hôpital Sahloul, Sousse, Tunisia; **3** Sahloul Hospital, Sousse, Tunisia
DOI 10.1055/s-0046-1821488

Aims Constipation is a common indication for colonoscopy, but the diagnostic yield of the procedure in patients with isolated constipation, in the absence of alarm features, remains debated. We aimed to compare the prevalence of colonic neoplastic and structural lesions in patients undergoing colonoscopy for isolated constipation versus other lower gastrointestinal indications.

Methods We conducted a retrospective single-centre study including consecutive adult patients who underwent colonoscopy Sahloul hospital. Indications and findings were extracted from colonoscopy reports. *Isolated constipation* was defined as constipation without associated melena, rectorrhagia, diarrhea or anemia. The "other indications" group included patients with at least one of these features. Primary outcomes were the detection of colonic polyps and tumors. Diagnostic yields were compared using χ^2 tests.

Results A total of **120 colonoscopies** were analyzed; approximately **73 %** of patients were aged 50 years or older. Constipation was the main indication, and **isolated constipation** accounted for about **65 %** of procedures, while the remaining **35 %** were performed for other indications (including anemia, melena, rectorrhagia and/or diarrhea).

The overall polyp detection rate was **23.2 %**, and colorectal tumors were found in **4.6 %** of examinations. In patients with **isolated constipation**, polyps were detected in **14.4 %** of procedures and tumors in **2.0 %**. In contrast, among patients with **other indications**, the polyp detection rate reached **35.7 %**, and tumor detection **9.5 %**. Both polyp and tumor yields were significantly lower in isolated constipation compared with other indications ($p < 0.001$ and $p = 0.020$, respectively). The rate of complete colonoscopy did not differ significantly between groups (around **71 %** vs **66 %**, $p = 0.44$).

Conclusions In this cohort, colonoscopy performed for isolated constipation had a substantially lower yield for polyps and colorectal tumors than colonoscopy performed for other lower gastrointestinal indications, although neoplastic lesions were not absent. These findings support a more selective use of colonoscopy in patients with isolated constipation and highlight the importance of alarm features such as anemia, bleeding and diarrhea in guiding the indication.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP162 The occurrence of papillary stenosis after intraductal radiofrequency ablation after endoscopic papillectomy: a single center experience

Authors Cho CM[1], Dong-Wook L[1]
Institute 1 Kyungpook National University School of Medicine, Daegu, Republic of Korea
DOI 10.1055/s-0046-1821489

Aims Intraductal radiofrequency ablation (ID-RFA) has been introduced as a therapeutic option for residual or recurrent ampullary tumors after endoscopic papillectomy. However, papillary stenosis is a common adverse event. We evaluated the incidence of papillary stenosis following ID-RFA and investigated potential risk factors.

Methods We conducted a retrospective review of patients who underwent ID-RFA for residual or recurrent ampullary tumors after papillectomy at a single tertiary center (May 2019–October 2024). ID-RFA was performed using an 18- or 22-mm ELRA catheter (Taewoong, Seoul, South Korea) placed in the lower common bile duct under fluoroscopic guidance, with 10 W at 75 °C delivered by a VIVA Combo generator (STARmed, Seoul, South Korea). Clinical outcomes and the occurrence of papillary stenosis were analyzed, and risk factors were assessed using univariate analysis [1–3].

Results A total of 14 patients (median age, 60 years; range, 43–83; 6 females) underwent ID-RFA. Two were excluded due to surgical resection after ID-RFA or incomplete ablation, leaving 12 patients for analysis. During follow-up, no tumor recurrence was observed. Papillary stenosis developed in 8 patients (66.7 %). Comparisons between patients with and without stenosis showed no significant differences in the interval between papillectomy and ID-RFA (9.8 ± 13.3 vs. 5.5 ± 4.2 months, $P = 0.542$), ablation duration (120 ± 56 vs. 150 ± 60 s, $P = 0.410$), or stent placement duration (45.1 ± 8.4 vs. 30.0 ± 16.2 days, $P = 0.55$).

Conclusions ID-RFA is an effective treatment for residual or recurrent ampullary tumors following endoscopic papillectomy, with no recurrences observed in this cohort. However, papillary stenosis was a frequent adverse event, occurring in two-thirds of patients. No significant risk factors were identified. Larger, comparative studies are required to establish optimal strategies for stent type and placement duration to minimize this complication.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP163 Lower gastrointestinal bleeding: diagnostic value of colonoscopy

Authors Jemai R[1], Houssem H[2], Souilem E[3], Dahmeni W[2], Jaziri H[2], Elleuch N[2], Braham A[2], Ben Slama A[2], Ksiaa M[2]
Institutes 1 Mohamed Taher Maamouri Hospital, Nabeul, Tunisia; 2 Sahloul Hospital, Sousse, Tunisia; 3 Hôpital Sahloul, Sousse, Tunisia
DOI 10.1055/s-0046-1821490

Aims Rectal bleeding and melena are classical alarm symptoms that warrant colonoscopic evaluation to exclude colorectal neoplasia and other organic lesions. However, the diagnostic value of colonoscopy in this setting may vary according to patient profile and local practice. We aimed to describe colonoscopic findings in patients undergoing colonoscopy for lower gastrointestinal bleeding.

Methods We conducted a retrospective study including only adult patients who underwent colonoscopy for *lower gastrointestinal bleeding* (rectal bleeding and/or melena) at Sahloul University Hospital. Demographic data, indications and endoscopic findings were extracted from colonoscopy reports. The main lesions of interest were colorectal polyps, colorectal tumors, diverticulosis, angiodysplasia and hemorrhoids. The diagnostic value of colonoscopy was expressed as the proportion of procedures in which each lesion type was identified.

Results A total of **48 colonoscopies** performed for lower gastrointestinal bleeding were included. **Colorectal polyps** were detected in approximately **31 %** of examinations, and **colorectal tumors** in about **6 %**. **Diverticulosis** was observed in nearly **one quarter** of patients, and **angiodysplasia** in around **6 %** of cases.**Hemorrhoids** were particularly frequent, identified in **almost one out of five** patients, representing a substantial proportion of likely or contributory causes of bleeding. Most colonoscopies were complete, allowing full colonic evaluation in the majority of cases and accurate characterization of the underlying etiology of bleeding.

Conclusions In this cohort of patients undergoing colonoscopy specifically for lower gastrointestinal bleeding, nearly one third had colorectal polyps, a non-negligible proportion had colorectal cancer, and hemorrhoidal disease was very commonly identified. These findings confirm the **high diagnostic value** of colonoscopy in the setting of lower gastrointestinal bleeding and highlight hemorrhoids, alongside neoplastic and diverticular lesions, as major etiologies. They support colonoscopy as a first-line investigation in this clinical context.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP164 Rethinking colonoscopy for isolated constipation: limited diagnostic value in a 153-patient series

Authors Jemai R[1], Souilem E[2], Houssem H[3], Dahmeni W[3], Elleuch N[3], Jaziri H[3], Braham A[3], Ben Slama A[3], Ksiaa M[3]
Institutes **1** Mohamed Taher Maamouri Hospital, Nabeul, Tunisia; **2** Hôpital Sahloul, Sousse, Tunisia; **3** Sahloul Hospital, Sousse, Tunisia
DOI 10.1055/s-0046-1821491

Aims Isolated constipation in the absence of alarm features is a frequent indication for colonoscopy, but the appropriateness and diagnostic value of the procedure in this setting remain controversial. We aimed to evaluate the diagnostic yield of colonoscopy in patients undergoing the examination for isolated constipation and to assess the impact of age on the detection of colonic lesions.

Methods We conducted a retrospective single-centre study including adult patients who underwent colonoscopy for *isolated constipation* at Sahloul University Hospital. Isolated constipation was defined as constipation in the absence of rectal bleeding, melena, diarrhea or anemia as recorded in the colonoscopy report. Demographic data, colonoscopy completeness and endoscopic findings were collected. Colonoscopies were classified as **abnormal** if at least one significant organic lesion was present: colorectal polyp, colorectal tumor, diverticulosis, angiodysplasia or hemorrhoids; otherwise, they were considered **normal**. Patients were stratified by age (< 50 vs ≥ 50 years). Comparisons were performed using χ^2 or Fisher's exact test.

Results A total of **153 colonoscopies** performed for isolated constipation were included. Among these patients, **112 (73.2 %)** were aged ≥ 50 years and **41 (26.8 %)** were < 50 years. Colonoscopy was complete in **71.2 %** of cases. Overall, the examination was normal in **108/153 patients (70.6 %)** and abnormal in **45/153 (29.4 %)**. The main lesions identified were:

Colorectal polyps: **22/153 (14.4 %)**
Colorectal tumors: **3/153 (2.0 %)**
Diverticulosis: **17/153 (11.1 %)**
Angiodysplasia: **3/153 (2.0 %)**
Hemorrhoids: **1/153 (0.7 %)**.

Colorectal polyps and tumors combined were found in **25/153 patients (16.3 %)**, and all colorectal tumors occurred in patients aged ≥ 50 years. The proportion of abnormal colonoscopies was **17.1 % (7/41)** in patients < 50 years versus **33.9 % (38/112)** in those ≥ 50 years ($p = 0.068$), and colorectal polyps and/or tumors were observed in **9.8 % (4/41)** of patients < 50 years and **18.7 % (21/112)** of those ≥ 50 years ($p = 0.22$). These differences did not reach statistical significance.

Conclusions In this 153-patient series of colonoscopies for isolated constipation, over **70 %** of examinations were normal and colorectal polyps and cancer were uncommon, especially in patients < 50 years, with all cancers occurring in those aged ≥ 50 years. As age-related differences were not statistically significant, colonoscopy for isolated constipation appears to have limited diagnostic value, and its use should be more selective and guided by individual risk and the presence of true alarm features.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP165 Characteristics and outcomes of colorectal EMR in elderly and very elderly patients versus younger patients in the cradle of the Mediterranean diet

Authors De Cusatis D[1, 2], Palma R[2], Pietro S[1], Di Feo E[3, 1], Mancusi M[2], Iovino P[2], Santonicola A[2]
Institutes **1** Gastroenterology and Digestive Endoscopy Unit, "San Luca" Hospital, Vallo della Lucania, SA, Italy; **2** Gastrointestinal unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Salerno, Italy; **3** Department of Medicine and Surgery, University of Salerno, Salerno, Italy
DOI 10.1055/s-0046-1821492

Aims The evidence guiding the use of Endoscopic mucosal resection (EMR) in elderly and very elderly patients remains limited. It's known that the Mediterranean diet (MD) has healthy properties, and Cilento is an area in southern Italy, considered the cradle of the MD, with a high number of long-living individuals [1–23].

The primary outcome was to evaluate the safety and efficacy of EMR in these patients. Furthermore, we aimed to identify specific variables correlated with age to contribute to a more tailored approach in this growing patient group, particularly in our geographic area (▶ **Table 1**).

▶ **Table 1**

	Age < 65 y (n = 145)	*Age ≥ 65 y (n = 257)*	*P value*	*Age < 80 y (n = 344)*	*Age ≥ 80 y (n = 58)*	*P value*
Women	59 (40,7 %)	85 (33,1 %)	0.115	125 (36,3 %)	18 (31,0 %)	0.527
Mean age, y (Standard deviation)	55,7 (7,3)	74,2 (6,4)	< 0.001*	64,9 (9,7)	83,3 (3)	< 0.001*
Number of polyps	167	305		402	70	
Location of polyps			0.983			0.958
Rectus	16 (9,6 %)	28 (9,2 %)	1.000	36 (9 %)	8 (11,4 %)	0.601

Methods We conducted a multicenter retrospective study analyzing 402 patients undergoing EMR for colorectal lesions ≥ 10 mm between January 2020 and April 2025. Patients were stratified into age groups: < 65 vs ≥ 65 years, and < 80 vs ≥ 80 years. Demographics, polyp characteristics, technical outcomes, histology, and adverse events were compared between groups. A subanalysis was performed to evaluate the outcomes for lesions ≥ 20 mm. Correlation analyses explored the associations between clinical, procedural, and histological variables.

Results EMR achieved high technical success across all age groups, with complication rates of 2.4 % in patients < 65 years and 4.8 % in those ≥ 65 years, and no perforations in any group. In patients aged 80 years or older, the prevalence of adenocarcinoma was significantly higher (10 % vs. 3.6 %, p = 0.043), and a moderate correlation was observed between lesion size and high-grade dysplasia/adenocarcinoma (r = 0.64). Younger patients more frequently underwent en bloc resection, while elderly patients presented with more complex lesions. Follow-up rates remained low across groups.

Conclusions EMR is a safe and effective technique for removing colorectal polyps in elderly and very elderly patients, with complication rates and efficacy comparable to those in younger cohorts. Age alone should not preclude EMR. A comprehensive patient-centred assessment, including lesion characteristics, comorbidities, and life expectancy, optimises outcomes. Vigilant surveillance is recommended for elderly and very elderly patients, particularly for large lesions due to their higher malignant potential.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821493

Aims Exploring the Outcomes and safty from a multicentre UK series of LA-ERCPs performed across five centres located in the Northeast of UK.

Methods Retrospective multicentre case series of consecutive patients undergoing LA-ERCP between September 2020 up to August 2025 at Northumbria, Sunderland, Freeman, NorthTees and Jamescook Hospitals. Thirty-eight consecutive patients undergoing LA-ERCP were included. Data were collected on demographics, indications, imaging, baseline bloods, procedural success, adverse events, and hospital stay. Technical success was defined as successful

cannulation of the papilla; therapeutic success was defined as successful stone removal or other definitive intervention [1–7].

Results A total of 38 LA-ERCPs were performed. The median age was 59 years (IQR 54-67). The cohort was predominantly female (23/38, 60.5 %). Common indications included choledocholithiasis and cholangitis. Pre-procedure MRCP was performed in the majority of cases. Median bilirubin was 16.5 µmol/L (IQR 12-54.5) and ALP 286.5 U/L (IQR 173-625.5).

Technical success (cannulation) was achieved in 37/38 (97.4 %) cases with a single case of successful cannulation but unsafe sphincterotomy . Therapeutic success (stone removal) was achieved in 33/38 (86.8 %) cases. Three cases (7.9 %) were classified as procedure failure, which included the failed sphincterotomy case and two cases that required subsequent surgical management despite initial cannulation (▶ **Table 1**).

▶ **Table 1**

Outcome	Count/Total	Rate (%)
Technical Success (Cannulation)	37/38	97.4 %
Therapeutic Success (Stone Removal)	33/38	86.8 %
Procedure Failure	3/38	7.9 %
Post-ERCP Pancreatitis	1/38	2.6 %
Bleeding	2/38	5.3 %
Perforation	0/38	0.0 %
Cholangitis	0/38	0.0 %
Surgical Adverse Events	1/38	2.6 %

Complications included pancreatitis (1 case, 2.6 %), bleeding (2 cases, 5.3 %), and surgical adverse events (1 case, 2.6 %). No cases of post-ERCP cholangitis or perforation were recorded. The median length of stay was 2 days (IQR 1–4).

Conclusions In this multicentre UK series in the Northeast, LA-ERCP demonstrates a very high technical success rate (97.4 %) and an acceptable therapeutic success rate. The complication profile is favorable, with low rates of post-ERCP pancreatitis and bleeding, and no perforations. LA-ERCP offers a reliable and safe alternative for biliary access post-RYGB in centers with appropriate expertise.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP167 Endoscopic Transmural Drainage of Walled-off Necrosis: Comparative Outcomes of EUS-Guided versus Conventional Approaches

Authors ÖDemiş B[1], Ünver NG[1], Kenarlı K[1], Macif A[1]

Institute 1 Ankara Bilkent City Hospital, Ankara, Türkiye

DOI 10.1055/s-0046-1821494

Aims Walled-off necrosis (WON) is a complex sequela of acute pancreatitis that often necessitates interventional management. Endoscopic transmural drainage has emerged as the preferred first-line approach, especially with the increasing availability and refinement of endoscopic ultrasonography (EUS) guidance. This study aimed to present endoscopic management of patients with WON and to identify factors associated with technical and clinical success.

Methods Patients who underwent endoscopic transmural drainage for symptomatic WON at a tertiary referral center were analyzed retrospectively. Two different techniques—conventional and EUS-guided—were used as endoscopic drainage modalities. Data on demographics, etiology of pancreatitis, collection size, drainage indications, procedural details, and outcomes were collected. Clinical and technical success, complications, recurrence and reintervention rates, and the impact of anatomical features such as paracolic extension, disconnected pancreatic duct syndrome (DPDS), and colonic fistula were analysed and compared according to endoscopic modalities [1, 2].

Results A total of 73 patients (mean age: 54.6 ± 13.9 years; 46.6 % male) underwent a total of 76 transmural drainage procedures. The median size of WON collections was 14cm (IQR:11–17cm), and the most common indication was infection (62.5 %). Colonic fistula and DPDS were identified in 5 (6.8 %) and 38 (52.1 %) patients, respectively. Technical success was assessed per procedure. Overall technical success was 97.4 % (74/76), with 100 % (36/36) success in the conventional group and 95.0 % (38/40) in the EUS group. Clinical success was achieved in 84.9 % (62/73) of patients, with similar outcomes between conventional (83.3 %) and EUS-guided (86.5 %) drainage(p = 0.961). Reintervention was required in 67.1 %, and direct endoscopic necrosectomy was performed in 31.5 %. Total number of interventional sessions was 294 (mean 4.0 per patient). Complications occurred in 28.7 % of patients, most commonly bleeding (15.1 %), generally managed endoscopically.

Conclusions Endoscopic transmural drainage is an effective and safe intervention for the management of WON, with high technical and clinical success. EUS-guided drainage offers significant advantages by allowing intervention in patients without luminal bulging and in those with smaller collections, thereby expanding treatment eligibility to a broader patient population.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP168 Lemmel syndrome: epidemiological profile and diagnostic methods

Authors Iemrabott A[1], Kadiri M[2], Lagdali N[3], Ajana FZ[3], Borahma M[4]

Institutes 1 Ibn Sina University Hospital, Rabat, Morocco; 2 Hospital Ibn Sina, Rabat, Morocco; 3 Mohammed V University, Rabat, Morocco; 4 Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco

DOI 10.1055/s-0046-1821495

Aims Lemmel syndrome is a rare condition defined as obstructive jaundice caused by a periampullary duodenal diverticulum, in the absence of biliary lithiasis or neoplasia. To date, few cases have been reported and the etiopathogenesis has not been fully established.

The aim of our study was to illustrate the epidemiological profile and diagnostic approaches for cases of Lemmel syndrome managed in our department

Methods This was a retrospective descriptive study spanning 5 years, from May 2019 to October 2025,

including all patients admitted for obstructive jaundice who underwent endoscopic retrograde cholangiopancreatography (ERCP). The diagnosis of Lemmel syndrome was established based on clinical, biological, and imaging findings in all patients and on the results of ERCP.

Results Among the 810 patients who underwent ERCP, 3 patients (0.37 %) were diagnosed Lemmel syndrome. All patients were women with a median age of 82 years [79-85]. All patients had cholestatic jaundice associated with pain in the right hypochondrium and epigastrium, two of whom had grade 1 cholangitis and one had grade 2 cholangitis. One patient also presented with pancreatic-type pain and vomiting. Biochemically, all patients (n = 3) showed cytolysis and cholestasis jaundice, and one patient had a lipase level more than three times the normal. Contrast-enhanced CT imaging revealed dilation of the common bile duct (CBD) and intrahepatic bile ducts without visible obstruction in all cases (n = 3), and associated stage C pancreatitis in one case.

One patient underwent endoscopic ultrasound, which revealed a large periampullary diverticulum, with the ampulla specifically located on the rim of the diverticulum, compressing the CBD without stones.

ERCP was performed in all three patients. The major duodenal papilla, with a normal orifice, was located within a periampullary duodenal diverticulum. Contrast injection showed upstream dilation of the common bile duct without stones or neoplasia. Sphincterotomy allowed effective biliary drainage.

The outcome was favorable in all our patients, with normalization of liver function tests.

Conclusions Although it is a rare condition, Lemmel syndrome should always be considered in patients presenting with obstructive jaundice. Early diagnosis is essential to avoid serious complications. ERCP with sphincterotomy wan be an effective treatment for Lemmel syndrome.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP169 Simulation-based endoscopy training for Upper GI bleeds using porcine models

Authors Chan C[1], Tai C[1]

Institute 1 Royal Free London NHS Foundation Trust, London, United Kingdom

DOI 10.1055/s-0046-1821496

Aims The increasing demand for endoscopy as both a diagnostic and therapeutic tool must be supported by the development of endoscopy training. Confidence in endoscopic skills is particularly critical when managing acute scenarios such as upper gastrointestinal bleeds (UGIB).

Recent endoscopy trainee surveys in the UK have highlighted the deficits in haemostasis training, accompanied by low reported confidence and independence. Techniques such as glue injection and Danis stent are particularly difficult skills to train in, and trainees have called for further simulation-based training [1].

An innovative method using ex vivo animal tissue was introduced to assist in training such endoscopy techniques.

Methods A half-day consultant-run course was developed with a focus on utilisation of porcine stomachs, supplemented with pre-course reading and handbook. We created a low-cost porcine model by drilling holes into a black box in which overtubes were used to keep the porcine stomachs patent. Bleeding was simulated using cannulas which allowed red dye to flow into the stomach.

The stations were split into variceal haemostasis and non-variceal haemostasis. Participants received hands on experience banding oesophageal varices, gluing gastric varices, inserting Danis stent and inserting Sengstaken-Blakemore tube in the variceal haemostasis station. In the other, they practised using the gold probe, injecting adrenaline, and using through-the-scope clips and over-the-scope clips.

Results Between 2021 and 2025, four sessions of training were hosted. 54 responses of qualitative feedback were received. Participants reported high levels of satisfaction with the course, particularly the opportunity for hands-on experience and live demonstration. A prominent theme was the value of the haemostasis station, particularly the ability to practise glue injection and Danis stent deployment. These are techniques in which endoscopy trainees have previously reported low independence and limited experience. Participants also described the benefit in practising over-the-scope clips, a procedure in which trainees have been found to have little or no encounters with.

Another recurring theme from participants was the simulation of both technical skills and working within the multidisciplinary team during these scenarios. Participants cited the benefits in practising communication with other healthcare professionals within the endoscopy team. Suggestions for improvement included increasing the time per station and expanding the range of endoscopic techniques taught, such as those related to nutrition interventions.

Conclusions The use of ex vivo porcine tissue in simulating UGIB provides a low-cost and effective method of endoscopy training provision. This method of teaching offers practical experience and directly addresses previously suggested improvements to haemostasis endoscopy training using simulation. Participant feedback emphasises the value of hands-on experience in a variety of interventions and highlights the opportunity in using this model for other endoscopic interventions, including nutrition-related procedures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP170 Results of switching from Intravenous to Subcutaneous Infliximab in patients with Inflammatory Bowel Disease in clinical remission: A multicenter real-life cohort

Authors Labie C[1], Sickersen G[1], Antoine E[1], Combes M[2], Barthe C[3], Jeanneau L[3], Becam E[4], Blanchet E[4], Olivier R[1]

Institutes 1 Poitiers University Hospital, Poitiers, France; 2 Hospital De Niort, Niort, France; 3 Hospital Center De Saintonge, Saintes, France; 4 Hospital Saint-Louis De La Rochelle, La Rochelle, France

DOI 10.1055/s-0046-1821497

Aims Early literature on Inflammatory Bowel Disease (IBD) regarding the switch from intravenous (IV) to subcutaneous (SC) infliximab has reported reassuring mid-term efficacy and treatment persistence rates. However, real-world data remain limited.

Methods We conducted a retrospective, multicenter, observational study across four french centers: one tertiary and three secondary care institutions. Eligible patients were adults (≥ 18 years) with IBD in clinical remission for at least 6 months under IV infliximab who subsequently switched to SC infliximab. Exclusion criteria included clinical remission < 6 months, combination with another advanced biological therapy, corticosteroid use within the past 4 months, pregnancy, or breastfeeding.The primary endpoint was the treatment persistence rate of SC infliximab at week 48 (W48). Secondary endpoints included: differences in persistence according to prior IV optimization status and combination therapy; changes in clinical scores (Harvey–Bradshaw Index, partial Mayo score) and inflammatory biomarkers between IV and SC treatment; reasons for SC treatment discontinuation; disease relapse rate under SC infliximab; correlation between clinical symptoms and objective evidence of relapse; and the incidence of adverse events (AEs) and serious adverse events (SAEs).

Results Eighty-seven patients treated with SC infliximab (IFX-SC) were included. IV-to-SC transitions occurred between July 2022 and July 2024.The median age was 40 years, and most patients had Crohn's disease (86.2 %). The mean duration of IV therapy before switching was 5.4 years, predominantly at a non-optimized standard dose (77 %). At the time of switching, 17.2 % were on

combination therapy with an immunosuppressive agent , and 33.3 % had previously received at least one other biological therapy. Regarding the primary endpoint, persistence of SC infliximab at W48 was 74.4 % (65/87). There was no statistically significant difference among subgroups: combination therapy with immunosuppressive agent(66.6 %, p = 0.53), previously optimized IV treatment (70 %, p = 0.78), or standard IV dosage(76.6 %, p = 0.57). Clinically and biologically, no significant differences were observed between IV and SC periods in clinical scores, mean leukocyte count, CRP, or albumin levels. Fecal calprotectin showed no significant change (IV: 107 µg/g vs SC: 281 µg/g, p = 0.16). Among the 22 discontinuations, most were due to clinical relapse (n = 16, 72.7 %). Objective evidence of disease activity (elevated fecal calprotectin, imaging, or endoscopy) was confirmed in only 6 of these 16 patients (37.5 %). Other causes of discontinuation included injection fatigue and poorly tolerated local injection reactions. SC infliximab optimization was required in 22/87 cases (25.3 %), with a treatment persistence rate of 77.3 % at W48 in this subgroup. Only 5 optimized patients were among the 22 who discontinued IFX-SC. Overall SC infliximab tolerance was good, with few AEs (5.7 %), including only one SAE. The 74.4 % persistence rate at W48 was lower than previously reported in the literature (e.g., GETAID PEREM study, with 95.3 % persistence at W48).

Conclusions In real-world conditions, switching from IV to SC infliximab proved safe, effective, and well tolerated, with a 74.4 % persistence rate at week 48. The main reason for discontinuation was clinical relapse (16/22), which was not consistently supported by objective evidence, in a population largely not optimized under SC therapy. These findings highlight the importance of individualized dose optimization, to objective evidence of relapse in patients who may be anxious about switching to the SC and close follow-up to enhance long-term treatment persistence with SC infliximab.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP171 Photo documentation of anatomical landmarks at gastroscopy and colonoscopy in clinical practice : do we adhere to ESGE standards?

Authors Wallis S[1], Besherdas K[2]
Institutes 1 Royal Free Hospital, London, United Kingdom; 2 Royal Free Hospital, London, United Kingdom, United Kingdom
DOI 10.1055/s-0046-1821498

Aims The aim of this study was to retrospectively assess the photo-documentation at gastroscopy and colonoscopy in clinical practice and compare this to the recommended sites as per the ESGE guidelines.

Methods This was a single centre, retrospective analysis of 62 consecutive patients attending the endoscopy unit in a district general hospital during September and October 2025. The endoscopy reports were scrutinized for photographic evidence of the anatomical landmarks. The images capture on the Medilogic GI Reporting Tool were analysed and compared to the recommended ESGE guidelines.

Results 62 procedures were included, with standards followed in 77 % of procedures. Procedures were performed by a range of professionals including gastroenterologists (n = 26), general surgeons (n = 21), and clinical nurse endoscopists (n = 15).

In gastroscopies, BSG guidelines were followed in 72.4 % of cases. In most cases, only one photo site was missing including the incisura (n = 2), duodenal bulb (n = 2), gastro-oesophageal junction (n = 1), and middle body of stomach (n = 1). In two cases, multiple photos were missing. Of the procedures where a photo was missing, a trainee endoscopist was present during half of the procedures (n = 4).

For colonoscopies, terminal ileum or appendix orifice were photographed in 100 % of procedures. In 11.5 % of procedures, rectum in retroflexion was not photographed and in one case retroflexion could not be completed as a polyp was being retrieved.

Gastroenterogists were least likely to follow guidelines (65 % followed), clinical endoscopists were most likely to (87 % followed). Surgeons were 76 %.

Conclusions The British Society of Gastroenterology (BSG) and Association of Upper Gastrointestinal Surgeons (AUGIS) recently published a position statement in view of the variability of performance of a high-quality gastroscopy and an unacceptably high rate of failure to diagnose cancer at endoscopy. This set out the minimum expected standards in diagnostic upper gastrointestinal endoscopy. One recommendation is that photo-documentation should be made of relevant anatomical landmarks and any detected lesions. This practice encourages mucosal cleansing, mucosal inspection and ensures a complete examination. The European Society of Gastrointestinal Endoscopy (ESGE) guidelines describe a systematic approach to photo-documentation with a recommendation of eight anatomical landmarks to improve diagnostic endoscopy quality of endoscopy. For colonoscopy a minimum of two anatomical landmarks are recommended to confirm caecal intubation (appendix orifice, Ileo-caecal valve, tri radiate fold) and retroflexion in the rectum.

In this study, photographic evidence of anatomical landmarks as per ESGE guidelines is only documented in 77 %, with poorest compliance in gastroscopies particularly in the presence of trainee endoscopists. This study also observed substandard photo documentation of retroflexion during colonoscopy. Photographic documentation improves the diagnostic quality of endoscopy and acts as a medico-legal record of an adequate/complete procedure. We conclude, there remains room for improvement in the photographic documentation in both gastroscopy and colonoscopy of anatomical landmarks in clinical practice.

eP172 Lymphocytic Esophagitis: A Diagnostic Challenge. Case Series

Authors Marcé Colomet R[1], Valentin Gomez F[1], Gonzalez Miyar R[1], Abad Guerra J[1], Calleja Panero JL[1]
Institute 1 Puerta de Hierro Majadahonda University Hospital, Majadahonda, Spain
DOI 10.1055/s-0046-1821499

Background: Lymphocytic esophagitis (LE) is an emerging, underrecognized esophageal disorder with dense peripapillary intraepithelial lymphocytic infiltrate and minimal granulocytic inflammation. Its clinical features overlap with gastroesophageal reflux disease (GERD) and eosinophilic esophagitis, making diagnosis difficult. Dysphagia is the most common symptom, and endoscopic findings are variable. Histology is essential. This series highlights endoscopic variability and the importance of biopsies [1–7].

Case Report: Five patients with histologically confirmed LE are described.

Case 1: A 73-year-old woman with multinodular goiter presented with recurrent food impaction. EGD showed stenosis at 20 cm, edematous mucosa, and whitish exudates.

Case 2: A 56-year-old man with asthma had dysphagia and heartburn. EGD revealed Los Angeles (LA) grade D esophagitis.

Case 3: A 57-year-old woman with chronic gastritis and autoimmune hepatitis reported dysphagia and pyrosis. EGD showed patchy erythematous mucosa in the proximal and mid esophagus with LA grade A esophagitis.

Case 4: An 83-year-old woman with prior multinodular goiter surgery presented with dysphagia and heartburn. EGD revealed edema, concentric rings, and LA grade B esophagitis.

Case 5: An 88-year-old woman with hypothyroidism, GERD, and chronic gastritis underwent EGD for dysphagia. A single mucosal ring was seen in the cervical esophagus.

Discussion: LE shows wide clinical and endoscopic variability. Symptoms such as dysphagia and food impaction are nonspecific. Endoscopic findings range from normal mucosa to strictures, rings, edema, erythema, or exudates, often

mimicking GERD, eosinophilic, or infectious esophagitis. Histology is the diagnostic standard, showing peripapillary lymphocytosis, epithelial damage, and few granulocytes. Because the disease is patchy, multiple biopsies are recommended. Awareness is essential to prevent misdiagnosis and guide management, typically acid suppression and treatment of associated conditions.

Conclusion: LE is a rare, challenging diagnosis. This series emphasizes heterogeneous presentation and the importance of biopsies. Increased clinician awareness may improve diagnostic accuracy and outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP173 Uncovering the Links Between Obesity, Race, Gender, and Upper GI Bleeding: Findings From a National Cohort of 2.8 Million Patients

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Amina Z[1], Mustacchia P[1]

Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1821500

Aims Amidst the growing concern over obesity's health effects, particularly on upper gastrointestinal bleeding (UGIB), this study utilizes the Nationwide Admission Database (HCUP) to explore how obesity, race, and gender influence UGIB and its readmission rates. Covering 2019 to 2024, the research analyzes over 2.8 million adult hospital admissions, specifically examining 234,024 patients with obesity-related diagnoses. The aim is to assess whether obesity correlates with increased UGIB incidences and subsequent short-term readmissions, thereby providing insights into the demographic and clinical factors that may exacerbate UGIB risks and healthcare burdens.

Methods From 2019 to 2024, the Nationwide Admission Database (HCUP) was accessed to study 2,858,576 adult hospital admissions, analyzing the influence of obesity, race, and gender on upper gastrointestinal bleeding (UGIB) and 30-day and 60-day readmission rates. The study stratified patients by obesity status, using chi-square tests and logistic regression to evaluate UGIB incidence and readmission differences. ROC curves with Area Under the Curve (AUC) assessed predictive accuracy, with statistical significance established at $p<0.05$.

Results From 2019 to 2024, the Nationwide Admission Database (HCUP) was utilized to analyze 2,858,576 adult hospital admissions, focusing on 234,024 patients diagnosed with diverticulitis, including 112,014 obese individuals (BMI > 30). Chi-square tests revealed no significant difference in UGIB incidence between obese and non-obese groups ($p=0.795$). However, among obese patients with UGIB, significant associations were found with 30-day ($p=0.032$) and 60-day ($p=0.041$) readmissions. African Americans showed a significant association with UGIB incidence ($p<0.001$). Logistic regression indicated race impacted 30-day readmissions ($p<0.05$ for Black and Hispanic patients) and gender influenced 60-day readmissions, notably in males and Hispanics ($p<0.001$ and $p=0.031$, respectively). ROC analysis demonstrated moderate predictive accuracy for UGIB (AUC = 0.71) and readmissions, with 60-day predictions showing better performance (AUC = 0.89).

Conclusions This study examines obesity, race, and gender in UGIB outcomes. While obesity didn't raise initial UGIB risk ($p=0.795$), it was linked to higher 30- and 60-day readmissions. African Americans showed notable disparities. Predictive model challenges highlight the need for targeted care and research.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP174 Language Proficiency and Procedural Performance: Examining Disparities in Manometry

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Amina Z[1], Mustacchia P[1]

Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1821501

Aims This study explores how English proficiency impacts manometry performance in patients with esophageal motility disorders. We retrospectively analyzed inpatient data (2023–2024), comparing outcomes between English as a second language (Group A) and native speakers (Group B). Using propensity score matching, we isolated the effect of language on procedure duration and failed swallows, aiming to highlight how language barriers may influence diagnostic accuracy and clinical outcomes.

Methods We performed a retrospective study analyzing inpatient data from 2023 to 2024 at our institute, focusing on patients undergoing manometry. The study compared outcomes between patients with English as a second language (Group A) and native English speakers (Group B). We applied propensity score matching to equalize baseline characteristics between groups, examining the impact of race and language on manometry performance indicators such as procedure duration and failed swallows. Descriptive statistics evaluated performance across demographics, while logistic regression was employed to analyze the influences of gender, race, and language, reporting coefficients and p-values for statistical relevance.

Results Our analysis included 26 patients who underwent manometry: 14 in Group A and 12 in Group B. We assessed outcomes based on procedure duration and the number of failed swallows. Results showed that Group A experienced longer procedure times (45 ± 5 min) compared to Group B (30 ± 3 min, $p<0.01$) and more failed swallows (10 ± 3 vs. 4 ± 2, $p<0.021$). Additionally, Hispanic patients had increased procedure duration ($p=0.032$) and failed swallows ($p=0.012$). Regression analysis indicated a significant positive correlation between English proficiency and reduced procedure duration and failed swallows (Coefficient = 3.59).

Conclusions Our retrospective study highlights significant differences in manometry performance based on English proficiency. Non-native speakers experienced longer procedure times and higher rates of failed swallows, indicating challenges faced by these patients. These findings suggest that language barriers can affect healthcare quality and patient safety. To address these issues, improving communication through language services and culturally sensitive care is essential. Targeted interventions for non-native speakers could improve procedural outcomes and ensure more equitable healthcare for all.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP175 A Nationwide Examination of the Vascular and Intestinal Hazards Associated With Smoking

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Amina Z[1], Mustacchia P[1]

Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1821502

Aims This investigation utilizes the Healthcare Cost and Utilization Project (HCUP) National Database to explore the relationship between smoking and the prevalence of arteriovenous malformation (AVM) and diverticulitis. Spanning hospital admissions from 2019 to 2024, the study focuses on a significant cohort of 2,858,576 adults. By analyzing data retrieved via ICD codes, this research aims to elucidate whether a statistically significant link exists between tobacco usage and increased incidence rates of these conditions, contributing to the broader understanding of smoking-related health risks.

Methods This study analyzed hospital admissions from 2019 to 2024 using the Nationwide Admission Database (HCUP), focusing on 2,858,576 adults. The main objective was to determine whether smoking increases the incidence of arteriovenous malformation (AVM) and diverticulitis. Using ICD codes, data were extracted from the national database, and a specific subset of 92,483 individuals was selected to explore the relationship between smoking and the occurrence of AVM and diverticulitis. Both smoking status and the presence of AVM were recorded as binary variables. To evaluate the significance of the observed association between smoking and AVM incidence, a Chi-squared test of independence was performed.

Results The analysis assessed the relationship between smoking and the incidence of arteriovenous malformation (AVM) in a cohort of 92,483 individuals consisting of 50,939 smokers (55.1 %) and 41,544 non-smokers (44.9 %). Of these, 46,668 individuals (50.5 %) were diagnosed with AVM, while 45,815 (49.5 %) were not. A Chi-squared test indicated a statistically significant association between smoking and the presence of AVM ($p = 0.025$, $df = 1$). The results suggest that smokers may be at a slightly higher risk of developing AVM and diverticulitis compared to non-smokers.

Conclusions The findings from this study demonstrate a statistically significant association between smoking and increased incidence of AVM, as evidenced by the analysis of data from 92,483 individuals in the HCUP National Database. This correlation suggests potential pathophysiological mechanisms where smoking could exacerbate or contribute to the development of AVM and diverticulitis. These results necessitate further investigation into how smoking influences vascular and digestive system health, with implications for public health policies aimed at reducing smoking rates.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP176 When the Tumor Starts to Bubble – A Rare Sign Observed During Excision of a Colon Adenocarcinoma with Mucinous Component

Authors Lima P[1], Pereira B[1], Rodrigues B[1], Mendo R[1], Barreiro P[2, 1], Cristina C[1]

Institutes **1** Gastroenterology Department, Unidade Local de Saúde de Lisboa Ocidental, Lisbon, Portugal; **2** Lusíadas Hospital, Advanced Endoscopy Center of Lisbon, Lisbon, Portugal

DOI 10.1055/s-0046-1821503

Abstract Text

We present the case of an 80-year-old man, with no relevant medical history, referred to our center for a 45-mm mixed granular Laterally Spreading Tumor (LST) of the transverse colon, identified on a previous colonoscopy. After discussing therapeutic options with the patient, endoscopic submucosal dissection (ESD) was proposed for removal of the lesion.

The procedure was performed under light sedation, confirming at 60 cm from the anal verge the presence of a 45-mm mixed granular LST with a main nodule > 1 cm, involving approximately 50 % of the luminal circumference. The crypt/microvascular pattern was preserved (JNET type 2B). In this context, an attempt was made to remove the lesion using the ESD technique [1–3].

During submucosal dissection, the appearance of apparent "mucus bubbles" was observed, mimicking the fish-mouth sign seen in main-duct IPMNs, initially raising the suspicion of a possible perforation. The procedure was continued and, after careful evaluation with redefinition of the dissection plane, perforation was excluded. It was suspected that these findings represented encapsulated mucinous components in the submucosa underlying the main nodular component. The procedure was completed, achieving complete en-bloc resection. It lasted 150 minutes, with no recorded complications.

The histopathological examination confirmed a low-grade adenocarcinoma, Sm1a, with evidence of acellular mucin extravasation, no lymphovascular invasion, low-grade budding, and complete resection.

To the authors' knowledge, images of mucin "bubbles" during submucosal dissection have only recently been described in a case report, making this the second reported case documenting this "sign." This case is presented due to its rarity, the correlation between optical diagnosis and histopathology, and the importance of recognizing this finding during endoscopic resection in order to suspect neoplasms with a mucinous component and avoid misdiagnosis. Illustrative iconography of the procedure is provided.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP177 Predicting the Inevitable? Readmission Risk in Cirrhotic Patients With Variceal Bleeding: A Nationwide HCUP Analysis (2019–2024)

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Amina Z[1], Mustacchia P[1]

Institutes **1** Nassau University Medical Center, East Meadow, United States of America; **2** Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1821504

Aims This study analyzed gender-specific variations in variceal bleeding using the Nationwide Admission Database (HCUP), examining 2,858,576 adult admissions from 2019 to 2024. Focusing on cirrhotic patients, it evaluated differences in 30-day and 60-day readmission rates between genders. Chi-square tests assessed incidence and readmission disparities, while logistic regression explored the impact of gender and race on readmission probabilities. ROC curves and AUC values gauged the models' predictive accuracy, enhancing understanding of gender-based outcomes in cirrhosis management.

Methods Data from the Nationwide Admission Database (HCUP) from 2019 to 2024, covering 2,858,576 admissions, was used to examine gender-specific variations in variceal bleeding among cirrhotic patients. The study focused on assessing 30-day and 60-day readmission rates, using chi-square tests to evaluate incidence and readmission differences between genders and other demographic factors. Logistic regression models analyzed the impact of gender and race on readmission likelihood, particularly among obese patients, with ROC curves and AUC values measuring the predictive accuracy of these models.

Results From 2019 to 2024, HCUP data on 2.8 million adult admissions identified 94,124 patients with cirrhosis and variceal bleeding. Of these, 43.8 % were female. Chi-square analysis showed significant gender disparities in readmissions, with females experiencing higher rates. The 30-day readmission rate had a chi-square of 49,003 ($p = 0.214$); the 60-day rate showed $p < 0.001$. Logistic regression revealed gender and race effects, with White females showing the highest coefficients. The 30-day model had strong predictive accuracy (AUC).

Conclusions This study highlights significant gender disparities in cirrhotic patients with variceal bleeding, with females showing higher 60-day readmission rates than males. Chi-square tests and logistic regression confirmed gender as a key factor influencing readmissions, with White females exhibiting higher risk coefficients. The 30-day readmission model demonstrated high

predictive accuracy (AUC), emphasizing the need for gender-specific interventions to manage cirrhosis and reduce readmissions. These findings support personalized strategies for improving care and outcomes in diverse patient groups.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP178 Respiratory Virus, Gut Reaction: Exploring the Emerging Association Between RSV and Irritable Bowel Syndrome

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Amina Z[1], Mustacchia P[1]

Institutes **1** Nassau University Medical Center, East Meadow, United States of America; **2** Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1821505

Aims Respiratory Syncytial Virus (RSV) is commonly associated with respiratory illness, but recent studies suggest potential links to other chronic conditions. Irritable Bowel Syndrome (IBS), a prevalent gastrointestinal disorder, may correlate with viral infections, hinting at a multifaceted pathogenesis. This study leverages the Nationwide Admission Database (HCUP) with data from 2,858,576 adults between 2019 and 2024 to investigate the relationship between RSV and IBS. Employing logistic regression, random forest, and gradient boosting, we aim to clarify the potential influence of RSV on IBS prevalence and assess the impact of demographic factors

Methods This study analyzed data from the Nationwide Admission Database (HCUP), involving 2,858,576 adults from 2019 to 2024 to explore the relationship between Respiratory Syncytial Virus (RSV) and Irritable Bowel Syndrome (IBS). We utilized logistic regression, random forest, and gradient boosting to evaluate predictive capabilities. Logistic regression assessed predictors like SEX and RACE, while machine learning models explored their predictive accuracy through AUC values from ROC curves. A binomial test determined the significance of IBS occurrence among RSV patients.

Results From 2019 to 2024, data on 2,858,576 adult hospital admissions was gathered from the HCUP, focusing on patients diagnosed with IBS and RSV. Out of 100,124 patients with IBS, 43,510 tested positive for RSV. The incidence rate of IBS among RSV patients stood at 50.84 % with a p-value of 0.00016. Logistic regression analysis indicated a statistically significant association between RSV-positive female sex ($p = 0.043$) and RSV – positive white race ($p = 0.0415$) with IBS. Both random forest and gradient boosting models demonstrated predictive capabilities with AUC scores of 0.69.

Conclusions The findings reveal a significant incidence of IBS among patients with RSV, suggesting a potential linkage between respiratory viral infections and gastrointestinal disorders. The statistically significant associations of IBS with the female sex and white race highlight demographic susceptibilities that warrant further investigation. Advanced predictive models, which demonstrated moderate accuracy (AUC = 0.69), underscore the complexity of predicting IBS in RSV-infected patients. This study invites further research to confirm these associations and explore the mechanisms behind the influence of RSV on IBS, potentially leading to targeted therapies and improved patient outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP179 Beyond Ranson: SIRS Score Demonstrates Superior Predictive Value for Acute Pancreatitis Outcomes

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Amina Z[1], Mustacchia P[1]

Institutes **1** Nassau University Medical Center, East Meadow, United States of America; **2** Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1821506

Aims Acute pancreatitis varies in severity and requires early risk assessment. Traditional Ranson criteria are limited by delayed accuracy. This study evaluates the Systemic Inflammatory Response Syndrome (SIRS) score as an early predictor of outcomes, using HCUP data (2019–2024) to assess its link to LOS and readmission.

Methods In our study, we performed a retrospective analysis of the HCUP National Database from 2019 to 2024 to identify patients with acute pancreatitis using specific ICD codes. We collected data on comorbidities, insurance status, educational levels, and hospital admissions. SIRS criteria were assessed on days 1, 2, and 3 of hospital admission. We applied binary logistic regression to identify independent risk factors for readmission. Further, we used area under the receiver operating characteristic curve (AUROC) and relationship mapping techniques to evaluate the risk and predictive accuracy of various variables in the logistic regression model.

Results Data from the Healthcare Cost and Utilization Project (HCUP) National Database were used to analyze hospital admissions from 2019 to 2024, encompassing a total of 2,858,576 adults. Among these, 58,546 patients were diagnosed with pancreatitis, with 21,015 (approximately 44 %) being female. The analysis revealed that patients with higher Systemic Inflammatory Response Syndrome (SIRS) scores on day 1 experienced increased Length of Stay (LOS) ($p = 0.012$). Similarly, higher SIRS scores on day 2 were associated with increased LOS ($p = 0.0234$), while lower SIRS scores corresponded to reduced LOS ($p = 0.031$). These findings suggest that SIRS criteria could serve as an alternative to the Ranson score for predicting LOS in patients with acute pancreatitis.

Conclusions The findings from our study using the HCUP National Database indicate that the Systemic Inflammatory Response Syndrome (SIRS) score effectively predicts hospital outcomes, such as length of stay, in acute pancreatitis patients. Our data shows that higher SIRS scores correlate with increased length of stay, supporting the score's utility as an early, dynamic assessment tool in clinical settings. The results emphasize the need for further research into integrating SIRS scores into standard practice, potentially enhancing management strategies and improving outcomes by enabling more targeted and timely interventions for acute pancreatitis

eP180 EUS-guided duodenojejunostomy and trans-LAMS afferent limb stenting for malignant afferent loop syndrome after Roux-en-Y hepaticojejunostomy

Author Kim B[1]

Institute **1** presbyterian medical center, Jeonju-si, Republic of Korea

DOI 10.1055/s-0046-1821507

Abstract Text

Afferent loop syndrome (ALS) after Roux-en-Y hepaticojejunostomy is an uncommon but clinically significant complication, particularly when secondary to malignant recurrence. We report the successful endoscopic management of malignant ALS using a sequential approach combining EUS-guided duodenojejunostomy with a lumen-apposing metal stent (LAMS) and trans-LAMS stenting of the distal afferent limb [1–5].

A 62-year-old man with extrahepatic cholangiocarcinoma had previously undergone Roux-en-Y hepaticojejunostomy and was receiving concurrent chemoradiotherapy for tumor recurrence. He presented with progressive abdominal pain and vomiting of one week's duration. Physical examination revealed abdominal distension without peritoneal signs. Laboratory tests demonstrated mild anemia (hemoglobin 11.1 g/dL), normal liver biochemistry, and markedly elevated CA 19-9 (> 12,000 U/mL). Computed tomography (CT) revealed recurrent tumor infiltration at the jejunojejunal anastomosis with pronounced dilatation of both the Roux limb and the afferent limb, confirming malignant ALS.

Endoscopic decompression of the Roux limb was initially attempted by deploying an uncovered self-expandable metal stent (SEMS, 20 × 100 mm) across the jejunojejunal obstruction using a colonoscope. Although the Roux limb improved radiologically, follow-up CT demonstrated persistent and progressive dilation of the afferent limb, indicating continued obstruction.

Subsequently, linear EUS was advanced to the duodenal bulb, where the markedly dilated afferent limb was identified. The limb was punctured with a 19-gauge FNA needle, and bile aspiration confirmed correct intraluminal entry. A guidewire was advanced, and a 10 × 20 mm Hot Spaxus LAMS was deployed, establishing a duodenojejunostomy. While interval CT showed partial decompression, a distal afferent limb stricture consistent with malignant involvement remained.

Using the newly created LAMS tract as an access route, a colonoscope was advanced, and a 0.025-inch guidewire was successfully negotiated across the distal stricture. A second uncovered SEMS (20 × 100 mm) was then deployed, achieving complete drainage of the afferent limb. Final CT confirmed full decompression of both limbs with all stents appropriately positioned.

The patient experienced rapid clinical improvement, resumed oral intake, and was discharged in stable condition. This case demonstrates that EUS-guided duodenojejunostomy with LAMS followed by trans-LAMS enteral stenting is a feasible and effective minimally invasive strategy for malignant ALS in patients with surgically altered anatomy. This approach may serve as a valuable alternative to surgical or percutaneous interventions in selected cases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP181 Diagnostic Challenge in a Gastric Subepithelial Lesion: Endoscopic Full-Thickness Resection with Final Diagnosis of Schwannoma

Authors Ivanov G[1], Plotogea O[1], Pavel C[1], Enache V[1], Constantinescu G[1], Ilie M[1]

Institute 1 Clinical Emergency Hospital of Bucharest, Bucharest, Romania

DOI 10.1055/s-0046-1821508

Background & Aims: Gastric subepithelial lesions (SELs) represent a heterogeneous group of benign and malignant entities, including gastrointestinal stromal tumors (GISTs), leiomyomas, lipomas, and schwannomas. Although endoscopic ultrasound (EUS) with fine-needle biopsy (FNB) plays a central role in diagnostic work-up, histological yield remains variable due to sampling limitations. Endoscopic full-thickness resection (EFTR) has emerged as both a diagnostic and therapeutic tool when tissue diagnosis is inconclusive and the malignant potential of an SEL cannot be confidently excluded. We report a case that highlights challenges in obtaining a definitive diagnosis and underscores the value of EFTR combined with immunohistochemical evaluation and follow-up [1].

Methods / Case Description:A 46-year-old woman with recent diagnosis of an ulcerated gastric lesion was referred for further evaluation due to persistent physical asthenia and upper abdominal pain. Laboratory findings revealed mild microcytic hypochromic anemia. EUS demonstrated a well-defined, heterogeneous hypoechoic submucosal lesion located along the greater curvature toward the gastric fundus, with a mixed elastography pattern. EUS-FNB was performed with differential diagnosis including neuroendocrine tumor, ectopic pancreas, fibrinoid polyp, and lymphoma; histopathology was negative for malignancy and excluded ectopic pancreas, but remained non-diagnostic.

Due to diagnostic uncertainty and symptomatic context, the patient underwent therapeutic endoscopic re-evaluation. A centrally ulcerated, polypoid, subepithelial lesion measuring approximately 3 × 2 × 2 cm was confirmed during upper endoscopy, and EFTR was performed with complete en-bloc resection and closure using an over-the-scope Padlock clip. The immediate post-procedural course was uneventful. Histopathology of the resected specimen suggested a submucosal lipoma without atypia.

At 6-month surveillance endoscopy, a residual submucosal lesion was noted at the previous resection site, with the Padlock clip still in situ, suggesting partial resection or persistent lesion tissue. Multiple biopsies were obtained. Final pathology revealed a gastric schwannoma, positive for S-100 protein and negative for CD117/DOG-1, with a low proliferative index (Ki-67 = 1 %), confirming a benign, low-risk neoplasm.

Results: Despite negative FNB and initial lipoma diagnosis, final immunohistochemistry on targeted control biopsies established a definitive diagnosis of schwannoma. No complications or recurrence were detected on follow-up.

Conclusions: This case illustrates that EUS-FNB may yield false-negative or misleading results in SELs, and that EFTR represents a valuable approach for both therapeutic management and diagnostic confirmation. Immunohistochemistry and systematic surveillance remain essential when histology does not correlate with endoscopic and imaging characteristics.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP182 Unequal Access, Uneven Preps: The Influence of Insurance and Socioeconomic Status on Colonoscopy Preparation – A National Database Analysis

Authors Natt D[1], Ram mohan RM[1], Achal P[1], Magam R[2], Amina Z[1], Mustacchia P[1]

Institutes 1 Nassau University Medical Center, East Meadow, United States of America; 2 Nassau University Medical Center, East Meadow, NY, USA, United States of America

DOI 10.1055/s-0046-1821509

Aims Race significantly influences the quality of colon preparation for colonoscopies, which are vital for early colorectal cancer detection and prevention. Disparities exist among racial groups, shaped by cultural norms, healthcare access, and personal health behaviors. This study examines these factors to better understand the root causes of such inequalities. These insights can help healthcare providers and policymakers improve equity in colorectal cancer prevention and ensure fair access to effective screening.

Methods This retrospective study analyzed colonoscopy records from 2010 to 2023. Data included information on colonoscopy reports, gender, race, colon preparation quality, socioeconomic status, and insurance coverage. Chi-squared tests were used to evaluate the relationships between poor colon preparation and categorical variables, including race, socioeconomic status, and insurance status. Logistic regression analysis was performed to assess the combined impact of these variables on colon preparation outcomes. Statistical significance was determined with a p-value threshold of 0.05.

Results The study included data from 3,330 individuals who underwent colonoscopies between 2010 and 2023, with 64 % of participants being female.

Racial demographics were as follows: 24.2 % Hispanic, 48 % White, 15 % Black, 6 % Asian, and 3 % Other. Analysis revealed a significant association between race and poor colon preparation (Chi-square = 40.78, $p < 0.01$), with Hispanics experiencing the highest rate of poor outcomes ($p = 0.023$). Additionally, lower socioeconomic status showed a strong correlation with inadequate preparation (Chi-square ≈ 20.86, $p \approx 0.00011$), and the lack of insurance was also significantly associated with poor outcomes (Chi-square ≈ 15.48, $p \approx 0.000083$).

Conclusions This study highlights significant disparities in colon preparation quality among racial groups, with outcomes heavily influenced by socioeconomic status and insurance coverage. The findings emphasize that race, financial constraints, and lack of insurance are critical determinants of colonoscopy preparation quality. Despite its limitations, this study underscores the importance of addressing these disparities. Healthcare providers and policymakers must incorporate these demographic considerations into strategies to ensure equitable access to colorectal cancer screenings and improve prevention efforts for underserved populations

eP183V A Novel Peaked Cap Technique for Assisting Colonic Endoscopic Submucosal Dissection

Authors Tang X[1], Xu J[1], Deng M[1], Lü M[1]
Institute 1 The Affiliated Hospital of Southwest Medical University, Luzhou, China
DOI 10.1055/s-0046-1821510

Problem to solve Traditional transparent caps in colonic endoscopic submucosal dissection (ESD) often fail to provide sustained mucosal retraction, leading to poor submucosal visualization and increased risk of incomplete resection or perforation, especially in large or fibrotic lesions.

Innovation We developed a novel, low-cost "peaked cap"—a custom-designed transparent cap with a peaked extension adhered using nail art adhesive—that enables continuous and active retraction of the mucosal flap during ESD, thereby maintaining a clear submucosal visual field and facilitating precise dissection.

Results The "peaked cap" was successfully applied in a 77-year-old female with a 3 × 4 cm laterally spreading tumor in the transverse colon. The device allowed smooth submucosal dissection, excellent visibility, and complete en bloc resection without adverse events. Histopathology confirmed tubulovillous adenoma with clear margins.

Conclusions The "peaked cap" is an effective, economical, and easily reproducible innovation that enhances submucosal exposure and safety during colonic ESD, offering a practical solution particularly valuable in resource-limited settings.

eP184 Diagnostic Performance of Endoscopic Ultrasound for Esophageal Cancer Staging: A Systematic Review and Meta-Analysis

Authors Zheng K[1], Khalaf K[1], Rizkala T[2], Alasmi Y[1], Bucheeri MAGA[1], Harb M[1], Hu M[1], Jayawardena R[1], Khan A[1], Li H[1], Na C[1], Mahamud O[1], Nishimura T[1], Slotin A[1], Youssef M[1], Yuan Y[3], May G[1], Mosko J[1], Calo N[1]
Institutes 1 St. Michael's Hospital, Toronto, Canada; 2 Humanitas Research Hospital, Milano, Italy; 3 McMaster University, Hamilton, Canada
DOI 10.1055/s-0046-1821511

Aims Accurate loco-regional staging is essential in the management of esophageal cancer, guiding decisions regarding surgical resection, neoadjuvant therapy, and endoscopic interventions. Endoscopic ultrasound (EUS) is widely used for evaluating tumor depth (T stage) and regional lymph node involvement (N stage), but reported diagnostic performance varies across studies. This systematic review and meta-analysis aimed to synthesize evidence on the accuracy of EUS for staging esophageal cancer.

Methods A comprehensive literature search was performed in MEDLINE, Embase and Cochrane Library until May 27, 2025. We identified primary studies reporting the diagnostic performance of conventional EUS (linear or radial) for esophageal cancer staging compared with histopathology as the reference standard. We excluded studies using miniprobe or non-conventional EUS techniques, as well as patients who received neoadjuvant radiochemotherapy. Pooled sensitivity, specificity, PPV, NPV, accuracy, overstaging and understaging for T and N staging were calculated using a bivariate random-effects model. Heterogeneity was assessed with the I^2 statistic.

Results Thirteen studies comprising 1,232 patients were included for T-stage evaluation, and seven studies comprising 575 patients for N-stage evaluation. Of three retrospective and nine prospective studies, most used a radial probe (n = 11) with only two using a linear probe. All studies included esophageal adenocarcinoma, with nine also looking at squamous cell carcinoma. Overall accurate T staging rate was 0.79, with over- and understaging rates of 0.10 and 0.08, respectively. EUS demonstrated high sensitivity and specificity for T1 and T3 disease with diagnostic accuracy ranging from 0.90 to 0.93. Both sensitivity and specificity were high for diagnosing early esophageal cancer (T1) at 0.88 [95 % CI 0.62-1.00] and 0.86 [95 % CI 0.64, 0.99], respectively. Overstaging was most common in T2 disease (0.24). For nodal staging, EUS demonstrated moderate sensitivity (0.80; 95 % CI 0.71–0.87) and specificity (0.72; 95 % CI 0.62–0.83), with an overall accuracy of 0.76 (95 % CI 0.72–0.80), and similar rates of over- and understaging (0.12 and 0.11)

Conclusions Conventional EUS provides a strong diagnostic performance for T staging in esophageal cancer with high diagnostic accuracy across all T stages, although there is a risk of overstaging of T2 disease. Nodal staging performance remains modest and supports complementary staging, such as fine-needle aspiration/biopsy or other imaging modalities, to improve diagnostic accuracy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP185 Diagnostic Performance of Endoscopic Ultrasound for Rectal Cancer Staging: A Systematic Review and Meta-Analysis

Authors Zheng K[1], Khalaf K[1], Rizkala T[2], Alasmi Y[1], Bucheeri MAGA[1], Harb M[1], Hu M[1], Jayawardena R[1], Khan A[1], Li H[1], Na C[1], Mahamud O[1], Nishimura T[1], Slotin A[1], Youssef M[1], Yuan Y[3], May G[1], Mosko J[1], Calo N[1]
Institutes 1 St. Michael's Hospital, Toronto, Canada; 2 Humanitas Research Hospital, Milano, Italy; 3 McMaster University, Hamilton, Canada
DOI 10.1055/s-0046-1821512

Aims Accurate loco-regional staging is essential in the management of rectal cancer, guiding decisions regarding surgical resection, neoadjuvant therapy, and endoscopic interventions. Endoscopic ultrasound (EUS) is widely used for evaluating tumour depth (T stage) and regional lymph node involvement (N stage), but reported diagnostic performance varies across studies. This systematic review and meta-analysis aimed to synthesize evidence on the accuracy of EUS for staging rectal cancer.

Methods A comprehensive literature search was performed in MEDLINE, Embase and Cochrane Library until May 27, 2025. We identified primary studies reporting the diagnostic performance of conventional EUS (linear or radial) for rectal cancer staging compared with histopathology as the reference standard. We excluded studies using miniprobe or non-conventional EUS techniques, as well as patients who received neoadjuvant radiochemotherapy. Pooled sensitivity, specificity, PPV, NPV, accuracy, overstaging and understaging for T and N staging were calculated using a bivariate random-effects model. Heterogeneity was assessed with the I2 statistic.

Results Twelve studies comprising 1,216 patients were included for T-stage evaluation, and nine studies comprising 451 patients for N-stage evaluation. Of the four retrospective and eight prospective studies, most used a radial probe (n = 9), with three using a linear probe. Ten studies included rectal adenocarcinoma.

EUS demonstrated high specificity for early disease (T1: 0.98; 95 % CI 0.93–1.00) with corresponding sensitivity of 0.77 (95 % CI 0.65–0.87) and accuracy of 0.94 (95 % CI 0.89–0.98). T2 staging showed moderate sensitivity (0.77; 95 % CI 0.67–0.86) and specificity (0.85; 95 % CI 0.78–0.91), with overstaging occurring in 14 % of cases. Performance was also good with more advanced T3 (sensitivity 0.86; specificity 0.91; accuracy 0.88), and T4 disease (sensitivity 0.84; specificity 1.00; accuracy 0.98). Understaging was most common with T4 lesions (0.19; 95 % CI 0.01–0.48). For nodal staging, EUS demonstrated lower sensitivity (0.64; 95 % CI 0.46–0.78) and specificity (0.80; 95 % CI 0.61–0.95), with an overall accuracy of 0.74 (95 % CI 0.66–0.81).

Conclusions In rectal cancer, EUS provides reliable staging accuracy for T1 and advanced rectal lesions (T3/4), supporting its role in selecting candidates for local excision and informing neoadjuvant therapy decisions. However, EUS demonstrates limited performance for T2 lesions and nodal staging and hence, findings support integrating EUS with pelvic MRI and selective pathological confirmation to optimize staging-directed treatment planning.

eP186 Endoscopic Ultrasound guided Hepaticogastrostomy: a real-life cohort from the Netherlands

Authors de Jong DM[1], Van Driel LMJW[1], Inderson A[2], Poley JW[3], Van Wanrooij RLJ[4], Voermans RP[4], Didden P[5], De Wijkerslooth TR[6], Van Delft F[7], Venneman NG[8], Verdonk RC[9], Van Nes JP[1], Bruno MJ[1], Lammers WJ[1]

Institutes **1** Department of Gastroenterology and Hepatology, Erasmus MC University Medical Center, Rotterdam, Netherlands; **2** Department of Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands; **3** Department of Gastroenterology and Hepatology, Maastricht University Medical Center+, Maastricht, Netherlands; **4** Department of Gastroenterology and Hepatology, Amsterdam University Medical Center, Amsterdam, Netherlands; **5** Department of Gastroenterology and Hepatology, University Medical Center Utrecht, Utrecht, Netherlands; **6** Department of Gastrointestinal Oncology, Netherlands Cancer Institute – Antoni van Leeuwenhoek, Amsterdam, Netherlands; **7** Department of Gastroenterology and Hepatology, Radboud University Medical Center, Nijmegen, Netherlands; **8** Department of Gastroenterology and Hepatology, Medisch Spectrum Twente, Enschede, Netherlands; **9** Department of Gastroenterology and Hepatology, St. Antonius Hospital, Nieuwegein, Netherlands

DOI 10.1055/s-0046-1821513

Aims In selected patients with altered surgical anatomy, inadequate biliary drainage of the left hepatic duct, or duodenal obstruction, Endoscopic Ultrasound Guided Hepaticogastrostomy (EUS-HGS) offers the possibility to acquire internal biliary drainage via the stomach. This approach may reduce bile salt loss and improve quality of life compared to percutaneous transhepatic biliary drainage. However, outcomes of EUS-HGS outside highly selected study cohorts remain unclear and are likely overestimated in the literature due to selective reporting and bias. We aimed to evaluate the real-world outcomes of this technically demanding procedure in a nationwide cohort [1].

Methods In this multicenter, retrospective cohort study, all consecutive patients who underwent an attempted EUS-HGS between 2009 and 2025 among nine Dutch hospitals were included. The primary outcome was technical success, defined as adequate stent positioning confirmed by endoscopy and fluoroscopy. Secondary outcomes included clinical success, defined as the absence of further biliary drainage interventions during follow-up; procedural and post-procedural complications, classified according to the AGREE criteria; and time to recurrent biliary obstruction (RBO), defined as the occurrence of symptoms and/or interventions related to biliary obstruction. Predictors of RBO were analyzed using competing risk regression, and overall survival was estimated by the Kaplan–Meier method (▶ **Table 1**).

▶ **Table 1**

	EUS-HGS attempt (n = 105)
Procedural time, median [IQR], minutes	62 [44.5 – 87.5]
EUS-GE in same session – n (%)	12 (11.4)
Bile duct puncture attempt – n (%)	98/105 (93.3)
Successful bile duct puncture – n (%)	95/98 (96.9)
Wire advancement – n (%)	92/95 (96.8)
Fistula formation – n (%)	88/92 (95.7)
▪ 6Fr cystotome / Balloon dilatation	- 83 (90.2) / 5 (9.8)
Stent placement – n (%)	86/88 (97.7)
▪ HGS	- 81 (92.0)
▪ HGS + AGS	- 1 (1.1)
▪ AGS only	- 4 (4.5)
Stent types – n (%)	
▪ pcSEMS	50 (61.0)
▪ ucSEMS + fcSEMS	29 (35.4)
▪ Other	3 (3.6)

Results A total of 107 procedures among 105 patients were included. Median age was 68 years [IQR 59–76], and 55 % were male. Overall technical success was 77 % (81/105). Bile duct puncture was performed in 98/105 patients (93 %) and was successful in 95/98 (97 %). Deep guidewire insertion was achieved in 92/95 patients (97), with tract dilation in 88/92 (96 %). Stent placement was performed in 85/88 patients (97 %) and was technically successful in 81/85 (95 %). The majority (62 %) received a dedicated partially covered SEMS, while 36 % received a combination of two stents: one long uncovered SEMS to avoid migration and one shorter covered SEMS to avoid bile leakage. Procedural and post-procedural complications occurred in 15 % and 17 % of patients, respectively, including one procedure-related death. Among patients with technically successful EUS-HGS, clinical success was achieved in 63 of 81 (78 %), corresponding to an overall clinical success rate of 60 % (63/105) when analyzed by intention to treat. RBO was observed in 23/81 patients (28 %) during a median follow-up of 61 days [IQR: 23 – 131], with no significant risk factors identified. Median overall survival was 91 days [IQR: 66–155]. Survival did not differ between stent types (p = 0.81).

Conclusions EUS-HGS was technically feasible in almost 4 out of 5 patients while adequate bile drainage was achieved in more than three-quart in this group. This is relatively low compared to the literature with technical success rates around 95 % and clinical success rates of around 88 % (1), and therefore prospective studies are warranted to optimize patient selection, standardize stent choice, and minimize complications.

eP187V Modified endoscopic submucosal dissection of a gastric fundus subepithelial lesion using modified-snare knife and clip-and-dental floss pre-traction

Authors Tang X[1], Xu J[1], Deng M[1], Lü M[1]
Institute 1 The Affiliated Hospital of Southwest Medical University, Luzhou, China
DOI 10.1055/s-0046-1821514

Problem to solve Endoscopic submucosal dissection (ESD) for gastric subepithelial lesions, particularly those originating from the muscularis propria, is technically challenging due to limited submucosal exposure, poor maneuverability of conventional knives, and high instrument costs. These factors can prolong procedure time and increase the risk of perforation or bleeding.

Innovation We developed a cost-effective modified-snare knife (MSK) from a standard snare, reducing instrument cost to one-ninth of a conventional dual knife. Combined with clip-and-dental floss pre-traction, this innovation provides sustained traction and improves submucosal visualization, enhancing dissection precision and safety.

Results The technique was successfully applied to resect a 2.2 cm gastric fundus GIST originating from the muscularis propria. En bloc resection was achieved in 50 minutes without moderate or severe adverse events. Histopathology confirmed complete removal of a spindle cell GIST.

Conclusions The combined use of MSK and clip-and-dental floss traction offers a safe, feasible, and highly cost-effective alternative to conventional ESD for gastric subepithelial tumors. This approach improves exposure and dissection efficiency while significantly reducing operational costs.

eP188 Diagnostic yield of the Japan NBI Expert team (JNET) classification system in a UK observational study

Authors Khani A[1], Zhang D[2], Suzuki N[3], Landy J[3]
Institutes 1 St Mark's Hospital at Northwick Park, London, United Kingdom; 2 Imperial College Healthcare Trust, London, United Kingdom; 3 Wolfson Unit for Endoscopy, St Mark's Hospital, London, United Kingdom
DOI 10.1055/s-0046-1821515

Aims The Japan NBI Expert Team (JNET) classification enables optical prediction of colorectal polyp histology. Evidence from Western settings remains limited. Lesion size may also impact diagnostic accuracy. We evaluated the diagnostic performance of JNET in a Untied Kingdom (UK) cohort and explore whether lesion size influences accuracy, using histopathology as the gold standard [1, 2].

Methods A retrospective observational study was performed across three UK endoscopy units, Northwick Park (St Marks), Central Middlesex and Ealing Hospitals London during the period of January 2020–August 2024. Endoscopy reports were screened for the keyword "JNET." Procedures were included if a colorectal polyp had an assigned JNET classification. Exclusion criteria were absence of histology and inflammatory bowel disease.

For each lesion, data collected included location, size, JNET, morphology (Paris or Laterally spreading tumour (LST)) and histopathology. Accuracy data was calculated for each JNET subtype and compared across lesion size. We used the Cochran–Armitage test to assess trends across size categories.

Results A total of 697 lesions were analysed: 270 in the right colon, 169 in the left colon, and 258 in the rectosigmoid/rectum. Histology comprised 25 hyperplastic, 20 sessile serrated, 330 low-grade dysplasia, 234 high-grade dysplasia and 88 T1 cancers (22 T1a, and 66 T1b). Morphology included: 6 % Ip, 11 % Isp, 27 % Is, 9 % IIa, 11 % IIc, 29 % LST-G, and 7 % LST-NG. Lesion size distribution was 149 ≤ 10 mm, 160 = 11–20 mm, 217 = 21–40 mm, and 171 > 40 mm. The overall accuracy was 95 %, 70 %, 67 % and 90 % for JNET 1, 2A, 2B and 3 respectively. Accuracy significantly improved with increasing lesion size for JNET 1 (85 % to 99 %, $p < 0.001$) but conversely declined significantly for JNET 2A (74 % to 60 %, $p = 0.004$), 2B (89 % to 50 %, $p < 0.001$) and JNET 3 (97 % to 85 %, $p = 0.001$).

Conclusions The JNET classification demonstrated reasonable, but slightly lower overall diagnostic yield compared with Asian cohorts. Lesion size significantly influenced JNET performance. Larger lesions improved accuracy for JNET 1 but reduced it for JNET 2A, 2B, and 3. These findings emphasise that lesion size is an important consideration when using JNET in practice. Standardised training may optimise diagnostic reliability and support implementation of optical diagnosis pathways in colorectal polyp assessment in the UK.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821516

Abstract Text

A 54-year-old male patient with gastroesophageal reflux disease was submitted to modified Nissen fundoplication. On postoperative day 2, the patient presented with nausea and vomiting after eating and an acute abdominal X-ray showed gastric herniation into the chest. The patient was sent for emergency laparoscopy, which revealed a large hiatal hernia involving the entire stomach. Surgical treatment consisting of hiatoplasty and fundoplication repair was performed. After three days, the patient developed septic shock secondary to empyema in the right hemithorax and a chest drain was placed. The methylene blue swallow test revealed leakage of the dye through the drain. Enteral fasting was maintained and the patient received exclusive parenteral nutrition. Thoracoscopy was performed for cleaning and drainage of the pleural cavity. After approximately 60 days, the enteral diet was reintroduced and there was an increase in drain output. A chest CT revealed a gastropleural fistula in the posterior area of the fundoplication. Endoscopy showed the presence of a recess in the region of the fundoplication and fistula measuring 30 mm. Using videothoracoscopy, a transfistula guidewire was inserted through the nostril and externalized through the right chest wall. Through this guide, a vacuum therapy tube (VTT) with a fenestrated film (a customized Levin 16Fr tube) was positioned inside the fistula and externalized through the chest. However, there was no improvement in the fistula in subsequent examinations. Since surgical retreatment was not feasible, we chose a VTT with a silver sponge of sufficient size to occlude the entire fistula. The sponge was changed every 7-10 days with the aid of the guidewire. We observed the formation of granulation tissue and a reduction in the size of the fistula. After four changes, the fistula had closed and the VTT was removed. The patient had resumed oral feeding and was dis-

charged with an open chest drain. There was progressive improvement during outpatient follow-up and the chest drain was removed [1, 2].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

A 55-year-old woman with Familial Adenomatous Polyposis and prior proctocolectomy underwent surveillance endoscopy, which identified a 20 mm polypoid lesion in the superior duodenal angle near the minor papilla. NBI chromoendoscopy revealed enlarged crypts and an irregular pattern suggestive of high-grade dysplasia. Endoscopic mucosal resection was performed after submucosal injection of diluted epinephrine, followed by diathermic snare resection. Active oozing bleeding occurred but was effectively controlled with an over-the-scope clip, achieving immediate hemostasis. The patient experienced only mild post-procedural abdominal pain and no adverse events such as perforation or delayed bleeding. Histopathology showed a tubular adenoma with focal high-grade dysplasia and free pedicle margin. Annual surveillance was recommended [1, 2].

Abstract Text

A 32-year-old woman with deep endometriosis underwent surgical resection of endometriotic foci. Intraoperatively, resection of a nodule involving the left pelvic wall extending to the pelvic floor musculature and the left pararectal region was performed. An inadvertent 4-cm injury to the mid-rectum occurred, compromising approximately 70 % of the circumference. A decision was made to perform a rectosigmoidectomy with closure of the rectal stump and creation of an end colostomy. Two months later, during the procedure for intestinal reconstruction, a fistula was identified on the lateral rectal wall, 3.5 cm from the anal verge. The fistula was surgically closed, followed by a mechanical colorectal anastomosis and protective ileostomy. Prior to ileostomy reversal, a stenosis of the colorectal anastomosis was identified, and colonoscopy was requested to evaluate the possibility of dilation. Endoscopic examination revealed, 7 cm from the anal verge, circumferential scar retraction consistent with a complete anastomotic stenosis, with no identifiable lumen for conventional dilation. Treatment consisted of dissecting the center of the stenosis using a needle-knife, followed by guidewire passage and contrast injection under fluoroscopic guidance, delineating the pre-anastomotic intestinal loop. Hydrostatic balloon dilation was then performed up to 12 mm. Afterward, passage of the gastroscope through the stenosis was achieved. One week later, repeat colonoscopy demonstrated a patent anastomosis, allowing scope passage and dilation up to 15 mm. Eleven days after that, another dilation was performed using a balloon up to 16.5 mm, immediately before ileostomy closure. The patient had an uneventful postoperative course and resumed normal bowel function [1–2]

eP192 Impact of Comorbidity Burden on Post-Colonoscopy Outcomes Following Polypectomy: A Retrospective Audit Using the Charlson Comorbidity Index

Authors Sheppard R[1], McCullagh D[1], Mcbrearty A[1], Battisti K[1]

Institute **1** Ulster Hospital, Dundonald, United Kingdom

DOI 10.1055/s-0046-1821519

Aims Colonoscopy with polypectomy is central to colorectal cancer prevention with an increasing number of older and comorbid patients undergoing endoscopic therapy. This audit aimed to evaluate whether higher Charlson Comorbitiy Index (CCI) scores were associated with an increased risk of post-procedural complications, hospitalisation, recurrence, and all-cause mortality during follow-up.

Methods A retrospective review was performed of 194 consecutive patients who underwent colonoscopy with polypectomy for benign polyps between October 2018 and November 2022 at the South Eastern Health and Social Care Trust, Northern Ireland. Patients with malignant polyps or colorectal cancer were excluded. Data collected included CCI score, post-procedural bleeding, hospitalisation, polyp recurrence at surveillance colonoscopy, and all-cause mortality at follow-up. Patients were stratified into low (CCI ≤ 2), moderate (3–5), and high (≥ 6) comorbidity groups. Associations between CCI category and outcomes were tested with chi-square analysis.

Results A total of 194 patients were included (median CCI 3, range 0-10). 33.5 % were low-CCI, 52.5 % moderate-CCI and 14 % high-CCI.

Mortality:During follow-up, 18 patients (9.3 %) died from all causes. All deaths occurred among patients with CCI ≥ 3. Mortality increased significantly with higher comorbidity, rising from 0 % in low-CCI patients to 7.8 % in moderate and 37.0 % in high-CCI groups, showing a significant trend ($\chi^2 = 31.6$, $p < 0.001$).

Complications**:**Post-polypectomy bleeding occurred in two patients (1.0 %), one with CCI 1 and one with CCI 8. Nine patients (4.6 %) required hospitalisation following the procedure, primarily within the moderate and high CCI groups.

Polyp recurrence:A total of 21 patients (10.8 %) developed polyp recurrence during surveillance follow-up. Recurrence rates increased with higher comorbidity, 7.7 % in low CCI, 6.9 % in moderate CCI and 33.3 % in high CCI. This indicates a statistically significant association between higher CCI and recurrence (p = 0.004).

Recurrences were also analysed by surveillance interval:

First surveillance colonoscopy: 9 patients (43 % of recurrences; 2 low-CCI, 4 moderate-CCI, 3 high-CCI). Two of these patients subsequently demonstrated persistent polyp detection at their next procedure (CCI 4 and 8).

Second surveillance colonoscopy: 6 patients developed new recurrence (29 %; 2 low, 1 moderate, 3 high CCI). One of these (CCI 10) had persistent recurrence at subsequent follow-up.

Third surveillance colonoscopy**:** 6 patients (29 %; 1 low, 2 moderate, 3 high CCI)

Conclusions This audit demonstrates a clear and statistically significant association between comorbidity burden and both all-cause mortality and polyp recurrence following colonoscopic polypectomy for benign polyps. Although immediate procedural complications were uncommon across all comorbidity groups, long-term outcomes differed substantially, with both mortality and recurrence increasing sharply in patients with a CCI ≥ 6.

Analysis of recurrence patterns revealed that patients with higher CCI scores not only had greater overall recurrence rates but were also more likely to experience persistent polyp detection across successive surveillance procedures.

These findings suggest a potential threshold of CCI ≥ 6, beyond which the benefits of repeated endoscopic intervention for benign lesions may be outweighed by procedural burden and limited life expectancy. In such cases, an individualised approach including careful risk-benefit assessment should be considered.

Routine integration of frailty and comorbidity assessment into colonoscopy pathways may improve patient selection, guide individualised management, and support more informed discussions regarding the long-term risks and benefits of benign polypectomy in comorbid populations.

eP193 Gaseous dissection during ESD: how, why, where & what to do

Authors Amza TI[1], Dragan AV[1], Bengus A[1], Mateescu RB[1, 2], Voiosu AM[2, 1]
Institutes **1** Colentina Hospital, Bucharest, Romania; **2** Carol Davila University of Medicine and Pharmacy, Bucharest, Romania
DOI 10.1055/s-0046-1821520

Background: Perforation of the digestive wall may occur during endoscopic submucosal dissection (ESD) and unless recognized and timely treated it can lead to severe adverse events. Microperforations may be harder to detect in extensive lesions and prolonged exposure to insufflation can lead to postprocedural emphysema. Recognition and limitation of this uncommon event and appropriate conservative management are essential.

Case presentation:A 71-year-old patient without significant comorbidities underwent screening colonoscopy which revealed an 8 cm, granular mixed-laterally spreading tumor (LST-GM) involving over 80 % of the middle rectum. We performed “butterfly-tunneling” ESD under general anesthesia with endotracheal intubation with the patient in left lateral decubitus. The ESD lasted 4 hours and a small perforation was closed via through-the-scope clips halfway through the procedure. Pathology confirmed R0 resection of a traditionally serrated adenoma.

The immediate postoperative course was uneventful. Awaiting discharge at 24 hours the patient developed anterior cervical discomfort and mild dysphonia. Clinical examination identified a peculiar one-sided distribution of subcutaneous emphysema in the latero-cervical region, and palpable crepitus extending along the lateral aspect of the right lower limb. There were no signs of respiratory or haemodynamic compromise or abdominal guarding.

Contrast-enhanced CT confirmed extensive subcutaneous emphysema involving the cervical region, abdominal wall, and right lower limb, without pneumoperitoneum, contrast extravasation, abscess, or active bleeding. On reviewing the procedure, it was apparent that prolonged carbon dioxide insufflation through the 2 mm perforation was likely to have occurred before closing and the left lateral position accounted for the peculiar unilateral distribution of the gas. Delayed resumption of orthostatism finally allowed migration of the free gas along the fascial planes and led to the presenting symptoms.

Careful clinical monitoring and conservative management including short-term fasting, intravenous fluids, and prophylactic antibiotics were initiated. The emphysema regressed spontaneously, and the patient was discharged after 48 hours. Follow-up colonoscopy showed an asymptomatic 12 mm stenosis that was dilated by CRE balloon.

Conclusion: This case illustrates a rare occurrence of post procedural emphysema following rectal ESD due to prolonged insufflation before closure. Conservative treatment led to complete resolution. In protracted procedures using insufflation, rapid closure of potential microperforations is advised as soon as compromise of resection is avoided.

eP194 The edge of resection: endoscopic-laparoscopic cooperative techniques for large gastric tumors

Authors Amza TI[1], Forminte M[1], Popp C[1], Mateescu RB[1, 2], Voiosu AM[2, 1]
Institutes **1** Colentina Hospital, Bucharest, Romania; **2** Carol Davila University of Medicine and Pharmacy, Bucharest, Romania
DOI 10.1055/s-0046-1821521

Abstract Text

Minimally invasive hybrid techniques combining endoscopy and laparoscopy have expanded therapeutic options for subepithelial gastric tumors and early neuroendocrine neoplasms. However, their implementation remains limited, and real-world data from European centers are still scarce. We present two-cases highlighting the organ-preserving and oncologic adequacy of laparoscopic–endoscopic cooperative techniques for challenging gastric lesions.

Case 1: Endoscopic evaluation in a 67-year-old woman revealed a 5-cm subepithelial lesion on the gastric lesser curvature, initially suggestive of leiomyoma. Given its size and location, we elected to perform laparoscopic-endoscopic cooperative surgery for local resection. The endoscopist delineated the lesion and performed semicircumferential submucosal injection and dissection with controlled full-thickness resection under laparoscopic assistance, after which the surgical team completed the procedure by retrieving the lesion and closing the gastric defect. Final pathology confirmed an R0 resection of a 5-cm low-mitotic index (Ki-67 1 %) GIST, with no recurrence at 1-year follow-up [1].

Case 2: A 58-year-old patient with a type III gastric neuroendocrine tumor (NET) underwent non-exposed endoscopic wall-inversion surgery (NEWS), an endoscopy-driven full-thickness resection technique performed with laparoscopic assistance. Endoscopic inspection identified the lesion on the anterior gastric wall, in close proximity to the gastroesophageal junction, and allowed precise demarcation of its margins using coagulation marking. Under laparoscopic visualization, controlled seromuscular dissection was performed externally while preserving the integrity of the mucosal and submucosal layers. Endoluminal traction was established primarily through a snare, complemented by clip-line counter-traction to optimize lesion exposure and ensure stable tissue manipulation throughout the dissection. Following laparoscopic closure of the seromuscular defect, which resulted in inward inversion of the targeted gastric segment, the endoscopist completed an *en bloc* intraluminal resection using TT and IT knives. The specimen was retrieved in its entirety, without violation of the mucosal surface. Histopathologic examination confirmed a pT2, R0 gastric NET with a mitotic index of 13 mitoses per 2 mm² and no lymphovascular invasion. At the 6-month follow-up, both endoscopic ultrasound and contrast-enhanced computed tomography demonstrated no evidence of residual or recurrent disease.

Conclusion: These two cases illustrate the clinical value of advanced collaborative techniques such as LECS and NEWS for gastric tumors requiring precise,

full-thickness resection while minimizing morbidity and preserving gastric anatomy. Both procedures achieved complete oncologic resection with uneventful recovery, emphasizing the role of multidisciplinary endoscopic–surgical strategies in expanding curative, organ-preserving options for selected gastric neoplasms.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP195 Effectiveness and Safety of Upadacitinib in Patients with Crohn's Disease and Ulcerative Colitis: a Korea Multicenter Retrospective Cohort Study

Authors Baek DH[1], Jun L[2], Kim S[2], Jung Y[3], Choi G[3]

Institutes **1** Department of Internal Medicine, Pusan National University School of Medicine, Busan, Republic of Korea; **2** Chosun University College of Medicine, Internal Medicine, Gwangju, Republic of Korea; **3** Soonchunhyang University College of Medicine, Internal Medicine, Cheonan-si, Republic of Korea

DOI 10.1055/s-0046-1821522

Aims Upadacitinib (UPA), a selective JAK1 inhibitor, has shown robust efficacy in clinical trials for Crohn's disease (CD) and ulcerative colitis (UC). However, real-world evidence in Asian populations remains limited. We aimed to evaluate the real-world effectiveness and safety of UPA in Korean patients with CD and UC across multiple centers.

Methods We conducted a retrospective study across three Korean academic centers including adults with UC or CD treated with UPA. A total of 79 patients were analyzed (UC 30; CD 49). Clinical, biochemical, and endoscopic outcomes were assessed at week 16 for UC and week 12 for CD, and adverse events (AEs) were evaluated throughout follow-up.

Results Among 79 patients, 88.6 % (70/79) had prior exposure to at least one biologic therapy. In UC (n = 30), baseline disease activity was moderate to severe (median partial Mayo 8; endoscopic subscore 3). By week 16, substantial improvements were observed, with reductions in the partial Mayo score (to 2), endoscopic subscore (to 0), CRP, and fecal calprotectin (4034.8 → 185.5 µg/g). The UPA continuation rate was 96.7 %, with discontinuation due to loss of response (n = 1) or an adverse event (n = 1). (Table 1) In CD (n = 49), baseline CDAI was high (mean 284.8), with a mean SES-CD of 10.4 and a median of two prior advanced therapies. By week 12, CDAI improved to 80.3, accompanied by reductions in CRP and fecal calprotectin (1408.6 → 458.4 µg/g). The UPA continuation rate was 83.6 %, with discontinuation due to primary non-response (n = 1), loss of response (n = 5), or adverse events (n = 2). (Table 2) Across the entire cohort, the most frequent AEs were acne (49.4 %), lymphopenia (11.4 %), anemia (6.3 %), herpes zoster (5.1 %), and infections (6.3 %); no thromboembolic events or malignancies occurred. (Table 3).

Conclusions Upadacitinib demonstrated substantial clinical, biochemical, and endoscopic improvements in both UC and CD in this real-world Korean multicenter cohort. High continuation rates, particularly in UC, support its effectiveness even in biologic-experienced patients. The safety profile was consistent with clinical trials, with no thromboembolic events or malignancies observed. These findings support UPA as an effective and well-tolerated therapeutic option for refractory IBD in routine practice.support UPA as an effective and well-tolerated therapeutic option for refractory IBD in routine practice.

Abstract Text

We report a case of a male patient with multiple gastro-duodenal-jejunal angiodysplasias, previously treated with argon plasma coagulation (APC) through double-balloon enteroscopy (DBE) advanced up to 200 cm. Due to recurrent bleeding, an anterograde DBE was performed using Endorail. Angiodysplasias distal to the first tattoo were treated with APC, exploring up to 330 cm of the small bowel. The Endorail system is recently approved for enteroscopy with CE marking. It uses a magnetic balloon that can be advanced beyond the enteroscope tip, filled with a ferromagnetic fluid, and magnetically anchored to the patient's abdomen, allowing it to be straightened and guided along the device. Once the challenging bowel segment is negotiated, the balloon guide can be retrieved. The Endorail system appears to enable deeper exploration of the small bowel in difficult cases [1, 2].

eP197 Real-time Surgical Decision-making Enhanced by Intraoperative Endoscopic Ultrasound in Pancreatic Tumor Management

Authors Pinto-Carta R[1], Vera Torres A[1], Gomez-Gutiérrez MA[1], Gómez Giraldo ZF[1], Vergara C[2], Bejarano A[3], Sierra Arango F[1]

Institutes **1** Fundación Santa Fe de Bogotá, Bogotá, Colombia; **2** Independent Researcher, Bogotá, Colombia; **3** Clinica Colsanitas, Bogotá, Colombia

DOI 10.1055/s-0046-1821524

Problem to solve Precise intraoperative localization of small, deep, or non-palpable pancreatic lesions remains challenging in minimally invasive pancreatic surgery. Laparoscopic ultrasound (LUS), although standard, may have limited accuracy due to restricted maneuverability, intervening air, or fibrosis, especially for lesions < 10 mm or located in complex anatomical regions. These limitations can hinder real-time surgical navigation, compromise margin assessment, and risk unnecessary pancreatic parenchymal resection. A reliable, high-resolution intraoperative imaging adjunct capable of providing immediate feedback and seamless integration into the surgical workflow is needed.

Innovation We developed a structured, preplanned integration of intraoperative endoscopic ultrasound (EUS) as an innovative adjunct during pancreatic tumor resection. This approach consists of: (1) incorporation of EUS as a predetermined intraoperative step; (2) same-operator continuity, with the endoscopist responsible for preoperative staging also performing the intraoperative examination; (3) sterile deployment of a linear-array echoendoscope without altering patient positioning or compromising the surgical field; and (4) continuous, real-time communication between endoscopist and surgeon to guide lesion localization, define resection planes, and verify post-resection status.

▶ **Table 1** Summary of Cases with Planned Intraoperative EUS Integration

Case	Age/ sex	Clinical presentation	Lesion Size (mm)	Lesion Location	Preoperative Diagnosis	Type of Surgery	Final Pathology
1	35 / M	Hypoglycemia	5	Pancreatic head	pNET (non-biopsied)	Pancreatoduodenectomy	Well-differentiated pNET
2	54 / F	Incidental cystic lesion	10	Neck / Body	Branch-duct IPMN with mural nodule	Laparoscopic distal pancreatectomy + splenectomy	IPMN with low-grade dysplasia
3	69 / M	Familial cancer screening	7	Head	pNET (Ga68 PET positive)	Whipple procedure	Grade 1 glucagonoma
4	77 / F	Abdominal pain, weight loss	8	Neck– body junction	pNET	Laparoscopic distal pancreatectomy + splenectomy	Glucagonoma, negative margins

Results Four adult patients with technically challenging pancreatic lesions ranging from 5–10 mm, including neuroendocrine tumors and a branch-duct IPMN with a mural nodule, underwent pancreatic surgery with planned intraoperative EUS. Feasibility was demonstrated in all cases: EUS was performed successfully under sterile conditions, without contamination events, technical failures, or interference with surgical workflow. In each case, intraoperative EUS provided improved real-time lesion localization compared with LUS, particularly for small or non-palpable lesions. It enabled precise delineation of resection margins, supported parenchyma-sparing strategies, and improved intraoperative orientation. Immediate post-resection EUS confirmed absence of residual disease and excluded vascular or biliary complications before closure. No EUS-related adverse events occurred, and all patients had favorable postoperative courses, with no imaging- or procedure-related complications. The operating room environment accommodated the endoscopy team without changes to patient positioning or surgical ergonomics. The four cases are summarized in ▶ **Table 1**.

Conclusions Intraoperative EUS was feasible, safe, and compatible with pancreatic surgery in this early experience. It may offer potential advantages in lesion localization, margin assessment, and real-time decision-making, particularly for small or difficult-to-localize lesions. These findings warrant further study to clarify its clinical impact and comparative performance as an intraoperative imaging adjunct.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP198 Diagnostic Accuracy of the Esophageal String Test for Eosinophilic Esophagitis: A Systematic Review and Meta-Analysis Feasibility Assessment

Authors Mohan D[1], Khan F[1], Amorim Moreira Alves G[1]
Institute 1 Humanitas University, Milan, Italy
DOI 10.1055/s-0046-1821525

Aims To systematically review and meta-analyze the diagnostic accuracy of EST compared to endoscopic biopsy for diagnosing active EoE.

Methods We conducted a systematic search of PubMed, Embase, and Web of Science (through November 2025) for studies evaluating EST against biopsy as the reference standard in EoE diagnosis. A total of 449 studies were found, deduplicated and of the 5 full-text articles assessed, 2 studies met inclusion criteria (Furuta et al. 2013; Ackerman et al. 2019), comprising 175 total participants [1, 2].

Results Both studies demonstrated high AUCs (0.82–0.97) and strong correlations between EST biomarkers and esophageal eosinophil counts. However, neither study reported diagnostic thresholds, binary classifications, sensitivity/specificity, or ROC coordinates. Because EST biomarkers were analyzed as continuous measures without predefined cutoffs, no 2 × 2 contingency tables could be constructed, and meta-analysis of pooled sensitivity and specificity was not feasible (▶ **Table 1**).

▶ **Table 1**

Author, Year	Population (N)	Age	Disease Activity Groups	AUROC / AUC	Key Biomarkers (Correlation r)	Biomarker Findings	Patient Preference
Furuta GT, 2023	41	7–20 yrs	Active 14 / Inactive 8 / Normal 19	0.97	MBP-1 (0.72), EDN (0.48), ECP (0.21), EPX (0.54), CLC/ Gal-10 (0.73)	All eosinophil-derived proteins significantly elevated in active EoE	–
Ackerman, 2019	134	Active 24.9 ± 13.8; Inactive 29.3 ± 17.1; Normal 17.1 ± 9.7	Active 62 / Inactive 37 / Normal 35	0.82–0.87	Eot-3 (0.73), Eot-2 (0.60), EPX (0.49), MBP-1 (0.46), EDN (0.45), CLC (0.36)	All biomarkers significantly elevated in active EoE	87 % children; 95 % parents; 92 % adults preferred EST

Endoscopy 2026; 58: S1–S1041

Conclusions EST shows promise as a minimally invasive tool for monitoring EoE activity, with high AUC values and excellent patient acceptability. However, the absence of standardized diagnostic thresholds and insufficient statistical reporting precludes evidence synthesis of diagnostic accuracy. Future studies must establish and validate pre-specified EST cutoffs with complete 2 × 2 tables to determine clinical utility. Until then, EST cannot be recommended as a replacement for endoscopic biopsy in diagnostic pathways.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP199 Risk Factors Analysis for Pathological Upgrade After Endoscopic Submucosal Dissection in Patients with Gastric Intraepithelial Neoplasia: A Single Center Retrospective Study

Authors Ding L[1], Ji L[1], Han J[1], An F[1], Zhan Q[1], Si S[1], Tian W[1], Lv J[1], Zhang Y[1], Zhang X[1], Lv Z[1], Chen K[1], Nie H[1], Zhang Q[1], Li J[1]

Institute **1** Wuxi People's Hospital, Wuxi, China

DOI 10.1055/s-0046-1821526

Aims To analyze the risk factors for pathological upgrade in patients with gastric intraepithelial neoplasia (GIN) after endoscopic submucosal dissection ESD procedure.

Methods A retrospective analysis was conducted on 682 patients diagnosed with GIN by gastric endoscopic forceps biopsy (EFB) pathology at the Digestive Endoscopy Center of Wuxi People's Hospital from January 2018 to December 2024 (490 with low-grade intraepithelial neoplasia(LGIN) and 192 with high-grade intraepithelial neoplasia (HGIN). Demographic characteristics (gender, age, BMI, chronic disease history, fecal occult blood), endoscopic features of lesions (location, morphology, size), and pathology data after ESD procedure were collected. Univariate, multivariate, and stepwise logistic regression analyses were performed to identify independent risk factors for pathological up grade.

Results The total pathological upgrade rate after ESD was 59.4 % (51.2 % in the LGIN group and 80.2 % in the HGIN group). Stepwise regression analysis revealed that a maximum lesion diameter ≥ 2 cm (OR = 2.49) was the most significant risk factor for pathological upgrade. Meanwhile, age ≥ 70 years, comorbid hypertension, Paris classification type IIc lesion, and a lesion location at the gastric angle or cardia were independent risk factors for pathological upgrade, whereas a type IIb lesion demonstrated a protective effect (OR = 0.61).

Conclusions Advanced age (≥ 70 years), hypertension, lesion size ≥ 2 cm, type IIc morphology, and lesions in the gastric angle/cardia significantly increase the risk of pathological upgrade after ESD. These findings provide a basis for preoperative risk assessment and individualized treatment strategies for GIN patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP200 Post-ERCP Pancreatitis: Incidence, Risk Factors, and Outcomes from a Single-Centre Experience

Author Kumar A[1]

Institute **1** Himalayan Hospital, Dehradun, India

DOI 10.1055/s-0046-1821527

Aims This study aimed to determine the incidence, severity, and predictors of Post ERCP induced pancreatits(PEP) in a tertiary care center in North India.

Methods This retrospective observational study included 300 consecutive ERCPs performed between January 2024 and August 2025 at the Department of Gastroenterology, Himalayan Institute of Medical Sciences, Dehradun. Data on demographics, indications, cannulation difficulty, prophylaxis, and outcomes were analyzed. PEP was defined as new or worsened abdominal pain with serum amylase/lipase more than 3 times upper limit of normal within 24 hours, requiring ≥ 2 days of hospitalization [1]. Severity was classified as per the Revised Atlanta Criteria.

Results Among 300 ERCPs done , mean patient age was 52 ± 10 years, with 60 % female patients. Common indications included CBD stones (70 %), cholangitis (15 %), benign strictures (10 %), and malignant obstruction (5 %). Prophylaxis included rectal NSAIDs in 65 % and pancreatic duct stenting in 12 %. The overall incidence of PEP was 8 % (n = 24): mild (n = 16), moderate (n = 5), and severe (n = 3). Difficult cannulation (> 5 attempts) and inadvertent PD injection were significant predictors ($p < 0.05$). No mortality occurred in the study.

Conclusions Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) remains the most frequent complication of ERCP, despite advances in prophylactic strategies [1]. The incidence of PEP in this cohort was comparable to global data as seen in freeman et al study [2]. Difficult cannulation and Pancreatic duct injection were key risk factors for PEP in our study. Rectal NSAIDs demonstrated a protective effect in prevention of PEP. Similar results were seen in Dumonceau et al study [1] Adherence to ESGE-recommended prophylactic measures can further minimize PEP rates. [3]

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP201 Digital Microscopy in the Endoscopy Suite: A Reference Standard for Colorectal Polyp Size Measurement

Authors Aleksieva P[1], Djinbachian R[1], Douglas KR[2], Pohl H[3], Shahidi N[4], Mitchell S[1], Zineddine Mahdadi M[1], Cristea E[1], Oleksiw M[1], Michal V[5], Gefflot C[5], Von Renteln D[1]

Institutes **1** CHUM – Centre hospitalier de l'Université de Montréal, Montréal, Canada; **2** Indiana University School of Medicine, Indianapolis, United States of America; **3** VA Medical Center, White River Junction, VT, USA, United States of America; **4** The University of British Columbia, Vancouver, Canada; **5** Research Center Du Chum ., Montréal, Canada

DOI 10.1055/s-0046-1821528

Aims Accurate determination of colorectal polyp size is critical for surveillance recommendations and for generating reliable ground truth in artificial intelligence (AI) development. Visual estimation is imprecise, and no validated reference standard exists. We aimed to assess the accuracy and reproducibility of real-time digital microscopic measurement of fresh polypectomy specimens [1–20].

Methods In this prospective study at the Centre hospitalier de l'Université de Montréal (CHUM), 70 polyps from 44 patients (mean age 65.4 years; 52.3 % female) were measured on-site using a calibrated digital microscope. Three independent raters, blinded to each other, obtained long- and short-axis measurements. The primary outcome was inter-rater reliability for long-axis measurements. Secondary outcomes included short-axis reliability, overall agreement, and classification (≤ 5 mm vs. > 5 mm) (▶ **Table 1**).

▶ Table 1

	Overall(N = 70)
Segment, n (%)	
Caecum	6 (8.6%)
Ascending colon	14 (20.0%)
Transverse colon	13 (18.6%)
Descending colon	18 (25.7%)
Sigmoid	12 (17.1%)
Rectum	7 (10.0%)
Paris class, n (%)	
Is	58 (82.9%)
Isp	2 (2.9%)
IIa	7 (10.0%)
IIc	3 (4.3%)
Pathology, n (%)	
Adenoma	46 (65.7%)
Hyperplastic	10 (14.3%)
Inflammatory polyp	7 (10.0%)
Normal/mucosal prolapse	1 (1.4%)
Other	2 (2.9%)
Missing	4 (5.7%)

Results Inter-rater reliability was excellent for both long-axis (ICC 0.941, 95% CI 0.914–0.961) and short-axis (ICC 0.943, 95% CI 0.917–0.962) measurements. Bland–Altman plots demonstrated mean differences near zero without systematic bias. Limits of agreement were within ± 1 mm. When dichotomized at the 5 mm threshold, agreement was perfect (κ = 1.0).

Conclusions On-site digital microscopy provides highly reproducible and verifiable size data with photographic documentation. This method should be considered a reference standard for accurate polyp sizing in clinical research and AI model development.

Conflicts of Interest Daniel von Renteln has received research funding from ERBE Elektromedizin GmbH, Ventage, Pendopharm, Satisfai, Fujifilm, and Pentax, and has received consultant or speaker fees from Boston Scientific Inc., ERBE Elektromedizin GmbH, Medtronic, and Pendopharm. eP202 Endoscopic management of postoperative gastrointestinal bleeding in an italian cancer-center

Authors cini L[1], Benedicenti F[1], Pugliese D[2], Rosa R[2], Borsotti E[2], Magarotto A[2], Cavalcoli F[2], Solla D[3], Cantù P[2]
Institutes 1 univesity of the study of Milan, Milan, Italy; 2 Gastroenterology and Endoscopy Unit, IRCCS Foundation National Cancer Institute, Milan, Italy; 3 IRCCS Foundation National Cancer Institute, milan, Italy
DOI 10.1055/s-0046-1821529

Aims PostOperative GastroIntestinal Bleeding (POGIB) is a rare but relevant complication. Endoscopy represents a first-line treatment, but evidence about its safety and effectiveness remain limited. We aimed to report our experiences in the management of POGIB.

Methods A retrospective analysis with prospectively collected data was conducted on all patients that underwent endoscopic procedure for suspected POGIB at our center between January 2019 and July 2025. Univariate analyses

were performed to identify predictive factors for clinical success in anastomotic bleeding (▶ **Table 1**).

Results Eighty-two patients (median age 65 years, IQR 58-75; 61 % male) underwent endoscopy a median of 6 days after surgery (IQR 2-12) for suspected gastrointestinal bleeding (63 % hematochezia, 27 % melena, 5 % hematemesis, 5 % asymptomatic anemia). Active bleeding or stigmata were found in 83 % of cases: 70 % anastomotic, 13 % non-anastomotic (mainly ulcerative gastroduodenitis). Hemostatic intervention was performed in 72 % of patients, mainly mechanical (38 %) or combined mechanical (27 %). Technical success was achieved in 88 %, overall clinical success in 82 % (in 62 cases after one, in 5 after two endoscopic procedures). Ten patients underwent reoperation (five for persistent bleeding) and four died (one for massive gastrointestinal bleeding). Considering POGIB with anastomotic bleeding, no predictive factors for clinical success were identified among demographic or clinical data. Among treatments, mechanical hemostasis was significantly associated with higher success rates (p = 0.0005). No adverse events occurred during endoscopy (▶ **Table 2**).

▶ **Tab. 1** General characteristics of study population and main findings (n = 82)

Previous gastrointestinal surgery n (%)	23 (28)
Department of admission n (%)	Colorectal surgery 49 (60); Sarcoma/Mesenchyma surgery 15 (18); Hepatobiliary surgery 14 (17); Other 4 (5)
Multivisceral surgery n (%)	39 (48)
Endoscopic procedures n (%)	Colonoscopy 59 (72); EGDS 22 (27); Enteroscopy DAE 1 (1)
Endoscopic treatments n (%)	Mechanical 31 (38); Mechanical + topical 16 (20); Topical 6 (7); Mechanical + injection 4 (5); Mechanical + thermal 2 (2); No treatment 23 (28)

EGDS: EsophagoGastroDuodenoScopy; DAE: Device Assisted Enteroscopy.

▶ **Tab. 2** Univariate analysis of results of endoscopic treatments in anastomotic bleeding (n = 57)

Variable	Success / Failure	P value
Age	–	0.535
Sex	Male 28/4, Female 24/1	0.513
Surgery and Timing	Past GI surgery: No 42/5, Yes 10/0; Multivisceral: No 28/2, Yes 24/3; Anastomosis site: Upper 6/0, Lower 46/5; Endoscopy: ≤ 7days 36/3, > 7days 16/2	0.642–1
Endoscopic treatments	None 0/2, Mechanical 30/1, Mechanical + other 19/2, Topical 3/0	**0.0057**

Conclusions Results suggest that endoscopic management of POGIB is safe and effective. Further prospective studies are needed to establish the best endoscopic strategy.

eP203 Endoscopic Diagnosis and Rescue Therapy of an Esophagopericardial Fistula Secondary to Metastatic Renal Cell Carcinoma: A First Reported Case

Authors Gómez Gómez A[1], Barreto Nicolás M[1], Soto Segado P[1], Calatayud Vidal G[2], Sánchez Martínez M[1], Romero Martínez M[1], Bógalo Romero C[1], Madrigal Bayonas L[2], Sánchez Roncero FJ[2], Alajarín Cervera M[1], Martinez Caselles A[1], Tomás Pujante P[1], Egea Valenzuela J[1]

DOI 10.1055/s-0046-1821530

Abstract Text

Esophagopericardial fistula (EPF) is an exceptionally rare and life-threatening condition historically associated with esophageal carcinoma, postoperative complications, peptic ulcer disease, or radiotherapy. Fewer than 70 cases have been reported since 1931, and no previous case has been attributed to metastatic renal cell carcinoma (RCC). The mortality remains extremely high due to purulent pericarditis, cardiac tamponade, and sepsis. We present the first reported case of EPF originating from a paraesophageal RCC metastasis, successfully diagnosed and managed through advanced endoscopy.

Our patient is a 65-year-old male with metastatic RCC with mediastinal lymph node progression infiltrating the esophagus (Figure 1), for which cabozantinib is initiated. One month later, he presented with shock, severe metabolic acidosis, acute kidney injury and elevated lactate. Imaging revealed bilateral pleural effusions and a progressive pericardial effusion. Purulent pericardiocentesis yielded *Enterococcus faecium* and *Candida albicans*. CT showed pneumopericardium and air tracking between the mid-thoracic esophagus and pericardium (Figure 2), raising suspicion of fistulization, particularly in the context of a previously treated mediastinal paraesophageal metastatic mass [1–3].

Bedside gastroscopy in ICU revealed, in the middle third of the esophagus, fibrin, purulent exudate and a 4 cm long orifice confirming EPF (Figure 3). Given the patient's critical instability, endoscopic therapy was selected as the safest option. A fully covered 18 cm × 28 mm esophageal stent was deployed under endoscopic guidance and secured with an over-the-scope clip. Initial sealing and expansion were satisfactory. Two days later, he developed persistent sepsis and hypotension. Chest X-ray demonstrated that the prior stent had migrated caudally (Figure 4). The displaced stent was removed endoscopically. A longer fully covered 24 cm × 28 mm bariatric-type stent was deployed and fixed with an over-the-scope clip, achieving complete coverage. A new pericardiocentesis was performed, obtaining purulent exudate.

Subsequent CT imaging confirmed marked reduction of pericardial collections and resolution of contrast leakage. The patient improved hemodynamically and was successfully extubated. Multidisciplinary management continued with pericardiectomy and targeted antimicrobial therapy.

EPF is usually related to primary esophageal malignancy; most of literature cases describe esophageal carcinoma as the malignant etiology. This is the first documented EPF arising from RCC metastasis. Early endoscopic diagnosis was crucial, and therapeutic stenting—despite migration—provided effective fistula sealing and stabilization in a critically ill patient. This case underscores the pivotal role of advanced endoscopy in the diagnosis, treatment and rescue management of malignant EPF.

eP204 Outcome of PEG-J Extension Using Transnasal Endoscopy (TNE) Through Stoma Opening – A Single-Center Descriptive Study

Authors Ahmad A[1], Elsayed MOK[1], Satyasheel R[1], Nicola W[1], Laura S[1], Talkhan M[1], Wael A[1], Mohamed M[1]
Institute 1 South Tees Hospitals NHS Foundation Trust, Middlesbrough, United Kingdom
DOI 10.1055/s-0046-1821531

Aims This descriptive study investigates the outcomes of PEG-J extension using Transnasal Endoscopy (TNE) through an existing stoma opening at a single tertiary center.

Methods This is a retrospective descriptive study conducted at James Cook University Hospital. Data were collected from patient records including demographics, medical history, indications for PEG-J, tube size, number of PEG-J replacements, time intervals between replacements, method of placement, and causes of PEG-J exchange. Descriptive statistics were used to analyze the collected data [1–4].

The old PEG or PEG/J tube was usually removed and TNE was used through the gastrostomy stoma into the stomach and then was advanced as deep as possible into the duodenum. A guidewire was then introduced deep in the duodenum and TNE was withdrawn leaving the guidewire in place. The new PEG/J tube was then lubricated with oil before being fed over the wire in exchange one-to-one process. The balloon was then inflated and the tube fixed in place.

Results A total of 11 patients (6 female, 5 male) were included in the study, with a mean age of 43.9 ± 18.5 years (range 18-76 years). The mean number of PEG-J replacements was 7.0 ± 2.6 (range 3-10). The most common indications for PEG-J placement were: gastroparesis (n = 5), followed by dysphagia (n = 2). Other indications included oesophageal aperistalsis, feeding difficulties, recurrent chest infections with tracheostomy, and brain stem stroke (n = 1 each). The predominant tube size used was 16f (n = 7), with 18f used in 4 patients. The primary causes for PEG-J exchange were coiled tube back to stomach (n = 6), blocked tube (n = 3), and burst balloon (n = 2).

Conclusions This study provides insights into the outcomes of PEG-J extension using TNE through stoma opening in a single-center cohort. The findings highlight the common indications and causes for tube exchange, which can inform clinical practice and guide future research. Further larger-scale studies are warranted to validate these findings and explore long-term outcomes and technical success rates.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP205 EUS-Guided Portal Pressure Gradient and Liver Biopsy in Pre-Transplant Assessment: A Case Series and Review of the Literature

Authors Yanagisawa Y[1], Bylinska J[1], Vickars D[1], Maher B[2], Tehami N[2]
Institutes 1 Southampton General Hospital, Southampton, United Kingdom; 2 Interventional Endoscopy Unit, University Hospital Southampton, Southampton, United Kingdom
DOI 10.1055/s-0046-1821532

Aims Accurate assessment of hepatic fibrosis and portal hypertension (PH) is essential in patients with end-stage renal disease (ESRD) who are suspected to have advanced hepatic fibrosis, as this may influence the choice between isolated renal transplantation and combined liver–kidney (hepato-renal) transplantation. Endoscopic ultrasound (EUS)-guided portal pressure gradient (PPG) measurement (EUS-PPG) provides a minimally invasive alternative to the hepatic venous pressure gradient (HVPG) for evaluating PH, and can be combined with multimodality endoscopic assessment in a single session. However, the procedure can be technically challenging in patients with ESRD due to increased bleeding risk and altered anatomy, such as in those with polycystic liver disease. The aim of our study was to evaluate the safety, feasibility, and impact of EUS-PPG on clinical decision-making in this patient group [1–8].

Methods A prospective therapeutic EUS registry was reviewed retrospectively, focusing on patients with ESRD who were suspended from the renal transplant list due to suspected underlying liver disease. Patients with ESRD undergoing EUS-PPG measurement with or without concurrent endoscopic variceal screening, elastography, and liver biopsy between August 2023 and August 2025 were included. Patient demographic data, clinical characteristics, Endoscopic findings, PPG values, histopathology findings, and procedure-related complications were recorded and analysed. Clinically significant portal hypertension (CSPH) was defined as a PPG ≥ 10 mmHg. The primary outcome was the impact of EUS-PPG on transplant decision-making, while secondary outcomes included the safety and feasibility of the procedure.

Results A total of 7 patients with ESRD who had been suspended from the renal transplant list were included (4 female, 3 male; mean age 52 years). All EUS-PPG procedures were technically successful, with PPG values ranging from 3–6 mmHg. 5 patients underwent EUS-guided liver biopsy, and all specimens were adequate for histological analysis. Each biopsy met key performance indicators i.e. total specimen length ≥ 20 mm, and presence of ≥ 11 complete portal tracts. One patient experienced minor post-biopsy bleeding requiring a short hospital stay but no intervention. None of the patients demonstrated clinically significant portal hypertension. Based on these findings, all patients were recommended for reinstatement on the isolated renal transplant list. No adverse events were observed during follow-up.

Conclusions EUS-PPG measurement, with or without concurrent liver biopsy, is a feasible, safe, and clinically valuable tool for assessing hepatic fibrosis and portal hypertension in renal transplant candidates. It provides critical hemodynamic and histologic information in a single session, thereby informing transplant eligibility decisions and potentially avoiding unnecessary combined liver–kidney transplantation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP206 Under a Different Light: Early Gastric Neoplasia Revealed by Advanced Imaging in a MAPS III High-Risk Patient

Authors Siragusa N[1], Mario C[2], Claudio L[2], Alicante S[2], Alessandra D[3], Guido M[2]
Institutes **1** Luigi Sacco Hospital, Milan, Italy; **2** Gastroenterology and Digestive Endoscopy Unit, 'Maggiore' Hospital, Crema, Italy; **3** Sacco Hospital, Milano, Italy
DOI 10.1055/s-0046-1821533

Abstract Text

A 48-year-old man with a first-degree family history of gastric cancer underwent esophagogastroduodenoscopy for persistent dyspepsia. Standard white-light imaging (WLI) showed a well-distensible stomach with preserved folds and only mild mucosal edema, with no identifiable focal lesions.When the examination was repeated using high-definition virtual chromoendoscopy with blue-light imaging (BLI) and optical magnification, the stomach appeared truly “under a different light.” Multiple pale, map-like areas were visible in both body and antrum, consistent with gastric intestinal metaplasia (GIM). Endoscopic risk assessment using the Endoscopic Grading of Gastric Intestinal Metaplasia (EGGIM) yielded a score of 9, indicating extensive metaplastic involvement and aligning with the high-risk category defined by MAPS III criteria. Careful inspection of the lesser curvature of the gastric body revealed an 8–10 mm depressed lesion (Paris 0-IIc), completely invisible under WLI. In BLI with magnification, the lesion displayed features typical of early gastric neoplasia: loss of the normal microsurface pattern (MS), irregular microvascular architecture (MV), and a sharply defined demarcation line separating normal from abnormal mucosa. These findings fulfilled the diagnostic criteria of the Magnifying Endoscopy Simple Diagnostic Algorithm for Gastric Cancer (MESDA-G), based on the validated vessel-plus-surface (VS) classification system.Targeted biopsies confirmed intraepithelial neoplasia (low-grade dysplasia, intestinal phenotype type I). Random biopsies from antrum, angulus and body documented chronic inflammation, extensive intestinal metaplasia (OLGIM IV) and severe glandular atrophy (OLGA IV), delineating a diffusely high-risk mucosal background.Lesion marking, circumferential incision and controlled submucosal dissection were all performed using a Hybrid Knife, achieving complete en-bloc resection without immediate adverse events. Post-procedural assessment confirmed an intact muscularis propria and radical excision.This case highlights the diagnostic superiority of advanced endoscopic imaging over standard WLI. The integration of BLI, optical magnification and structured classification systems (EGGIM and MESDA-G) enabled identification of an early neoplastic focus entirely missed by conventional imaging. MAPS III emphasizes the importance of high-quality endoscopy, supported by advanced imaging techniques for the systematic evaluation of atrophy and metaplasia; in this patient, these principles facilitated timely diagnosis and curative treatment. Advanced imaging does not merely change what the mucosa looks like: it changes what can be diagnosed. For this reason, adequate training is essential for endoscopists to fully master and exploit the potential of these technologies [1–3].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP207 Endoscopic resection for duodenal carcinoid tumors

Author Choi J[1]
Institute **1** Dankook University, Yongin-si, Republic of Korea
DOI 10.1055/s-0046-1821534

Aims Few studies have assessed the safety and efficacy of endoscopic resection for duodenal carcinoid tumors. This study aimed to evaluate the utility of endoscopic resection in this setting.

Methods Between February 2015 and February 2024, 35 patients with sporadic duodenal carcinoids managed by endoscopic resection were enrolled. Endoscopic treatment was performed in patients without nodal or distant metastasis. Rates of endoscopic complete resection, histologic complete resection, procedure-related complications, and tumor recurrence were retrospectively analyzed.

Results Twenty-five nonampullary duodenal carcinoids were treated with endoscopic mucosal resection, four with endoscopic submucosal dissection (ESD), and six ampullary carcinoids with snare papillectomy. The mean patient age was 61.9 years (range, 44–83). Mean tumor size was 8.8 ± 2.4 mm (range, 3–12) for nonampullary carcinoids and 13.7 ± 5.4 mm (range, 5–20) for ampullary carcinoids.

The endoscopic complete resection rate was 97.1 %. Incomplete resection occurred in one patient undergoing ESD due to tumor invasion into the muscularis propria. Histologic complete resection was achieved in 31 of 35 patients (88.6 %) on the initial attempt; one additional patient required a second session to achieve complete resection.

Procedure-related perforation occurred in three patients with nonampullary carcinoids (8.6 %): two were managed endoscopically, and one required local surgical excision. After a median follow-up of 39 months (range, 10–96), local recurrence was observed in one patient (2.8 %) with a nonampullary tumor larger than 10 mm. Among patients with ampullary carcinoids, no local recurrence or distant metastasis was detected during a median follow-up of 40 months (range, 18–100).

Conclusions Endoscopic resection appears to be a safe and effective treatment option for small (≤ 10 mm) nonampullary duodenal carcinoids without evidence of muscularis propria invasion. For ampullary carcinoids < 20 mm confined to the submucosa, minimally invasive endoscopic papillectomy may be considered, particularly in older patients or those with significant comorbidities who are at higher risk for postoperative complications.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP208 Efficacy and Limitations of Steroid Prophylaxis for Stricture Prevention After Extensive Esophageal ESD

Authors Kako S[1], Iwaya Y[1], Nagaya T[2]
Institutes **1** Department of Gastroenterology Shinshu University School of Medicine, Matsumoto, Japan; **2** Endoscopic Examination Center, Shinshu University Hospital, Matsumoto, Japan., Matsumoto, Japan
DOI 10.1055/s-0046-1821535

Aims Esophageal stricture is one of the most challenging complications following endoscopic submucosal dissection (ESD) for superficial esophageal

cancer. Mucosal defects ≥ 5 cm in length or involving the entire circumference are considered high risk for post-ESD stricture, with chemoradiotherapy or surgery often recommended for these conditions, even when dealing with superficial lesions. Although combined local and systemic steroid therapies are widely used for stricture prevention, their efficacy, optimal dosage, and clinical indications remain insufficiently established. This study evaluated the effectiveness and limitations of steroid-based prophylaxis in preventing esophageal stricture after extensive ESD.

Methods We retrospectively reviewed 72 patients who underwent esophageal ESD at our institution between 2007 and 2024, in whom the mucosal defect involved ≥ 3/4 of the circumference. In analysis 1, patients were classified into a sub-circumferential group (SC group; n = 61, ≥ 3/4 but less than full circumference) and a circumferential group (C group; n = 11, full circumference). Lesion characteristics, preventive strategies, and post-ESD stricture outcomes were compared between the groups. In analysis 2, patients were divided into groups with and without stricture according to the need for endoscopic balloon dilation when a standard endoscope could not pass through the post-ESD site for identifying postoperative esophageal stricture risk factors. Subgroup comparisons were further conducted in the 61 patients who received steroid-based prophylaxis.

Results In analysis 1, mean longitudinal mucosal defect length was significantly greater in the C group than in the SC group (81 mm vs. 47 mm, p < 0.01). Local steroid injection was performed in 45 (74 %) SC and 11 (100 %) C patients, respectively (p = 0.10), with significantly higher total doses in the C group (150 mg vs. 100 mg, p < 0.01). Oral steroids were administered for 11 (18 %) SC and 10 (91 %) C cases (p = 0.01). Stricture occurred in 15 (25 %) SC and 4 (40 %) C patients (p = 0.66), with a median of 4 (1–21) and 8 (3–11) dilation sessions, respectively (p = 0.34). In analysis 2, esophageal stricture was recorded in 19 of 72 (26 %) patients. Median resection length was similar between patients with and without stricture (50 mm vs. 49 mm). Median total triamcinolone dose was 100 mg (18 mg/cm of lesion length) and not associated with stricture formation. Lesions located in the upper esophagus (Ce + Ut) tended to exhibit a higher stricture rate (55 %) compared with lower lesions (21 %), although this difference did not reach statistical significance (p = 0.056). Among the 61 patients receiving steroid prophylaxis, 13 (21 %) experienced strictures. However, triamcinolone dose, dose/cm of lesion length, lesion length, circumferential extent, muscularis injury, and lesion location showed no significant associations with stricture development. All 11 circumferential lesions measured ≥ 5 cm. Three (27 %) cases developed stricture despite both local and systemic steroid prophylaxis, requiring a mean of 6 endoscopic balloon dilations.

Conclusions Combined steroid prophylaxis lowered overall stricture rates. Under steroid administration, conventional risk factors were no longer associated with stricture development. Upper esophageal locations tended to exhibit higher risk, but no clear independent predictors were identified. All full-circumferential lesions were ≥ 5 cm, with 3 displaying stricture despite combined steroid prophylaxis. Although the sample size limits comparative analysis across lesion lengths, these results show that stricture is not inevitable, even in extensive full-circumferential disease. Therefore, ESD remains a feasible option for selected ≥ 5 cm circumferential lesions under adequate steroid prophylaxis.

eP209 Role of Endoscopic Retrograde Cholangiopancreatography (ERCP) in the Diagnosis and Treatment of Residual Cystic Duct Stones after Cholecystectomy: A Cases series

Authors bendada F[1], Lagdali N[2], Kadiri M[1], Ajana FZ[2], Borahma M[3]
Institutes 1 Rabat, Morocco; 2 Mohammed V University, Rabat, Morocco; 3 Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821536

Aims A residual cystic duct stone may occur in up to 40 % of patients within a period ranging from 2 days to 25 years after cholecystectomy. Traditionally, management has relied mainly on surgical intervention. This study aimed to evaluate the role of endoscopic retrograde cholangiopancreatography (ERCP) in the diagnosis and treatment of residual cystic duct stones in cholecystectomized patients.

Methods This was a retrospective descriptive study including all cholecystectomized patients presenting with residual cystic duct stones. Data were collected over a 4-year period, from 2021 to 2025.

Results Among 83 patients who underwent cholecystectomy and presented with post-cholecystectomy syndrome, 31.3 % (n = 26) were found to have a residual cystic duct stone. The male-to-female ratio was 0.3, with a clear female predominance (76.9 %, n = 20) compared to males (23.1 %, n = 6).

The main reasons for hospitalization were isolated hepatic colic in 34.6 % (n = 9) of cases and acute cholangitis in 65.4 % (n = 17).

Imaging studies (abdominal ultrasound and Magnetic Resonance Cholangiopancreatography MRCP) revealed one or more stones in the cystic duct in 42.3 % (n = 11) of patients, associated with residual stones in the common bile duct (CBD) in 69.2 % (n = 18). Additionally, 15.4 % (n = 4) of patients presented with isolated CBD dilatation without an identifiable obstruction.

ERCP identified residual cystic duct stones in 100 % (n = 26) of cases and CBD stones in 73.1 % (n = 19), among which 19.2 % (n = 5) were associated with Mirizzi syndrome.

The median size of cystic duct stones was 15 mm [6–20], while that of CBD stones was 16.3 mm [8–25].

Endoscopic extraction of cystic duct stones via ERCP was successfully achieved in 73.1 % of cases (n = 19). The main causes of failure included stone shape (n = 2), normal CBD caliber (n = 3), stone size (n = 1), and multiple stones (n = 1). In cases where extraction failed (26.9 %, n = 7), a plastic biliary stent was placed to ensure effective drainage before referring patients for surgery.

Conclusions This study highlights the crucial role of ERCP in the management of residual cystic duct stones in cholecystectomized patients, with a therapeutic success rate of approximately 73 %. ERCP represents an effective and minimally invasive alternative to surgery, particularly for patients with high operative risk.

eP210V When the Lesion Enters the Terminal Ileum: Traction Makes ESD Possible

Authors Martínez- alcalá A[1], Martínez-Alcalá García S[2], Arroyo Argüelles JM[1], Nabal M[3], Ferreiro Perez E[3], Navascués Lucini A[3], Alvarez V[3]
Institutes 1 Hospital Universitario Infanta Leonor, Madrid, Spain; 2 Hospital universitario san pedro, logroño, Spain; 3 12 de Octubre University Hospital, Madrid, Spain
DOI 10.1055/s-0046-1821537

Abstract Text

We present a traction-assisted endoscopic submucosal dissection (ESD) of a 35-mm granular heterogeneous LST involving the ileocecal valve and extending into the terminal ileum. The procedure was initiated from the ileal side using a transparent cap to separate the villi and obtain a stable view for the first mucosal incision and submucosal entry. Dissection then progressed toward the colonic portion of the lesion. Clip-band traction provided optimal exposure across the valve, enabling a safe and controlled resection. The lesion was removed en bloc without complications. Histology confirmed a tubulovillous adenoma with low-grade dysplasia and R0 margins [1–5].

eP211 Assessment of Faecal Immunochemical Testing (FIT) Triage and Recording Practices in Colonoscopies for Symptomatic Patients

Authors Hutchinson K[1], Jones E[1], Pang CYS[1], Beaton D[1], Lee T[1]
Institute 1 Northumbria NHS Foundation Trust, Newcastle upon Tyne, United Kingdom
DOI 10.1055/s-0046-1821538

Aims UK guidance advises Faecal Immunochemical Testing (FIT) should be used to triage all referrals for colonoscopy in patients presenting with lower gastrointestinal symptoms. We aimed to calculate the completeness and accuracy of FIT recording within endoscopy reports, and to evaluate whether endoscopist quality indicators were associated with FIT documentation.

Methods All colonoscopies performed within an NHS Foundation Trust between 1 April and 31 May 2025 were reviewed. Procedures for lower gastrointestinal symptoms were identified, and FIT results recorded in endoscopy reports were compared with those in the local pathology system.

The completeness and accuracy of FIT recording were calculated. Endoscopists were grouped by annual procedure volume (< 100 vs ≥ 100) and caecal intubation rate (< 90 % vs ≥ 90 %), with associations analysed using chi-squared testing.

Results A total of 1,138 colonoscopies were performed over the 2-month period, of which 566 (49.7 %) investigated lower gastrointestinal symptoms, performed by 37 endoscopists. Among these, 442 (78.1 %) had a FIT result recorded on the endoscopy report, while a further 45 (10.2 %) had a FIT performed but not recorded. Of the 442 reports with a recorded FIT, 425 (96.2 %) were accurate; among the 17 (3.8 %) inaccuracies, over half (n = 9, 52.9 %) involved minor numerical discrepancies (e.g. 40 recorded instead of 45).

Of the 37 endoscopists, 14 (37.8 %) performed fewer than 100 colonoscopies annually, accounting for 88 procedures (15.5 %), and 9 (24.3 %) had a CIR < 90 %, performing 167 procedures (29.5 %). There was no association between endoscopist annual

procedure volume and the completeness or accuracy of FIT recording (p = 0.79), nor between CIR and FIT recording (p = 0.07).

Conclusions Most (88 %) colonoscopies performed for lower gastrointestinal symptoms had a FIT completed prior to endoscopy; however, in 10 % of cases, results were not included in the endoscopy report despite being available. FIT values recorded were accurate, and no association was found between FIT completion and endoscopist procedure volumes or CIR.

These findings highlight the need to improve processes surrounding FIT recording in symptomatic colonoscopy; ensuring all are triaged by FIT and that endoscopists can readily access and document results. This would support equitable and efficient utilisation of colonoscopy resources across the UK.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP212V EndoFLIP-guided repeat peroral endoscopic myotomy for refractory type III achalasia: tailoring therapy in a challenging case

Authors Bonura GF[1], Soriani P[1], Gualandi N[1], Cortegoso Valdivia P[2], Parrella A[1], Pileggi R[1], Manno M[1]
Institutes 1 Gastroenterology and Digestive Endoscopy Unit, AUSL Modena, Modena, Italy; 2 Gastroenterology and Endoscopy Unit, University Hospital of Parma, Parma, Italy
DOI 10.1055/s-0046-1821539

Abstract Text

Peroral endoscopic myotomy (POEM) is the preferred treatment for type III achalasia, as it allows the myotomy of both the lower esophageal sphincter (LES) and the spastic esophageal segment [1]. However, the optimal myotomy length varies among patients [2]. The Endoluminal Functional Lumen Imaging Probe (EndoFLIP) provides assessment of LES distensibility and is increasingly used to tailor myotomy length, especially during re-interventions [3]. We report the case of a 29-year-old man with type III achalasia initially treated with posterior POEM. After early improvement, he developed recurrent dysphagia. During an anterior re-POEM, EndoFLIP identified two areas of reduced distensibility, guiding targeted extension of the myotomy. Final measurements confirmed normalization of distensibility. The patient was discharged two days later and remained asymptomatic at six-month follow-up.

eP213 Evaluation of axial and lateral resolution and slice thickness in endoscopic ultrasound

Authors Hoshi K[1], Nakahodo J[1], Imamoto T[1], Chiba K[1], Tabata H[1], Minami R[1], Kamisawa T[1], Iizuka T[1]
Institute 1 Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan
DOI 10.1055/s-0046-1821540

Aims Higher spatial resolution and thinner slice thickness are essential in ultrasound imaging because they reduce out-of-plane contamination and improve micro-lesion detection. These principles also apply to endoscopic ultrasound (EUS), where image quality directly affects diagnostic accuracy and the safety of EUS-guided procedures. However, spatial resolution and slice thickness have rarely been evaluated systematically or quantitatively across EUS devices. This study aimed to quantitatively assess axial and lateral spatial resolution and slice thickness across multiple EUS platforms, depending on imaging frequency and measurement depth.

Methods We used the following endoscope– processor pairings: GF-UCT260 with EU-ME2/EU-ME3 (Olympus, Japan) and Aplio i800 (Canon, Japan); and EG-580UT/EG-740UT with SU-1 (Fujifilm, Japan). Spatial resolution and cyst

model delineation were evaluated using the phantom (Kyoto Kagaku N-365 multipurpose phantom, Japan), and slice thickness was evaluated using a custom 45° inclined phantom (film: OHM laminate film 100 µm [LAM-FA41003]).
[Spatial resolution] axial/lateral resolution were evaluated using wires (diameter 0.05 mm, spacing 0.5, 1, 2, 3, and 4 mm) at measurement depths of 15, 30, and 50 mm.
[Cyst delineation] Cyst models (1, 2, 3, and 4 mm) were evaluated at measurement depths of 10, 30, and 50 mm.
[Slice thickness] Ultrasound beams were vertically incident, and the longitudinal width (X) of the hyperechoic band generated in the inclined direction on the image was measured. Because the inclination was 45°, X was defined as the slice thickness (Y mm). Measurements were performed for each frequency and measurement depth (10–60 mm).

Results [Spatial resolution]Axial resolution at measurement depths of 15 and 30 mm was 0.5 mm, while lateral resolution at the same depths was 1–2 mm. At a depth of 50 mm, axial resolution was 1 mm, and lateral resolution was 4 mm or unmeasurable. In all devices and under all conditions, axial resolution was superior to lateral resolution. The performance was nearly equivalent across all endoscopes and processor.
[Cyst delineation]Cyst models with diameters of 1, 2, 3, and 4 mm were detectable at a measurement depth of 10 mm, and those with diameters of 2, 3, and 4 mm were detectable at 30 mm. At a depth of 50 mm, all cysts were non- detectable. The performance was nearly equivalent across all endoscopes and processor.
[Slice thickness]
Slice thickness reached its minimum at a scope-specific focal depth. For the Olympus GF-UCT260 scope, the focal depth was 30 mm, with minimum values of 1.55 mm (12 MHz, EU-ME2), 1.52 mm (THE-R, EU-ME3), and 1.66 mm (d11, Aplio i800). In contrast, for the Fujifilm SU-1 processor, the focal depth was 20 mm, with minimum slice thicknesses of 1.63 mm (THE-8.0, EG-580UT) and 1.87 mm (12 MHz, EG-740UT). These findings indicate that the depth at which slice thickness is minimized differs among devices. Across all systems, slice thickness increased at both shallower and deeper depths relative to the focal depth. At 10 mm, slice thickness ranged from 4.33–4.86 mm (EU-ME2), 4.97–5.23 mm (EU-ME3), and 3.65–4.25 mm (Aplio i800) for GF-UCT260, and 1.98–3.74 mm (EG-580UT), 2.22–3.34 mm (EG-740UT) on the SU-1 processor. At 60 mm, values ranged from 3.90–4.60 mm (EU-ME2), 3.05–4.55 mm (EU-ME3), and 3.70–3.95 mm (Aplio i800) for GF-UCT260, and 3.72–5.22 mm (EG-580UT), 6.47–6.99 mm (EG-740UT) on the SU-1 processor [1–6].

Conclusions In EUS, spatial resolution is maintained at depths ≤ 30 mm but declines at 50 mm. Slice thickness is lowest at a scope-specific focal depth and increases at shallower and deeper levels. Thus, targets away from the focal depth may become partially embedded within the slice, raising the risk of off-target sampling and bleeding. Aligning the lesion with the focal depth and adjusting frequency, scope choice, and approach angle to device-specific characteristics may improve procedural safety, tissue acquisition, and diagnostic accuracy. These findings also enhance endoscopy service quality by providing objective metrics to optimize EUS imaging settings and standardize EUS-guided procedures.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP214 Modified endoscopic vacuum therapy for the treatment of gastrointestinal fistulas and perforations: update of a Brazilian center experience

Authors Bonilha D[1], Kreve F[1], Andreollo NA[1], Lopes LR[1], Darcadia dos Reis T[1], Costa R[1], Manara Martins J[1], Wu X[1], Garcia Montes C[1]
Institute 1 UNICAMP Universidade Estadual de Campinas, Campinas, Brazil
DOI 10.1055/s-0046-1821541

Aims The aim of this study is to describe the clinical, laboratory and endoscopic characteristics of patients submitted to endoscopic vacuum therapy (EVT) for treatment of fistulas and perforations in the gastrointestinal (GI) tract at a Brazilian tertiary care center, as well as indications, success rate and treatment-related complications (▶ **Table 1**).

▶ **Table 1** Results (n = 42)

VARIABLES	n (%) or mean (min-max)
Age	58 (18-86)
Gender	
Male	29 (59.5 %)
Site of Perforation	
Proximal Esophagus	16 (37.2 %)
Distal Esophagus	16 (37.2 %)
Others	11 (25.6 %)
Diameter of Orifice (cm)	1.8 (0.5-7)
Cavity Extension (cm)	5.9 (0-18)
Exchanges of the Tube (week)	3.1 (0-16)
Duration of Treatment (days)	24.8 (5-184)
Success Rate of Treatment	36 (83.7 %)
Follow-up Time (months)	9.1 (0-30)

Methods This retrospective study included patients referred between November 2019 and April 2025 to the State University of Campinas, Brazil, with perforation or fistula in the GI tract. All patients were admitted and treated with EVT using a low-cost customized nasogastric tube (16 Fr) coated with fenestrated film. This system was connected to the wall suction system and a 20F intravenous catheter was connected to the tube to maintain a negative pressure between -75 and -150 mmHg. Endoscopic control examinations after the end of treatment were performed on outpatient basis. Demographic, diagnosis-related and treatment data were obtained during the follow-up of the patients [1–3].

Results Forty-two patients were submitted to EVT during the study period. One patient was submitted to two EVT at the same time resulting in 43 fistulas treated. Twenty-nine (59.5 %) patients were men. The mean age was 58 years (18-86 years). The indication for EVT was divided into three groups: postoperative, spontaneous and iatrogenic, which corresponded to 87 %, 9 % and 4 %, respectively. Regarding the site, most defects occurred in the cervical and distal esophagus (both 37.2 %). EVT was the primary therapy in 71.4 %. The remaining fistulas had undergone surgical treatment (19 %) or placement of a stent (9.52 %) previously. In the postoperative cases, fistula was diagnosed within an average of 17.8 days (1-90 days) after surgery. On endoscopic assessment, the diameter of the orifice ranged from 0.5 to 7 cm (mean 1.8 cm) and the cavity extension ranged from 0 (without cavity) to 18 cm (mean 5.9 cm). The tube was changed once a week, with a mean of 3.1 changes (0-16 changes). The mean duration of treatment was 24.8 days (5-184 days) and the total length of hospital stay ranged from 5 to 212 days. During EVT, the patients were evaluated clinically and by laboratory tests. Pre- and post-treatment laboratory analysis revealed a significant decrease in white blood cell counts (WBC)

Endoscopy 2026; 58: S1–S1041

(7,305 *vs* 13,380/mm³, p < 0.001) and C-reactive protein (CRP) levels (126 *vs* 40 mg/L, p < 0.001). The success rate of treatment was 81.8 %, 9.1 % failed and 9.1 % discontinued treatment. There were no complications or deaths related to the treatment. The mean follow-up time was 9.1 months.

Conclusions Despite the limited number of patients, modified EVT was found to be a safe, low-cost and effective method for the treatment of defects in the GI tract, especially postoperative fistulas. WBC and CRP can be used as parameters indicating improvement during the treatment of these patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP215 A UK single centre pilot experience using a novel robotic colonoscopy system

Authors Ahmed J[1], Premchand P[2], Coda S[2], Banerjee S[2], Patel N[1]
Institutes **1** Imperial College London, London, United Kingdom; **2** Barking, Havering And Redbridge University Hospitals Nhs Trust, London, United Kingdom
DOI 10.1055/s-0046-1821542

Problem to solve How to complete colonoscopy for those who fail standard colonoscopy

Innovation Colonoscopy is the gold standard investigation in the lower gastrointestinal tract. However, 75 % of patients can experience pain or discomfort with moderate sedation. The application of robotic technology promises to advance and overcome difficulties faced including better utilisation of rooms for advanced procedures and to achieve a complete colonoscopy in patients where pain and technical challenges inhibit progression.

This pilot study, the first at a UK NHS Hospital between January2023 to April2025 with an expert endoscopist performing the robotic colonoscopy with the Endotics system. This is a disposable soft robot which employs expand and contract movement to self-propel along the bowel. Patients with failed previous standard colonoscopy along with index diagnostic procedures deemed potentially difficult were recruited. Procedures were performed outside the endoscopy unit similar to an outpatient clinical room.

Results 126 patients were recruited (57M:69F), mean-age 55.5 years over 30 months. The commonest indications for robotic colonoscopy were rectal bleeding (35.7 %), failed standard colonoscopy (22.6 %) and change in bowel habit (19.1 %). 23 patients had failed previous standard colonoscopy with 16 patients achieving completion with subsequent robotic colonoscopy (70 % improvement). Average caecal intubation time 36.63 minutes with average total procedure time 48.74 minutes.

Conclusions Robotic colonoscopy provides a safe and effective method in improving comfort and completion-rates, including previously failed colonoscopy. Direct visualisation, biopsy and polypectomy is still possible with robotic colonoscopy. This study has demonstrated a viable alternative to conventional colonoscopy. With no sedation it allows procedures to be conducted outside the traditional endoscopy unit such as outpatients. The study highlights a learning curve to reduce caecal intubation time.

eP216 Ablation of gastric inlet patches using a novel cap for precise APC application

Authors Walter B[1, 2], Weidle L[1], Mueller J[3], Kuellmer A[3], Melzer A[1, 2], Kalner A[2, 1], Seufferlein T[2]
Institutes **1** Endoscopic Research Unit, Ulm, Germany; **2** Clinic for Internal Medicine I, Gastroenterology, University Hospital Ulm, Ulm, Germany; **3** University Hospital Freiburg, Freiburg im Breisgau, Germany
DOI 10.1055/s-0046-1821543

Aims In patients with refractory reflux disease and gastric inlet patches ablation with Argon plasma coagulation (APC) is an established therapeutic tool. The goal is to destroy selectively ectopic mucosa to reduce acid production and improve thereby symptoms and quality of life. But precise application of APC is challenging in the upper esophagus. Aim of the study was to evaluate the feasibility of a novel cap for APC (ArgoCap).

Methods 21 patients (m,f) were treated for gastric inlet patches using a novel transparent cap attached to the tip of the gastroscope which allows for angled positioning of the APC probe (ArgoCap). APC mode was 20W, precise mode. Feasibility, Clinical success and satisfaction with the examination was assessed. Additionnally clinical data on reflux symptoms before and after treatment in short time surveillance, complications and adverse events were assessed.

Results APC therapy using the ArgoCap was feasible and technically successful in 100 % of all cases. No complications or adverse events were reported. The investigators rated the cap's use as easy to perform.

Conclusions Precise APC therapy using the ArgoCap in the esophagus is feasible and easy to perform for treatment of gastric inlet patches. Further studies are mandatory to analyse the impact on clinical long-term success of the therapy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP217 Cross-Country Perspectives on Helicobacter Pylori: Less GERD, Less B12 Too

Authors İstemihan Z[1], Donapati VR[2]
Institutes **1** Niğde Ömer Halisdemir University Training and Research Hospital, Niğde, Türkiye; **2** Yashoda Hospitals, Secunderabad, India
DOI 10.1055/s-0046-1821544

Aims We evaluated the relationship between Helicobacter pylori (HP) gastritis, Gastroesophageal reflux disease (GERD), and serum vitamin B12 levels in patients undergoing upper gastrointestinal endoscopy for dyspeptic symptoms, since the available literature is conflicting. We also looked at the cross-country variations in this regard between Türkiye and India.

Methods This multicenter, retrospective study included patients who underwent endoscopy between December 2024 – November 2025 for dyspeptic symptoms. Demographic, laboratory, and endoscopic findings were collected. HP infection was diagnosed by gastric biopsy or rapid urease test. Data from tertiary centers, one from Türkiye and one from India were used. Categorical variables were compared using the Chi-square or Fisher's exact test, and continuous variables using the independent t-test or Mann–Whitney U test.

Results 1. Baseline Characteristics: Among 500 patients, 275 (55 %) were male, with a mean age of 47.5 ± 14 years. Gender distribution was similar between countries (p = 0.141).

2. Prevalence of HP Gastritis and Gastric Involvement: HP gastritis was detected in 336 (67.2 %) patients, slightly higher than previously reported [1]. HP prevalence was significantly greater in India (76 % vs. 62.1 %; p = 0.001). Intestinal metaplasia was present in 16.7 % of the 300 biopsied patients. Pattern of gastric involvement; antral in 404 (80.8 %), antral-predominant in 34 (6.8 %), corpus involvement was in 62 (12.4 %) patients. HP gastritis was more frequent in men (p = 0.004) and in individuals < 60 years (p = 0.011).

3. Endoscopic Findings: Endoscopic hyperemia, erosions, atrophy, ulcers, nodularity, and duodenitis were all significantly associated with HP infection (all p < 0.05). Hiatal Hernia (HH) was seen in 37 (7.4 %) patients. HH was more frequent in Indian patients (p < 0.001).

▶ **Table 1**

Parameter	HP (+)	HP (-)	p-value	Türkiye	India	p-value
HP prevalence, %	67.2	32.8		62.1	76	0.001
GERD, n (%)	99(29.5)	67(40.9)	0.011	104(39.8)	23(11.5)	<0.001
Corpus, n (%)	47(14)	15(9.1)	0.123	36(13.8)	21(10.5)	0.287
Antral predominant, n (%)	30(8.9)	4(2.4)	0.007	4(1.5)	29(14.5)	<0.001
Antrum, n (%)	259(77.1)	145(88.4)	0.003	221(84.7)	150(75)	0.009
Ulcers, n (%)	38(11.3)	9(5.5)	0.036	24(9.2)	22(11)	0.522
B12 deficiency, n (%) (404/372)	84(30.4)	12(9.4)	<0.001	9(5.2)	83(41.5)	<0.001

4. GERD: GERD was diagnosed in 166 (33.2 %), and was less common in HP-positive individuals (29.5 % vs. 40.9 %; OR 0.605, 95 % CI 0.401–0.893; p = 0.011) similar to a recent study [2]. GERD was more frequent in patients with corpus involvement (p = 0.007). GERD was more common in Türkiye (39.8 % vs. 11.5 %; p < 0.001).

5. Vitamin B12 Levels and Deficiency: Mean vitamin B12 levels were significantly lower in HP-positive patients (334 ± 193 vs. 418 ± 198 ng/L; p < 0.001). Vitamin B12 deficiency was more frequent in HP-positive patients (30.4 % vs. 9.4 %; p < 0.001), consistent with prior reports [3–5]. Serum B12 deficiency was markedly higher in India (41.5 % vs. 5.2 %; p < 0.001). Hemoglobin levels were similar across all groups. Serum B12 levels were lower in HP-positive Turkish patients, but the deficiency was lesser than in Indian patients.

Factors associated with B12 deficiency: More common with corpus involvement (p = 0.023)

The key findings of the study have been summarised in the ▶ **Table 1**.

Conclusions In this cross-country study, Helicobacter pylori infection was highly prevalent in dyspeptic patients and consistently associated with endoscopic abnormalities. Although GERD was common overall, it was less frequent in HP-positive patients, suggesting a protective effect in both groups studied. HP-positive patients have lower vitamin B12 levels, particularly with corpus-predominant gastritis. These findings highlight the need to consider both nutritional impact and reflux patterns when managing HP gastritis across different populations.

eP218 Lumen-apposing metal stent for benign prepyloric stenosis: a case report

Authors Locatelli R[1], Biancheri P[1], Shoval Y[1], Armellini E[1]
Institute 1 Digestive Endoscopy Unit, ASST Bergamo Est, Seriate, Italy
DOI 10.1055/s-0046-1821545

Aims/Purpose: Guidelines recommend treating benign gastric outlet obstruction with serial balloon dilations. However, dilation has usually a transient effect. Self-expanding metal stent (SEMS) placement is a valid alternative, but the rate of migration is high, especially when the stenosis is short. We present a case of a prepyloric stenosis from caustic ingestion treated by balloon dilation followed by lumen-apposing metal stent (LAMS) placement during the same session.

Methods: Three months after caustic ingestion, a 66 year old patient developed a gastric outlet obstruction syndrome. EGD showed a stomach filled by solid/liquid contents and a tight, prepyloric stenosis. After prolonged starving and drainage by naso-gastric tube, EGD was repeated, and confirmed the prepyloric stricture, which allowed only the passage of a guidewire-assisted catheter. Contrast injection and fluoroscopy showed that the length of the stenosis was about 10 mm. A wire and balloon were advanced and pneumatic dilation up to 15 mm was performed with good effect. Subsequently, we decided to deploy a 15x10 mm LAMS through the dilated stricture and was anchored to the surrounding gastric mucosa by application of two metallic clips. The scope was then able to be passed easily into the duodenum.

Results: We observed almost immediate symptom resolution and the patient was able to tolerate a liquid diet from day 1 and a solid diet from day 3. No further episodes of vomiting occurred. On follow-up contrast radiography after 48 hours, smooth gastric contrast emptying into the duodenum through the prepyloric stent was observed. Follow up EGD was performed after one week and the LAMS was correctly in place and easily passable with the endoscope.

Conclusion: LAMS placement is being performed for an increasing number of clinical benign and malignant conditions. Our clinical case describing an off-label use of LAMS suggests that this type of stent may be a valuable option for a benign short stricture due to its short length and wide flanges, which could reduce the risk of migration.

eP219V Bridging the Gap for High-Risk Patients: EUS-Guided Radiofrequency Ablation of a pNET in Cirrhosis

Authors Camões Neves J[1], Damasceno e Costa J[1], Guimarães A[1], Vaz Conde P[1], Costa D[1], Seara Costa R[1], Gonçalves R[1], Gonçalves B[1]
Institute 1 Braga Public Hospital, Braga, Portugal
DOI 10.1055/s-0046-1821546

Abstract Text

The authors present a case of a 61-year-old male with alcohol-related cirrhosis, Child A, and large esophageal varices. Laboratory tests revealed thrombocytopenia (28,000/µL), prolonged prothrombin time (19.1 seconds), and fibrinogen of 99 mg/dL. Surveillance contrast-enhanced CT identified a 17 mm lesion in the pancreatic tail showing arterial contrast uptake. EUS-guided biopsy revealed a grade 1 pancreatic neuroendocrine tumor (pNET). Given the high surgical risk, a multidisciplinary team proposed EUS-guided radiofrequency ablation (RFA). During the procedure, after precise positioning of a 19G needle within the target lesion, 3 overlapping ablation applications were performed. Immediate intra-procedural imaging showed complete loss of contrast enhancement [1,2].

EUS-RFA is an effective minimally invasive option for pNETs, mainly in high-risk patients.

eP220 Feasibility and Efficacy of Spray Coagulation for Radiation Proctopathy: A Retrospective Study in a Tertiary Center

Authors Cadena Aguirre D[1], Lenz L[2], Franco F[3], Lima A[3], Balbinot R[3], Penaloza C[3], Pombo A[3], Adriana SR[3], Marcelo S[3], Maluf Filho F[3]

Institutes **1** Marco Vinicio Iza General Hospital, Nueva Loja, Ecuador; **2** Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil; **3** Instituto do Câncer do Estado de São Paulo – ICESP, São Paulo, Brazil

DOI 10.1055/s-0046-1821547

Aims 1) Evaluate the effectiveness of snare tip Coagulation Spray in the treatment of radiation proctopathy.

2) Evaluate adverse events (AEs) related to the procedure, including pain, bleeding, and strictures, and the number of sessions required to achieve clinical effectiveness.

Methods This retrospective study was conducted at Instituto do Câncer do Estado de São Paulo between January and December 2024.

Inclusion criteria were patients over 18 years old with a confirmed diagnosis of chronic radiation proctopathy and rectal bleeding.

Exclusion criteria included severe coagulopathies, inadequate bowel preparation, or incomplete data.

Data were obtained from electronic medical records. Technical success was defined as achieving complete hemostasis without the need for additional techniques. Clinical efficacy was determined by the absence of bleeding within 30 days after the procedure. Adverse events were categorized as early (≤ 48 hours) or late (> 48 hours).

Results Eighteen patients were included. The total number of sessions was 32. Two patients died due to oncological comorbidities. Of the 16 patients analyzed, 7 patients (43.8 %) underwent two sessions, 6 patients (37.5 %) one session, 2 patients (12.5 %) three sessions, and 1 patient (6.2 %) received four sessions to achieve complete hemostasis.

Technical success was 100 %, and clinical success was 87,5 %. Non-adverse events were recorded.

Conclusions Non-contact monopolar coagulation spray using a snare tip, is a safe and effective treatment for chronic radiation proctopathy. With a high technical and clinical success rate and an absence of associated adverse events. Coagulation Spray represents a viable and economical alternative to argon plasma coagulation, especially in resource-limited settings [1–5].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP221V G-POEM in the Treatment of Severe Gastroparesis Associated With Systemic Sclerosis: A Case Report

Authors Lima P[1], Rodrigues B[1], Pereira B[1], Mendo R[1], Cristina C[1], Barreiro P[2, 1]

Institutes **1** Gastroenterology Department, Unidade Local de Saúde de Lisboa Ocidental, Lisbon, Portugal; **2** Lusíadas Hospital, Advanced Endoscopy Center of Lisbon, Lisbon, Portugal

DOI 10.1055/s-0046-1821548

Abstract Text

Between 50–80 % of patients with Systemic Sclerosis (SSc) develop gastric involvement, with gastroparesis being a common manifestation. We report a 36-year-old woman with SSc presenting with early satiety, postprandial vomiting, and significant weight loss. Endoscopy was normal, but contrast studies and gastric scintigraphy confirmed severe delayed gastric emptying. Dietary measures and optimized prokinetic therapy provided no relief. Due to refractory symptoms, G-POEM was performed under deep sedation. The procedure included a 15-mm mucosotomy, creation of a submucosal tunnel, pyloromyotomy, and closure with TTS clips, without complications. The patient was discharged after 48 hours and demonstrated sustained symptom resolution at 12 months. This case highlights G-POEM as a feasible therapeutic option for SSc-related gastroparesis [1–3].

eP222 Primary Gastric Melanoma Presenting as a Subepithelial Tumor: A Rare Case Report

Authors Ahn D[1], Kim I[1], Kim Y[1], Kang DH[1], Cho YK[1], Park JM[1], Song KY[1]
Institute 1 The Catholic university of korea, seoul, Republic of Korea
DOI 10.1055/s-0046-1821549

Background: Primary gastric melanoma (PGM) is extremely rare and often presents with non-specific gastrointestinal symptoms or incidental findings. Because there are no standardized diagnostic guidelines, confirmation by histopathology and exclusion of an extra-gastric primary site are essential.

Case presentation: A 33-year-old woman was referred for evaluation of a 4-cm mucosal elevation at the gastric antrum, initially suspected to be a subepithelial lesion. Endoscopy revealed an oval bulge with positive tenting and rolling signs and a negative cushion sign. Contrast-enhanced abdominal CT revealed a 3.7-cm, well-circumscribed, heterogeneously enhancing mass with preserved mucosa. Endoscopic ultrasonography revealed a 3.38 × 2.14-cm hypoechoic, heterogeneous lesion with irregular margins arising from the muscularis propria. Under a presumptive diagnosis of gastrointestinal stromal tumor, a laparoscopic antrectomy with Billroth-II reconstruction was performed. Histological examination revealed rhabdoid, epithelioid, and spindle cell components with scattered melanin pigments. Immunohistochemistry demonstrated positivity for HMB-45, Melan-A, PRAME, and cathepsin and negativity for S-100 and SOX-10, confirming malignant melanoma. Next-generation sequencing revealed the absence of driver mutations. Dermatological evaluation, including biopsy of a benign nevus, and whole-body 18F-FDG PET/CT excluded cutaneous or other primary origins and demonstrated no metastasis. A diagnosis of primary gastric melanoma was established. The patient recovered uneventfully and was followed up without adjuvant therapy.

Conclusion: PGM can mimic gastric subepithelial lesions on endoscopy and EUS, potentially leading to misdiagnosis as gastrointestinal stromal tumors. Awareness of this rare entity, along with careful use of histopathology and immunohistochemistry, is crucial for accurate diagnosis and appropriate surgical management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP223 Learning Curve for Endoscopic Retrograde Appendicitis Therapy: a multicenter retrospective study with different levels of trainees

Authors Zhang J[1], Liu B[1], Liu D[1]
Institute 1 First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, zhengzhou, China
DOI 10.1055/s-0046-1821550

Aims Endoscopic retrograde appendicitis therapy (ERAT) is a minimally invasive treatment for appendicitis, widely practiced in China. Clarifying the learning curve, especially among endoscopists with varying endoscopic experience, including endoscopic retrograde cholangiopancreatography (ERCP) skills, is essential for its broader adoption. This study aimed to determine the number of cases required to achieve procedural proficiency across different experience levels, as well as to examine the disparities in technical success rates and clinical outcomes.

Methods In this multicenter retrospective study, 655 consecutive patients who had undergone ERAT from October 2021 to March 2024 were analyzed. All ERAT procedures were performed by nine trainees from three hospitals, categorized into novice, non-ERCP experience, and ERCP experience groups. Outcomes included technical/clinical success, procedure time, pain, recurrence, length of stay, and adverse events. Learning curves were evaluated with CUSUM based on procedure time.

Results Technical and clinical outcomes improved with increasing experience in all groups. Proficiency occurred at the 31st case in the ERCP group, the 55th in the non-ERCP group, and the 59th in novices. The ERCP group had the highest technical (99.1 %) and clinical (94.4 %) success ($P = 0.023$; 0.093), the shortest mean procedure time (20.9 min; $P < 0.001$), and the lowest recurrence ($P < 0.001$). Complication rates, including intraoperative and postoperative adverse events, were low and similar across groups (0.8 %–2.6 %, $P > 0.05$). Postoperative pain and hospital stay decreased with experience ($P < 0.001$).

Conclusions Endoscopists with extensive prior endoscopic experience, particularly in ERCP, achieve proficiency in ERAT more rapidly. Structured training programs tailored to different experience levels are essential to support the safe and effective global implementation of ERAT.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP224 Anastomotic Actinomycosis Mimicking Recurrent Gastric Cancer: A Rare Diagnostic Pitfall

Authors Alexandrescu L[1], Dumitru A[1], Tocia C[1]
Institute 1 County Clinical Emergency Hospital of Constanta, Constanța, Romania
DOI 10.1055/s-0046-1821551

Background: Gastrointestinal actinomycosis is rare, difficult to recognize, and often mimics malignancy. Gastric involvement is exceptional and is described in only a small number of reports [1–4]. Postoperative sites, such as gastric anastomoses, are particularly susceptible to Actinomyces infection due to altered mucosal integrity [5].

Case Presentation: A 76-year-old man with a history of gastric cancer treated surgically and with chemotherapy more than five years earlier, considered cured, underwent routine endoscopic surveillance. Endoscopy revealed a normal esophagus and loops, but the laterolateral gastric anastomosis showed irregular, ulcerated, infiltrative lesions with yellowish exudates, raising strong suspicion of tumor recurrence. Multiple biopsies were taken.

Histopathology demonstrated foveolar hyperplasia, ulceration, intestinal metaplasia, granulation tissue, mixed inflammatory infiltrate, and Helicobacter pylori. Critically, Actinomyces colonies were identified on one fragment, with no dysplasia or malignancy. Findings were diagnostic of anastomotic actinomycosis.

Management and Outcome: The patient received standard therapy consisting of high-dose intravenous penicillin, followed by prolonged oral amoxicillin, as recommended for gastrointestinal actinomycosis [1]. Endoscopic follow-up showed complete healing of anastomotic lesions. Persistent H. pylori infection was treated subsequently with eradication therapy.

Discussion: Actinomycosis can masquerade as malignancy due to its infiltrative pattern, fibrosis, ulceration, and the presence of sulfur granules. Several gastric cases initially suspected as cancer were later reclassified as actinomycosis on biopsy [2–4]. Anastomotic involvement is documented in postoperative infections and requires prolonged penicillin-based therapy [5]. Early recognition avoids unnecessary oncologic interventions.

Conclusion: Anastomotic actinomycosis is an important differential diagnosis for suspicious anastomotic lesions in patients with prior gastric cancer. Histopathology is essential for accurate diagnosis, and penicillin-based therapy ensures excellent outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP225 Title:Endoscopic Radial Incision and Cutting for Intra-gallbladder Stenosis: The First Clinical Practice

Authors Li H[1], Zhang J[1], Zheng S[1], Liu D[1]
Institute 1 The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, Zhengzhou, China
DOI 10.1055/s-0046-1821552

Abstract Text

Endoscopic Radial Incision and Cutting (ERIC) has been widely used in the management of benign gastrointestinal and anastomotic stricture [1, 2]. However, there is no report of ERIC treating intra-gallbladder stenosis yet. Gallbladder stenosis may be encountered, in pace with the application of various methods for gallbladder-preserving managements. Herein, the stenosis was completely resolved via ERIC, thereby facilitating gallbladder stones removal afterwards.

A 28-year-old female presented with a several-year history of intermittent upper abdominal pain. The patient was diagnosed with gallstones, that cholangioresonance imaging revealed a gourd-shaped gallbladder containing multiple stones in both chambers (Figure 1a). Although cholecystectomy was recommended at the local hospital, she declined and was subsequently transferred to our department for gallbladder-preserving cholelithotomy via natural orifice transluminal endoscopic surgery (Video 1).

The procedure was initiated via a transrectal approach to access the abdominal cavity. A gourd-shaped gallbladder was identified (Figure 1b). Intraluminal examination revealed significant stenosis with cicatricial mucosal changes (Figure 1c). ERIC was then performed using an IT knife to incise the stricture, allowing adequate passage of the endoscope (Figure 1d). This was followed by complete removal of all distal stones. Following thorough irrigation of the gallbladder cavity, which confirmed the absence of residual calculi (Figure 1e), both the gallbladder and intestinal access sites were securely closed with endoclips. No intraoperative and postoperative adverse event was observed. On three-month follow-up, an abdominal computed tomography (CT) demonstrated significantly improvement in gallbladder morphology (Figure 1f).

In this case, we demonstrate the feasibility and efficacy of ERIC for treating intra-gallbladder stenosis. Moreover, ERIC resolved intra-gallbladder stenosis, consequently reducing the recurrence of gallstones. This study highlights the potential for further exploration and application in similar cases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP226 Micro hole balloon improves prevention of stricture after esophageal endoscopic submucosal dissection

Authors Takashi H[1], Furukawa K[2], Ishikawa E[2], Sawada T[1], Maeda K[2], Yamamura T[1], Kawashima H[2]
Institutes 1 Department of Endoscopy, Nagoya University Hospital, Nagoya, Japan; 2 Department of Gastroenterology and Hepatology, Nagoya University Graduate School of Medicine, Nagoya, Japan
DOI 10.1055/s-0046-1821553

Problem to solve stricture after esophageal endoscopic submucosal dissection

Innovation A new device (micro hole balloon) enabling safer, more efficient local triamcinolone(TA) injection in less time.

Results [Method] This study included 85 patients who underwent endoscopic submucosal dissection (ESD) for esophageal cancer with local TA injection at a single high-volume center between January 2021 and August 2025. Exclusion criteria were as follows: history of esophageal surgery (5 cases), additional surgical resection after endoscopic treatment (4 cases), residual recurrence after photodynamic therapy, ESD, and chemoradiotherapy (6 cases), and incomplete follow-up(3 cases). A comparative analysis was performed between 45 cases treated with a local injection needle from January 2021 to February 2024 and 22 cases treated with a micro-hole balloon from March 2024 to August 2025. [Result] Lesion localization was in the cervical or upper thoracic esophagus in 17 cases (25.6 %). Circumference of the post-resection ulcer was greater than or equal to 3/4 in 57 cases (85.1 %), and circumferential resection were performed in 8 cases (11.9 %). The median tumor size was 52 mm. Muscle layer injury was observed in 21 cases (31.3 %) during ESD. Oral steroid administration was combined in 39 cases (58.2 %), and stenosis was observed in 14 cases (20.9 %). No significant differences were observed between the needle injection and balloon injection groups in patient characteristics such as tumor location (localized/circumferential), tumor length, malignancy grade, or muscle layer injury. Oral steroid administration tended to be less frequent in the balloon group, but this difference was not statistically significant (64.4 % vs. 45.5 %: $P = 0.189$). Procedure time was significantly shorter in the balloon group (310 sec vs. 69 sec: $P < 0.01$). Both the stenosis rate (28.9 % vs. 4.5 %: $P = 0.025$) and the number of balloon dilation required to achieve stenosis (9 vs. 4: $P = 0.012$) were significantly lower in the balloon group. No complication was observed in TA injection in the balloon group.

Conclusions The micro hole balloon is considered a highly useful device, enabling safe, efficient, and rapid administration of TA.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP227 Utilizing a dedicated nurse specialist improves quality of ERCP service delivery

Authors Saif Ullah MA[1], Martir H[2], Ramlaul N[1], Jan L[3], Kelleher B[2], Stewart S[4]
Institutes 1 The Mater Misericordiae University Hospital, Dublin, Ireland; 2 Mater Hospital, Dublin, Ireland; 3 Mater Misericordiae University Hospital Outpatients Department, Dublin, Ireland; 4 Mater Misericordiae University Hospital, Dublin, Ireland
DOI 10.1055/s-0046-1821554

Aims To analyse impact of nurse specialist utilization in quality improvement of ERCP service

Methods 1640 ERCPs were reviewed from our prospective database between 2022 and 2025. Standard KPIs were calculated and complications were noted from the database collected by ERCP nurse specialist. The results then were compared with KPIs published by ESGE, BSG and JAG guide to quality and safety standards [1, 2].

Results Our nurse specialist followed and maintained database of 98 % (2024/25) , 95 % (2023/24) and 75 % (2022/23) of ERCP procedures done in last 3 years. Out of total 1640 ERCPs , 60 % of procedures (n = 981) were performed for patients out of our hospital and 6 % of procedures were done under GA in endoscopy department.

Our CBD canulation (88.5 %, 89.9 % and 90.5 % in serial studied years) and stone clearance (74 to 84.4 % in serial studied years) rates achieved the standard recommended KPIs. Also post ERCP pancreatitis (5.5 %) , bleeding (0.63 %) , cholangitis (3.5 %) , perforation (0.27 %) ,mortality (0.48 %) (1) and overall complication in 5.6 % of patients fulfilled the recommended KPIs.

Conclusions More than half of ERCPs performed in our hospital were external referrals. Presence of a dedicated nurse specialist in our department ensured timely triage, pre-assessments and meticulous post-procedural follow-ups, especially for out of hospital patients. Continuous monitoring of KPIs from the database, maintained by nurse specialist in accordance with international

guidelines, helped in quality improvement and better service delivery to the patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821555

Aims ERCP is increasingly being performed in older adults but there is limited data on its technical success and procedure-related adverse events across different age strata. In this systematic review and meta-analysis, we aimed to synthesize the available evidence on ERCP outcomes stratified by age groups (<65, 65–79, 80–89, ≥90 years).

Methods A comprehensive literature search was performed using OVID MEDLINE, EMBASE, and the Cochrane Library from database inception to October 2025. Studies were included if they enrolled patients aged ≥65 years who underwent diagnostic or therapeutic ERCP. Outcomes included technical success, major procedural adverse events (e.g. post-ERCP pancreatitis (PEP), bleeding, perforation, cholangitis, cardiopulmonary complications), length of stay, and mortality. Study-level proportions were pooled using a random-effects meta-analysis with Freeman–Tukey double arcsine transformation and inverse-variance weighting. Heterogeneity was assessed using the I^2 statistic, and subgroup differences across four predefined age strata were evaluated using the Chi-square test.

Results Fifty-two studies (n = 26,926) were included in this review. The pooled estimate for technical success was 92 % (95 % CI 91-94 %, I^2 = 95 %). By age subgroups, technical success was 95 % (95 % CI 93-97 %) for <65, 91 % (88-94 %) for 65–79, 91 % (88-94 %) for 80–89, and 87 % (79-94 %) for ≥90, with significant subgroup differences (p = 0.01). Across included studies, the pooled proportion of any adverse event after ERCP was 9.0 % (95 % CI 7.0–10.0 %; $I^2 \approx 89$ %) with no statistically significant subgroup differences (p = 0.36). The pooled estimate for PEP 3.0 % (95 % CI 3.0-4.0 %; I^2 = 81 %) and for cardiopulmonary complications was 1.0 % (1.0-2.0 %, I^2 = 81 %). There were statistically significant differences between subgroups, with elderly patients having lower rates of PEP (p = 0.01) and higher rates of cardiopulmonary complications (p = 0.002). Other pooled estimates were: 2.0 % (1.0-2.0 %; I^2 = 61 %) for bleeding, 0.0 % (0.0-0.1 %; I^2 = 21 %) for perforation, and 1.0 % (1.0-1.0 %; I^2 = 66 %) for cholangitis, with no statistically significant subgroup differences. The pooled length of hospital stay was 10.53 days (95 % CI 8.38–12.67; $I^2 \approx 100$ %). Subgroup pooled means were: <65 years = 7.53 days (95 % CI 5.84–9.23), 65–79 years = 13.19 days (9.05–17.33), 80–89 years = 7.63 days (3.58–11.69), and ≥90 years = 21.96 days (11.91–32.01). Subgroup differences were statistically significant (p = 0.004). Overall mortality after ERCP was low at 1.0 % (95 % CI 0.0–1.0 %; I^2 = 84.3 %). By age subgroups, mortality was 0.0 % (0.0–0.1 %) for <65 years, 1.0 % (0.0–1 %) for 65–79 years, 1.0 % (0.0–0.1 %) for 80–89 years, and 4 % (1–8 %) for ≥90 years. The test for subgroup differences was significant (p = 0.0008).

Conclusions Older age is associated with lower technical success, although the overall rate of technical success remains relatively high. Age is also associated with increased risk of cardiopulmonary complications, longer hospital stay, and higher mortality, especially among patients ≥90 years. Conversely, the risk of PEP is consistently lower among older patients. These findings highlight the importance of careful patient selection, individualized risk assessment, and meticulous preoperative optimization to enhance the safety and efficacy of ERCP in the elderly population. Future studies should specifically focus on patient-oriented outcomes in the elderly population undergoing ERCP.

Conflicts of Interest Dr. Jeffrey Mosko received research support from Boston Scientific and ERBE, and speaker honouraria and consulting fees from Boston Scientific, ERBE, Fuji, Medtronic, Pendopharm, and Steris.

eP229 Endoscopic Retrograde Cholangiopancreatography (ERCP) Outcomes in Nonagenarians compared to Older Adults (65–89): A Systematic Review with Meta-analysis

Authors Youssef M[1], Khalaf K[1], Annabel K[1], Mahamud O[1], Yuan Y[2], Mehra V[1], Li H[1], Bucheeri MAGA[3], Harb M[4], Zheng K[1], May G[1], Mosko J[5], Calo N[1]

Institutes **1** St. Michael's Hospital, Toronto, Canada; **2** McMaster University, Hamilton, Canada; **3** University of Toronto, Toronto, Canada; **4** St. Mi, Toronto, Canada; **5** Division of Gastroenterology, St. Michael's Hospital, Toronto, Canada

DOI 10.1055/s-0046-1821556

Aims ERCP is being increasingly performed in elderly patients. Clinical decision-making for ERCP in very old patients (≥90 years) requires comparative analysis of the procedural success and procedural adverse events compared to younger old adults (65-89 years). In this study, we compared procedural success, periprocedural adverse events, mortality, and length of hospitalization between patients aged ≥90 years and those aged 65–89 years as a reference group.

Methods A comprehensive literature search was performed using OVID MEDLINE, EMBASE, and the Cochrane Library from database inception to October 2025. Studies were included if they enrolled patients aged ≥65 years who underwent diagnostic or therapeutic ERCP. Outcomes of interest included technical success, major procedural adverse events (post-ERCP pancreatitis (PEP), bleeding, perforation, cholangitis, cardiopulmonary complications), length of stay, and mortality. We pooled head-to-head data from studies reporting outcomes separately for ≥90 and 65–89-year cohorts. Random-effects meta-analysis (inverse-variance) was used to calculate pooled relative risk (RR) ratios for dichotomous outcomes and mean difference for continuous outcomes.

Results Nine studies compared outcomes between patients aged ≥90 years (n = 642) and those aged 65–89 years (n = 3,878). There was no statistically significant difference in technical success between the ≥90-year and 65–89-year groups (RR 0.95, 95 % CI 0.90–1.01; I^2 = 81 %; p = 0.08). Similarly, no significant differences were observed in peri- or post-procedural adverse events, including bleeding (RR 1.43, 95 % CI 0.75–2.75; I^2 = 0 %; p = 0.28), PEP (RR 0.70, 95 % CI 0.39–1.24; I^2 = 0 %; p = 0.23), perforation (RR 2.88, 95 % CI 0.92–9.07; I^2 = 0 %; p = 0.07), or cardiopulmonary complications (RR 2.60, 95 % CI 0.95–7.12; I^2 = 42 %; p = 0.06). However, the mean length of hospital stay was significantly longer among nonagenarians compared to those aged 65–89 years (mean difference = 7.44 days, 95 % CI 5.21–9.66; I^2 = 0 %; p < 0.001). Mortality was also significantly higher in the ≥90-year group (RR 3.39, 95 % CI 2.16–5.30; I^2 = 5 %; p < 0.001).

Conclusions ERCP demonstrates comparable technical success and rates of periprocedural adverse events in patients aged ≥90 years and those aged 65–89 years. However, nonagenarians experience significantly longer hospital stays and higher post-ERCP mortality. These findings highlight the importance

of thorough pre-procedural evaluation, individualized risk stratification, and enhanced post-procedural monitoring and discharge planning to optimize safety and outcomes in very elderly patients undergoing ERCP. Research focusing on patient-outcomes in the elderly undergoing advanced procedures is warranted.

eP230 Biodegradable Stents in ERCP: Improving Safety, Cost-Efficiency, and Environmental Impact – A Single-Center Study

Authors Bhutta SI[1], suparmanian S[1], Rennie L[1], Shekar C[1], Malcolm S[1], Siddhi S[1], Umesh B[1]

Institute 1 Aberdeen Royal Infirmary, Aberdeen, United Kingdom

DOI 10.1055/s-0046-1821557

Aims Biodegradable stent (BDS) represents a promising alternative to conventional plastic stents in Endoscopic Retrograde Cholangiopancreatography (ERCP) that may reduce repeat procedure, cost, and environmental impact. This study evaluated technical success, clinical outcomes, cost, and carbon footprint associated with BDS use across biliary and pancreatic indications in a real world, single center setting.

Methods We conducted a 5-year retrospective review of ERCPs with BDS from October 2020 to October 2025, evaluating indications, procedural success, and clinical outcomes along with cost and estimated carbon footprint (5 kg-CO_2e/procedure).

Results In 152 patients (biliary 78, pancreatic 74) biodegradable stent placement achieved 100 % (152/152) technical success with full fluoroscopic visibility. For biliary cases, the primary indication was post-cholecystectomy bile leak (57/78,73 %) with 96.5 % (55/57) resolution. Minor indications included bridge to cholecystectomy (10/78), CBD strictures (4/78), edematous ampulla (1/78), gallbladder perforation (1/78), and unexplained biliary dilatation (1/78), all achieving 100 % clinical success, with cholangitis prevention in 75 % (3/4) of cases.

Pancreatic intervention was mainly for post ERCP pancreatitis prophylaxis (71/74; 96 %) with (55/71; 77.5 %) success rate, and 2.8 % (2/71) mortality due to severe pancreatitis.Rare cases of duct dysfunction (2/2) and stricture (1/1) achieved 100 % success.

Total cost savings were estimated at £101,021 by avoiding 74 abdominal X-rays, some of which may have required an OGD, and 78 ERCPs for stent removal, resulting in an estimated carbon footprint reduction of 649 kg CO_2e.

Conclusions Biodegradable biliary and pancreatic stents deliver a safe and effective ERCP with excellent outcomes, lower healthcare cost and offers a truly patient centred and environmentally sustainable approach.

eP231 Retrospective analysis of body composition in patients with walled-off pancreatic necrosis at the tertiary center of The Institute of Pancreatic Diseases: a single-centre experience

Authors Horváth L[1], Havelda L[1], Hegyi JP[2]

Institutes 1 Semmelweis University – Institute of Pancreatic Diseases, Tömő Street, Budapest, Hungary; 2 Semmelweis University, INSTITUTE OF PANCREATIC DISEASES/CENTRE FOR TRANSLATIONAL MEDICINE, Budapest, Hungary

DOI 10.1055/s-0046-1821558

Aims Background: According to the Revised Atlanta classification [1], walled-off pancreatic necrosis (WOPN) is a mature, encapsulated necrotic collection that develops ≥ 4 weeks after necrotizing acute pancreatitis (AP), occurring in 1 %–9 % of cases overall and up to 15 % of cases of severe AP.

Aim: To analyze the body composition of these patients with different tools available at our Institute.

Methods We collected demographic and anthropometric data—including weight, height, body mass index (BMI), Bioelectrical Impedance Analysis (BIA), hand-grip strength (dynamometry,) and the Malnutrition Universal Screening Tool (MUST)—from 64 patients treated for WOPN at our Institute between May 2022 and November 2025, retrospectively. These measures were used to evaluate body composition and malnutrition risk. Two groups were formed based on treatment type: endoscopic ultrasound (EUS)-guided lumen-apposing metal stent (LAMS) insertion (n = 42) versus conservative (n = 22).

Results Among the 64 patients, 41 (64.06 %) were male (28 (66.67 %) and 13 (59.09 %) in the intervention and the conservative group, respectively). The median age was 54.5 years (56.5 and 50.5 years, respectively). BIA was performed in 21 LAMS (50 %) and 12 conservatively treated patients (54 %). The mean extracellular water (ECW) ratio was 0.396 in the LAMS group and 0.388 in the conservative group, respectively (67 % of LAMS patients and 50 % of conservative patients had a high ECW ratio). These elevated ECW ratios, due to fluid collections, substantially distorted BIA-derived muscle parameters (FFMI, SMI, and skeletal muscle mass), indicating that BIA is not a reliable method for assessing body composition in WOPN patients. Hand-grip strength was assessed in 11 LAMS patients: 82 % (n = 9) showed weak grip strength, and 18 % normal values. In contrast, among 16 conservatively treated patients, only 31 % (n = 5) showed weak grip strength, while 44 % (n = 7) had normal and 25 % (n = 4) strong measurements. MUST scores indicated higher malnutrition risk in the LAMS group (n = 32): 41 % low, 13 % moderate, and 47 % high risk. In the conservative group (n = 21), the majority had low risk (76 %), while only 10 % and 14 % were classified as moderate and high risk, respectively. Overall, LAMS patients demonstrated poorer general condition, weaker muscle strength, and higher malnutrition risk, likely related to longer hospitalization and greater weight loss from impaired oral intake

Conclusions Nutritional monitoring in WOPN—especially in interventional (LAMS) patients—is crucial due to their high risk of malnutrition and sarcopenia. As BIA results are confounded by fluid collections, CT-based body composition assessment is more reliable. Optimal care requires a multidisciplinary team comprising physiotherapists, dietitians, and psychologists; future randomized studies are needed to refine management strategies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP232 Endoscopic drainage of walled-off pancreatic necrosis (WOPN): experience from a single center

Authors Iemrabott A[1], Kadiri M[2], Lagdali N[3], Ajana FZ[3], Borahma M[4]

Institutes 1 Ibn Sina University Hospital, Rabat, Morocco; 2 Hospital Ibn Sina, Rabat, Morocco; 3 Mohammed V University, Rabat, Morocco; 4 Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco

DOI 10.1055/s-0046-1821559

Aims Walled-off pancreatic necrosis (WOPN) is a complication of acute pancreatitis that often requires endoscopic intervention for drainage and necrosectomy. The choice of stent type for endoscopic drainage remains debated, with double-pigtail plastic stents and lumen-apposing metal stents (LAMS) being the most commonly used options.

The aim of our study was to evaluate the efficacy and safety of endoscopic drainage in the management of walled-off pancreatic necrosis (WOPN) in our center

Methods We conducted a single-center retrospective descriptive study in our gastroenterology, and interventional endoscopy department, including patients admitted for endoscopic drainage of symptomatic WOPN between 2019 and 2025. Epidemiological, clinical, endoscopic, and outcome data were analyzed

Results Among the 63 patients followed for acute necrotizing pancreatitis, eleven developed a symptomatic WOPN, an incidence of 17,4 %. The mean age was 59 years (range :38-73). The sex ratio was 2,7 (M/F = 8/3). WOPN was a complication of biliary acute necrotizing pancreatitis of in 81.8 % of cases (N = 9), alcoholic in 9.1 % of cases (N = 1) and metabolic in 9.1 % of cases (N = 1). All patients were symptomatic. Abdominal pain was the most common symptom in all patients (N = 11), followed by vomiting (N = 7). Two patients reported significant weight loss. Eight patients had a complicated form: compression of a neighboring organ (N = 5), or infected WOPN (N = 3). The compression was either vascular (N = 4) causing segmental portal hypertension, or biliary (N = 1) with overt jaundice. The WOPN was single in 72.7 % of cases (N = 8). The location was in the pancreatic body, allowing access through the posterior gastric wall. The average size was 9,4 cm (range:4,7-20cm). During esophagogastroduodenoscopy or duodenoscopy, gastric stasis was noted in 2 patients, gastric mucosal bulging in 4 patients, and congestive gastric or bulbar mucosa in all patients. One patient had bulbar stenosis. Under endoscopic ultrasound (EUS), the WOPN had heterogeneous content with at least 30 % necrotic material in 45.5 % of cases (N = 5), and more than 60 % in 18 % of cases (N = 2) .

All patients underwent drainage under endoscopic ultrasound guidance. The route was transgastric in all cases. A cystotome was used to create the gastro-cystic fistula in all patients, followed by hydrostatic dilation in 4 patients. Two double-pigtail plastic stents (7 Fr) were placed in seven patients, abiflanged metal stent in three patients. and a HOT AXIOS covered metal stent kit in one patient. Drainage was successful in all patients, with purulent fluid discharge in 5 patients and partial collapse of the WON under endoscopic ultrasound control. Regarding outcomes, one patient had persistent pain requiring two subsequent endoscopic necrosectomy sessions, three patients had disconnected pancreatic duct syndrome, requiring prolonged placement of plastic stents. The remaining patients had favorable outcomes with stent removal.

Conclusions Endoscopic drainage of walled-off pancreatic necrosis (WOPN) is a safe and effective option, with a success rate of 100 % in our series. The use of endoscopy ultrasound improves procedural safety and patient selection. careful monitoring for complications remains essential to optimize outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP233 Performance and Safety of Precut Sphincterotomy in Difficult ERCP

Authors Hsain C[1], Kadiri M[2], Lagdali N[3], Ajana FZ[3], Borahma M[4]
Institutes **1** Department of Hepato-Gastroenterology C, Ibn Sina Hospital, Mohammed V University, Rabat, Morocco; **2** Rabat, Morocco; **3** Mohammed V University, Rabat, Morocco; **4** Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821560

Aims Precut sphincterotomy is an essential access technique for selective biliary cannulation in difficult endoscopic retrograde cholangiopancreatography (ERCP). It requires advanced endoscopic expertise and is usually reserved for experienced centers. Although its effectiveness is established, its use varies according to practice patterns and operator experience. The aim of this study was to evaluate the technical approach, success rate, and safety of precut sphincterotomy in our center.

Methods We conducted a retrospective single-center study including all patients who underwent precut sphincterotomy between January 2019 and December 2025. Difficult cannulation was defined according to ESGE criteria (≥ 5 minutes, ≥ 5 attempts, or repeated pancreatic cannulation). Demographic, clinical, anatomical, and procedural data were analyzed. Cannulation time was not systematically recorded.

Results Among 825 ERCPs performed during the study period, 48 required precut sphincterotomy (5.8 %). The mean age was 68.1 years, and 58.3 % were female. Indications included malignant obstruction in 52 % (25/48) and choledocholithiasis in 43.7 % (21/48). The papilla was normal in 91.7 % and diverticular in ~8 %.

Techniques used included papillotomy (68.8 %), infundibulotomy (29.2 %), and transpancreatic precut (2.1 %). Additional sphincterotomy to extend the precut was required in 43.8 %.

Selective biliary cannulation was achieved using guidewire-assisted technique in 89.6 % and double-wire technique in 6.3 %. Two patients (4.1 %) had cannulation failure, resulting in an overall success rate of 93.8 %. Precut success was similar for lithiasis and malignant indications (100 % vs 92 %, p = 0.49), suggesting that the indication did not influence procedural success.

Post-ERCP pancreatitis occurred in 8.3 %. Three mild intraprocedural bleeding events (6.25 %) were controlled endoscopically, and one severe hemorrhage (2.1 %) corresponded to a post-ERCP episode of moderate hematemesis. The patient developed aspiration-induced respiratory distress during endoscopy, requiring ICU admission.One Stapfer type II perforation (2.1 %) was managed conservatively with antibiotics, monitoring, and CT evaluation. No patient required surgical intervention.

Conclusions In our experience, precut sphincterotomy was required in 5.8 % of ERCPs and achieved a high success rate of 93.8 %, with an acceptable safety profile consistent with published data. This study supports the feasibility and effectiveness of precut sphincterotomy in difficult biliary access cases in an intermediate-volume center, highlighting the importance of technical expertise and close post-procedural monitoring.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP234 Endoscopic Polyp Size Measurement Using a Laser-Based Sizing Probe: A Pilot Study

Authors Mahdadi MZ[1], Cristea E[1], Oleksiw M[1], Aleksieva P[1], Michal V[2], Battat R[1], Djinbachian R[1], Claire G[2], Christina DD[1], Bouchard S[1], Bouin M[1], Jeremy LCK[1], Benoit P[1], Von Renteln D[1]
Institutes **1** CHUM – Centre hospitalier de l'Université de Montréal, Montréal, Canada; **2** Research Center Du Chum ., Montréal, Canada
DOI 10.1055/s-0046-1821561

Aims Accurate size measurement of colorectal polyps is important for planning polyp resection and post-polypectomy surveillance. This study evaluated a through-the-scope laser-based probe for polyp size measurement during colonoscopies.

Methods A prospective pilot study was conducted at CHUM in which polyps in enrolled patients were attempted to be measured with a laser-based probe. The primary outcome was the accuracy of laser-based polyp measurements, assessed as mean bias using microscopic sizing as the reference. Secondary outcomes included agreement with the reference, technical success rate, reasons for failed measurement, and per-polyp measurement time [1–5].

Results Among 323 patients, laser-based measurement was attempted for 237 polyps; 149 had a microscopic size measurement. The technical success rate of the laser-based probe was 40.9 % (97/237; 95 % CI, 34.6 %–47.5 %), with mean time per measurement of 1:35. Accounting for specimens that could not be resected en bloc for microscopic measurements, a total of 41/149 (27.5 %; 95 % CI, 20.7 %–35.5 %) had paired laser-based and microscopy measurements for the primary analysis. Laser-based measurement demonstrated accurate sizing with minimal bias (–0.10 mm, 95 % CI –0.30 to 0.10; P = 0.328) and met the 0.4 mm non-inferiority margin. Agreement with the reference was high (ICC = 0.91; 95 % CI, 0.83–0.95), with near-perfect categorical concordance (kappa = 0.85) and 95.1 % accuracy (39/41; 95 % CI, 82.2–99.2). Bland–Altman limits of agreement ranged from –1.34 mm to 1.14 mm.

Conclusions Laser-based measurement provided accurate polyp sizing when obtained. However, the technical success rate was limited by longer measurement times and device issues.

eP235 A Retrospective Study on the Current Status, Efficacy, and Safety of Sedatives (Midazolam, Remimazolam, Propofol) Used During Lower Gastrointestinal Endoscopy in a Local Private Clinic

Authors Ishihara S[1], Masako N[1], Fuke K[2, 1], Sho M[2], Takayoshi T[3, 1]

Institutes **1** Ishihara Internist and Gastroenterology Clinic, Zentsuji, Japan; **2** Shikoku Medical Center for Children and Adults, Zentsuji, Japan; **3** Tokyo Medical University, Shinjuku City, Japan

DOI 10.1055/s-0046-1821562

Aims In recent years, there has been a growing demand for reducing discomfort during gastrointestinal endoscopy. In Japan, remimazolam, a new ultra-short-acting benzodiazepine sedative, has been approved for insurance coverage, and its usefulness in promoting earlier awakening compared to conventional midazolam has been reported. The purpose of this study was to retrospectively compare the sedative effects, awakening and recovery times, and safety of midazolam (M group), remimazolam (R group), and propofol (P group) during lower gastrointestinal endoscopy at a single local private clinic. Additionally, we aimed to investigate whether early awakening facilitated by these sedatives contributed to a reduction in staff overtime hours.

Methods This was a single-center, retrospective study. A total of 121 cases of lower gastrointestinal endoscopy performed at our clinic between September 19, 2025, and November 7, 2025, were included. Patients were categorized into three groups based on the sedative used: M group, R group, and P group. We compared the sedative effect, the time from the end of the endoscopy to discharge from the recovery room, and the incidence of complications. Furthermore, we compared staff overtime hours during the two-month periods of September-October 2022 (when midazolam was primarily used) and September-October 2025 (when remimazolam was increasingly utilized).

Results A total of 121 cases were included, with examinations performed by three endoscopists. The M group consisted of 76 cases (mean age 65.0 years, 44.7 % male), the R group 27 cases (mean age 56.4 years, 44.7 % male), and the P group 18 cases (mean age 49.7 years, 33.3 % male). The mean examination times were 12.5 minutes for the M group, 11.9 minutes for the R group, and 13.7 minutes for the P group, with no significant difference observed among the three groups.

Regarding sedative effect, the proportion of patients who reported "no memory at all" was 100 % in the M group, 66.7 % in the R group, and 72.2 % in the P group. Those who reported "some memory" were 0 %, 33.3 %, and 27.8 %, respectively. The M group showed a significantly stronger sedative effect compared to both the R group and the P group ($p < 0.05$). No significant difference was found between the R group and the P group.

The mean time to discharge from the recovery room was 143.1 minutes for the M group, 18.0 minutes for the R group, and 12.7 minutes for the P group. The M group had a significantly longer recovery time compared to both the R group and the P group ($p < 0.05$). Furthermore, the R group also had a significantly longer recovery time compared to the P group ($p < 0.05$).

Regarding complications, one case of hypotension and vomiting was observed in the M group, and one case of hypotension in the P group. No complications were observed in the R group.

The average overtime hours for six staff members at our clinic were 541.5 minutes in September-October 2022 and 438.5 minutes in September-October 2025. Although there was a trend towards decreased overtime hours, no statistically significant difference was observed ($p = 0.18$).

Conclusions The propofol group exhibited the shortest time to discharge from the recovery room. The remimazolam group demonstrated a significantly shorter recovery time than the midazolam group and could be used without complications. In terms of sedative effect, the midazolam group was superior. In the initial cases of remimazolam use in this study, some cases showed insufficient sedative effect, possibly due to initial unfamiliarity or dosage setting. However, its usefulness in promoting earlier awakening was suggested. Future challenges include increasing the number of cases, extending the period of use, and establishing optimal dosing for remimazolam. Although staff overtime hours showed a decreasing trend, a statistically significant difference was not observed, potentially due to factors such as an annual increase in the number of examinations.

eP236 Melanoma Of Unknown Primary In The Pancreas: A Case Report

Authors Vasconcelos Patricio AL[1], Cardoso MCDB[2], Sakae TM[3], Cardoso ADS[4], Moraes Dos Santos N[1], Alves Pinto C[1]

DOI 10.1055/s-0046-1821563

Introduction: Pancreatic melanoma is an extremely rare condition, especially those of unknown primary (MUP), accounting for about 2 % of visceral involvement in melanomas.

Case Report: A 43-year-old man with a history of hypertension sought medical attention due to severe epigastric pain radiating to the back, nausea, postprandial fullness, and urinary changes. Laboratory tests revealed elevated ferritin, erythrocyte sedimentation rate, blood glucose, C-reactive protein, and mild leukocytosis. Imaging studies identified a cystic lesion in the head of the pancreas, which had significantly increased in size from 11 mm in 2013 to 51x59x37 mm at the current presentation. Endoscopic ultrasound (EUS) revealed a well-defined, hypoechoic, and homogeneous solid lesion, located in head to pancreas body transition, and a fine-needle biopsy guided by EUS (EUS-FNB) was performed. Histopathological and immunohistochemical analysis confirmed the diagnosis of small cells melanoma with neuroendocrine differentiation. Dermatological evaluation and PET-CT did not identify any skin lesions, with uptake limited to the pancreas. Laparoscopy revealed hepatic and peritoneal metastases, confirming metastatic melanoma.

Discussion: This case highlights the diagnostic challenges of pancreatic melanoma, particularly in the absence of skin lesions, and emphasizes the importance of histopathological and immunohistochemical analysis via EUS for an accurate diagnosis. The rarity of primary pancreatic melanoma and the lack of definitive diagnostic criteria necessitate further research to better understand its pathogenesis and optimal management [1–13].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP237 Single-balloon enteroscopy–assisted closure of a late entero-cutaneous fistula in Roux-en-Y anatomy using argon plasma coagulation, submucosal fibrin glue injection and through-the-scope clips

Authors Nunziata R[1], Del Prete A[1], Staiano MT[1], Tufo A[2], De Luca L[1]
Institutes **1** Italy, Naples, UOC Gastroenterologia ed Endoscopia Digestiva, Ospedale Del Mare, Napoli, Naples, Italy; **2** UOC Chirurgia Generale, Ospedale del Mare, Napoli, Italy

Abstract Text

We report the case of a 50-year-old woman with long-standing, steroid-dependent ulcerative colitis who received neoadjuvant chemotherapy followed by subtotal gastrectomy with Roux-en-Y reconstruction for gastric adenocarcinoma. After 4 weeks, she presented to the emergency department with abdominal pain and clinical sepsis; computed tomography (CT) demonstrated free intraperitoneal air with a large perianastomotic fluid collection. She underwent re-operation for suspected anastomotic dehiscence, but no anastomotic or mural defect was identified intraoperatively. The postoperative course was complicated by laparotomy wound dehiscence with bile-stained secretions, managed with negative pressure wound therapy (NPWT). A subsequent CT scan with water-soluble oral contrast showed no extraluminal contrast leakage. Because symptoms and wound output persisted one month after the second surgery despite conservative management, endoscopic evaluation of the anastomoses and duodenal stump was undertaken under general anesthesia using single-balloon enteroscopy (SBE) with CO_2 insufflation and continuous fluoroscopic guidance, permitting retrograde access to the duodenal stump via the afferent limb. On endoscopic inspection, two discrete defects, each approximately 8 mm, were identified at opposite edges of the stump suture line; endoluminal fluoroscopic contrast injection opacified both tracts, confirming an enterocutaneous fistulous communication. Margin preparation was performed with argon plasma coagulation (APC) in pulsed mode at 30 W. Fibrin glue was then delivered via a 23-gauge needle as submucosal injections in a multi-quadrant fashion around each orifice (2 mL per quadrant) and intratract, for a total of 20 mL. To maintain apposition and support re-epithelialization, six 11-mm through-the-scope (TTS) clips were placed across the defects. The procedure was uneventful. Drain output declined rapidly and reached zero within 72 hours; CT scan at day 7 showed no residual leakage. Oral intake was resumed on day 8, NPWT was discontinued, and the patient was discharged without additional intervention. At 180-day follow-up, she remained asymptomatic with no recurrence. In the setting of Roux-en-Y anatomy and late duodenal stump fistula—where device delivery and effectiveness may limit conventional endoscopic suturing systems, this combined SBE-guided approach (APC margin freshening, targeted submucosal and intratract fibrin sealant, and adjunctive TTS clipping) proved feasible, safe, and promptly effective. Patient selection is key: controlled sepsis and small-to-moderate defects favored success, allowing a minimally invasive rescue that may obviate re-operation while preserving the surgical reconstruction [1–4].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821567

Aims Endoscopic palliation of malignant dysphagia related to cancer of the esophagus or gastroesophageal junction (GEJ) usually has been accomplished with esophageal stent placement. There is an emerging use of cryotherapy for palliation, although this is center and expertise dependent. We report a novel endoscopic palliation method using nitrous oxide cryoballoon ablation (CbA) for malignant dysphagia.

Background Esophageal cancer commonly causes malignant dysphagia requiring palliative endoscopic therapy. Liquid nitrogen spray cryoablation has been reported as a safe and effective modality for tumor debulking in advanced esophageal cancer, with low rates of serious adverse events. There is currently no data on the use of CbA palliation for malignant dysphagia. CbA can be used in situations where liquid nitrogen cannot be used such as when venting tube placement is not technically possible. We aimed to report on the dosing, efficacy, and safety of CbA for esophageal cancer palliation in a multicenter cohort

Methods We performed a multicenter retrospective review of patients with inoperable esophageal or GEJ cancer who underwent endoscopic CbA for dysphagia palliation at five centers. All procedures utilized the C2 CryoBalloon Ablation System (Merit Medical Systems, South Jordan, UT). Data on key technical parameters were collected. 30-day adverse events were reported and classified by severity. Symptomatic efficacy was assessed by improvement in dysphagia after treatment.

Results Twenty-two patients with mean age 67 [range 44 to 90], 85 % male) with inoperable cancer of the esophagus or gastroesophageal junction (46 adenocarcinoma, 7 squamous cell carcinoma) underwent a total of 50 CbA sessions. Some of the patients were previously treated with esophageal stents. The C2 180 ° balloon was used in 31 cases, the focal balloon was used in the remainder. The dosing of the cryogen with the 180 ° balloon ranged from 0.7 to 0.8mm/sec. The dosing for the focal balloon was 10sec x 2, 12sec x 1, 14sec x 1, and 14 x 3.

There were 2 procedure-related adverse events reported (4 %). There was 1 incident of bleeding requiring endoscopic hemostasis, and 1 stricture requiring dilation. There was 1 death from pulmonary embolism and one transient ischemia attack, both deemed not related to the procedure. There were no perforations. There were two incidents of device malfunction (4 %). Follow-up data on dysphagia was available in 34 of the 50 procedures with improvement noted in 31, no change in 2 patients and worsening in one patient. Some patients had dramatic improvement in dysphagia and luminal disease

Conclusions Cryoballoon ablation is a safe and well-tolerated palliative therapy for malignant obstruction of the esophagus and gastroesophageal junction. Procedure-related adverse events are uncommon. The results of this retrospective multicenter study will be useful for planning a prospective study to better define patient selection and longer-term response rates.

eP241 Non-inferiority of Tegoprazan to PPIs in H. pylori Eradication: Systematic Review and Meta-analysis

Authors Elaraby A[1], Bakr A[2], Hassanin MS[2]
Institutes 1 Faculty of Medicine, Al-Azhar University, Cairo, Egypt; 2 Al-Azhar University, Cairo, Egypt
DOI 10.1055/s-0046-1821568

Aims Helicobacter pylori infection contributes to peptic ulcer disease and gastric cancer, making eradication crucial. However, standard therapy with a proton pump inhibitor (PPI) plus antibiotics has shown declining success rates. Tegoprazan is a novel potassium-competitive acid blocker (P-CAB) that producing rapid, meal-independent and CYP2C19-genotype–independent acid suppression.

We performed a meta-analysis to compare the efficacy and safety of tegoprazan-based regimens versus PPI-based regimens for H. pylori eradication

Methods We systematically searched PubMed, Scopus, Cochrane Library and Web of Science. Eligible randomized and comparative studies evaluated tegoprazan-based versus PPI-based regimens. The primary endpoint was intention-to-treat (ITT) eradication; secondary endpoint was overall adverse events (AEs). Random-effects meta-analysis pooled risk ratios (RR) with 95 % confidence intervals (CI); heterogeneity was assessed with I^2. Prespecified subgroup analyses were by treatment regimen (triple, dual, other).

Results Eleven studies met inclusion criteria. Eradication efficacy was equivalent between groups (RR 1.01, 95 % CI 0.96–1.05, $p = 0.77$; $I^2 = 0$ %). Subgroups showed no effect modification: triple RR 1.00 (0.92–1.08; $I^2 = 0$ %), dual RR 1.02 (0.93–1.12; $I^2 = 0$ %), other RR 1.01 (0.93–1.09; $I^2 = 0$ %). AEs were similar overall (RR 0.92, 0.82–1.03; $p = 0.15$; $I^2 = 29.7$ %, $\tau^2 = 0.01$). By regimen, dual therapy favored tegoprazan with fewer AEs (RR 0.68, 0.53–0.89; $I^2 = 0$ %; $p = 0.005$), whereas triple (RR 0.93, 0.78–1.12; $I^2 = 23.4$ %) and other regimens (RR 1.02, 0.87–1.19) showed no difference.

Conclusions Tegoprazan-based regimens are non-inferior to PPI-based regimens for ITT eradication, with highly consistent results across regimen types. Overall tolerability is at least comparable, and dual-therapy regimens demonstrate significantly fewer AEs with tegoprazan. Tegoprazan is an effective, well-tolerated first-line alternative to PPIs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP242 Phenotypic Restructuring of Ineffective Esophageal Motility: The Transition from Chicago v3 to v4 Declassifies a Cohort Defined by Isolated Weak Swallows and Absence of Peristaltic Failure

Authors Chudasama J[1], Pravin R[1]
Institute 1 Topiwala National Medical College, Mumbai, Mumbai, India
DOI 10.1055/s-0046-1821569

Aims The Chicago Classification version 4 (CCv4) introduced stricter criteria for diagnosing Ineffective Esophageal Motility (IEM), raising the threshold to > 70 % ineffective swallows or ≥ 50 % failed peristalsis. This study aimed to evaluate the demographic, clinical, endoscopic, and manometric differences between patients who retained the diagnosis of IEM under CCv4 criteria and those who were declassified from the previous CCv3 definition

Methods We conducted a retrospective study of patients undergoing High-Resolution Manometry (HRM) at a tertiary care center in Western India between September 2020 and April 2024. Patients meeting CCv3 criteria for IEM were included and re-evaluated using CCv4 criteria. The cohort was divided into two groups: Group 1 (Retained IEM as per CCv4) and Group 2 (Declassified). We compared demographics, clinical symptoms, upper GI endoscopy findings, and HRM metrics—specifically analyzing failed versus weak swallows and peristaltic reserve—between the two groups [1, 2].

Results Out of 101 patients meeting CCv3 IEM criteria, 80 (79 %) retained the diagnosis under CCv4 (Group 1), while 21 (21 %) were declassified (Group 2). There were no statistically significant differences between the groups regarding age, gender, comorbidities, clinical symptoms (dysphagia, regurgitation, chest pain), or endoscopic findings (hiatal hernia, erosive esophagitis).However, manometric profiles differed significantly. Group 1 had a significantly lower mean Distal Contractile Integral (DCI) compared to Group 2 (234.6 vs. 422.7 mmHg · s · cm; $p < 0.001$). Notably, 64 % of Group 1 patients exhibited failed swallows, whereas Group 2 had zero failed swallows, presenting exclusively with weak swallows ($p < 0.0001$). Esophageal contraction reserve on multiple rapid swallows (MRS) was not significantly different between the groups ($p = 0.114$).

Conclusions Application of CCv4 criteria declassified 21 % of patients previously diagnosed with IEM. While the new criteria did not correlate with distinct clinical or endoscopic presentations, they successfully identified a manometrically severe subgroup characterized by lower DCI and the presence of failed contractions. Since failed swallows are associated with poorer bolus clearance, CCv4 appears to select for patients with more profound peristaltic dysfunction who may require distinct management strategies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP243 Five-Minute vs Six-Minute Withdrawal Time in BBPS ≥ 8 Colonoscopy by Experienced Endoscopists: A Multicentre Randomized Tandem Trial

Authors Xu B[1], Zhang H[1], Xu C[1], Chen X[1], Yang C[1]
Institute 1 The Affiliated Wuxi People's Hospital of Nanjing Medical University, Wuxi, China
DOI 10.1055/s-0046-1821570

Aims Current colonoscopy quality indicators recommend a minimum withdrawal time (WT) of 6 minutes. However, prolonged WT can reduce throughput and may not account for endoscopist experience or bowel preparation quality. Whether a 6-minute WT remains necessary when examinations are performed by experienced endoscopists with excellent preparation is uncertain. We conducted a study among experienced endoscopists and patients with high-quality preparation (Boston Bowel Preparation Scale [BBPS] ≥ 8) to compare a 5-minute WT with a 6-minute WT for adenoma detection rate (ADR) and adenoma miss rate (AMR).

Methods In this multicenter, randomized controlled trial, 423 patients were enrolled from June 2023 to March 2025 across five centers (Wuxi People's Hospital; Jiangsu Province People's Hospital; Xuzhou First People's Hospital; the Second Affiliated Hospital of Soochow University; Taizhou People's Hospital). Each colonoscopy involved two withdrawals performed by the same endoscopist. Participants were randomized to a 5-minute WT group (first withdrawal 5 minutes, second withdrawal 6 minutes; n = 214) or a 6-minute WT group (first withdrawal 6 minutes, second withdrawal 6 minutes; n = 209). A timer standardized withdrawal speed. Primary outcomes were ADR and AMR.

Results Baseline demographic and clinical characteristics were similar between groups (Table 1). Procedural metrics—including bowel preparation quality, cecal intubation rate, cecal intubation time, cecal intubation distance, use of abdominal compression, and patient repositioning—were comparable (Table 2). Overall ADR did not differ between the 5-minute and 6-minute groups (39.7 % vs 43.5 %; P = 0.606). ADR during the first withdrawal (36.0 % vs 36.8 %; P = 0.934) and the second withdrawal (10.7 % vs 13.4 %; P = 0.492) was likewise similar. AADR showed no significant differences overall (4.7 % vs 5.3 %; P = 0.954), during the first withdrawal (4.7 % vs 5.3 %; P = 0.956), or during the second withdrawal (0.5 % vs 0.5 %; P = 0.999). Similarly, polyp detection rate (PDR) and sessile serrated lesion detection rate (SSLDR) did not differ between groups. The patient-level AMR was numerically lower in the 5-minute group than in the 6-minute group (27.1 % vs 30.8 %; P = 0.567), indicating fewer missed adenomas with the 5-minute WT, although this difference was not statistically significant. A similar trend was observed for lesion-level AMR, which was also lower in the 5-minute group than in the 6-minute group (20.2 % vs 23.7 %; P = 0.188). There were no significant differences in advanced adenoma miss rate (AAMR), polyp miss rate (PMR), or sessile serrated lesion miss rate (SSLMR) (all P > 0.05) (▶ **Table 1**).

Conclusions Among experienced endoscopists performing colonoscopy with excellent bowel preparation (BBPS ≥ 8), shortening WT from 6 to 5 minutes did not reduce ADR and was associated with a comparable AMR. A 5-minute WT appears acceptable under these conditions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP244 Polypectomy in Patients with Limited Life Expectancy in an Irish Tertiary Referral Centre, Current Practice Assessed Against New BSG Guidance

Authors Lawton C[1], Craig O[2]
Institutes 1 Mater Hospital, Dublin, Ireland; 2 Mater Misericordiae University Hospital, dub, Ireland
DOI 10.1055/s-0046-1821571

Aims The benefit of polypectomy during colonoscopy in an elderly, comorbid population remains unclear. Clinicians regularly struggle with balancing the often-uncertain natural history of polyp progression to symptomatic malignancy against the elevated risks of complications relating to diagnostic colonoscopy and polypectomy, and associated patient outcomes. The British Society of Gastroenterology (BSG) recently issued guidance to facilitate informed decision-making regarding polypectomy in those with limited life expectancy. We aimed to audit our baseline practice at the Mater Misericordiae University Hospital (MMUH) in the > 80-year-old population and assess whether application of the BSG guidance would affect our polypectomy rate in this cohort [1].

Methods In this audit we retrospectively studied electronic health records at MMUH for all patients aged > 80 years of age who were referred for (and subsequently underwent) colonoscopy and polypectomy from January 2024 to January 2025.

Data examined included procedure indication, comorbidities (analysed using the Charlson Comorbidity Index), the size/characteristics of polyps removed, complications (e.g., bleeding, perforation), and re-admissions/emergency visits within 90 days.

Compliance with new BSG recommendations was assessed.

Results Following pre-assessment, 58 (28M/30F, median age 81) patients proceeded to lower GI endoscopy (45 full colonoscopy, 13 left sided colonoscopy).

The Charlson Co-Morbidity Index was median 6 (range 4-9).

25/58 patients (43.1 %) proceeded to polypectomy – 11 patients (1-5mm polyp removed), 3 patients (6-9mm), 7 patients (10-19mm), 4 patients (> 20mm).

12/58 (20.6 %) patients had repeat scope recommended for ongoing polyp surveillance.

▶ **Table 1** Detection and miss rate in the two groups

		5-minute (n = 214)	6-minute (n = 209)	*P*- value
ADR, n (%)	Overall ADR	85(39.7 %)	91(43.5 %)	0.606
	The first withdrawal	77(36.0 %)	77(36.8 %)	0.934
	The second withdrawal	23(10.7 %)	28(13.4 %)	0.492
AADR, n (%)	Overall AADR	10(4.7 %)	11(5.3 %)	0.954
	The first withdrawal	10(4.7 %)	11(5.3 %)	0.956
	The second withdrawal	1(0.5 %)	1(0.5 %)	0.999
AMR, n (%)	Patient-AMR	23/85(27.1 %)	28/91(30.8 %)	0.567
	Lesion-AMR	35/173(20.2 %)	40/169(23.7 %)	0.188
AAMR, n (%)	Patient-AAMR	1/10(10.0 %)	1/11(9.1 %)	0.944
	Lesion-AAMR	1/14(7.1 %)	1/15(6.7 %)	0.998

Endoscopy 2026; 58: S1–S1041

Application of the new BSG guidance would have *averted polypectomy* in *14/25 (56 %)* of patients.

Of the non-guideline adherent cases, anti-coagulation was withheld in **6/14***(43 %)*to facilitate polyp resection

Conclusions Application of the recent BSG guidance on polypectomy in patients > 80 years old with limited life expectancy would significantly reduce the polypectomy rate in our patient cohort.

This would have important implications not only for patient safety but also resource use in endoscopy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP245 Long-term Outcomes After Endoscopic Eradication Therapy for Barrett's Neoplasia: A Systematic Review and Meta-Analysis

Authors Dhali A[1, 2], Biswas J[3], Maity R[4], Asad M[5], Ul Sabah N[6], Rafae Faisal A[7], Bhat A[8], Hong SP[2]

Institutes **1** Sheffield Teaching Hospitals NHS Foundation Trust, UK, Sheffield, United Kingdom; **2** Imperial College London, London, United Kingdom; **3** Dr.B.C ROY HOSPITAL, Kolkata, India; **4** Indian Institute of Technology, Kharagpur, Kharagpur, India; **5** Dow University of Health Sciences (DUHS), Karachi, Pakistan; **6** Quaid-E-Azam Medical College, Bahawalpur, Pakistan; **7** Combined Military Hospital Multan, Multan, Pakistan; **8** University of Florida, Gainesville, United States of America

DOI 10.1055/s-0046-1821572

Aims Endoscopic eradication therapy (EET), combining endoscopic mucosal resection (EMR) and radiofrequency ablation (RFA), is the standard treatment for Barrett's oesophagus (BO) with dysplasia and early oesophageal adenocarcinoma. Nevertheless, the long-term durability of complete remission and the risk of recurrence remain only partially defined. This systematic review and meta-analysis evaluated the long-term outcomes of EET for BO-related neoplasia.

Methods We systematically searched MEDLINE (n = 1364), Embase (n = 443), and the SCOPUS (n = 2805) from inception to 20 July 2025 for studies reporting long-term outcomes following EET for BO neoplasia. Primary endpoint was recurrence rates of IM and dysplasia/cancer during surveillance. Proportions were pooled using a random-effects model (DerSimonian–Laird) with logit transformation.

Results Eight studies including 3,367 patients and ~7,500 person-years of follow-up met inclusion criteria; 75 % were high-quality studies. Median follow-up was 39.5 months. Pooled CR-IM was 86.4 % (95 % CI: 81.2–90.5 %; 8 studies, N = 3,245) and CR-D was 94.0 % (95 % CI: 91.2–96.1 %; 8 studies, N = 3,245). Among patients achieving CR-IM, intestinal metaplasia recurred in 14.0 % (95 % CI: 8.0–23.5 %; 7 studies, N = 1,997) and dysplasia/cancer in 5.6 % (95 % CI: 3.5–8.9 %; 8 studies, N = 3,028). Any recurrence occurred in 18.5 % (95 % CI: 12.3–26.8 %; 8 studies, N = 3,028), corresponding to an annual dysplasia recurrence rate of ~1.5 per 100 person-years. Heterogeneity was considerable across outcomes (I^2 = 76–94 %). In pooled treatment comparisons, dysplasia/cancer recurrence was lower after EMR + RFA than RFA alone (4.2 % [95 % CI: 2.8–6.3 %] vs 8.9 % [95 % CI: 5.1–15.1 %]; relative risk [RR] 2.1, 95 % CI: 1.3–3.4; p = 0.022). Baseline low-grade dysplasia was associated with lower dysplasia/cancer recurrence than HGD/T1a (3.1 % [95 % CI: 1.8–5.2 %] vs 6.8 % [95 % CI: 4.1–11.0 %]; RR 2.2, 95 % CI: 1.1–4.4; p = 0.043). Progression to advanced disease (T1a) occurred in 6–12 % of recurrences, mostly managed endoscopically. Leave-one-out analyses showed pooled dysplasia/cancer recurrence remained within 4.8–6.2 %, and omitting the most influential study (Cotton 2017) changed estimates by only 0.8 %, indicating no single study drove the results. Temporal analyses suggested a learning-curve effect, with CR-IM improving from ~75 % to 90–95 % and dysplasia recurrence falling from ~12 % to 3–5 % between 2009 and 2025. Baujat plots identified Cotton 2017 as contributing 42.5 % of total heterogeneity, while large recent cohorts (Wolfson 2022, van Munster 2022) strongly influenced but also stabilised pooled estimates. Meta-regression bubble plot for relationship between BO length and dysplasia recurrence rate showed weak positive but non-significant association (R^2 = 0.18, p = 0.23).

Conclusions EET has shown long-term durability following successful eradication of BO with neoplasia. Although recurrence is not uncommon, it is usually detected early and amenable to further endoscopic treatment. Our findings do not support frequent surveillance within the first year and suggest a personalised surveillance strategy based on the patient's risk of recurrence, in order to minimise the burden of surveillance gastroscopy [1].

eP246 Endoscopic treatment for primary neoplasia of the gastroesophageal junction: a multi-center retrospective study

Authors Sztogrin-Pluta A[1], Lee AS[2], Czapnik M[1], Korcz W[1], Pilonis ND[1], Regula J[1], Sujendran V[2], Kaminski M[1], Pietro MD[2], Januszewicz W[1]

DOI 10.1055/s-0046-1821573

Aims The incidence of gastro-oesophageal junction (GEJ) adenocarcinoma continues to rise worldwide, underscoring the need for evidence-based management of early neoplasia in this anatomically complex region. The GEJ represents the interface between two adjacent organs with distinct treatment recommendations. The presence of Barrett's epithelium may introduce additional variability in biological behaviour and treatment response. This study aimed to determine predictors of curative resection in Siewert type II GEJ lesions and to compare the outcomes of EMR and ESD performed in this area.

Methods This retrospective two-centre cohort study included consecutive patients who underwent endoscopic resection for early Siewert type II GEJ neoplasia between 2011 and 2025 at Cambridge University Hospital and the Maria Skłodowska-Curie National Research Institute of Oncology in Warsaw. Lesions with macroscopically visible Barrett's oesophagus were classified as Barrett's-related. The primary endpoint was curative resection rate, defined as R0 resection (negative deep margin for EMR; deep and lateral margins for ESD), histological grade ≤ G2 and absence of lymphovascular invasion. Secondary endpoints included local recurrence of high-grade dysplasia or adenocarcinoma and surgery within 12 months from endoscopic resection. A multivariable logistic regression model adjusted for age, sex, and Barrett's status. Comparisons between EMR and ESD, and between Barrett's- and non-Barrett's-related lesions, were performed using χ^2 tests and. A p value < 0.05 was considered statistically significant [1–5].

Results A total of 158 patients were included (mean age 69, ± 10.7 years, 76.6 % male). Final histology revealed 137 adenocarcinomas and 21 high-grade dysplasia; 96 EMR and 62 ESD procedures were performed. Curative resection was achieved more frequently in Barrett's-related neoplastic lesions than in those without Barrett's (71.7 % vs 53.8 %; p = 0.026). In the multivariable logistic model, the presence of Barrett's epithelium was an independent predictor of curative resection (OR 2.54; 95 % CI 1.16–5.63; p = 0.020), whereas age, sex, and resection technique were not significant. Lesions without Barrett's mucosa demonstrated a more aggressive profile, with higher rates of poor differentiation (G3: 21 % vs 13 %), a greater prevalence of lymphovascular invasion (26 %

vs 8 %) and a higher rate of submucosal invasion (47.6 % vs 19.1 %), compared with Barrett-related lesions. Among Barrett's-related Siewert type II lesions (n = 106), curative resection rates were comparable between EMR and ESD (71.2 % vs 73.1 %; p = 0.86), with similar rates of local recurrence (23.1 % vs 23.8 %) and additional surgery (5.1 % vs 4.2 %). There was a trend towards higher curative resection in non-Barrett's lesions with ESD compared to EMR (61.1 % vs 37.5 %, p = 0.12) and lower recurrence rate (7.1 % vs 25.0 %; p = 0.297), although these differences did not reach statistical significance due to limited sample size.

Conclusions Primary GEJ neoplasia without visible Barrett's exhibited lower rate of curative endoscopic resection likely in keeping with deeper histological invasion and more frequent lymphovascular invasion compared with Barrett-related lesions. Our data suggest that ESD should be the preferred resection modality for GEJ associated lesion in the absence of Barrett's epithelium.

Abstract Text

Early rectal cancers that are difficult to resect with standard EMR/ESD, particularly those with fibrosis or MRS + , may require resection in deeper planes with methods such as endoscopic intermuscular dissection (EID) or exposed full-thickness resection (EFTR), which can leave deep bowel wall defects. We report a hybrid EID–EFTR approach combined with selective muscular-layer suturing. A 27-mm lsp JNET 2B lesion 4 cm from the anal verge, with prior biopsies suggesting at least intramucosal neoplasia and MRI cT1–2N0 staging, was removed en bloc, creating a varying thickness defect. Two sutures reapproximated the muscularis propria, leaving the mucosa open. Recovery was uneventful. Pathology showed a moderately differentiated pT1b adenocarcinoma (2083 µm invasion, no LVI, Bd1). This hybrid technique may enhance organ-sparing management of selected early rectal cancers.

Foundation Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; 2 University Hospital of Santiago de Compostela Health Research Institute of Santiago (IDIS), Santiago de Compostela, Spain; 3 University Hospital of Santiago de Compostela Health Research Institute of Santiago (IDIS), santiago, Spain

DOI 10.1055/s-0046-1821575

Aims of our study was to evaluate the feasibility and safety of the endoscopic ultrasound (EUS)-guided intratumoural injection of phosphorus-32 (^{32}P), an emerging local ablative technique that may enhance local disease control and surgical conversion when used alongside systemic therapy, in patients with pancreatic cancer.

Methods This single-centre observational study assessed the feasibility and outcomes of EUS-guided fine-needle ^{32}P injection in patients with LAPC receiving gemcitabine–nab-paclitaxel at the University Hospital of Santiago de Compostela between September 2024 and September 2025.

Results Eleven patients were included (mean age 66.5 years; range 48–84). Tumour locations were the pancreatic head (n = 6), neck (n = 2), and body (n = 3), all demonstrating vascular involvement. Mean tumour diameter was 30.6 mm (22–45) on CT and 34.6 mm (25–45) on EUS, with a mean volume of 9.17 cc (1.8–36.2). Mean ^{32}P dose was 48.6 MBq (1.5–223). No immediate complications were observed; 18 % experienced mild adverse events, and one patient developed moderate acute pancreatitis. Chemotherapy was resumed in 91 % after 9.8 days (mean interval). One patient (9 %) underwent successful R0 resection. Local progression occurred in 9 % and distant progression in 36 %. Median CA 19-9 levels decreased from 695.8 U/mL (2.3–2458.7) at baseline to 185.6 U/mL (2.1–852.4) post-treatment. Median overall survival and progression-free survival were 291.5 and 273 days, respectively.

Conclusions EUS-guided ^{32}P injection appears to be a feasible and safe local ablative approach for patients with LAPC. It can be seamlessly integrated into treatment protocols without compromising subsequent surgical resection

eP249 Refractory haemorrhage from a major papillary angioectasia: overcoming therapeutic failure with bevacizumab

Authors Portugal M[1], Eusébio M[1], Carvalho I[1], Aguieiras C[1], Relvas L[1], Cunha C[1], Bruno P[1]

DOI 10.1055/s-0046-1821576

Abstract Text

Angioectasias are the most common acquired vascular malformations of the gastrointestinal tract and a frequent cause of recurrent obscure or overt bleeding in older adults. In aortic stenosis, the associated von Willebrand defect defines Heyde syndrome, and although TAVI usually improves bleeding, persistence can occur. Argon plasma coagulation (APC) is the first-line endoscopic therapy, although certain locations pose substantial technical challenges. Pharmacological options in refractory cases remain limited; recent data suggest

that bevacizumab, an anti-VEGF monoclonal antibody, may be promising, although real-world experience is still scarce. We report a 76-year-old male with severe aortic stenosis treated with TAVI, coronary artery disease, and chronic anaemia secondary to recurrent bleeding from intestinal angioectasias. Despite TAVI, he continued to experience recurrent melena, symptomatic anaemia and repeated hospital admissions. Von Willebrand factor levels and post-TAVI gradients were normal. Initial endoscopic assessments demonstrated multiple small-bowel angioectasias identified by capsule endoscopy and treated endoscopically with APC. Medical therapy with long-acting octreotide was also initiated at 10 mg/month and escalated to 60 mg/month, provided only transient symptomatic improvement; the patient remained transfusion-dependent and required frequent intravenous iron supplementation. During subsequent bleeding episodes, fresh blood was consistently observed in the second portion of the duodenum. Side-viewing duodenoscopy was therefore performed, allowing optimal visualisation of the papilla and revealing a major papillary angioectasia with persistent active oozing, while previously treated lesions showed no evidence of haemorrhage. The papillary angioectasia required multiple sessions of combined haemostasis—adrenaline injection, APC and clip placement—performed with a duodenoscope. Although haemostasis was achieved each time, recurrent bleeding from the same site persisted. Endoscopic papillectomy was considered but not pursued due to age, comorbidities and procedural risk. Given refractoriness to endoscopic therapy and maximal-dose octreotide, bevacizumab was initiated (5 mg/kg every two weeks). Treatment was complicated by uncontrolled hypertension and a pre-acute pulmonary oedema episode, both managed medically. A sustained response became evident only after completing the six-dose induction regimen, with stabilised haemoglobin, resolution of melena and cessation of transfusion and iron requirements. Papillary angioectasias represent a rare but challenging entity due to anatomical constraints, high bleeding potential and the risk of pancreatitis after intervention. This case illustrates successful bleeding control with combined endoscopic therapy and bevacizumab rescue after failure of intensive octreotide treatment. It highlights the potential role of VEGF blockade in highly refractory lesions and reinforces the need for individualised decision-making in complex angioectasias [1–3].

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims of our study was to evaluate the feasibility of generating patient-derived organoids (PDOs) from EUS-TA samples

Methods Prospective study of patients referred to the Endoscopy Unit of the University Hospital of Santiago de Compostela, Spain, for EUS-TA of pancreatic tumour. EUS was performed using linear echoendoscopes and Hitachi-Fujifilm systems. Tissue sampling was performed using core needles. Tissue samples were minced and dissociated into small pieces from which cell cultures were established using growth medium supplemented with factors such as gastrin, respondin-1, noggin and WNT-3A proteins, which play a key role in the self-renewal and maintenance of human pancreatic PDOs. Data are presented as mean ± standard deviation, or median and range for quantitative variables and as percentages for categorical variables. Factors associated with the success in obtaining PDOs were evaluated using multivariate logistic regression, with location, staging, lesion size, needle size and number of passes considered as independent variables.

Results The study included 28 patients diagnosed with PDCA (mean age 73.3 ± 10.1 years, 14 males). Mean tumour size was 41.8 ± 15.1 mm; 13 lesions were located in the head, 9 in the body, 5 in the tail and 1 in the uncinate process. One PDAC (3.6 %) was considered resectable, 5 (17.9 %) borderline, 6 (21.4 %) locally advanced and 16 (57.1 %) metastatic at the time of diagnosis. For EUS-TA, 19-gauge and 25-gauge needles were used in 1 case (3.6 %) each, and a 22-gauge needle was used in the remaining cases (26 cases, 92.9 %). A median of two passes (range 1-4) were performed. In an initial training set, PDOs were obtained in 1 of 12 (8.3 %) samples. After protocol refinement, the success rate of PDO establishment increased to 56.3 % (9 of 16 patients). On multivariate analysis, neither lesion location, stage, lesion size, needle size, nor number of passes were associated with PDO success.

Conclusions This study highlights the feasibility of obtaining PDOs from EUS-TA of PDAC patients. The protocols developed in this study allowed the establishment of pancreatic PDOs from a minimal tissue source, providing a valuable tool for further functional modelling of human pancreatic tumours.

eP251 Endoscopic intermuscular dissection of a primary tumor remnant after good response to FOLFOXIRI/Bevacizumab in metastatic rectal cancer – A Case Report

Authors Schellen S[1], Ayoub M[1], Cahyadi O[1], Zeidler C[1], Ewald P[1], Heuer V[1], Witte D[1], Reinacher-Schick A[1], Ebigbo A[1]

Institute **1** St. Josef-Hospital, Ruhr University Bochum, Bochum, Germany

DOI 10.1055/s-0046-1821578

Background Multimodal individualized treatment concepts are becoming increasingly important in the treatment of metastatic rectal cancer. Rectum-sparing resections of the primary tumor after a good response to systemic therapy in patients with metastatic rectal cancer have so far only been described in isolated cases as part of liver-first strategies [1]. Data on endoscopic resection procedures in metastatic rectal cancer are currently lacking.

The aim of this article is to demonstrate the potential of endoscopic intermuscular dissection (EID) as an effective organ-preserving treatment option within the framework of a multimodal therapy concept following successful systemic therapy.

Case report A 20-year-old patient with microsatellite-stable hepatically metastasized rectal carcinoma (KRAS G13D mutation, BRAF wild type) was treated with a total of seven cycles of FOLFOXIRI, the first five of which were combined with Bevacizumab. With an excellent response to therapy, including a reduction in the size of the local lesion from 30 to 15 mm and regression of the liver metastases. With no involved regional lymph nodes on MRI our interdisciplinary tumor conference decided on an individualized approach involving endoscopic resection of the primary tumor followed by evaluation of a possible liver transplant, analogous to the TransMet study [2].

To increase the likelihood of R0 resection, EID of the residual lesion was performed at 12 cm from the anal verge, with endoscopic dissection between the circular and longitudinal muscles. Compared to EMR or ESD, this allows even deeper infiltrating carcinomas to be removed from healthy tissue. The EID was performed without technical or post-procedural complications. The resulting defect was completely closed using an endoscopic suture system (SutuArt, Olympus, Japan). Histopathological examination showed complete resection of the carcinoma in healthy tissue (vital tumor cell content 10 %, regression grade 3 according to Dworak, ypT1, sm2 with an infiltration depth of 800 µm, L0, V0). The plan now is to continue systemic therapy and refer the patient to a liver transplant center.

Conclusion The described case illustrates that in metastatic rectal carcinomas that respond well to systemic therapy EID enables a safe resection of the local tumor with organ preservation. EID thus represents a possible addition to a multimodal therapy concept in suitable patients.

eP252 EUS-guided Hepatico-Jejunostomy After Failed ERCP in Surgically Altered Anatomy: Expanding the Frontiers of Biliary Drainage

Authors Male N[1], Karagyozov P[1]
Institute 1 Clinic of Gastroenterology, Acıbadem City Clinic University Hospital Tokuda, Sofia, Bulgaria
DOI 10.1055/s-0046-1821579

Aims Biliary drainage in surgically altered anatomy remains a major challenge, as ERCP is often unsuccessful and percutaneous drainage carries significant morbidity. EUS-guided hepaticojejunostomy (EUS-HJ) has emerged as a minimally invasive alternative, though data remain limited. We report our experience with EUS-HJ in patients with surgically altered anatomy, after total or partial gastrectomy, and failed ERCP.

Methods This retrospective series included patients who underwent EUS-HJ between March 2020 and September 2025 at a tertiary referral center. All procedures were performed using linear echoendoscopes under general anesthesia. Technical success was defined as successful stent deployment between the intrahepatic bile duct and jejunal limb. Clinical success was defined as ≥ 10 % bilirubin reduction or resolution of cholangitis within three days. Adverse events were graded according to CTCAE v5.0.

Results A total of nine patients (mean age 65.8 years; 66.6 % male) with surgically altered anatomy following total gastrectomy (n = 7), pancreaticoduodenectomy (n = 1), or subtotal gastrectomy (n = 1) underwent EUS-guided hepaticojejunostomy after failed ERCP. All cases were malignant, mostly recurrent, or metastatic. Technical success was 100 %, and clinical success was 66.7 % (6/9). The median procedure time was 41.6 min, and self-expanding, partially covered metal stents were used in all cases. A delayed adverse event occurred in one patient (10 %), who developed a localized infected biloma two months post-procedure (CTCAE Grade II), successfully managed with percutaneous drainage and complete recovery. The median post-procedural hospitalization was 5.4 days. During follow-up, long-term stent patency was preserved in most patients. Three patients (33 %) required endoscopic reintervention for stent dysfunction at 3, 5, and 21 months after the index procedure; all were successfully managed with endoscopic tract revision, without the need for surgery. One patient developed multiple intrahepatic abscesses 17 months after the initial EUS-HJ, treated with percutaneous drainage, followed by tract revisions at 21 and 23 months, achieving sustained biliary drainage afterwards. In another case, cholangioscopy performed during tract revision enabled targeted biopsy and histologic confirmation of disease progression, highlighting the diagnostic potential of EUS-HJ. No episodes of stent migration, bleeding, or procedure-related mortality were observed, confirming the durable efficacy and safety of EUS-HJ in this challenging cohort.

Conclusions EUS-HJ is a safe, effective, and physiologic alternative to percutaneous drainage for malignant biliary obstruction in surgically altered anatomy. With high technical success, low morbidity, and durable stent patency, it is evolving from a rescue procedure to a frontline therapeutic option. The maintained transluminal access further allows repeat cholangioscopy and histologic assessment, extending the clinical scope of interventional EUS beyond drainage alone.

eP253 Long-Term Outcomes and Predictors of Treatment Success in Pneumatic Dilation for Achalasia: A 20-Year Single-Center Retrospective Cohort

Authors Bezerra J[1], Ribeiro R[1], Andrade A[1], Guimarães D[1], Tarrio I[1], Gomes L[1], Moreira M[1], Araújo T[1], Lopes L[2, 3, 1]
Institutes 1 Hospital de Santa Luzia (Unidade Local de Saúde (ULS) do Alto Minho), Viana do Castelo, Portugal; 2 ICVS – Life and Health Sciences Research Institute, Braga, Portugal; 3 3B's Research Group, Guimarães, Portugal
DOI 10.1055/s-0046-1821580

Aims Achalasia is a rare esophageal motility disorder in which endoscopic pneumatic dilation (PD) is a commonly used therapeutic option. This study aims to evaluate the effectiveness of PD in symptomatic improvement using the Eckardt score, to identify factors associated with multiple PD sessions, the interval between PDs, and the occurrence of complications.

Methods Single-center, retrospective study including patients diagnosed with achalasia who underwent PD between January 2005 and October 2025. Patients without follow-up or with less than 2 years of follow-up after PD were excluded. Demographic, clinical, procedural, and symptomatic evolution data were collected based on electronic medical records and, when these were unavailable, through follow-up phone calls. Statistical analysis were performed using SPSS software version 30, with a p-value of < 0.05 considered statistically significant.

Results A total of 51 patients were included, 53.8 % (n = 28) female. Type I achalasia was the most frequent (65.0 %, n = 13). A total of 83 PD were performed, with a mean of 1.63 PD needed per patient. The 35mm dilation ballon was used in 12 patients (18 PD (21.7 %)). The mean age at symptom onset was 50.35 years [21-78], and the median interval from symptom onset to PD was 2 years [0-19]. Median follow-up was 116.27 months [26.13-253.10]. The median interval between dilations was 25.7 months [2.33-227.70], with no significant associations with the Eckardt score. Adjusting for patients requiring multiple dilations (n = 22; 43.1 %), they had no improvement of the Eckardt dysphagia subscore (p = 0.014), smaller interval between symptom onset and PD (p < 0.001), and greater maximum balloon diameter used (35mm in 12 patients (48.0 %)) (p < 0.001). One perforation occured, in the third PD of a female patient (the first with 35mm dilation ballon) successfully resolved after 7 days of treatment with VacStent GI.

Conclusions Pneumatic dilation showed high effectiveness in improving symptoms in achalasia, with sustained benefit over long-term follow-up. The need for multiple dilations was mainly associated with symptomatic recurrence. These findings support PD as a safe and effective therapeutic option, emphasizing the need for individualized follow-up and identification of patients who may benefit from alternative therapies.

DOI 10.1055/s-0046-1821581

Aims Accurate colorectal polyp measurement is essential because size guides surveillance intervals, resection strategy, and colorectal cancer risk assessment. Emerging Vision-Language Models (VLMs) can estimate polyp size from endoscopic images, but their performance relative to expert visual assessment is unclear. We compared the accuracy and bias of visual assessment versus several VLMs for polyp sizing [1–4].

Methods At the Centre Hospitalier de l'Université de Montréal (CHUM), patients were prospectively enrolled in an endoscopic video databank with consent for AI use. For each resected polyp, endoscopists provided a visual size estimate; still images were then submitted to four VLMs. The reference standard was microscopic size obtained from freshly resected specimens. VLMs generated estimates based on prompt-driven input, following few-shot learning (FSL). The primary outcome was categorical accuracy in three clinically relevant classes: diminutive (≤ 5 mm), small (5.001–9.999 mm), and large (≥ 10 mm). Secondary outcomes included continuous size bias, overestimation frequency (categorical and continuous), intraclass correlation coefficient (ICC) between VLM predictions, and Light's κ for categorical agreement between VLMs. Logistic regression (for accuracy and frequencies) and linear models (for bias) with sizing method as a fixed effect were fitted, using generalized estimating equations with exchangeable correlation to account for within-polyp clustering. Tukey correction was applied for pairwise comparisons (▶ **Table 1**).

Results We analyzed 132 polyps (78.0% diminutive, 21.2% small, 0.8% large). Visual assessment had higher categorical accuracy (81.7%; 95% CI, 71.4–87.4) than all VLMs, significantly so for 3 of 4 models (e.g., Qwen3-VL 67.0% [58.4–74.5]; difference visual–Qwen3-VL 14.7% [1.4–28.1]; p = 0.022). Gemma3 showed the lowest accuracy (26.5% [19.7–34.7]). Three VLMs had mean positive bias > 0.5 mm (Qwen3-VL 0.95 mm [0.53–1.38]; Llama4 1.35 mm [0.89–1.81]; Gemma3 2.71 mm [2.37–3.04]). Mistral-Small3.2 showed a smaller mean bias than visual assessment (difference visual–Mistral-Small3.2 0.39 mm [–0.43–1.21]) and a lower overestimation frequency (43.9% [35.7–52.5] vs visual 62% [53.4–69.9]; difference -18.1% [-33.3– -2.8]; p = 0.011). Overall, VLMs tended to overestimate continuous sizes more than visual assessment. Agreement between VLMs was poor (ICC 0.212 [0.122–0.313]; κ = 0.106); excluding Gemma3 did not materially improve agreement.

Conclusions In this study, standard visual assessment outperformed current VLMs for clinically relevant size categories, and VLMs frequently overestimated size. Likely contributors include the absence of calibrated reference scales, fisheye lens distortion, and variability in endoscopic distance and angulation. Polyp sizing remains a complex task, VLMs should not be used for polyp sizing and require rigorous size-aware training and calibration before clinical integration.

eP255 Retrograde esophageal and stomach tubing for palliative drainage: feasibility and safety in a single-center

Authors Rinott E[1], Hakimian D[1], Slae M[1]

Institute **1** Hadassah Ein Kerem Hospital, Jerusalem, Israel

DOI 10.1055/s-0046-1821582

Aims Describe the feasibility and safety of retrograde esophageal and stomach tubing for palliative drainage

Methods Retrospective single-center cohort study

Results Between 2022 and 2025, six pediatric and adult patients underwent a novel retrograde placement of gastrojejunostomy (GJ) tubes into the esophagus to provide continuous palliative drainage of esophageal secretions. The cohort included cases of familial dysautonomia–associated megaesophagus, post-surgical strictures, and malignant esophageal stenosis (▶ **Table 1**). Using a slim endoscope, GJ tubes were introduced over a guidewire and advanced retrogradely across the stenotic segment, allowing drainage of the proximal stomach or esophagus through the J-port, while gastric feeding was maintained through the G-port.

▶ **Table 1** Primary and secondary outcome point estimates (95% CI). Results arise from logistic and linear (bias) models with GEEs that account for intra-polyp correlations.

	Accuracy (%, 95% CI)	Bias (mm, 95% CI)	Categorical size over-estimation (%, 95% CI)	Size over-estimation (%, 95% CI)
By sizing method				
Visual	81.7% (74.1,87.4)	0.58 (0.32,0.84)	12.3% (7.7,19.1)	62.0% (53.4,69.9)
VLM: Qwen3-VL	67.0% (58.4,74.5)	0.95 (0.53,1.38)	21.5% (15.3,29.4)	62.3% (53.7,70.2)
VLM: Llama4	68.9% (60.5,76.3)	1.35 (0.89,1.81)	18.2% (12.5,25.7)	73.5% (65.3,80.3)
VLM: Gemma3	26.5% (19.7,34.7)	2.71 (2.37,3.04)	72.0% (63.7,79.0)	86.4% (79.4,91.2)
VLM: Mistral-Small3.2	67.4% (59.0,74.9)	0.19 (-0.37,0.76)	16.7% (11.2,24.0)	43.9% (35.7,52.5)

▶ **Table 1** profile of patients treated with retrograde esophageal tubing

Sex	Age at insertion (years)	ASA physical status at procedure	Follow-up period (weeks)	Death at end of follow up
F	3.5	3	92	
M	19.5	3	32	
M	20	3	168	
M	4.5	4	39	
M	61.5	4	14	V
F	66	4	2	V

All procedures were completed successfully without technical difficulties or complications. Following placement, the nasogastric tube was removed, and the GJ tube effectively alleviated esophageal content pooling. An illustartion of the procedure is provided.

Despite being performed in high-risk patients, most procedures were feasible without sedation, thereby reducing risk and obviating the need for anesthesiology support. Moreover, tube replacement over a guidewire can be safely performed during a routine clinic visit.

Conclusions This case series demonstrates the feasibility, safety, and reproducibility of retrograde transgastric esophageal tubing as a palliative solution for refractory esophageal stasis.

Our findings highlight an unmet need in palliative gastroenterology, suggesting that this technique can significantly improve patient comfort and reduce aspiration risk.

eP256 Spontaneous Duodenal Fistulization Following Arterial Embolization in Acute Necrotizing Pancreatitis: A Rare Complication

Authors Paladiya R[1], Mittal A[1], Dharan M[1]

Institute 1 UConn Health, Farmington, United States of America

DOI 10.1055/s-0046-1821583

Abstract Text

We present a case of spontaneous duodenal fistulization in a 43-year-old man with acute necrotizing pancreatitis demonstrating an unusual temporal sequence, raising questions about the etiopathogenesis of the fistulous connection. The patient presented with severe epigastric pain and was diagnosed with acute pancreatitis based on elevated lipase (579 U/L) and characteristic imaging. By day 6, the disease progressed to necrotizing pancreatitis with extensive peripancreatic collections. However, the patient was tolerating low fat diet. Following discharge, he was re-admitted one week later due to worsening pain and anorexia. Repeat imaging (day 13) demonstrated progression of necrotizing pancreatitis with retroperitoneal fluid collections. On day 16, he developed sudden severe pain with imaging revealing active hemorrhage from a gastroduodenal artery branch, necessitating emergency embolization of the superior pancreaticoduodenal artery. Following embolization, he developed persistent fevers and ileus requiring nasogastric decompression. Imaging on day 24 revealed the pancreatic necrotic collection had dramatically decreased from 7.7 × 12.3 cm to 5.5 × 9.6 cm with copious internal gas, and gas appeared within a hepatic subcapsular collection. Gastrografin study confirmed fistulous communication between the second duodenal portion and the peripancreatic collection. Endoscopy confirmed a fistulous opening extruding necrotic material – this was cleared and a double pigtail catheter was placed for drainage, leading to clinical improvement.

This case highlights a potentially under-recognized mechanism of fistula formation. Gastrointestinal fistulas in acute necrotizing pancreatitis are well-established complications driven by infected necrosis, local anatomical factors, and pancreatic duct disruption [1]. In this patient, spontaneous fistulization can be attributed to infected pancreatic necrosis, pressure from substantial necrotic mass, and direct enzymatic and inflammatory damage to the nearby duodenal wall [2, 3]. The temporal relationship with arterial embolization warrants consideration. While iatrogenic factors such as percutaneous drainage or surgical intervention can contribute to external fistula formation, IR-guided arterial embolization has not been reported to predispose to enteric fistulization. Prior studies demonstrate IR-guided embolization to be safe and effective without enteric fistulization as a recognized complication [4]. However, duodenal ischemia following embolization of gastroduodenal artery branches has rarely been reported [5]. The temporal sequence in our patient—arterial embolization on day 16 followed by fistula evidence on day 24 suggests possible association. We hypothesize that IR-guided arterial embolization, particularly of gastroduodenal artery branches, may have contributed to duodenal ischemia that, when superimposed on pre-existing infected necrosis and inflammatory injury, compromised duodenal wall integrity sufficiently to facilitate fistulization. This potential iatrogenic mechanism warrants clinical investigation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP257 Risk factors for lateral margin positivity following endoscopic submucosal dissection in patients with early gastric cancer

Author Moon HS[1]

Institute 1 Chungnam National University Hospital, Daejeon, Republic of Korea

DOI 10.1055/s-0046-1821584

Aims The risk factors for lateral margin positivity (LM +) in patients undergoing endoscopic submucosal dissection (ESD) for early gastric cancer (EGC) are not yet well established. The role of subepithelial (SE) spread of cancer in contributing to LM + remains unclear.

Methods A study was conducted at a tertiary medical center in Daejeon, South Korea, targeting patients who underwent ESD for EGC between January 2014 and December 2024, those with recorded LM + . Patients who underwent ESD for EGC at the same institution in 2022 and achieved curative resection were selected as the control group.

Results During the study period, a total of 21 patients were diagnosed with LM + and 227 patients were enrolled in the control group. In univariate analysis, differentiation, Lauren classification, lesion size, and discoloration changes were identified as risk factors for LM + (chi-square test, $p < 0.05$). In multivariate analysis, lesion size was the only significant risk factor (logistic regression, $p < 0.05$). The mean length of SE spread in the LM + group was significantly longer than

that in the control group. Furthermore, SE spread exceeding 5 mm was associated with an increased risk of LM + (OR = 15.077, p = 0.019, logistic regression).
Conclusions Larger lesion size and longer SE spread were risk factors of LM + . Therefore, these factors should be carefully considered during ESD.

eP258 Endoscopist Detection Skill Drives Neoplasia Yield in IBD Surveillance Colonoscopies

Authors Kek L[1], Broderick B[1], Harmsen WS[1], Ebner D[1], Coelho-Prabhu N[2]
Institutes 1 Mayo Clinic, Rochester, United States of America; 2 Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States of America
DOI 10.1055/s-0046-1821585
Aims Patients with inflammatory bowel disease (IBD) have a higher risk of dysplasia/neoplasia, requiring intensified surveillance colonoscopies. Colitis associated neoplasia (CAN) has flatter morphology, making it harder-to-detect. Serrated adenomas in routine screening colonoscopy have similar flat morphology. How neoplasia detection rates during IBD surveillance exams change based on baseline average risk colonoscopy performance is not known. Also, while there are well defined quality metrics for adenoma detection rate (ADR) and sessile serrated lesion detection rate (SSDR) in non-IBD colonoscopy, these metrics do not exist in IBD surveillance. We hypothesized that endoscopists with higher non-IBD SSDR have higher ADR and SSDR in IBD surveillance colonoscopies, while maintaining the same ADR trend. Thus, we have conducted a retrospective study to investigate baseline ADR and SSDRs compared to adenoma and serrated lesions detection rates during IBD surveillance colonoscopy.
Methods We performed a retrospective study of patients who underwent colonoscopy for an indication of IBD surveillance. A validated natural language processing (NLP) model was then used to report adenomas and sessile lesions found within pathology reports. The number of IBD surveillance colonoscopies per endoscopist was reviewed, and the top quartile, by procedure volume, was included for additional evaluation. Among this quartile, the baseline ADR and SSDR for average risk colonoscopies were calculated. To evaluate whether IBD ADR and SSDR varied across screening quartiles, we fit linear models with quartile as the predictor and diagnosis rate as the outcome. Overall significance was based on the likelihood ratio test and parameter estimates were examined to assess differences between quartiles.
Results Our study included 56 endoscopists and 5093 IBD surveillance colonoscopies performed between 2017-2023. Physicians in the top quartile were those performing greater than 24 IBD surveillance colonoscopies in this time period. There were significant differences in IBD ADRs among physicians when stratified by screening ADR quartiles (p-value < 0.0001). The ADR was 10 % among IBD surveillance colonoscopies for the lowest ADR quartile, and this rate was similar for the second and third quartiles. However, the diagnosis rate was 10 % higher for the fourth quartile of endoscopists when compared to the lowest quartile (p-value < 0.0001). The mean baseline non-IBD screening ADR was 37 % (SD 8.3) and the mean baseline screening SSDR was 13 % (SD 5.3 %). First quartile endoscopists had a baseline non-IBD ADR and SSDR of 27.2 % and 6.5 %, respectively. Fourth quartile endoscopists had a baseline non-IBD ADR and SSDR of 48.1 % and 20 %, respectively. Regarding SSDR in IBD surveillance, the differences in SSDR among IBD cases between the physicians based on screening ADR quartiles was significant (p-value < 0.001). SSDR in IBD cases was 3 % in first quartile physicians, similar to second and third quartiles. However, fourth quartile physicians had a higher rate of SSDR, 6 % higher than first quartile physicians (p-value 0.0003).
Conclusions Endoscopists with the highest screening ADR and SSDR also achieved significantly higher detection of adenomas and sessile serrated lesions during IBD surveillance. While lower quartiles showed similar performance, top quartile physicians detected 10 % more adenomas and 6 % more sessile lesions. Thus, these findings suggest that provider-level detection performance in screening colonoscopy meaningfully translates to IBD surveillance quality, given the improved detection of subtle, flat dysplasia typical of IBD.
Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP259 Establishing Reference Standards for Colorectal Polyp Size: Validation of Caliper Based Size Measurement

Authors Cristea E[1], Mahdadi MZ[1], Aleksieva P[1], Oleksiw M[1], Scavo L[1], Michal V[2], Djinbachian R[1], Battat R[1], Daoud DC[1], Bouchard S[1], Bouin M[1], Liu Chen Kiow J[1], Panzini B[1], von Renteln D[1]
Institutes 1 CHUM – Centre hospitalier de l'Université de Montréal, Montréal, Canada; 2 Research Center Du Chum ., Montréal, Canada
DOI 10.1055/s-0046-1821586
Aims Accurate measurement of resected colorectal polyps is essential for clinical management, research, and the development of artificial intelligence (AI)-based size estimation systems. Despite widespread use of caliper-based measurement for specimen sizing, formal validation against a reference standard is lacking. This study aimed to validate caliper-based measurement of resected colorectal polyps against high-resolution digital microscopy, a previously validated reference method [1–3].
Methods At the Centre hospitalier de l'Université de Montréal (CHUM), 143 polyps from 92 patients were measured immediately after resection using vernier digital calipers in the endoscopy suite. Independent measurements were subsequently obtained using high-resolution digital microscopy under blinded conditions. Agreement between methods was assessed using bias analysis, Bland-Altman limits of agreement, intraclass correlation coefficient (ICC), and categorical size concordance (▶ **Table 1**).

▶ **Table 1** Polyp characteristics, including location, morphology, and pathology. SSL, sessile serrated lesions.

Polyp characteristics (N = 143)	
Rectosigmoid, n (%)	46 (32.2 %)
Paris class, n (%)	
IIa	12 (8.4 %)
IIc	2 (1.4 %)
Ip	2 (1.4 %)
Is	125 (87.4 %)
Isp	2 (1.4 %)
Pathology, n (%)	
Adenoma / Neoplastic	93 (65.0 %)
Hyperplastic	29 (20.3 %)
Missing	2 (1.4 %)
SSL	3 (2.1 %)
Other	16 (11.2 %)

Results Caliper-based measurements demonstrated a mean bias of –0.22 mm (95 % CI: –0.34 to –0.11; $p < 0.001$) relative to the reference standard. The non-inferiority hypothesis with a 0.5 mm margin was not rejected (lower 95 % CI > –0.5 mm). Bland-Altman's limits of agreement were –1.57 to 1.12 mm, and the ICC was 0.88 (95 % CI: 0.82–0.92). Correct categorical classification occurred in 94.4 % of cases (95 % CI: 0.89–0.97; $\kappa = 0.81$).
Conclusions Caliper-based measurement provides accurate and reproducible estimates of polyp size when compared with digital microscopy, supporting its use for clinical and research applications requiring direct specimen measurement.

DOI 10.1055/s-0046-1821587

Abstract Text

A woman in her seventies was diagnosed with submucosal tumor on the lesser curvature of lower gastric body. The lesion increased in size and was histologically diagnosed as a gastrointestinal stromal tumor (GIST). Therefore, Endoscopic full thickness resection was performed using a scissor-type knife under general anesthesia. After the en block resection, the gastric defect was closed by Reopenable clip over-the-line method. The total procedure time was 67 min. The patient discharged uneventfully. Histological examination confirmed a low-risk GIST with free resection margin. Scissor-type knives are useful for safe and efficient procedures. They allow secure tissue grasping and soft coagulation, reducing device exchanges and bleeding risk. Their familiar grasp-and-cut mechanics also help lift the lesion away from surrounding tissue, minimizing injury [1, 2].

eP261V Simultaneous endoscopic ultrasound– and endoscopic retrograde cholangiopancreatography–related procedures using a novel flexible convex echoendoscope

Authors Matsubara S[1], Sunada R[1], Arai T[1], Nakagawa K[1], Murakami N[1], Ikeda M[1], Kuraoka N[1]
Institute 1 Saitama Medical Center, Saitama Medical University, Kawagoe, Japan
DOI 10.1055/s-0046-1821588

Problem to solve Situations requiring both endoscopic ultrasound (EUS)– and endoscopic retrograde cholangiopancreatography (ERCP)–related procedures are common in patients with biliopancreatic diseases. To minimize patient burden and hospital stay, these procedures are often performed sequentially in a single session, necessitating scope exchange between an echoendoscope and a duodenoscope. However, scope exchange increases procedure time, patient discomfort, infection risk, and reprocessing costs. Although Rocca et al. reported common bile duct stone cases underwent simultaneous EUS observation and ERCP using a radial echoduodenoscope [1], no reports have described performing both EUS– and ERCP–related procedures with a single echoendoscope. De Angelis et al. developed a convex echoendoscope enabling such combined procedures, but it never reached commercialization due to issues related to multidrug-resistant organisms [2].

Innovation The recently released oblique viewing convex echoendoscope (EG-740UT; Fujifilm, Tokyo, Japan) offers improved flexibility, wider angulation, an increased elevator angle, wider diameter of accessory channel, and an expanded optical field of view compared with conventional echoendoscopes. In addition, because the channel outlet exits on the distal and lower side of the optical lens, catheters can be more easily directed along the axis of the bile duct. These features enable the performance of ERCP. We report a retrospective study including consecutive patients underwent simultaneous EUS– and ERCP–related procedures using EG-740UT between August 2024 and November 2025 (▶ **Table 1**).

▶ **Table 1** Comparison of echoendoscope specifications

	Conventional scope	Novel scope
Scope model	GF-UCT260	EG-740UT
Manufacturer	Olympus	Fujifilm
Filed of view	100°	**140°**
Bending capacity		
Up/Down	130°/90°	**150°/100°**
Right/Left	90°/90°	**100°/100°**
Working channel	3.7 mm	**4.0 mm**

Results A total 17 patients (median 74 y/o [IQR:62-81]; 53 % male; 76 % native papilla) underwent combined EUS– and ERCP–related procedures for following indications: suspected malignant biliary obstruction (n = 13), suspected autoimmune pancreatitis with biliary stricture (n = 2), gallstone-related cholangitis with liver abscess (n = 1), and suspected choledocholithiasis (n = 1). EUS–related procedures included tissue acquisition (n = 12), hepaticogastrostomy (n = 3), abscess drainage (n = 1), and observation (n = 2). All ERCP–related procedures were performed for biliary indications. Biliary cannulation was successful in 14 (82 %) patients in median 8 minutes (IQR: 6-14.5). ERCP–related procedures in successful cases included sphincterotomy (n = 11), plastic stent placement (n = 9), metal stent placement (n = 5), brush cytology (n = 2), and forceps biopsy (n = 1, with median procedural time 28 minutes (IQR: 21.75-37). In the three cases of failed biliary cannulation, duodenoscope exchange led to successful cannulation in two cases, whereas one case required conversion to hepaticogastrostomy due to duodenal invasion. Adverse events developed in two patients (one case each of pancreatitis and cholecystitis), but none were considered specific to this combined procedure.

Conclusions Combined EUS– and ERCP–related procedures using EG-740UT was feasible. It may reduce procedure time, patient discomfort, infection risk, and reprocessing costs. Furthermore, in cases where ERCP is absolutely impossible—such as those with duodenal invasion—the procedure can be converted to a transluminal drainage approach without the need to change the endoscope, which represents an additional advantage. Further prospective studies are warranted.

Aims Previous studies have shown that patients with gastroesophageal reflux disease (GERD) have slower rates of gastric emptying than controls. However, the involvement of delayed gastric emptying (DGE) in the pathophysiology of gastro-esophageal reflux disease (GERD) remains debatable. The aim of this study was to investigate if treatment with prokinetics in addition to proton pump inhibitor (PPI) therapy improves clinical symptoms in dyspeptic GERD patients with or without DGE [1].

Methods Thirty consecutive patients refractory to PPI over a six-month period were included in the study. Gastric emptying scintigraphy was employed to determine DGE, which was designated when gastric emptying time (T1/2) was > 70 min. Patients were divided according to the presence of dyspepsia into the dyspeptic group (n = 12) and non-dyspeptic group (n = 18). In addition to esomeprazole (40 mg), mosapride citrate was administered to patients for 4 weeks. Symptoms were evaluated using a standardized questionnaire before and after treatment.

Results There was no statistical difference in age and sex between the dyspeptic group and the non-dyspeptic group (P = 0.92 and P = 0.23, respectively). Prevalence of esophagitis was similar between the dyspeptic and non-dyspeptic groups (58 % vs 39 %, P = 0.31). DEG was detected in 75 % of subjects in the dyspeptic group; while 28 % subjects in the non-dyspeptic group (P = 0.01) displayed DEG. Improvement in symptoms was greater in the dyspeptic group than that in the non-dyspeptic group (75 % vs 33 %, P = 0.02).

Conclusions Gastric emptying in dyspeptic patients with GERD is significantly slower than in non-dyspeptic patients regardless of esophagitis. Combination therapy with prokinetics in addition to PPI improves typical GERD symptoms in dyspeptic patients with GERD.

Aims This study aims to evaluate the safety,efficacy, and learning curve of SSD in colonicpolypectomy, particularly amongendoscopists new to ESD techniques.

Methods A retrospective multicenter study wasconducted, analyzing data from 36 patientswho underwent colonic polypectomy usingSSD at three hospitals in Thailand betweenMarch 2023 and September 2024 (▶ **Table 1**).

▶ **Table 1** Summary of result

Pateint demographics	Number	36
	Mean age (years)	65.8
	Gender (Male/Females)	13 (36.1 %)/ 23 (63.9 %)
Polyp Characteristics	Total Polyps Removed	40
	Mean Size (cm)	2.7 (range: 1.3–6.0)
	Large polyps (> 3 cm)	11/40 (27.5 %)
Procedural details	Mean Procedure Time (min)	116.8 (range: 25–360)
	Mean Procedure Time (min),Large vs. Small Polyps(> 3 cm vs. ≤ 3 cm)	157.5 vs. 96.4 (p = 0.185)
Safety & Outcomes	Complete Resection	39 cases (97.5 %)
	Perforation	0 case
	Bleeding	2 cases, mild bleeding (5.6 %)

Procedures were performed by threetrained endoscopists, each initially trainedon live porcine models under expertsupervision, followed by supervised clinicalprocedures before performingindependently.

Results Of the 40 resected polyps,50 % (20/40) were located in the sigmoid region, and 20 %(8/40) were rectal polyps. 7(17.5 %) were adenocarcinoma,16 (40 %) high-grade adenomas, 14 (35 %) low-grade adenomas,and 3 (7.5 %) sessile serrated lesions 39 (97.5 %) polyp has complete resection without perforation 2 (5.6 %) care have a minor bleeding

Conclusions - High Efficacy & Safety: SSD achieved a97.5 % complete resection rate with noperforations and only 5.6 % (2 cases) of mildbleeding, managed conservatively.

- Procedure Time: Mean procedureduration was 116.8 minutes, with nosignificant difference between larger (> 3cm) and smaller (≤ 3 cm) polyps (157.5 minvs. 96.4 min, p = 0.185).
- Clinical Impact: SSD simplifies ESD,making it a promising tool for broaderclinical adoption, particularly for noviceendoscopists.

eP264 Profile of CA19-9 according to endosonographic phenotypes of pancreatic tumors: a monocentric observational study

Authors bendada F[1], Lagdali N[2], Kadiri M[1], Ajana FZ[2], Borahma M[3]
Institutes **1** مستشفى ابن سينا, Rabat, Morocco; **2** Mohammed V University, Rabat, Morocco; **3** Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco
DOI 10.1055/s-0046-1821591

Aims CA19-9 remains the most widely used serum biomarker for the assessment of pancreatic tumors, particularly pancreatic ductal adenocarcinoma (PDAC). Its levels are influenced by tumor burden, cholestasis, inflammation and secretor status, which limits its diagnostic specificity. Meanwhile, endoscopic ultrasound (EUS) provides unmatched accuracy for characterizing pan-

creatic masses, allowing detailed assessment of tumor size, echostructure, necrosis, vascular invasion and ductal dilatation. However, the relationship between CA19-9 levels and EUS tumor phenotypes remains poorly defined. Understanding this association may help refine diagnostic performance and improve prognostic stratification. The objective of this study was to evaluate the relationship between CA19-9 and the endosonographic characteristics of both primary and metastatic pancreatic tumors in a real-life cohort.

Methods We conducted a monocentric, retrospective observational study including all patients who underwent EUS for suspicion of a pancreatic mass between 2023 and 2025. Clinical data included age, sex, comorbidities and risk factors. EUS variables included tumor location (head/body/tail), maximal diameter, shape, echostructure (homogeneous/heterogeneous), echogenicity, presence of necrosis, vascular infiltration, Wirsung duct dilatation and biliary dilatation. Serum CA19-9 levels were collected at the time of diagnosis. Histology and metastatic status were retrieved when available.

Results Among the 81 patients, 43 had a fully analysable CA19-9 value and documented metastatic status. Of these, 18 (42 %) had metastatic disease and 25 (58 %) had localized tumors. Tumors were predominantly located in the pancreatic head. Tumor size ranged from small focal lesions to large infiltrative masses.

CA19-9 levels showed very high variability across patients (range: 2 to 12,000 U/mL). Median CA19-9 did not differ significantly between metastatic and non-metastatic tumors ($p = 0.57$), reflecting both biological heterogeneity and the confounding effect of biliary obstruction, which was common in tumors of the pancreatic head.

A positive trend was observed between tumor size and CA19-9, although not statistically significant. Tumors with heterogeneous echostructure, intra-tumoral necrosis or vascular infiltration showed higher median CA19-9 levels compared to homogeneous, non-necrotic or non-infiltrative lesions, although again without statistical significance. Tumors located in the pancreatic head displayed the highest CA19-9 levels, likely due to associated cholestasis.

Non-adenocarcinoma tumors (notably neuroendocrine tumors) exhibited very low CA19-9 values, consistent with the known poor sensitivity of the marker in these subtypes.

Taken together, these results illustrate the complex interplay between tumor biology, local aggressiveness assessed by EUS, and CA19-9 expression. They also highlight the limitations of relying solely on CA19-9 for diagnostic or prognostic evaluation, particularly in the presence of biliary obstruction.

Conclusions In this cohort, CA19-9 levels did not significantly differ between metastatic and non-metastatic pancreatic tumors, but tended to increase in lesions with more aggressive EUS features, including larger size, heterogeneous echostructure, tumor necrosis and vascular infiltration. While CA19-9 remains an imperfect biomarker, its interpretation in conjunction with detailed EUS morphology may enhance diagnostic accuracy and help refine therapeutic decision-making. A larger, prospective multicentric study is warranted to confirm these findings and develop combined EUS–CA19-9 predictive models.

eP265 Time-Dependent Tissue Response After CO_2-Based Cryoablation Using a Prototype Needle in a Porcine Survival Model

Authors han SY[1], Lee J[2], Son H[3], Kim D[3], Kim G[3]
Institutes **1** Pusan National University Hospital, Busan, Republic of Korea; **2** Department of Internal Medicine, Pusan National University Hospital, Busan, Republic of Korea; **3** UNIST | Ulsan National Institute of Science & Technology, Ulsan, Republic of Korea
DOI 10.1055/s-0046-1821592

Aims To evaluate the time-dependent tissue response to CO_2-based cryoablation using a prototype cryoneedle—currently under development for EUS-guided pancreatic cancer therapy—by analyzing histologic changes in a porcine liver model. The goal was to determine whether the ablation boundary shows regeneration or evolves into fibrosis and sustained cellular destruction over several days.

Methods A custom-designed CO_2-driven prototype cryo-needle developed for future EUS-guided pancreatic tumor ablation was tested in porcine liver. Cryoablation was performed laparoscopically at two liver sites per animal using the following protocol:

Rapid cooling: temperature reaching **−60 °C within ~30 seconds**
Active freeze: 200–240 seconds of continuous cooling, maintaining **−50 to −60 °C** at the needle surface and **−5 to −15 °C** at 3–4 mm from the needle
Thaw phase: passive rewarming for ~60 seconds

Three pigs were sacrificed at **4 hours**, **5 days**, and **7 days**. Liver tissues underwent macroscopic inspection and microscopic evaluation (H&E, trichrome) to characterize necrosis, boundary-zone evolution, and fibrosis.

Results Laparoscopic cryoablation produced consistent ablation zones comparable to prior open procedures.

At 4 hours, clear coagulative necrosis was identified.
At 5 and 7 days, cryo-injured hepatocytes showed **progressive, time-dependent loss of viability**, accompanied by fibroblast proliferation, granulation tissue, and collagen deposition.Fibrotic changes extended beyond the necrotic core, indicating ongoing biologic injury rather than passive recovery.

Conclusions The prototype CO_2 cryo-needle, developed for eventual EUS-guided pancreatic cancer treatment, induces predictable acute necrosis followed by **sustained cellular destruction and progressive peri-ablational fibrosis** in porcine liver tissue. These findings demonstrate that cryoablation elicits a dynamic remodeling response and support continued optimization and miniaturization of the device for pancreatic cancer therapy.

eP266 Ambulatory endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) with early discharge: a safety evaluation in selected outpatients

Authors Stefani Donati D[1], Gambaccini D[1], Natali V[1], Venturini A[1], Tapete G[1], Bolognesi V[1], Visaggi P[1], Pancetti A[1], Marciano E[1]
Institute **1** Digestive Endoscopy Unit, Azienda Ospedaliera Universitaria Pisana, Ospedale Nuovo Santa Chiara, Pisa, Italy
DOI 10.1055/s-0046-1821593

Aims EUS-guided fine-needle biopsy (EUS-FNB) is essential for diagnosing pancreatic lesions, but evidence on its safety in a fully ambulatory setting with very early discharge is limited. We assessed the safety and feasibility of EUS-FNB in outpatients discharged after brief observation [1–4].

Methods Single-centre retrospective study of consecutive ASA I–II outpatients undergoing EUS-FNB for solid pancreatic lesions between 2024 and 2025. Procedures were performed with anesthesiology assistance using propofol, spontaneous breathing and continuous monitoring. After the procedure, patients were observed for 2 hours and discharged if fit according to the Post-Anesthetic Discharge Scoring System (PADSS). Patients were contacted by telephone at 48 hours to assess post-procedural symptoms and unplanned healthcare use. The primary endpoint was successful early discharge after 2 hours with adequate PADSS. Secondary endpoints were emergency department (ED) visits within 48 hours and major procedure-related adverse events (pancreatitis, clinically relevant bleeding, perforation).

Results One hundred ninety-five patients were included. All procedures were completed, and all patients achieved an adequate PADSS score allowing discharge after 2 hours (primary endpoint met in 100 % of cases). Within 48 hours, 3/195 patients (1.5 %) accessed the ED: two for severe abdominal pain (one requiring opioid analgesia) and one for fever with leukocytosis. Imaging excluded EUS-FNB-related complications in all cases, and no major adverse events occurred (0 %).

Conclusions Ambulatory EUS-FNB with anesthesiologist-guided propofol sedation and a standardised 2-hour observation period appears safe and feasible in carefully selected ASA I–II outpatients. This pathway may reduce hos-

pital bed occupancy and workload and accelerate diagnostic work-up for pancreatic diseases.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP267 Food Bolus Impaction and Eosinophilic Esophagitis: A Retrospective Analysis of Endoscopic Management and Outcomes (2020-2025)

Authors Dube A[1], Dietrich C[2], Jakobs R[1]
Institutes **1** Klinikum der Stadt Ludwigshafen am Rhein gGmbH, Ludwigshafen am Rhein, Germany; **2** GRN-Klinik Sinsheim, Sinsheim, Germany

DOI 10.1055/s-0046-1821594

Aims In adults in Western countries, foreign body ingestion typically presents as esophageal food impaction (EFI), often associated with underlying esophageal pathology, that should be diagnosed [1, 2]. We retrospectively analyzed endoscopic management, techniques (push vs. pull), and outcomes of EFI. Special attention was given to the prevalence of eosinophilic esophagitis (EoE) and the role of mucosal biopsies in diagnosis and management.

Methods We conducted a retrospective analysis of EFI cases using the hospital endoscopy database (OPS code 8-100.6) from 01/2020–09/2025. Outcomes included EFI frequency, endoscopic techniques, complication rates (minor vs. major), prevalence of EoE, baseline characteristics, aspiration, 30-day mortality, and biopsy rates during index endoscopy or short-term follow-up.

Results Of 109 cases identified, 32 were excluded, leaving 77 for analysis. Patients were at 77.92 % male, mean age 63 years. Hospital admission occurred in 41.56 %, with 53.25 % discharged and 5.2 % treated during hospitalization. Endoscopic management used the push technique in 54.55 % and the pull technique in 41.56 %; in 11.69 %, the technique was unspecified. Overall complications occurred in 11.69 % (push 7.14 %, pull 15.625 %, with respect to the respective technique), aspiration in 2.6 %, and mortality was 1.3 %. Biopsies were performed in 66.23 %, revealing underlying EoE in 15.58 % of patients.

Conclusions Consistent with other data, we also showed that EFI predominantly affects adult men [3]. The push-technique, said to be the primary technique, was applied more frequently than the pull-technique [1, 2, 4]. Complication rates were higher than previously reported, slightly more frequent with pull [3]. Biopsies revealed EoE in a substantial proportion, underscoring their importance during index endoscopy when the underlying cause is unclear. Although the push-technique seems to be associated with less complications and therefore the primary technique, endoscopic management should be individualized based on patient condition and clinical context.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821595

Aims Although there is strong evidence that non-anesthesiologist-administered propofol (NAAP) sedation is safe, the Anesthesiology community remains reluctant to endorse such a practice. We aimed to evaluate the safety of NAAP in comparison to the anesthesia propofol provider (AP) published in recent literature.

Methods A systematic review was performed across MEDLINE and Cochrane Central Register for all types of trials evaluating the safety of NAAP compared to AP sedation in GI endoscopic procedures from 2019 to 2024 to pool the rates of adverse events (AEs) related to NAAP. The effect size on study outcomes is presented either as the event rate or as the Risk Ratio (RR) with 95 % confidence interval (CI). A sensitivity analysis was performed by 1) severity of AE (Major: endotracheal intubation, hospitalization, permanent neurologic impairment, or death. Non-major: transient oxygen saturation 75 %–90 %, transient apnea, transient airway obstruction, allergic reaction, failed sedation, bradycardia or tachycardia (> 25 % change from baseline), hypo- or hypertension (> 25 % change from baseline); 2) non-advanced (gastroscopy, colonoscopy) versus advanced procedures 3) Patients' low (I-II) or high (III) ASA classification. We assessed the quality of evidence using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

Results One RCT and eleven cohort studies were included. In low-risk (ASA I-II) outpatients undergoing non-advanced GI endoscopic procedures, the pooled rates of major and non-major AEs were 0.00 % [95 % CI (0-0.01 %); $I^2 = 0$ %] and 11.60 % [95 % CI (4.01-27.2 %); $I^2 = 100$ %], respectively; there was very low confidence in estimates. In low-risk patients undergoing advanced GI endoscopic procedures, the pooled rate of major AEs was 0.05 % [95 % (CI 0.01-0.10 %); $I^2 = 98$ %] and non-major AEs 14.74 % [95 % CI (6.28-35.77 %); $I^2 = 100$ %], respectively. The pooled rate of non-major respiratory AEs in patients undergoing both non-advanced and advanced gastrointestinal endoscopic procedures with NAAP sedation was deemed low [1.26 %, 95 % (CI 0.73-1.78 %); $I^2 = 100$ %, and 5.28 %, 95 % (CI 0.70-9.85 %); $I^2 = 100$ %, respectively]. Comparing NAAP vs. AP in one RCT and three cohort studies, including 21223 patients, there were 82 AEs in the NAAP group and 907 AEs in the control AP group. Regarding major adverse events, there was no significant difference between the two groups in low-risk patients undergoing advanced GI endoscopic procedures [OR 0.50, 95 % CI (0.07-3.59); $I^2 = 0$ %] and in low-risk patients undergoing non-advanced GI endoscopic procedures. In terms of non-major AEs, no significant difference was detected between NAAP and AP in advanced endoscopic and non-ad-

vanced procedures [OR 0.91, 95 % CI (0.54-1.52); I^2 = 5 % and OR 1.03, 95 % CI (0.79-1.36); I^2 = 0 %]. Interestingly, NAAP was not associated with a higher rate of endoscopy-related AEs compared to AP [OR 1.24; 95 % CI (0.59-2.61); I^2 = 0 %]. The certainty of evidence was very low.

Conclusions The rate of adverse events in patients undergoing GI endoscopic procedures with NAAP sedation is extremely low, regardless of the patients' ASA score and the invasiveness of the endoscopic procedure.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP269V Multifocal low grade dysplasia of the stomach-ESD removal with the method of 2 wings butterfly

Authors Malamatenios MA[1], Pelekanou Z[2], Thomaidis T[1]

Institutes **1** Athens Medical Center, Marousi, Greece; **2** Iatriko A, Marousi, Greece

DOI 10.1055/s-0046-1821596

Abstract Text

This video shows 2 cases of patients with extended multifocal low-grade dysplasia in the antrum with proximal extension. The lesions were removed en-block via ESD with the method of 2 wings butterfly. This technique involves the creation of two submucosal flaps bilaterally while preserving a central submucosal septum between the two flaps, creating a structure which resembles the body of a butterfly between its wings. The flaps are created in the anterior and posterior wall of the stomach, while gravity reveals the central submucosal septum. The incision is then advanced from the distal to the proximal end of the lesion. Aim of this method is to use the gravitational effect in order to accelerate the dissection of large gastric lesions [1–3].

eP270 Time for a change? Rethinking the Rutgeerts Score in Postoperative Crohn's Disease with SES-CD and MM-SES-CD

Authors Souto M[1, 2, 3], Ferreira AI[1, 2, 3], Macedo Silva V[1, 2, 3], Moreira MJ[1, 2, 3], Cotter J[2, 3, 1]

Institutes **1** Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal; **2** ICVS/3B's – PT Government Associate Laboratory, Braga/Guimarães, Portugal; **3** Gastroenterology Department, Unidade Local de Saúde do Alto Ave, Guimarães, Portugal

DOI 10.1055/s-0046-1821597

Aims Crohn's disease (CD) often recurs after ileocolic resection, requiring reliable endoscopic assessment. While the Rutgeerts score is standard, its limitations highlight the need for alternatives. Simplified Endoscopic Score for Crohn's Disease (SES-CD) and Modified Multiplier SES-CD (MM-SES-CD) assess both ileal and colonic disease, potentially providing a more comprehensive evaluation. This study evaluates their predictive value for postoperative disease progression compared to Rutgeerts score [1].

Methods Longitudinal study of consecutive CD patients undergoing ileocolonoscopy for postoperative surveillance. Receiver operating characteristic (ROC) curve analyses compared Rutgeerts, SES-CD, and MM-SES-CD scores for predicting disease progression within one year after ileocolonoscopy. Multivariate logistic regression assessed score cutoffs, adjusting for confounders. Disease progression was defined as a composite endpoint, including clinical recurrence (Harvey-Bradshaw Index ≥ 4), therapy intensification, CD-related hospitalization, endoscopic balloon dilation, or surgery.

Results A total of 81 patients (48 ± 13 years; 55.6 % female) with 128 ileocolonoscopies were included. Regarding Montreal classification, 37 (45.7 %) patients had ileal and 44 (54.3 %) ileocolonic disease; 9 (11.1 %) patients had nonstricturing, nonpenetrating disease, 35 (43.2 %) structuring and 37 (45.7 %) penetrating disease. Nineteen (23.5 %) had perianal disease. The mean time between surgery and ileocolonoscopy was 133 ± 83months.

Disease progression occurred in 44 (34.4 %) cases at one-year follow-up. Rutgeerts score demonstrated fair accuracy (AUC 0.73; 95 % CI 0.64-0.80), which was similar to SES-CD (AUC 0.72; 95 %CI 0.63-0.79) and MM-SES-CD (AUC 0.72; 95 %CI 0.63-0.80).

The optimal thresholds for predicting disease progression were SES-CD > 4 (sensitivity 70.45 %; specificity 69.05 %) and MM-SES- CD > 17 (sensitivity 59.09 %; specificity 77.38 %). However, comparing scores cutoffs, Rutgeerts score > 1 showed the highest odds ratio for disease progression (OR 9.02, 95 %CI 3.20-25.46, p < 0.001).

Conclusions Rutgeerts score, SES-CD, and MM-SES-CD demonstrated similar predictive accuracy for postoperative disease progression. However, the Rutgeerts score > 1 had the strongest predictive value, supporting its continued use while also suggesting that SES-CD and MM-SES-CD can serve as viable alternatives for monitoring postoperative recurrence.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP271 The Unaddressed Gap in EUS-FNB: A Structured Evidence Review and Research Framework for AI-Enhanced Targeting Accuracy

Author Dubrovin V[1]

Institute **1** Saint-Petersburg, Russia

DOI 10.1055/s-0046-1821598

Problem to solve Endoscopic ultrasound (EUS) with fine-needle biopsy (FNB) remains a cornerstone of morphological verification for subepithelial and pancreatobiliary lesions. However, diagnostic performance varies considerably depending on operator expertise, needle selection, and subjective image interpretation. Across studies published between 2018 and 2024, the sensitivity of EUS-FNB ranges from 68 % to 89 %, and the proportion of nondiagnostic samples reaches 10–25 %, particularly in small, fibrotic, or heterogeneous lesions.

Recent developments in artificial intelligence (AI)- including convolutional neural networks (CNN), radiomics, and automated texture analysis- have demonstrated promising results in improving reproducibility and reducing subjectivity in EUS interpretation. Existing AI-EUS studies show AUROC values between 0.86 and 0.95 for differentiating pancreatic mass types and identifying suspicious echotextural patterns. These advancements suggest that incorporating AI into EUS-guided sampling may enhance the precision and consistency of morphological diagnosis.

Innovation Based on the collected evidence, we propose the rationale for developing an AI-supported concept- EUS-Precision- aimed at improving the targeting strategy and morphological yield of EUS-FNB through automated pattern recognition and real-time decision guidance. This is not presented as a ready-to-use system, but as a justified direction derived from existing evidence.

Results The literature analysis revealed several consistent trends:

- AI-enhanced EUS image interpretation improves interobserver agreement and reduces variability in assessing echogenicity, margins, vascular patterns, and internal heterogeneity. CNN-based models in pancreatic lesion analysis demonstrate classification accuracies of 82-94 %, surpassing non-expert interpretation.
- Radiomic feature extraction provides quantitative descriptors (texture, entropy, wavelet-based metrics) associated with malignant transformation in pancreatic solid lesions and gastrointestinal subepithelial tumors. Some studies report radiomic AUROC values of 0.87-0.93 for differentiating GIST from benign mesenchymal lesions.
- Factors associated with nondiagnostic FNB samples include lesion size < 15 mm, necrotic/heterogeneous internal architecture, and suboptimal targeting. Up to 20-30 % of sampling errors occur due to inaccurate selection of the puncture zone rather than needle type.
- AI-supported guidance systems tested in simulation environments or retrospective datasets improve selection of optimal puncture trajectories, reducing simulated nondiagnostic sampling by 15-22 %.

These data collectively justify the feasibility of an AI-supported concept such as EUS-Precision, which would integrate:(1) automated echotexture recognition,(2) radiomic-based risk stratification,(3) real-time highlighting of potentially optimal biopsy targets, and(4) decision-support cues to minimize sampling errors.

Conclusions AI-enhanced EUS interpretation represents a promising direction for improving the diagnostic performance of EUS-guided tissue acquisition. Based on existing evidence, integrating automated echotexture analysis and radiomic markers may improve reproducibility, reduce nondiagnostic sample rates, and support more accurate morphological verification-especially in small or visually challenging lesions.

The conceptual framework of EUS-Precision aligns with ESGE priorities in digital endoscopy, standardization, and operator-independent diagnostic pathways. In the future, such systems may be incorporated into endoscopic workstations as real-time decision-support tools, enhancing diagnostic precision and offering an educational resource for early-career endoscopists.

eP272V Treatment of huge retroperitoneal abscess caused by duodenal perforation, endoscopy or surgery?

Authors Han S[1], Deliang L[2]

Institutes **1** The First Hospital of Hebei Medical University, Shijiazhuang, China; **2** Department of Gastroenterology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

DOI 10.1055/s-0046-1821599

Abstract Text

In the case of duodenal perforation complicated by retroperitoneal enveloping purulent cavity, full irrigation and closure of the wound under an endoscope can achieve a good therapeutic effect, with less trauma and faster recovery than surgery.

eP273 Patient Radiation Exposure During Fluoroscopy-Guided Gastrointestinal Endoscopic Procedures

Authors Berrada G[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2]

Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821600

Aims The use of ionizing radiation in interventional gastroenterology is essential for performing complex procedures such as endoscopic retrograde cholangiopancreatography (ERCP), endoscopic placement of digestive stents via esophagogastroduodenoscopy (EGD), and biliodigestive anastomosis or cystogastrostomy performed under endoscopic ultrasound (EUS) guidance. However, prolonged exposure to X-rays represents a non-negligible risk for both patients and operators.This study aimed to assess patient exposure to ionizing radiation during these procedures and to identify factors influencing radiation dose.

Methods We conducted a retrospective study of procedures requiring fluoroscopy—ERCP, digestive stent placement, EUS-guided biliodigestive anastomosis, and EUS-guided cystogastrostomy—performed between May 2023 and August 2024 in the Internal Medicine B Department. Collected data included demographic characteristics, indication for the procedure, procedure type, fluoroscopy time, reference-point air kerma (Ka,r, expressed in mGy), and clinical or technical variables potentially influencing radiation exposure.

Procedure complexity was assessed using an adapted scale inspired by classifications of the American Society for Gastrointestinal Endoscopy (ASGE). An analytical study was performed to evaluate risk factors using JAMOVI software.

Results A total of 146 procedures were analyzed: 129 ERCPs (88.4 %), 7 EUS-guided biliodigestive anastomoses (4.4 %), 6 digestive stent placements (4.1 %), and 4 EUS-guided cystogastrostomies (3.1 %).The cumulative radiation dose (Ka,r) ranged from **2.59 to 297 mGy**, with a **median of 64.5 mGy (36.9–124)**.

Median fluoroscopy time was **5 min 30 s (3 min 40 s – 9 min 17 s)**, and the median total procedure duration was **100 minutes (83–120)**.

ERCPs were associated with significantly higher radiation exposure compared to EUS- or EGD-related procedures, with median doses of: **65 mGy (37–123.74)** for ERCP, **57.7 mGy (45.7–65)** for EUS-guided procedures and **33.3 mGy (27.6–73.6)** for digestive stent placement via EGD.

ERCPs classified as **ASGE GRADE II** showed slightly higher radiation doses, with a median of **69.7 mGy (37.6–123.1)**.

In our analysis, **age** was the only factor significantly influencing the total duration of ERCP procedures. Radiation exposure varied significantly according to ERCP indication ($p = 0.023$; $p < 0.05$). Patients undergoing biliary drainage for **obstructive jaundice due to lithiasis or malignancy** received higher radiation doses.

Conclusions Assessment of ionizing radiation exposure in the interventional endoscopy suite demonstrates significant variation according to procedure type, indication, and technical factors. Procedure complexity plays a key role; however, more complex procedures did **not** result in significantly higher radiation exposure.A better understanding of risk factors for elevated radiation dose—such as body habitus or operator expertise—may help strengthen radiation-protection strategies and optimize patient safety.

eP274 Psychological Impact of Endoscopy Practice: Evaluation of Stress, Anxiety and Professional Satisfaction

Authors Berrada G[1], Cherkaoui Malki M[1], Mechhor S[1], Mghyly F[1], Cherkaoui Malki O[1], Nadia B[2], Errabih I[2], El Bacha H[2]

Institutes **1** CHU Ibn Sina, Rabat, Morocco; **2** Université Mohammed V de Rabat (Présidence Site Irfane), Rabat, Morocco

DOI 10.1055/s-0046-1821601

Aims Endoscopic practice is a demanding activity that may generate substantial stress among healthcare professionals due to the technical complexity of procedures, the associated cognitive load, and the high level of responsibility inherent to these interventions. This study aims to analyze the psychological impact of endoscopy by assessing several dimensions, including procedural stress, anticipatory anxiety, and professional satisfaction, in relation to individual and occupational characteristics of endoscopists.

Methods An observational study was conducted among healthcare professionals involved in endoscopic procedures. Data were collected using a structured questionnaire including demographic variables (age, sex, city, years of experience, practice of physical activity, caffeine consumption, smoking habits) and elements related to endoscopy workflow organization (number of staff in rotation, years of endoscopic experience).Stress and satisfaction were assessed using the New Job Stress Scale and the Job Satisfaction Score, adapted to endoscopic practice. The questionnaire consisted of multiple items rated on a 1-to-5 Likert scale (1 = strongly disagree, 5 = strongly agree), and scores were summed. Higher scores reflected greater levels of work-related stress or job satisfaction.

Results Preliminary results included 27 participants: 22 residents, 3 professors/attending physicians, and 2 nurses, with respective endoscopic experience of 1 year (0–2 years), 5 years (4.5–5.5 years), and 1 year and 7 months (11 months–2 years and 3 months). A total of 48.1 % of participants were aged between 25 and 31 years.On a 1-to-10 scale, procedural stress had a median value of 6.5 (3–9) among residents, 9 (7–9.5) among professors/attending physicians, and 6 (5.5–6.5) among nurses. Anticipatory anxiety scores were 6 (5–9.75), 7 (4.5–8.5), and 5, respectively. Technical proficiency at the end of training was self-rated at 6 (1–7) out of 10.According to the New Job Stress Scale, the "work overload" section had a mean score of 15.1 ± 7.7 out of 30, the "ambiguity with healthcare personnel" section a score of 14.4 ± 5.8 out of 20, and the "professional relationships and support" section a score of 9.1 ± 4.1 out of 20.The Job Satisfaction Score showed an overall mean satisfaction of 8.67 ± 3.81 out of 15, and satisfaction regarding the work environment was 7.67 ± 3.14 out of 15.

Conclusions This study highlights the psychological impact of endoscopic practice, with varying degrees of stress and satisfaction according to professional status, experience, and working conditions. These findings emphasize the importance of optimizing organizational strategies to improve practitioners' well-being and enhance the acquisition of endoscopic skills. Better stress management within endoscopic practice may contribute to increased professional satisfaction and ultimately improve the quality of patient care.

eP275V Dysplastic lesions of the duodenum: Removal via ESD

Authors Malamatenios MA[1], Spiliadi C[1], Zografos K[1], Pelekanou Z[2], Thomaidis T[1]

Institutes **1** Athens Medical Center, Marousi, Greece; **2** Iatriko A, Marousi, Greece

DOI 10.1055/s-0046-1821602

Abstract Text

We present two cases involving 50- and 75-year-old patients with large dysplastic lesions (40 mm and 50 mm) located in the second portion of the duodenum. Histology showed low-grade dysplasia with focal high-grade areas in the first case and predominant high-grade dysplasia in the second. Both lesions were situated near, but not involving, the ampulla of Vater, with a safety distance of more than 10 mm. En bloc resection was achieved using endoscopic submucosal dissection (ESD). Traction was applied in one case to clarify the cutting plane. The mucosal defects were successfully closed with a combination of the zipper-closure technique and the clip-and-string method. Both patients were discharged on postoperative day two. Follow-up endoscopy at three months showed no residual or recurrent lesions [1–3].

Abstract Text

Endoscopic mucosal incision and decompression appears to be a safe and effective treatment for submucosal hematomas of the esophagus and stomach. This technique can rapidly relieve retrosternal pain, prevent dysphagia caused by luminal compression, and reduce the risk of mucosal ischemia, necrosis, and related complications.

eP277 Predictive Factors of Failure of Common Bile Duct Clearance in Patients with Bile Duct Stones Without Cholangitis

Author Vora K[1]

Institute **1** Govind Ballabh Pant Hospital, New Delhi, India

DOI 10.1055/s-0046-1821604

Aims To identify the predictors of failed CBD stone clearance without cholangitis during ERCP

Methods retrospective analysis of patients who underwent ERCP for CBD stone clearance at a tertiary care centre in New Delhi between January 2023 and July 2023. Univariate and multivariate analyses were performed to identify predictors of CBD stone clearance (▶ **Table 1**).

▶ **Table 1** Univariate analysis on predictors of CBD Clearance

(A) Baseline Lab parameters				
S. No	**Parameters**	**Not cleared (66)**	**Cleared (179)**	**P value**
1	Hb (g/dL)	11.9 (10.5-12.97)	11.9 (10.9-12.7)	0.83
3	Platelets (cells × 10^5/mm^3)	2.3 (1.63-2.87)	2.3 (1.7-3.0)	0.59
4	Total Bilirubin (mg/dl)	0.9 (0.5-2.05)	0.7 (0.5-1.3)	0.076
5	ALT (IU/L)	34 (20-94)	42 (23-83)	0.28
6	AST (IU/L)	38.5 (27-75.5)	41 (26-78)	0.97
7	ALP (IU/L)	188 (129-346)	180 (127-312)	0.86
8	CBD Diameter > 15mm	13(19.7 %)	19 (10.6 %)	0.06
9	CBD Diameter in mm	11.93 ± 4.57	10.68 ± 3.41	**0.02**
10	Stone No (> 3)	3 (4.5 %)	12(6.7 %)	0.52
11	Stone Size > 12 mm	16 (24.2 %)	16 (8.9 %)	**0.001**
12	Stone Size in mm	9.97 ± 4.90	7.73 ± 3.36	**0.0001**
13	Location of stone (proximal)	12 (18.2 %)	18 (10.1 %)	**0.57**
14	PAD	6 (9.1 %)	17 (9.5 %)	0.94
15	Bulky Papilla	6 (9.1 %)	5 (2.8 %)	**0.03**
16	Difficult cannulation	16 (24.2 %)	14 (7.8 %)	**0.001**
17	CBD Diameter > 15mm	9 (13.6 %)	20 (11.2 %)	0.10
18	CBD Diameter in mm	13.11 ± 5.10	11.72 ± 3.34	**0.02**
19	Stone No (> 3)	3 (4.5 %)	19 (10.6 %)	0.51
20	Stone Size in mm	13.77 ± 6.03	8.93 ± 3.89	**0.0001**
21	Location of stone (proximal)	8 (12.1 %)	18 (10.05 %)	**0.02**
22	CBD stricture	4 (6.1 %)	3 (1.6 %)	0.06
23	Hepatolithiasis	8 (12.1 %)	10 (5.6 %)	0.08
24	Impacted stone	16 (24.2 %)	5 (2.8 %)	**0.0001**
25	Use of a Basket for Extraction	1 (1.5 %)	3 (1.7 %)	0.94

Results A total of 245 patients were included in the analysis. Successful clearance was achieved in 73.06 % of the cases. Univariate analysis revealed that abdominal pain, CBD diameter, stone size > 12 mm, and stone size/CBD diameter > 1 on magnetic resonance cholangiopancreatography (MRCP) were significantly associated with failed clearance. Endoscopic and cholangiographic parameters, such as bulky papilla, difficult cannulation, CBD diameter, stone size > 12 mm, middle location of the stone, stone size/CBD diameter > 1, impacted stone, and CBD stricture, were also significantly associated with failed clearance. On multivariate analysis, middle stone location (odds ratio [OR] 4.44; 95 % CI, 1.67-11.75), stone size/CBD diameter > 1 (OR 5.22; 95 % CI, 1.14-23.78), CBD stricture (OR 5.06; 95 % CI, 1.006-25.52), and impacted stone (OR 9.33; 95 % CI, 2.17-39.99) were identified as independent predictors of failed CBD clearance [1–7].

Conclusions dentifying these predictive factors may help stratify patients for appropriate advanced management strategies, such as cholangioscopy-assisted extraction, electrohydraulic lithotripsy, or surgical management.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP278 Digital Decision Support in Acute Gastrointestinal Bleeding: Addressing Clinical Variability and the Need for a Standardized Care Pathway

Author Dubrovin V[1]
Institute 1 Saint-Petersburg, Russia
DOI 10.1055/s-0046-1821605

Problem to solve

Acute gastrointestinal bleeding (GIB) requires rapid risk stratification, timely intervention decisions, and accurate triage. Despite validated risk scores (Rockall, Glasgow-Blatchford), substantial variability in clinical decision-making persists. CDSS interest is growing, yet no unified approach integrates prognostic models, endoscopic findings, and clinical parameters.

Key gaps include:

- variability in therapeutic decisions across experience levels;
- limited calibration of scores in high-risk patients;
- absence of a standardized early triage and management pathway;
- limited integration of guideline-based recommendations into routine workflow.

Innovation

A literature review (PubMed, Embase, Scopus; 2018-2025) assessed:

- prognostic value of Rockall and GBS for rebleeding, mortality, and urgent intervention;
- management algorithms for non-variceal GIB;
- existing digital tools and CDSS components;
- factors driving decision-making variability.

Non-clinical, low-quality, and non-representative studies were excluded.The review highlights the potential of digital CDSS to integrate clinical, laboratory, and endoscopic parameters into a structured and standardized decision pathway.

Results 1. Risk score performance.

- GBS shows high sensitivity for identifying low-risk patients (GBS 0-1 = minimal adverse event risk).
- Rockall score offers acceptable accuracy for rebleeding prediction (AUC ≈ 0.73) but is less reliable for mortality.
- Both tools insufficiently incorporate real-time endoscopy and dynamic hemodynamics.

2. Clinical gaps.

- large decision variability;
- weak calibration in high-risk groups;
- lack of unified triage pathway;
- limited incorporation of guidelines into workflow.

3. Potential of digital CDSS.

CDSS studies show improved structure of clinical decisions, better adherence to recommendations, greater consistency across clinicians, and reduced assessment time.No validated GIB-specific digital model currently integrates endoscopic, clinical, and dynamic parameters.

Conclusions Rockall and GBS remain important but fail to incorporate endoscopic stigmata and dynamic patient changes. Persistent gaps – decision variability, absence of standardized triage, and limited implementation of guidelines – underline the need for updated digital solutions.

Digital CDSS represent a promising direction for standardizing GIB management. The literature supports developing multifactorial algorithms that combine laboratory, clinical, and endoscopic data.

Future Directions.

Future work should focus on developing and validating digital CDSS, including web-based and EMR-integrated tools, capable of real-time adaptation and reducing clinician variability. Integration within the ESGE framework could support the creation of a unified standardized pathway for GIB management.

eP279V A mass in rectum

Authors Han S[1], Deliang L[2]
Institutes 1 The First Hospital of Hebei Medical University, Shijiazhuang, China; 2 Department of Gastroenterology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China
DOI 10.1055/s-0046-1821606

Abstract Text

This case presents an 18-year-old male patient with a complex five-year history of intermittent rectal bleeding, marked by recurrent symptoms and mutiple failed surgical interventions, culminating in a diagnosis of Mucosal Prolapse Syndrome (MPS) following the exclusion of other potential benign and malignant pathologies.

The patient ultimately underwent underwater endoscopic mucosal resection (UEMR) was successfully cured. UEMR enables rapid and precise mucosal resection while significantly minimizing electrical injury, thereby safeguarding adjacent tissues and effectively mitigating the risk of complications such as delayed bleeding or stricture formation.

The patient's postoperative recovery was uneventful, with no recurrence of symptoms at three-month and six-month follow-ups.

eP280 Cystotome use for impassable biliopancreatic strictures: efficacy and safety — Systematic review and single center case series

Authors Marcellier G[1], Edery N[1], Pratico C[1], Jais B[1], Berson A[1], Maire F[1], Rivallin P[1], Prat F[1]
Institute 1 Hospital Beaujon AP-HP, Clichy, France
DOI 10.1055/s-0046-1821607

Aims Most biliary or pancreatic duct strictures can be passed with a guidewire but a subset of especially tight ones remain impassable by standard dilation devices. Alternative techniques, such as drilling into the stricture, may be needed in such instances. Data on the efficacy and safety of this rescue technique are scarce. We conducted a systematic literature review complemented by our single-center experience using a 6Fr electrocautery device for "impassable" biliopancreatic strictures.

Methods A systematic review of PubMed, Embase, Google Scholar, and Cochrane library was performed, including studies using a cystotome for biliary or pancreatic strictures that could not be dilated with standard accessories. Alternative devices (e.g., Soehendra stent retriever) were excluded. Primary outcomes was the combination of technical success (ability to traverse the stricture and deploy a stent) and safety (absence of procedure-related adverse event). Clinical success (short- and long-term) were collected if available. Our review was supplemented with cases performed at Beaujon Hospital (Clichy, France) from 2020 to 2025.

Results A total of 99 patients were included (90 patients from 9 studies and 9 from our center). The primary composite outcome, combining technical success and safety, was achieved in 90 % of patients. Technical success, allowing stent insertion in the desired position, was 100 % (99/99). Clinical success was achieved in 94 % (81/86).

Adverse events occurred in 10 % of patients (11/99). All complications were considered mild or moderate, with no case of perforation or severe (Clavien-Dindo grade ≥ 3) adverse event observed. Four Patients (4 %) had papillary bleeding following ERCP (including one during sphincterotomy, before the use of the cystotome in our cohort and without information for the others), three patients (3 %) had mild pancreatitis developed after a pancreatic ERCP. One patient (1 %) had a cholangitis. One study included transient abdominal pain as an adverse event and reported 3 cases without documented pancreatitis.

Endoscopy 2026; 58: S1–S1041

Conclusions Cystotome-assisted electrosurgical drilling appears to be technically reliable and effective for complex biliopancreatic strictures that are resistant to standard dilation. This comprehensive study could encourage to integrate the cystotome in the endoscopists' ERCP toolbox.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP281 Advanced Endoscopic Solutions for Foreign Body Extraction in the Pancreatobiliary System: Eliminating the Need for Surgical Intervention

Authors Tishkov I[1], Boeva I[1], Kerezova Z[1], Stoichkov Y[1]
Institute **1** University Hospital Sofiamed, Sofia, Bulgaria
DOI 10.1055/s-0046-1821608

Aims The retrieval of complex foreign bodies lodged deep within the pancreatic and biliary ducts (PBDs) often constitutes a high-risk procedure, frequently necessitating surgical intervention when conventional methods fail. The primary aim of this case presentation is to validate and demonstrate the decisive therapeutic benefit and safety profile of cholangioscopy/pancreatoscopy-assisted ERCP for the extraction of highly challenging, proximally migrated foreign objects. This work supports the establishment of advanced endoscopic techniques as the definitive, non-surgical first-line treatment in specialized endoscopy centers [1–3].

Methods We present two illustrative clinical cases requiring advanced endoscopic visualization and retrieval:

Case 1 (Pancreatic Duct: A female patient presented with right upper quadrant pain indicating complications from a proximally migrated prophylactic pancreatic stent, which had moved deep into the pancreatic tail. Due to the deep position and technical challenges of the migrated stent, the extraction required direct visualization via SpyGlass Pancreatoscopy. The retrieval was successfully accomplished using SpyBite Biopsy Forceps under real-time endoscopic guidance, as standard techniques were rendered ineffective.

Case 2 (Biliary Duct): A complex case involving a patient with a history of complicated open cholecystectomy. The patient suffered from recurrent, severe episodes of cholangitis and associated symptoms. Imaging confirmed the presence of an inadvertent surgical foreign body—a protective drainage tube—which had been retained within the Ductus Choledochus (common bile duct). Definitive management was achieved via ERCP guided by SpyGlass Cholangioscopy, allowing for the precise targeting and safe removal of the intra-choledochal drain.

Both procedures were performed to eliminate the necessity for high-morbidity surgical exploration.

Results The endoscopic procedures achieved a 100 % technical success rate for the complete retrieval of both complex foreign bodies. Crucially, both patients successfully avoided major surgery, demonstrating the profound clinical impact of the technology. Both individuals were managed minimally invasively, leading to rapid recovery and discharge within 48 hours without major post-ERCP complications.

Conclusions The successful management of a deeply migrated pancreatic stent and a surgically retained biliary drain, both previously challenging indications, underscores the decisive role of cholangioscopy/pancreatoscopy-assisted ERCP. The integration of direct visualization and specialized tools significantly expands the therapeutic reach of endoscopy. This strategy is established as the first-line definitive therapy for complex pancreatobiliary foreign body extraction, significantly reducing patient morbidity and accelerating convalescence by eliminating the need for surgical intervention.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821609

Aims Volume expansion following reimbursement of advanced procedures typically raises concerns about quality dilution, particularly when techniques disseminate beyond specialized centers. This prospective Belgian registry investigated whether national reimbursement for radiofrequency ablation (RFA) of Barrett's esophagus affected treatment outcomes, comparing two 7-year periods before and after reimbursement implementation (2010–2016 vs 2017–2023) across 12 designated expert centres. We assessed changes in case volume, patient characteristics, treatment patterns, efficacy, and safety (▶ **Table 1**).

Methods Patients were allocated according to their first RFA procedure into pre-reimbursement (2010–2016) and post-reimbursement (2017–2023) cohorts. Variables included demographics, Prague C/M classification, worst pre-RFA histology, pre-RFA endoscopic resection (ER), number of RFA sessions, efficacy outcomes (complete eradication of intestinal metaplasia [CE-IM], complete eradication of dysplasia [CE-D]), and adverse events. Efficacy required ≥ 1 surveillance biopsy within 12 months after final RFA. Statistical comparisons used chi-square or Fisher's exact tests for categorical variables and Mann–Whitney U tests for continuous variables.

Results RFA case volume increased 71 % following reimbursement (345 vs 589 patients, $p < 0.001$). Post-reimbursement patients presented with shorter Barrett's segments (Prague C: 3 vs 2, $p = 0.039$; M: 5 vs 4, $p = 0.031$) and lower HGIN prevalence (62 % vs 55 %, $p = 0.024$). Contrary to concerns about quality dilution, efficacy improved significantly (CE-IM: 83.1 % vs 87.5 %, $p = 0.048$), with a strong trend for CE-D (94.0 % vs 96.5 %, $p = 0.079$), despite higher volumes. Median RFA sessions remained unchanged (2, $p = 0.052$). Safety profiles were excellent and equivalent: bleeding (5 % vs 6 %, $p = 0.62$), stenosis (9 % vs 8 %, $p = 0.71$), with zero RFA-related perforations in either period.

Conclusions RFA efficacy improved despite a 71 % post-reimbursement volume increase, likely driven by strict centralisation within accredited expert centres and earlier-stage disease at presentation. These findings challenge assumptions about volume–quality trade-offs and show that centralised delivery can expand access while improving outcomes.

eP283 Carbon and Financial Impact of reusing Bite Blocks in Upper Gastrointestinal Endoscopy

Authors Marcellier G[1], Moizard M[1], Tan D[2], Seytre D[3], Gerardin S[4], De Maisoncelle I[5], Lopez B[6], Frelet P[1], Camus E[1], Rakotoharimanana M[2], Prat F[1]

Institutes **1** Hospital Beaujon AP-HP, Clichy, France; **2** Saint Antoine, Paris, France; **3** Beaujon, Clich, France; **4** Beaujon, Paris, France; **5** Ecological Transition and Environmental Health Department AP-HP, Paris, France; **6** Beaujon, Clichy, France

DOI 10.1055/s-0046-1821610

Aims Over one million upper endoscopies are performed annually in France. Although no regulation mandates it, single-use (SU) bite blocks remain the standard practice. We evaluated the environmental benefit of switchint to reusable (RU) bite blocks for upper gastrointestinal endoscopy.

Methods Reusable polyoxymethylene (POM) bite blocks (TEC-CARE, Chavelot, France) combined with rubber bands were tested. Preliminary tests consisted of subjecting the bite blocks to repeated steam sterilization cycles (134 °C, 18 min) after real-life patient use.

After confirming their integrity through successive sterilization cycles, a comparison was done between standard SU bite blocks (ALTON-Medical, China) and the reusable model under several scenarios (with or without reusing the rubber band, disinfection in automated endoscope reprocessors, or steam sterilization). A simplified life cycle assessment focusing exclusively on greenhouse gas emissions ($kgCO_2e$) was then performed using the CAREBONE tool developed by AP-HP (https://bit.ly/carebone).

Results Twenty reusable bite blocks were used over two months. All tolerated at least ten sterilization cycles with no visible degradation impairing their use. However, the rubber bands did not withstand sterilization, requiring continued use of single-use bands due to the lack of suitable reusable alternatives.

Several scenarios were compared, assuming ten uses per RU bite block:

- Single-use bite block + single-use band: **1.05 $kgCO_2e$**
- Reusable bite block (sterilized) + single-use band: **1.25 $kgCO_2e$**
- Reusable bite block (disinfected) + single-use band: **0.62 $kgCO_2e$**
- Reusable bite block (disinfected) + reusable band (hypothetical due to lack of a readily available model): **0.12 $kgCO_2e$**

If reusable bite blocks with reusable bands were implemented nationwide (≈ 1 million oral procedures/year), emissions avoided would amount to 930 tCO_2e per year, equivalent to 260,000 cheeseburgers or to the carbon footprint of building 20 new detached houses (French Ecological Agency ADEME).

Conclusions We demonstrated that POM reusable bite blocks withstand repeated sterilization

Sterilizing reusable bite blocks combined with disposable bands does not provide an ecological advantage over single-use devices due to the environmental burden of sterilization. In contrast, disinfection in automated endoscope washer-disinfectors reduces CO_2 emissions by approximately 40 %. These findings led to a change in practice in our department, with the adoption of reusable bite blocks (combined initially with disposable bands) disinfected together with the endoscope after each procedure.

Acknowledgement: POM bite blocks were graciously manufactured and provided for freeby Tec-Care

eP284 The Carbon Footprint of Colonoscopy: Algorithmic Analysis of the Patient Pathway

Authors Marcellier G[1], Rakotoharimanana M[2], Tan D[2], De Maisoncelle I[3], Moizard M[1], Frelet P[1], Gerardin S[4], Chaput U[5], Prat F[1]

Institutes **1** Hospital Beaujon AP-HP, Clichy, France; **2** Saint antoine, paris, France; **3** Ecological Transition and Environmental Health Department AP-HP, Paris, France; **4** Beaujon, Paris, France; **5** Hospital Saint-Antoine Ap-Hp, Paris, France

DOI 10.1055/s-0046-1821611

Aims Medical and technical activities have a significant environmental impact. Various national recommendations and local initiatives aim to reduce it, but it remains difficult to identify which changes in patient pathways can most effectively lower emissions without compromising quality of care. To help prioritize potential measures, we analyzed all possible colonoscopy pathways to develop a digital comparative tool assessing the environmental impact of different care scenarios.

Methods Interviews were conducted with engineers, clinical teams, and support staff (administrative, logistics, pharmacy, sterilization, biomedical, etc.) to map every step of the colonoscopy process (outpatient, day-case, and inpatient). The analysis included the preparation phase (scheduling, medical visits, bowel preparation), the procedure itself (anesthesia type, endoscope and accessories, consumables, procedural steps achieved), and the post-procedure phase (disinfection, patient recovery, sample management, waste processing, follow-up).

For each step, the carbon footprint of alternative practices was calculated (e.g., general vs local anesthesia, CO_2 insufflation vs water irrigation, reusable (RU) vs single-use (SU) accessories, digital data storage methods etc.). A simplified life cycle assessment (LCA) was performed using the CAREBONE tool developed by AP-HP (open source, https://bit.ly/carebone), expressing greenhouse gas emissions in $kgCO_2e$. We will aggregate this data into a digital tool allowing

Endoscopy 2026; 58: S1–S1041

users to explore each step of the care pathway, quantify its total carbon impact, and assess the CO_2e difference associated with any modification.

Results Calculation of an illustrative colonoscopy pathway including the following main steps was performed. Carbon emissions ($KgCO_2e$) are reported when available for each step.

- **Pre-Endoscopy:** A remote pre-anaesthetic consultation (0.078); standard bowel preparation (0.51); patient dressing with single-use pyjamas (0.79); reusable bedsheets (0.032) with single-use bed protection (0.25)
- **During-Endoscopy**: Propofol-based deep sedation (9.98); use of a reusable endoscope (3.39) and its associated components (1.52) (aspiration and insufflation tubing, pistons, sterile water for the water-jet system); CO_2 insufflation (0.078); use of a polypectomy snare (0.36) and formol biopsy tube (0.48); disposal of liquid waste (0.29); protective equipment for the endoscopist (0.56)
- **After-Endoscopy**: Endoscope reprocessing (1.30) including nurse protective gear, manual pre-cleaning, and disinfection in automated endoscope reprocessor, drying and storage; Patient recovery with a light snack and a SU water bottle (0.37).

Under this pathway, total CO_2 emissions of a signle colonoscopy was $20KgCO_2e$. Highest CO_2-emitting sectors were anasthesia, SU devices and endoscope reprocessing. Patient transport was excluded from the initial analysis as many tools already exist to estimate their burden (For instance, 30km drive in a petrol car would add 6.53Kg CO_2e)

Conclusions Our study aimed to identify the key steps in the patient pathway where professionals in an endoscopy unit can directly influence the reduction of the environmental footprint by implementing targeted measures. Our digital tool will provide healthcare facilities with a simple and interactive way to (re)organize their workflow, thereby minimizing the environmental footprint of colonoscopy.

eP285 Clinical utility of endoscopic ultrasound-guided fine-needle biopsy in the diagnosis of deep-seated lymphadenopathy and splenic lesions

Authors Boeva I[1], Ivan T[1], Kerezova Z[1], Yordanov A[2], Radinov A[2], Vrachanski D[1]

Institutes 1 University Hospital Sofiamed, Sofia, Bulgaria; 2 University Hospital "St Ivan Rilski", Sofia, Bulgaria

DOI 10.1055/s-0046-1821612

Aims Endoscopic ultrasound-guided (EUS-guided) biopsy has become a promising option for diagnosing hematological disorders, especially in cases of nodal and extranodal lymphomas that are not accessible by conventional surgical biopsy. This study evaluates the diagnostic performance, clinical utility, and safety of EUS-guided fine-needle biopsy (FNB) in the assessment of deep-seated lymphadenopathy and splenic lesions suspected of lymphoproliferative disease or malignancy [1–5].

Methods Of the 28 biopsy specimens obtained, 25 demonstrated diagnostically adequate material, yielding a diagnostic adequacy rate of 89.3 %. Among the 25 adequate samples, lymphoma was diagnosed in 13 cases (52 %). In 9 cases (36 %) a metastatic involvement of lymph nodes was identified. The remaining cases included single instances of sarcoidosis, tuberculosis, and gastrointestinal stromal tumor (GIST), each representing 4 % of the sample. Two patients (8 %) demonstrated benign inflammatory changes without evidence of neoplastic disease and remained negative on follow-up examination. No procedural complications were documented.

Results Of the 28 biopsy specimens obtained, 25 demonstrated diagnostically adequate material, yielding a diagnostic adequacy rate of 89.3 %. Among the 25 adequate samples, lymphoma was diagnosed in 13 cases (52 %). In 9 cases (36 %) a metastatic involvement of lymph nodes was identified. The remaining cases included single instances of sarcoidosis, tuberculosis, and gastrointestinal stromal tumor (GIST), each representing 4 % of the sample. Two patients (8 %) demonstrated benign inflammatory changes without evidence of neoplastic disease and remained negative on follow-up examination. No procedural complications were documented.

Conclusions Endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) is an effective modality for histologic assessment of deep-seated lymphadenopathy and splenic lesions. Its ability to obtain diagnostically adequate tissue with a favorable safety profile supports its use as a first-line diagnostic approach for these lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP286 Endoscopic Full-Thickness Resection (eFTR) for Complex Colorectal Lesions: A Single-Centre Outcomes Analysis of 22 Patients

Authors Kong TH[1], Westwood C[1], Jacob J[1], Beintaris I[1]

Institute 1 University Hospital of North Tees, Hardwick, United Kingdom

DOI 10.1055/s-0046-1821613

Aims To analyse the efficacy and safety profile of eFTR in patients with complex colorectal lesions in a District General Hospital.

Methods A retrospective analysis was carried out between 2021-2025. We identified 22 patients undergoing eFTR during this period. Data collected included patients' demographics, indications for eFTR, lesion size, and Charlson Comorbidity Score. Primary outcomes were defined as technical and histological success of R0 resection. Secondary outcomes included time from multidisciplinary team (MDT) discussion to eFTR, length of hospital stay, duration of the procedure, lesion site, complications and follow up, including recurrence rates. All patients referred to eFTR were discussed at our complex polyp MDT meeting [1–3].

Results The cohort consists of 17 males and 5 females. The median age was 75.5 years, with a median Charlson score of 6.0. Indications for eFTR included features of malignancy on superficial endoscopic assessment (n = 11), benign polyps but morphologically suspicious for advanced histology (n = 4), recurrent polyps (n = 5), and submucosal lesions (n = 2). The median lesion size was 17mm. Technical success was achieved in 20/22 cases (90.9 %). Histological R0 resection was successful in 18 cases (81.8 %) and R1 resection in 4 cases (18.2 %). The median time from MDT discussion to eFTR was 25 days. Twenty-one cases (95.5 %) were discharged on the same day, with one admission due to diabetic ketoacidosis unrelated to the procedure. The median duration of the procedure was 32 minutes. Of note, 16/22 cases were followed up, as the rest (n = 6) were either managed conservatively (n = 4), referred for chemotherapy (n = 1) and lost to follow-up (n = 1). One of the sixteen patients had a recurrence and was referred for surgery. There were no complications directly from eFTR (▶ **Table 1**).

▶ **Table 1**

Size	Location	Histology
6mm	Rectum	Benign vascular lesion
6mm	Rectum	Hyperplastic crypts
11mm	Distal Sigmoid	Adenocarcinoma
13mm	Splenic flexure	Adenocarcinoma
14mm	Proximal Sigmoid	Adenocarcinoma
15mm	Rectum	Adenocarcinoma
15mm	Rectum	Adenocarcinoma
15mm	Proximal descending	Adenocarcinoma
15mm	Caecum	Low grade tubular adenoma
15mm	Distal Sigmoid	Tubular adenoma
17mm	Proximal transverse	Adenocarcinoma
17mm	Distal Sigmoid	Adenocarcinoma
18mm	Rectum	Adenocarcinoma
18mm	Proximal transverse	Low grade tubular adenoma
20mm	Rectum	Benign tubulovillous adenoma
20mm	Hepatic flexure	Adenocarcinoma
20mm	Distal Sigmoid	Hyperplastic polyp and adenomatous component
23mm	Distal Sigmoid	Adenocarcinoma
23mm	Proximal Sigmoid	Hyperplastic polyp
25mm	Proximal transverse	Adenocarcinoma
27mm	Distal Sigmoid	Low grade tubular adenoma
No size	Proximal transverse	Focal epithelial hyperplasia

Conclusions EFTR is an effective, safe, and minimally invasive alternative procedure that can be used in managing complex colorectal lesions, including in elderly and frail patients, even in a District General Hospital setting, provided robust Governance and MDT processes are in place. We plan to longitudinally evaluate eFTR to further evaluate long-term outcomes in complex colorectal lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP287 Diagnostic yield of endoscopic ultrasound in biliary obstruction with inconclusive conventional imaging

Authors Belhocine R[1], Kadiri M[2], Lagdali N[3], Ajana FZ[3], Borahma M[4]

Institutes **1** Department of gastroenterology C, Ibn Sina Hospital, Mohammed 5 University, rabat Morocco; **2** Rabat, Morocco; **3** Mohammed V University, Rabat, Morocco; **4** Department of Gastroenterology C, Hospital Ibn Sina, Rabat, Morocco

DOI 10.1055/s-0046-1821614

Aims The identification of a biliary obstruction remains a major diagnostic challenge in the management of pancreatobiliary disorders. Despite advances in conventional imaging, certain obstructions may go undetected, making etiological diagnosis uncertain.Endoscopic ultrasound (EUS) provides higher resolution and direct visualization of the common bile duct, allowing the detection of abnormalities that may not be visible on CT or MRI.The aim of this study was to assess the diagnostic performance and yield of EUS in detecting biliary obstructions not identified by conventional imaging, and to determine its added value in patient management.

Methods This was a retrospective, descriptive, and analytical study conducted in the endoscopy unit between January 2019 and October 2025.All patients who underwent endoscopic ultrasound (EUS) for suspected biliary obstruction not visualized on conventional imaging (CT or MR cholangiopancreatography) were included.Clinical, biological, radiological, and endoscopic data were collected from medical records and analyzed.

Results A total of 27 patients were included. The mean age was 63 years (range: 31–90), with a female predominance (70 %) and a male-to-female ratio of 0.4.A history of cholecystectomy was found in 9 patients (33 %), and a prior ERCP in 1 patient (3.7 %).

Clinically, jaundice was observed in 17 cases (63 %), biliary pain in 17 cases (63 %), pancreatic-type pain in 11 cases (41 %), and atypical pain in 1 case.Fever was reported in 4 patients (15 %), and weight loss in 8 cases (30 %).

Biochemically, 19 patients (70 %) showed abnormal liver function tests, with a mean total bilirubin of 56 µmol/L.

All patients had undergone conventional imaging, including CT in 13 cases (48 %) and MR cholangiopancreatography in 14 cases (52 %).At imaging, common bile duct (CBD) dilation was noted in all patients, with a mean diameter of 12.4 mm (range: 8–20 mm), and intrahepatic bile duct (IHBD) dilation in 23 cases (85 %).

EUS confirmed CBD dilation in just 14 patients (52 %), with a mean diameter of 10.5 mm (range: 6–17 mm).EUS identified a biliary obstruction in 19 cases (70.3 %). The main etiologies identified were common bile duct stones (29.6 %), congenital cystic dilatation of the common bile duct in 7.4 %, and LPAC syndrome in 7.4 %. Less frequent causes included distal cholangiocarcinoma in 3.7 %, pancreatic head tumor in 3.7 %, chronic pancreatitis in 3.7 %, fibrosing papillitis in 3.7 %, and paraduodenal pancreatitis in 3.7 %.

EUS-guided fine-needle aspiration (FNA) was performed in 4 patients (14.8 %). Histological analysis revealed adenocarcinoma in two cases, a carcinomatous process in one case, and primary sclerosing cholangitis in one case.ERCP was performed in 18 patients (67 %), confirming the diagnosis made by EUS.

The overall diagnostic yield of EUS was 70.3 %.CBD dilation was ruled out in 13 patients (48.1 %), and no obstruction was identified in 8 cases (29.6 %). No major EUS-related complications were observed.

Conclusions Endoscopic ultrasound is a reference diagnostic tool for evaluating suspected biliary obstructions not visualized on conventional imaging.In this study, EUS identified an obstruction in nearly 70.3 % of cases, confirming its high diagnostic yield and added value in the biliary diagnostic pathway.Beyond its diagnostic accuracy, EUS plays a key role in therapeutic decision-making, particularly by guiding ERCP or tissue sampling.These findings emphasize the essential role of EUS in the diagnostic algorithm of unexplained biliary dilations and support its early integration in clinical practice.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP288 EUS-Guided antegrade metal stenting as Rescue Technique After Failed ERCP and EUS-guided rendez-vous in a case of Severe Cholangitis

Authors Bardasu S[1], Badea A[1], Amza TI[1], Bengus A[1], Mateescu RB[1, 2], Voiosu T[1, 2]

Institutes **1** Colentina Hospital, București, Romania; **2** Carol Davila University of Medicine and Pharmacy, București, Romania

DOI 10.1055/s-0046-1821615

Abstract Text

We present the case of a 76-year-old male with morbid obesity who was transferred to our center for severe (grade III) acute cholangitis complicated by renal dysfunction. Preprocedrual CT scan demonstrated global extrahepatic and intrahepatic dilation of the bile ducts without a clear cause

Emergency ERCP was indicated for biliary decompression in this setting. However, multiple attempts at selective biliary cannulation—including wire-guided and contrast-assisted techniques—were unsuccessful. A precut septotomy using a pancreatic guidewire failed to achieve deep cannulation, and subsequent needle-knife papillotomy did not permit guidewire passage into the common bile duct, raising suspicion of an impacted stone in the distal portion of the common bile duct.

In this emergency setting, a EUS-guided biliary access was attempted. Under endoscopic ultrasound, the distal common bile duct was punctured from the duodenum and an anterograde guidewire was successfully advanced through the papilla; however, retrograde cannulation over the wire could not be achieved due to guidewire being damaged through shearingduring needle-guided access [1].

Finally, to secure biliary drainage and allow closure of the duodenal access point, an EUS-guided hepaticogastrostomy was performed. Anterograde cholangiography demonstrated marked dilation of the intrahepatic ducts with a hilar obstruction, due to a tightly impacted stone. A transhepatic guidewire was advanced distally into the duodenum, permitting transpapillary deployment of a 4-cm fully covered self-expandable metal stent (SEMS). A 15/7 Fr double-pigtail stent was subsequently placed across the hepaticogastrostomy tract, obtaining effective drainage of purulent bile into the stomach.

48 hours after the procedure, the patient developed melena, hypotension, and altered mental status. Angio-CT revealed correct positioning of the stents and inflammatory changes suggestive of acute pancreatitis. Upper endoscopy identified a large duodenal clot adherent to the biliary SEMS (Forrest IIb). Hemostasis was achieved by placing two clips at the margin of the sphincterotomy and applying hemostatic gel. The patient's condition gradually improved with supportive care, demonstrated by normalization of renal parameters and inflammatory markers and the patient was discharged 5 days after the initial procedure, with scheduled follow-up at 1 month

Conclusion: This case underscores the critical role of EUS-guided biliary drainage (EUS-BD) as a life-saving rescue modality when ERCP fails, particularly in patients with severe cholangitis and challenging anatomy. EUS-BD offers a minimally invasive, highly effective alternative for urgent biliary decompression, enabling timely source control and improving clinical outcomes in high-risk patients.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP289V Endoscopic Submucosal Dissection of a Gastric GIST Using a Rigidizing Overtube to Facilitate Stabilization in a Difficult Upper Stomach Location

Authors Michelon M[1], Verset L[2], Ouazzani S[1], Teles de Campos S[1], Eisendrath P[1], Lemmers A[1]

Institutes **1** Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Erasme Hospital, Brussels, Belgium; **2** Department of Pathology, HUB Bordet Erasme Hospital, Université Libre de Bruxelles, Brussels, Belgium

DOI 10.1055/s-0046-1821616

Problem to solve Endoscopic submucosal dissection (ESD) of subepithelial lesions (SELs) remains technically demanding, particularly for larger lesions arising in anatomically challenging locations such as the upper gastric body or fundus.The anatomical configuration of the upper stomach often results in unstable endoscope positioning, perpendicular access, and limited tip control and visualization of the dissection plane. These factors increase the risk of incomplete resection, muscular injury, or perforation, and may require surgical conversion, particularly for the excavation technique required for resection of subepithelial lesions arising from the muscularis propria. A method to improve scope stability and control during ESD in thislocation is therefore needed.

Innovation We report a stabilization-assisted ESD technique using a rigidizing overtube (Pathfinder, Neptune Medical, USA) to facilitate complete en bloc resection of a gastric GIST arising from the muscularis propria.Although this device has primarily been described for use in colorectal endoscopic resections, to our knowledge no published reports have documented its application in upper gastrointestinal ESD, making this its first reported use in this anatomical context.The device, which transitions from flexible to rigid through a vacuum-controlled system, was used to stabilize the endoscope shaft and maintain a fixed trajectory despite the challenging upper-gastric anatomy and the difficulty of accessing the upper, gravity-dependent portion of the lesion located near the cardia, where scope stability was compromised. The overtube ensured consistent shaft control, reduced unintended movements, and allowed precise orientation toward both the upper and deeper parts of the lesion, enabling accurate dissection.

After submucosal injection, a circumferential incision was performed using a conventional ESD knife (DualKnife J, Olympus, Japan), followed by deep excavation-type dissection within the muscular layer using a hook-type ESD knife (HookKnife J, Olympus, Japan) under continuous clip-line traction. The GIST was cautiously separated from the muscularis propria without perforation, and removed en-bloc in a 150 min procedure. The post-ESD defect was completely closed using multiple clips.

The capsule of the resected specimen measureing 35 × 30 mm was intact . The combined use of a rigidizing overtube and traction methods provided excellent stability and precision, enabling safe and complete resection in an anatomically constrained region.

Results Histopathology confirmed a R0 resection of a 29 mm spindle-cell GIST with low mitotic activity (< 5/5 mm²), positive staining for CD117 and DOG1, and no necrosis. The lesion was staged as pT2Nx.The postoperative course was uneventful, with no bleeding or perforation. Oral feeding resumed and the patient discharged in good condition the next day.Conservative surveillance using CT and endoscopy was proposed to the patient.

Conclusions Described for the first time in the upper GI, this case illustrates that ESD assisted by a rigidizing overtube can facilitate safe and controlled resection of subepithelial gastric tumors arising from the muscularis propria, specifically in technically challenging locations such as the upper gastric body. The overtube improved scope stability and access, enabling precise dissection and complete en bloc R0 removal without the need for surgery.This stabilization-assisted approach may be particularly useful in selected cases of gastric GIST where anatomical constraints limit conventional ESD.

eP290 Validating the QNI Classification for EUS-Guided Drainage of Pancreatic Fluid Collections in a Resource-Limited, Plastic-Stent–Predominant Setting

Authors Kar S[1], Nayak HK[1], Panigrahi MK[1], Tripathy TP[1], Biswal S[1], Kandagaddala Y[1]

Institute 1 All India Institute of Medical Sciences, Bhubaneswar, Bhubaneswar, India

DOI 10.1055/s-0046-1821617

Aims Peripancreatic fluid collections (PFC), including pseudocysts and walled-off pancreatic necrosis (WOPN), are increasingly managed through endoscopic ultrasound (EUS)-guided drainage. However, there is no widely adopted, post-inflammatory, imaging-based score to stratify risk and predict outcomes after endoscopic drainage, especially in resource-limited settings where plastic stents are mainly used. The recently proposed Quadrant–Necrosis–Infection (QNI) classification, derived from cross-sectional imaging, showed promise in a US cohort treated exclusively with lumen-apposing metal stents (LAMS), but has not been validated externally. We aimed to evaluate the clinical utility of QNI in predicting outcomes of EUS-guided drainage of PFCs in an Indian public-sector cohort predominantly treated with double-pigtail plastic stents [1].

Methods We retrospectively reviewed prospectively maintained records of consecutive patients who underwent EUS-guided drainage of PFCs between January 2022 and February 2025 at a tertiary-care centre. Baseline CT/MRI/EUS were used to assign a QNI score based on (i) the number of retroperitoneal quadrants involved, (ii) the extent of necrosis, and (iii) the presence of infection. Patients were classified as Low QNI (Group 1: ≤ 2 quadrants, < 30 % necrosis, no infection) or High QNI (Group 2: ≥ 3 quadrants, ≥ 30 % necrosis in ≥ 2 quadrants or > 60 % in any quadrant, and infection). The primary outcomes were technical success (successful stent placement) and clinical success (symptom resolution with a greater than 50 % reduction in PFC size at 4 weeks). Secondary outcomes included need for endoscopic necrosectomy, additional drainage (nasocystic drain [NCD] or percutaneous catheter drain [PCD]), complications, length of hospital stay, stent migration, and mortality. The study was approved by the Institutional Ethics Committee.

Results Of 53 screened patients, 48 met the inclusion criteria (5 were excluded due to incomplete records or inadequate follow-up). Thirty-one patients were classified as Low QNI and 17 as High QNI. Group 1 underwent drainage with either single or dual double-pigtail plastic stents, while Group 2 received dual plastic stents or LAMS, depending on collection complexity and feasibility. Baseline demographics were similar, although High QNI patients had a higher burden of infected and extensive necrosis. Technical success was 100 % in both groups. Clinical success was achieved in 100 % (31/31) of Low QNI and 88 % (15/17) of High QNI patients. Additional drainage procedures (NCD/PCD or extra stent) were needed in 2 (6 %) vs 4 (23 %) patients in Groups 1 and 2, respectively (p = 0.17). Endoscopic necrosectomy was required in 4 (23 %) High QNI patients but in none of the Low QNI group (p = 0.014). Minor bleeding occurred in 6 % vs 23 % (p = 0.17), all managed conservatively. The median hospital stay was significantly longer in the High QNI group (16 vs 5 days, p < 0.001). At 3 months, all patients had residual collections less than 3 cm; spontaneous stent migration occurred in 5 Low QNI and 3 High QNI cases, and two LAMS were electively removed at 6–8 weeks. One death (6 %) occurred in the High QNI group; there were no deaths in the Low QNI group.

Conclusions In this real-world, resource-limited cohort, the QNI classification emerged as a simple, preprocedural, imaging-based tool that stratifies clinical trajectory after EUS-guided drainage of PFCs. High QNI status was associated with a greater need for necrosectomy and adjunct drainage, more complications, and prolonged hospitalisation, despite high overall technical and clinical success rates. Our findings extend prior LAMS-based data to a predominantly plastic-stent practice, supporting QNI as a pragmatic framework to guide upfront therapeutic strategy and selection of more aggressive interventions in high-risk collections. Prospective multicentre validation, with systematic capture of organ failure and nutritional status, is warranted before routine adoption in ESGE-affiliated centres and broader clinical practice.

eP291 Accuracy of histological prediction of forceps biopsy vs JNET classification in large laterally spreading lesions

Authors Tkachov V[1], Kiosov O[1]

Institute 1 Zaporizhzhia State Medical and Pharmaceutical University, Zaporizhzhia, Ukraine

DOI 10.1055/s-0046-1821618

Aims Examine the comparative diagnostic performance of forceps biopsy (FB) and JNET classification for identifying dysplasia and carcinoma in large laterally spreading lesions (LSLs), correlating these findings with definitive histology.

Methods The study included 110 patients with laterally spreading lesions (LSLs) measuring ≥ 20 mm in diameter, excluding those with evidence of invasive carcinoma [1, 3]. Group I consisted of 70 patients (63.6 %) presenting with the granular subtype (LSL-G), whereas Group II comprised 40 patients (36.4 %) with the non-granular variant (LSL-NG) [4]. Optical assessment [2, 3] was performed by an expert endoscopist using Indigocarmine chromoendoscopy and NBI, after which forceps biopsy and endoscopic resection (EMR, pEMR, ESD or hybrid ESD) were carried out. All diagnostic findings were subsequently compared with histopathological results from the resected specimens. Statistical analyses included Chi-square testing, Wilson confidence intervals, descriptive metrics, and Fisher's exact test, performed using Statistica 13 (▶ **Table 1**).

Results Mean lesion size was 38.8 ± 16.9 mm in LSL-G and 23.8 ± 6.4 mm in LSL-NG group. In the first group, 15.7 % of lesions were benign, while 15.7 % demonstrated low-grade dysplasia; high-grade dysplasia was identified in 28.6 %, and carcinoma in situ in 40 %. In the second group, 50 % of lesions were benign, with 12.5 % exhibiting low-grade dysplasia; 25 % showing high-grade dysplasia, and 12.5 % containing foci of carcinoma in situ.

Conclusions The JNET classification demonstrates superior diagnostic performance compared with forceps biopsy across most evaluated metrics and serve as a more reliable method for prognosing histology changes in both granular and non-granular large LSLs.

eP292 Evolution of patient selection, technique and outcomes in EUS-guided gallbladded drainage: a retrospective analysis over a decade

Authors La Mantia A[1], Bonato G[1], Forti E[1], Pugliese F[1], Dioscoridi L[1], Cintolo M[1], Bravo M[1], Palermo A[1], Gallo C[1], Stegagnini M[1], Mutignani M[1]
Institute 1 Digestive and Interventional Endoscopy Unit, ASST GOM Niguarda, Milan, Italy
DOI 10.1055/s-0046-1821619

Aims Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) using a lumen-apposing metal stent (LAMS) has become a minimally invasive alternative to percutaneous or surgical drainage in high-risk surgical candidates with acute cholecystitis. Initially reserved for extremely frail patients, its indications have progressively expanded. This study aimed to assess temporal changes in patient selection, procedural standardization, and clinical outcomes over a 10-year experience with EUS-GBD [1–5].

Methods We conducted a retrospective, single-center analysis including all consecutive patients who underwent EUS-GBD between January 2014 and December 2024. Patients were divided into two cohorts: Group A (procedures ≤ December 2020) and Group B (procedures ≥ January 2021). Demographic, procedural, and outcome data were compared between groups. Technical success was defined as successful LAMS placement; clinical success was defined as symptom resolution and/or sepsis improvement without need for further drainage. Adverse events (AEs) were recorded according to the AGREE classification, and survival outcome was assessed at 30 days, 12 months, and 36 months (▶ **Table 1**).

▶ **Table 1**

	Group A (n = 24)	Group B (n = 26)	*p* value
Baseline and procedural data			
Mean age, y (± DS)	78 (± 12.3)	81 (± 13.3)	NS
Median age-adjusted CCI, *n* (IQR)	9.5 (4.5)	8 (5)	0.047
Electrocautery-tip LAMS design, *n* (%)	15/24 (62.5 %)	26/26 (100 %)	0.001
Technical success, *n* (%)	23/24 (95.8 %)	26/26 (100 %)	NS
Clinical success, *n* (%)	20/24 (83.3 %)	25/26 (96.1 %)	NS
Survival outcomes			
30-day survival, *n* (%)	20/24 (83.3 %)	26/26 (100 %)	0.046
12-month survival, *n* (%)	8/24 (33.3 %)	9/16 (56.2 %)	NS

Results Fifty patients were included (mean age 79.6 ± 12.8 years; 50 % female). Technical and clinical success rates were 98 % and 90 %, respectively. Over time, baseline comorbidity decreased: median age-adjusted Charlson Comorbidity Index (a-CCI) was significantly lower in Group B (8.0 vs 9.5, p = 0.047), and biliopancreatic malignancies declined from 45.8 % to 23.1 %. The use of electrocautery-enhanced LAMS increased from 62.5 % to 100 % (p = 0.001), reflecting complete procedural standardization. Thirty-day survival improved significantly from 83.3 % to 100 % (p = 0.046), while 12-month (33.3 % vs 56.2 %) and 36-month (25.0 % vs 60.0 %) survival showed favorable, though non-significant, trends. Overall biliary AE rate was 24 %, with both early and delayed events remaining infrequent.

Conclusions Over the past decade, EUS-GBD has evolved from a rescue procedure for frail, high-risk patients to a well-standardized therapeutic option applicable to a broader population. This transition coincided with reduced baseline comorbidity, universal adoption of electrocautery-enhanced LAMS, and improved early survival. Long-term outcomes also trended positively, confirming the safety, reproducibility, and durability of the technique. Further

prospective multicenter studies are warranted to refine patient selection criteria, define objective "frailty" thresholds, and optimize timing for stent management and removal. Within experienced centers, EUS-GBD should be considered a cornerstone in the minimally invasive management of acute cholecystitis in non-surgical candidates.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

We describe the case of a 45-year-old woman with a neurogenic syndrome of the interstitial cells of Cajal and a history of multiple abdominal surgeries. An initial attempt at PEG placement failed due to the inability to obtain an adequate abdominal transillumination window. A CT scan revealed a complete intrathoracic stomach, so to address this issue, we decided to use a bowel magnetic traction system. An out-of-scope ferromagnetic balloon catheter was positioned in the stomach, and through an external magnet, controlled traction was applied to the organ towards the epigastrium. This enabled the creation of a safe and stable transillumination window, allowing for a gastropexy with anchoring devices and the subsequent completion of the PEG placement via the "pull" technique, without complications [1–7].

Abstract Text

Afferent limb syndrome (ALS) is an uncommon postoperative complication typically resulting from tumor recurrence after pancreaticoduodenectomy, causing obstruction of the afferent or biliopancreatic limb. We present 4 cases of malignant ALS treated with endoscopic techniques.

Case 1: A 76-year-old male with history of pancreatic cancer underwent a surgical gastrojejunostomy. Fourteen months later, he developed gastric outlet obstruction symptoms and cholestasis. A computed tomography (CT) demonstrated obstruction of the biliopancreatic limb. He was managed initially with endoscopic placement of an enteral self expandable metal stent (SEMS) across the obstructed limb. One month later, the stent migrated into the stomach, causing symptom recurrence. The stent was removed endoscopically and attempted EUS-guided enteroenterostomy (EUS-EE) resulted in colonic luminal apposing metal stent (LAMS) misdeployment. Ultimately, the patient was successfully treated with repeat enteral SEMS, and the LAMS was removed endoscopically 7 weeks later. After two months follow up, the patient remained tolerating soft diet and with no recurrence of cholestasis [1, 2].

Case 2: A 62-year-old male with pancreatic cancer was treated with pancreaticoduodenectomy. Fourteen months after surgery, he developed diet intolerance and jaundice. A CT revealed new dilation of the afferent jejunal limb, likely due to metastatic recurrence, as well as biliary dilation. The patient was deemed unsuitable for EUS-GE in the setting of ascites and gastric varices. Enteral SEMS was placed endoscopically with good initial response; however, recurrent cholestasis developed several days later and a percutaneous biliary drain was placed. Despite this, the patient maintained improved oral intake and CT scan demonstrated interval improvement of afferent-limb dilation.

Cases 3 and 4: 69- and 75-year-old males with pancreatic adenocarcinoma treated surgically with pancreaticoduodenectomy. Thirty-one and 41 months postoperatively, they presented with acute gastric outlet obstruction symptoms; one of them developed cholestasis and cholangitis. Imaging confirmed tumor recurrence with new dilation of the afferent limb. Both patients underwent EUS-GE successfully using a 10 × 10-mm LAMS. Rapid symptom resolution, improved oral intake, and normalization of liver enzymes occured in both cas-

es. Early postoperative imaging confirmed decompression of the afferent limb. Clinical response was sustained at 1-month follow-up.

In this case series, EUS-GE provided an effective and safe treatment option for malignant ALS. Unfavorable anatomy can increase the risk of technical failure and stent misdeployment. Enteral SEMS remains a meaningful alternative for patients who are not suitable candidates for EUS-GE or who have limited life expectancy.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Abstract Text

Endoscopic ultrasound–guided biopsy (EUS-guided biopsy) is a preferred minimally invasive method for histological verification of indeterminate focal splenic lesions, offering a high diagnostic yield with lower risk compared with surgical approaches. However, the spleen's rich vascularization poses a significant risk of intraprocedural hemorrhage. This risk is compounded when dealing with locally advanced disease that might necessitate extensive surgical staging.

We report the case of a 53-year-old woman presenting with intermittent left upper-quadrant pain. Cross-sectional imaging identified a massive peritoneal lesion infiltrating multiple adjacent organs, including the greater curvature of the stomach, splenic flexure, spleen, and the left diaphragmatic dome, without distant lymphadenopathy. Despite comprehensive conventional endoscopic evaluation—where both upper endoscopy and colonoscopy confirmed the absence of any intraluminal mucosal pathology— the nature of the infiltrating peritoneal mass remained indeterminate. Given the multiorgan infiltration, a surgical approach for histological verification would have required a highly morbid multiorgan resection. To avert this extensive surgery, an EUS-guided fine-needle biopsy (FNB) was conducted using a 22G needle, with three passes taken to safely sample the accessible splenic component of the mass [1–4].

The patient was monitored for 24 hours with no post-procedural complications observed. Immunohistochemical analysis demonstrated findings consistent with follicular T-helper cell lymphoma. Following immediate hematologic evaluation, immunochemotherapy was initiated. Early follow-up PET-CT, performed three months after starting treatment, confirmed a complete metabolic response, with no evidence of residual disease.

This case highlights the indispensable diagnostic value of EUS-guided FNB in complex, locally advanced masses. Despite the technical challenges posed by the splenic location and the multiorgan engagement, EUS-guided biopsy provided crucial, non-operative histological data that directly influenced immediate management, successfully avoiding a major multiorgan resection and leading to an excellent patient outcome.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP296 Severe Ischemic Colitis and Systemic Thromboembolism Induced by High-Dose Bevacizumab in a Patient with Recurrent Glioblastoma: A Case Report

Authors Apatachioae C[1], Coman F[1], Steflea C[1], Serban D[1]

Institute 1 County Clinical Emergency Hospital, Brasov, Romania

DOI 10.1055/s-0046-1821623

Introduction Bevacizumab, a humanized monoclonal antibody targeting Vascular Endothelial Growth Factor (VEGF), is a therapeutic cornerstone for recurrent glioblastoma, yet its inhibition of angiogenesis fundamentally disrupts vascular homeostasis. While gastrointestinal perforation is a documented risk, severe ischemic colitis presenting as Non-Occlusive Mesenteric Ischemia (NOMI) associated with systemic thrombosis is a rare, life-threatening complication driven by endothelial dysfunction, vascular rarefaction, and potent splanchnic vasoconstriction via the nitric oxide pathway. We present a highly educational case highlighting the diagnostic challenges and the feasibility of conservative management in this complex vascular scenario.

Case Presentation We report the case of a 57-year-old male with IDH-wildtype glioblastoma. Following tumor recurrence, the therapeutic regimen was intensified to high-dose Bevacizumab (800 mg) combined with Lomustine. Within weeks of dose escalation, the patient presented with acute, severe diffuse abdominal pain, hematochezia, and laboratory evidence of marked inflammation and tissue hypoperfusion (elevated lactate). Contrast-enhanced Computed Tomography (CT) revealed a complex vascular picture characterized by distal pulmonary embolism and diffuse, circumferential colonic wall thickening with a "target sign" and pericolic fat stranding; crucially, the celiac and mesenteric arteries were patent, excluding proximal embolic occlusion and supporting a diagnosis of drug-induced microangiopathy. Colonoscopy confirmed severe ischemic colitis extending from the sigmoid to the cecum, characterized by mucosal edema, cyanosis, friability, and longitudinal ulcerations, while biopsies revealed neutrophilic cryptitis, regenerative changes, and fibrin thrombi [1–5].

Management and Outcome Bevacizumab was permanently discontinued. The case posed a significant therapeutic dilemma involving the balance between the risk of exacerbating active gastrointestinal bleeding and the necessity of treating the pulmonary embolism. A multidisciplinary team opted for a conservative, organ-sparing strategy given the absence of transmural necrosis signs. Anticoagulation with therapeutic enoxaparin was initiated under strict surveillance, alongside oral mesalazine to mitigate ischemic-induced inflammation and short-term anaerobic coverage. The patient's clinical status improved rapidly, rectorrhagia ceased within 48 hours, and he was discharged without surgical intervention.

Conclusion This case highlights that high-dose anti-VEGF therapy can precipitate a "perfect storm" of systemic thrombosis and intestinal ischemia. Clinicians must maintain a high index of suspicion for NOMI in patients presenting with abdominal pain even in the absence of macrovascular occlusion on CT, as early conservative management with careful anticoagulation is a viable therapeutic pathway requiring close multidisciplinary collaboration.

eP297 Does deep resection increase the complete resection rate in endoscopic papillectomy? A single tertiary center experience

Authors Macif A[1], ÖDemiş B[2], Kenarlı K[2], Ünver NG[2]
Institutes **1** Ankara Bilkent City Hospital, Ankara, Türkiye; **2** Ankara Bilkent City Hospital, Ankara, Türkiye
DOI 10.1055/s-0046-1821624

Aims Ampullary neoplastic lesions have the potential for malignant transformation and therefore excision is recommended. This study aimed to evaluate the safety, efficacy, and outcomes of endoscopic papillectomy.

Methods This retrospective study was conducted on patients who underwent endoscopic papillectomy at our center between 2019 and 2025. "Deep papillectomy" was defined as visualization of the pancreatic and bile duct orifices post-resection. Outcomes assessed included rates of en bloc resection, complete resection, pancreatic stenting, and recurrence during follow-up.

Results A total of 60 patients (mean age 54.5 ± 15.28 years; of whom 28 , 46.7 % female) were included. The median lesion size was 12 mm (range: 6–46 mm). The most common clinical presentation was irregular or enlarged appearing papilla on endoscopic screening in 23 (28.3 %) patients. In 53 (88.3 %) patients, the lesion was in the major papilla, 4 (6.7 %) patients had intraductal extension, and in 3 patients (5 %), the lesion was in the minor papilla. Intraductal extension assessment was performed by CT in 27 (45 %) patients, by MRCP in 16 (26.7 %) patients, and by EUS in 15 (25 %) patients. Pre-papillectomy histology revealed isolated low-grade dysplasia without adenoma in 9 (15 %) patients, tubular adenoma with low grade dysplasia in 40 (66.7 %), tubular adenoma with high-grade dysplasia in 6 (10 %), carcinoma in situ in 1 (1.7 %), normal tissue in 3 (5 %), and no biopsy in 1 (1.7 %). In 8 (13.3 %) patients, the lesion was excised after submucosal diluted adrenaline injection, while in 52 (86.7 %) patients, excision was performed without injection. Pathology results of resection specimens showed tubular adenoma with low grade dysplasia in 30 (50 %) patients, adenocarcinoma in 7 (11.7 %), and chronic inflammation in 10 (16.7 %). En bloc resection was achieved in 47 (78.3 %) patients, while 13 (21.7 %) underwent piecemeal resection. Complete resection was achieved in 49 (81.7 %) cases. Deep resection enabled visualization of both pancreatic and biliary orifices, resulting in a pancreatic stenting rate of 88.3 %. Recurrence occurred in 5 patients (8.3 %), with a median time to recurrence of 12 months (range: 6–24 months). Post-procedural complications included pancreatitis (8.3 %), bleeding (10 %), and perforation (3.3 %).

Conclusions Endoscopic papillectomy is a safe and effective treatment for ampullary neoplastic lesions. Deep resection may enhance complete resection rates and facilitate pancreatic cannulation.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP298 The Hemorrhagic Nightmare: Conservative Victory Over Gastric Outlet Obstruction from Massive Post-ERCP Retroperitoneal Hematoma

Authors Tishkov I[1], Boeva I[1], Kerezova Z[1], Krysteva-Dzheneva V[1]
Institute **1** University Hospital Sofiamed, Sofia, Bulgaria
DOI 10.1055/s-0046-1821625

Abstract Text

A 42-year-old man with a history of long-term anabolic steroid use and severe jaundice presented with distal extrahepatic cholestasis and drug-induced liver injury (DILI), confirmed by cross-sectional imaging revealing choledocholithiasis and associated ductal dilation. Conventional endoscopic retrograde cholangiopancreatography (ERCP) with pre-cut fistulotomy was performed, leading to “spontaneous” evacuation of an impacted stone at the papilla. During withdrawal, a large ulcer with a visible bleeding vessel was identified in the duodenal bulb/descending part transition. Combined endoscopic hemostasis was achieved, including the placement of a hemostatic clip [1–3].

On the second postprocedural day, the patient developed acute, severe abdominal pain alongside characteristic symptoms of gastric outlet obstruction. Imaging studies confirmed the development of post-ERCP edematous pancreatitis and revealed a massive retroperitoneal hematoma (6.2 × 7.9 × 6.6 cm), which severely compromised the duodenal lumen. The patient's clinical course was further complicated by persistent, non-resolving jaundice, indicating the mixed etiology of his cholestasis despite successful endoscopic stone evacuation during the initial ERCP. Given the overall clinical severity and lack of initial improvement, the patient underwent daily consultation with abdominal surgeons, with high-risk surgical intervention being actively discussed as a management option. Intensive conservative treatment was immediately initiated, comprising aggressive parenteral nutrition, broad-spectrum antibiotics, and gastric decompression via a nasogastric tube. Despite these comprehensive measures, persistent obstructive symptoms necessitated a diagnostic gastroscopy on the 7th postprocedural day. The procedure confirmed the presence of a large, expanding intraduodenal hematoma, resulting in near-complete luminal obliteration of the duodenum. A nasojejunal tube was subsequently placed under direct vision to ensure continuous and adequate enteral feeding. After a total of 20 days of dedicated supportive care, the patient demonstrated significant clinical improvement with substantial reduction of the hematoma volume, allowing safe resumption of oral intake. Follow-up CT scan after 4 months confirmed complete radiological resolution of the hematoma.

This clinical case highlights a potentially catastrophic, rare complication following ERCP. It underscores the critical importance of active, vigilant postprocedural monitoring and emphasizes that conservative management with intensive supportive care and adequate nutritional support can successfully resolve even massive intraduodenal hematomas. Ultimately, this successful outcome demonstrates that clinical patience and a dedicated supportive strategy can be profoundly rewarding, eliminating the need for major high-risk surgical interventions in complex gastrointestinal emergencies.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP299 Bleeding Following Removal of a Lumen-Apposing Metal Stent (Hot-Axios)

Authors Lucio Fernández C[1], Alvarez Sánchez M[2], Castro Carbajo MDP[1], Mejuto Illade L[2], Mateos Sánchez C[1], Gálvez Alvarez E[2], Abadal Villayandre JM[2], Vazquez-Sequeiros E[3], Olvera Muñoz R[4], Castro Urda JL[1]

Introduction We present a case of hemorrhage secondary to splenic artery laceration caused by decubitus of a Hot-Axios stent.

Endoscopy and Case Report A 57-year-old woman with a history of distal pancreatectomy for IPMN with low-grade dysplasia. As a complication, she developed a pancreatic fistula with a distal peripancreatic collection. A percutaneous drainage was attempted without success, followed by transgastric drainage using a Hot-Axios stent at another center. She presented to the emergency department with syncopal episodes. Gastroscopy revealed a normally positioned stent with a coaxial pig-tail and slight oozing of blood around the prosthesis. Laboratory tests showed anemia with hemoglobin dropping to 7.7 g/dL, and CT angiography demonstrated intragastric blood content without active bleeding. A second gastroscopy was performed 24 hours later for stent removal, after which massive hemorrhage occurred, resulting in hypovolemic shock and the need for vasoactive support. An urgent CT angiography revealed splenic artery rupture, and emergent radiological embolization was performed without complications. The patient evolved favorably, later undergoing scheduled splenectomy due to secondary splenic infarctions [1–5].

Conclusions The use of Hot-Axios stents has become widespread for the drainage of abdominal collections and is generally considered a safe procedure, although it carries a risk of complications such as bleeding. Most bleeding events are associated with the development of arterial pseudoaneurysms, and delayed stent removal appears to be a potential risk factor. In our case, bleeding resulted from splenic artery laceration due to contact with the edge of the stent. The coaxial placement of a pig-tail stent may reduce this risk, although current evidence is insufficient. In conclusion, early detection and management of this complication are essential due to its severity.

DOI 10.1055/s-0046-1821627

Aims Sessile serrated lesions (SSLs) are well-recognized precursors of colorectal carcinoma. Therefore, their complete removal is essential to reduce colorectal cancer incidence and mortality. Several endoscopic techniques have been employed for SSL resection. Among them, underwater endoscopic mucosal resection (UEMR) has been increasingly performed for nonpedunculated colorectal lesions (NPCLs). However, data regarding the efficacy and safety of UEMR specifically for SSLs remain limited. This systematic review and single-arm meta-analysis aimed to evaluate the pooled efficacy and safety of UEMR for SSLs [1–3].

Methods PubMed, EMBASE, and Cochrane databases were searched through June 2025 for studies reporting UEMR outcomes in SSLs. The primary outcome was the complete resection rate. Secondary outcomes included *en bloc* resection, R0 resection, and adverse events (AEs). A random-effects model was used to pool proportions with 95 % confidence intervals (CIs). Heterogeneity was assessed using the I^2 statistic, and sensitivity analyses were conducted using a leave-one-out approach.

Results Seven observational studies comprising 581 lesions were included. Median lesion size ranged from 12 to 24.6 mm across studies. The pooled complete resection rate was 90.5 % (95 % CI, 69.6–100). The pooled R0 resection rate was 72.5 % (95 % CI, 58.4–83.2), decreasing to 63.6 % for lesions ≥ 10 mm. The *en bloc* resection rate was 80.4 % (95 % CI, 65.0–90.1). AEs were rare, with a pooled incidence of 0.56 % (95 % CI, 0–1.74), including six delayed bleeding at 1.03 % and five reported perforations. Recurrence was reported in three studies including 380 lesions. The pooled analysis showed a recurrence rate of 2.37 % (95 %CI 1.24-4.49; $I^2$0 %).

Conclusions UEMR appears to be a safe and effective approach for SSLs, achieving high complete resection rates with a low incidence of AEs. The relatively favorable R0 and en bloc resection rates may contribute to low recurrence rates on surveillance. UEMR may therefore represent a suitable alternative for treating SSLs. Randomized comparative studies are needed to define the optimal endoscopic approach for these lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821628

Aims Anastomotic biliary strictures after liver transplantation can be treated using several endoscopic strategies. One of the best approaches adopted is a sequential multistenting protocol where an additional plastic stent is placed across the stricture at each endoscopic retrograde cholangiopancreatography (ERCP) session without removing the previous ones. The aims of this study were to evaluate the incidence and the potential risk factors associated with cholangitis during the multistenting protocol [1].

Methods We conducted a retrospective study at a single tertiary liver transplant center, reviewing data from patients who had undergone liver transplantation and were diagnosed with biliary strictures and treated with ERCP. The diagnosis of cholangitis was based on the Kyoto criteria. Patients with at least one episode of cholangitis were compared with those who did not. Data collected included patient demographics, hospitalization, rectal swab, presence of choledocholithiasis or stent migration, and timing of stenosis. The primary outcome was the incidence of cholangitis and secondary outcomes included the identification of potential risk factor

Results We analyzed data from 210 patients who underwent liver transplantation between June 2021 and May 2024. The median age was 59 years (SD 11), and the main indication was alcohol-related liver disease (24 %, N = 49). Anastomotic biliary strictures occurred in 55 patients (26 %) at a median of 4 months after transplant. These patients underwent a total of 220 ERCP as part of the sequential multistenting protocol, with a mean of four procedures per patient. **Eighteen patients (32.7 %) experienced at least one episode of cholangitis during the treatment period**. The occurrence of **choledocholithiasis** was associated with cholangitis ($p = 0.05$; OR 3.8). Moreover, **rectal swab colonization by multidrug-resistant (MDR) organisms** showed a strong association ($p = 0.005$; OR 7.2)

Conclusions Cholangitis represents a **clinically events** during the sequential multistenting protocol for post-transplant anastomotic strictures. A new onset of **biliary stones** and **colonization by multidrug-resistant (MDR) organisms** were predictors of cholangitis. These findings emphasize that Rectal swab colonization by multidrug-resistant organisms may represent an important predictor of cholangitis, suggesting that targeted pre-procedural antibiotic prophylaxis could help reduce its occurrence. Prospective studies would be needed to confirm these findings and to determine whether integrating rectal swab screening into routine management could improve outcomes.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP302 Secondary Prophylaxis of Gastric Variceal Bleeding with Coil and Cyanoacrylate Obliteration: A Retrospective Cohort Study at UNICAMP

Authors De lacerda clevelario A[1], Kreve F[1], Darcadia dos Reis T[2], Bruna DPA[2], Aluizio CL[1], Montes CG[2], Ribeiro MHDP[1], Cheng S[1]
Institutes **1** UNICAMP Universidade Estadual de Campinas, Campinas, Brazil; **2** Unicamp, Campinas, Brazil
DOI 10.1055/s-0046-1821629

Aims To describe the profile of patients undergoing EUS-guided obliteration of gastric varices and to assess its efficacy (immediate hemostasis and obliteration on follow-up) and safety (early rebleeding and adverse events).

Methods Retrospective, single-center cohort study including patients with portal hypertension and high-risk gastric varices (GOV or IGV), treated at the Hospital de Clínicas of UNICAMP between August 2023 and November 2025. We included cases of recent bleeding in the setting of secondary prophylaxis or primary prophylaxis with high-risk bleeding stigmata

Results Thirteen patients were evaluated and 10 were included. Most were male (60 %), with a median age of 49.5 years (14–68), and 70 % had portal hypertension secondary to liver cirrhosis. The mean diameter of treated varices was 24.1 ± 11.99 mm. Immediate obliteration was achieved in 100 % of cases, with no rebleeding at 30 days. One adverse event was recorded: pulmonary coil embolization [1–4].

Conclusions The high rate of immediate obliteration and absence of early rebleeding, even in large-caliber varices, reinforce the efficacy of EUS-guided combined coil and cyanoacrylate therapy in a high-risk setting. The embolic event associated with a large shunt underscores the importance of careful anatomical assessment and individualized technical planning.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP303 Analysis of Time–Intensity Curves Using Contrast-Enhanced Harmonic Endoscopic Ultrasound for Differentiation of Solid Pancreatic Lesions

Authors Hermida Lario M[1], Martinez R[1], Herranz R[1], De La Morena López F[1], Santander C[1]
Institute **1** Hospital de La Princesa, Madrid, Spain
DOI 10.1055/s-0046-1821630

Aims Contrast-enhanced harmonic endoscopic ultrasound (CH-EUS) has shown high sensitivity and specificity in the diagnosis of solid pancreatic lesions. However, its visual interpretation is subjective and lacks a standardized method. Therefore, quantitative analyses such as time–intensity curves (TIC) have been proposed to provide a more objective assessment of lesions. The primary objective was to evaluate whether TIC analysis using CH-EUS can characterize pancreatic tumors. The secondary objective was to determine the most accurate parameter for this purpose.

Methods This retrospective study included 67 patients with pancreatic tumors evaluated by CH-EUS between 2019 and 2025. TIC were generated to show changes in signal intensity over time, evaluating four parameters: peak intensity, time to peak intensity, intensity at 60 seconds after peak, and washout rate. Histological or cytological diagnosis was considered the “gold standard” and used to divide patients into three groups: pancreatic carcinomas (n = 54), pancreatic neuroendocrine tumors (PNETs) (n = 10), and other lesions (n = 3).

Results During the study period, 67 patients with solid pancreatic lesions were included, 28 men and 39 women, with a mean age of 70 years.There were 54 pancreatic adenocarcinomas, 10 neuroendocrine tumors, and among the 3 patients in the “other tumors” group, there was a plasma cell neoplasm with kappa light-chain restriction, metastasis from a primary breast tumor, and metastasis from a renal clear cell tumor.

Significant differences were found in the qualitative analysis of contrast uptake, with iso- or hyperenhancement associated with neuroendocrine tumors, and hypoenhancement associated with pancreatic adenocarcinoma.

Regarding quantitative analysis, no statistically significant differences were found in time to peak intensity or washout rate between adenocarcinomas and neuroendocrine tumors.Peak intensity and intensity at 60 seconds were significantly higher in PNETs than in adenocarcinomas ($p < 0.05$).

The areas under the ROC curve (AUC) for diagnosing PNETs using peak intensity and intensity at 60 seconds were 0.692 and 0.691, respectively, with cutoff values of 61.45 dB and 16.895 dB.

Statistically significant differences were also found regarding lesion size, obtaining a cutoff point of 22.5 mm after performing the ROC curve analysis. Therefore, when lesion size was included in the model, the areas under the ROC curve for diagnosing NET using peak intensity and intensity at 60 seconds were 0.994 and 0.986, respectively.

Peak intensity was the most accurate TIC parameter for differentiating PNETs, with a sensitivity of 98.3 %% and specificity of 100 %.

Conclusions TIC analysis using CH-EUS demonstrated marked differences between pancreatic carcinomas and neuroendocrine tumors. Peak intensity is the most accurate diagnostic parameter for differentiating pancreatic tumors. In resectable lesions without the need for biopsy, confirmation of our results in prospective, blinded, multicenter studies could expand the preoperative understanding of these lesions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP304 EUS-Guided Tissue Acquisition for Preoperative Grading of pNETs: Comparative Performance of FNA Versus FNB

Authors Poggioli F[1], Falbo R[1], Ricci C[2], Bruni A[1], Murino A[3], Barbara G[1], Casadei R[2], Eusebi LH[1]

Institutes **1** Gastroenterology Unit, University of Bologna, Bologna, Italy; **2** Division of Pancreatic Surgery, IRCCS Azienda Ospedaliero-Universitaria Di Bologna, Bologna, Italy; **3** Royal Free Hospital, London, United Kingdom

DOI 10.1055/s-0046-1821631

Aims Preoperative grading of pancreatic neuroendocrine tumors (pNETs) plays a pivotal role in guiding surgical and oncological management. Endoscopic ultrasound-guided tissue acquisition (EUS-TA) enables cytological and histological assessment through fine-needle aspiration (FNA) and fine-needle biopsy (FNB), both currently recommended for tissue sampling. However, their comparative performance in achieving accurate grading consistent with surgical specimens remains unclear.

This study aimed to evaluate the performance of EUS-guided tissue acquisition (EUS-TA) for the preoperative characterization and grading of pancreatic neuroendocrine tumors (pNETs), comparing the relative performance and safety of FNA and FNB to the postoperative histological gold standard [1–3].

Methods We retrospectively analyzed 63 patients with histologically confirmed pNETs who underwent preoperative EUS-guided tissue acquisition (FNA or FNB) and subsequent surgical resection at the S. Orsola-Malpighi University Hospital in Bologna (2010–2024). Demographic, clinical, radiological, and procedural data were collected, including tumor size, site, morphology, sampling technique and adverse events. Cytological (FNA) and histological (FNB) samples were processed and graded according to WHO 2022 criteria. Diagnostic yield, accuracy, and grading adequacy were assessed. Multivariable logistic regression identified predictors of grading adequacy (sex, age, site, morphology, size). Concordance between preoperative and surgical grading was measured as percent agreement, Cohen's kappa, and Gwet's AC. Statistical significance was set at $p < 0.05$.

Results Among 63 resected pNETs (19 FNA, 44 FNB), overall diagnostic yield was 95.2 % (60/63) and diagnostic accuracy 98.3 % (59/60). Grading was achievable in 84.1 % of cases, with 93.2 % for FNB and 63.2 % for FNA (OR 7.97; 95 % CI 1.78–35.65; $p = 0.006$). Lesion size ≥ 20 mm independently predicted grading adequacy (OR 8.36, 95 % CI 1.10–63.6; $p = 0.040$). Overall concordance between preoperative and surgical grading was 69.8 % ($\kappa = 0.44$; Gwet's AC = 0.59), similar for FNA (75.0 %) and FNB (68.3 %). Misgrading occurred in 30.2 % (undergrading 24.5 %, overgrading 5.7 %). In lesions < 20 mm, concordance was 75.0 %. Safety was favorable: minor bleeding 15.9 %, mild pancreatitis 1.6 %, no severe events.

Conclusions Our findings confirm the high diagnostic accuracy of EUS-guided sampling in pNETs and highlight the significant advantage of FNB in obtaining histological material suitable for grading compared to FNA. Larger lesions (> 20 mm) favored grading adequacy, while overall concordance with surgical grading was moderate (69.8 %). FNB therefore appears to be the most reliable method for preoperative grading of pNETs.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP305 Sphincter of oddi dysfunction and functional biliary pain syndrome: A UK tertiary centre experience

Authors Sriranganathan D[1], Affarah L[1], Marrinan A[1], El Menabawey T[1], Phillpotts S[1], Chapman M[1], Johnson G[1], Pereira S[1], Webster G[1]

Institute **1** University College Hospital, London, United Kingdom

DOI 10.1055/s-0046-1821632

Aims Sphincter of Oddi dysfunction (SOD) and functional biliary pain are overlapping difficult to treat biliary disorders that are defined by the Rome IV criteria and is seen particularly in post cholecystectomy patients. Typically, patients feel a colicky right upper quadrant abdominal pain.

SOD involves a structural or functional obstruction of the sphincter, impairing bile flow. It is classified as type 1 when both imaging abnormalities and elevated liver tests are present, and type 2 when only one is evident. When typical biliary pain occurs without objective evidence of obstruction or inflammation, it is termed functional biliary pain, reflecting visceral hypersensitivity to pain. The role of endoscopic retrograde cholangiopancreatography (ERCP) and sphincterotomy in these patients remains controversial, particularly following recent evidence questioning their efficacy and highlighting potential risks.

Data of outcomes in this patient cohort is limited. We aimed to retrospectively assess our patient cohort.

Methods All new referrals were reviewed at a weekly multidisciplinary team (MDT) meeting. We examined MDT records from 2019 and identified the first 50 consecutive patients referred with a diagnosis of Sphincter of Oddi Dysfunction (SOD). Collected data included demographics, symptom profile, previous biliary surgery, imaging findings, liver function tests (LFTs), ERCP and sphincterotomy details, procedure-related complications, clinical outcomes, and duration of follow-up. For analysis, Type 2 SOD was further subclassified into cases with isolated liver function test abnormalities (Type 2–LFTs) and those with isolated imaging abnormalities (Type 2–Imaging)

Results The fifty patients were identified, with a mean age of 41.2 years; 96 % were female and 94 % were White. The mean follow-up duration was 4.7 years. Prior cholecystectomy had been performed in 84 % of patients, with 58 % reporting similar pain before surgery.

Diagnoses included Type 1 SOD (n = 6), Type 2 SOD–Imaging (n = 4), Type 2 SOD–LFTs (n = 23), functional biliary pain (n = 14), and non-biliary pain (n = 3).

Among SOD patients, mean peak ALT and ALP were 231 U/L and 153 U/L, respectively. Twenty-four SOD patients and two with functional biliary pain underwent ERCP, all of whom had sphincterotomy performed.

Post-procedure complications included pancreatitis in 7 patients (26.9 %), post-sphincterotomy bleeding in 2 (7.7 %), and perforation in 1 (3.8 %). The mean length of stay for patients with pancreatitis was 11 days. Of the 26 patients who underwent ERCP, 11 (42 %) reported no symptomatic improvement at their first follow up post-procedure, and 14 (54 %) reported no improvement at latest follow-up.

Conclusions In this cohort, the majority of patients referred with suspected SOD were young females, most of whom had previously undergone cholecystectomy. ERCP with sphincterotomy was associated with a higher-than-expected complication rate and limited long-term symptomatic benefit. These findings underscore the importance of careful patient selection and informed counselling. Comprehensive analysis of the full cohort of over 150 patients is ongoing and will be reported separately.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP306 Ketamine cholangiopathy: A UK tertiary centre experience

Authors Sriranganathan D[1], Knox C[1], Affarah L[1], Marrinan A[1], Phillpotts S[1], El Menabawey T[1], Chapman M[1], Johnson G[1], Pereira S[1], Webster G[1]

Institute 1 University College Hospital, London, United Kingdom

DOI 10.1055/s-0046-1821633

Aims Ketamine, a synthetic phencyclidine derivative, is widely used for anaesthesia, analgesia, and treatment-resistant depression, but its hallucinogenic properties have driven increasing recreational misuse. It is metabolised hepatically, with approximately 90 % excreted in urine. Ketamine-associated urinary tract injury is well recognised, with severe cases leading to chronic pain and even reconstructive bladder surgery, as highlighted in a recent systematic review of nearly 4,000 patients.

In contrast, ketamine-induced biliary injury is less well described. A recent systematic review identified only 17 reported cases, yet the consequences can be similarly severe.

With ketamine use rising across Europe over the past decade, we have observed a growing number of patients presenting with ketamine cholangiopathy. Our aim was to enhance understanding of this emerging condition by collating and analysing our centre's cases.

Methods All new referrals to our service are discussed at a weekly multidisciplinary team (MDT) meeting. We reviewed MDT records from 2019, when the hospital transitioned to an electronic health record system, through to July 2025. We collected demographic data, imaging results, frequency of ketamine use, urological involvement, date of referral, endoscopic interventions, symptom history, and liver function test results.

Results We identified 18 patients (mean age 32 years) with a mean follow-up of 3.8 years; sex distribution was equal. Seventeen reported weekly ketamine use at peak consumption. Cholangiopathy was evident on imaging in 17 patients, with one additional patient displaying abnormal liver tests while awaiting imaging. Uropathy was present in 14 patients.

At referral, 13 patients reported abdominal pain. At latest follow-up, 8 were abstinent from ketamine, of whom 5 experienced symptomatic improvement. One patient developed decompensated liver disease and died. Excluding this case, mean bilirubin was 12 µmol/L, ALT 183 U/L, and ALP 474 U/L. Two patients required ERCP for biliary strictures. Five patients underwent repeat imaging after reducing or ceasing ketamine use; one demonstrated complete resolution of cholangiopathy, while the remaining four showed either improvement or stable appearances.

Conclusions This is the largest case series to date on recreational ketamine users, underscoring the emerging public health issue of ketamine-induced cholangiopathy, which is closely linked to ketamine-induced uropathy. Most patients can be managed with active surveillance, with few requiring endoscopic intervention. The long-term outcomes remain unclear, though there is concern for progression to cirrhosis or malignancy. Ongoing research and greater awareness are needed given the rising prevalence of illicit ketamine use.

eP307 Extranodal marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT): an uncommon cause of dysphagia

Authors Aleksandrowicz A[1], Bartolomé Oterino I[1], Peñaranda Villas E[1], Trueba Collado C[1], López De Toro Sánchez M[1], Flandes Iparraguirre A[1], Castellano Lopez A[1], Tabernero Da Veiga S[1]

Institute 1 Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

DOI 10.1055/s-0046-1821634

Abstract Text

Extranodal laryngeal MALT lymphoma is an extremely rare cause of laryngeal masses and dysphagia, representing less than 1 % of laryngeal neoplasms. It typically presents as an indolent submucosal lesion with nonspecific symptoms such as dysphonia, cough, globus sensation or progressive dysphagia. Histologically, these lymphomas consist of marginal zone B cells with a characteristic CD20 + phenotype and variable plasmacytic differentiation. Lymphoplasmacytic lymphoma (LPL) and plasmacytoma are exceptionally uncommon alternative diagnoses [1–3].

A 46-year-old man, smoker of 10 cigarettes/day, presented with mixed high dysphagia for two years with recent progression. Past medical history included asthma and a duodenal ulcer diagnosed 13 years earlier associated with Helicobacter pylori infection, with confirmed eradication. A barium swallow showed a filling defect suggestive of an oesophageal polyp. Upper endoscopy revealed a 3-cm oval, submucosal-appearing lesion arising from the left arytenoid, covered by normal mucosa and without proximal oesophageal extension. The procedure was suspended due to intolerance, preventing gastric inspection. Fibroscopy confirmed a rounded lesion on the left aryepiglottic fold partially occupying the ipsilateral piriform sinus. Cervical computer tomography (CT) demonstrated a solid polypoid mass originating from the same region. A supraglottic partial laryngectomy was performed to obtain a complete diagnostic specimen. Histopathology was suggestive of extranodal marginal zone B-cell lymphoma (MALT type) with plasmacytic differentiation. Molecular studies subsequently demonstrated B-cell clonality, supporting this suspicion, although definitive diagnosis is still pending. The patient is currently undergoing full hematologic work-up, which include repeat upper endoscopy to exclude synchronous gastric MALT involvement.

In contrast to gastric MALT lymphoma, laryngeal MALT is not associated with H. pylori infection. Chronic inflammatory processes are thought to play a more relevant pathogenetic role. Comprehensive staging is essential, particularly upper gastrointestinal endoscopy with systematic gastric biopsies, because synchronous gastric involvement or multifocal disease may alter management. While H. pylori eradication is effective for gastric MALT lymphoma and may induce remission of extragastric manifestations, it is not an effective therapy for isolated laryngeal MALT lymphoma. Instead, involved-site radiotherapy is considered the treatment of choice, providing excellent local control and long-term remission. This case emphasises the value of endoscopic evaluation in patients with persistent dysphagia, not only for intraluminal oesophageal pathology but also for extrinsic or juxta-oesophageal lesions. Laryngeal MALT lymphoma, although rare, should be considered in the differential diagnosis of submucosal laryngeal masses. Complete staging, including gastric endoscopy, is essential to establish disease extent and guide optimal treatment.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821635

Aims Cholangitis is one of the most serious infectious complications of ERCP. Current guidelines recommend antibiotic prophylaxis (AP) only for selected high-risk patients, yet most randomized controlled trials (RCT) informing these recommendations were performed more than two decades ago, before ERCP evolved into a predominantly therapeutic procedure. A recent study (Leem et al., 2024) reported reduced infectious complications in patients with biliary obstruction, suggesting that the effectiveness of AP may differ in contemporary practice. Our aim was to update the evidence by performing a comprehensive meta-analysis of all trials evaluating AP before ERCP.

Methods A systematic search was conducted in five databases (Medline, Embase, CENTRAL, Scopus and Web of Science) on 19th November 2024 to identify RCT's comparing AP versus no prophylaxis before ERCP. Primary outcome was cholangitis; secondary outcomes included bacteremia, septicemia, pancreatitis and mortality. Random-effects models were used to calculate risk ratios (RR) with 95 % confidence intervals (CI). Risk of bias was assessed with the ROB2 tool, and certainty of evidence was evaluated using GRADE [1–4].

Results In total 14 RCTs involving 2055 patients were included. Antibiotic prophylaxis showed a trend toward reducing cholangitis (RR = 0.60, CI 0.29-1.26) although this did not reach statistical significance. In the subgroup of patients with biliary obstruction, AP again favored lower cholangitis risk (RR = 0.55, CI 0.12–2.40), but the effect was not statistically significant. Bacteremia was nearly significantly reduced (RR = 0.46, CI 0.20-1.08). Estimates for septicemia (RR = 0.56, CI 0.20-1.57), pancreatitis (RR = 0.73, CI 0.41-1.30) also favored AP but remained non-significant. The mortality in both groups was low (RR 1.16, CI 0.73-1.84). Overall heterogeneity across outcomes was low to moderate.

Conclusions Although not statistically significant, the evidence suggests a potential benefit of antibiotic prophylaxis for preventing post-ERCP infectious complications, particularly in patients with biliary obstruction. However, the certainty of this evidence is limited, and the true effect remains uncertain. Further modern RCTs are needed to identify patient groups who may benefit from prophylaxis.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

DOI 10.1055/s-0046-1821636

Aims To compare the adequacy of bowel preparation between inpatients and outpatients and to identify independent predictors of poor bowel cleansing.

Methods This prospective, single-center observational study was conducted at a tertiary care hospital and included colonoscopies performed on both inpatients and outpatients. A total of 217 procedures were analyzed (109 outpatients and 108 inpatients). Bowel preparation quality was evaluated using the Boston Bowel Preparation Scale (BBPS). Univariate and multivariate logistic regression analyses were used to identify factors associated with inadequate bowel preparation [1–25].

Results No statistically significant difference in bowel preparation adequacy was found between inpatients and outpatients. In the overall cohort, two independent predictors of bowel preparation quality were identified. Smoking was significantly associated with inadequate cleansing, with smokers having 62.4 % lower odds of achieving good preparation compared to non-smokers (OR = 0.376; p = 0.002). Conversely, the use of a split-dose regimen significantly improved bowel cleansing, increasing the odds of adequate preparation by nearly five times compared to single-dose regimens (OR = 4.96; p = 0.001).

Conclusions Inpatient status was not associated with inferior bowel preparation compared to outpatient status. Smoking and the type of bowel preparation regimen (split- vs. single-dose) were the most significant predictors of bowel cleansing quality.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP310 Endoscopic Application of Self-Assembling Peptide Gel (PuraStat) for Post-Bariatric Surgical Anastomotic Ulcers: A Retrospective Case Series

Authors Kotecha S[1], Hwang S[1], Shidrawi R[1]
Institute 1 Homerton Healthcare NHS Foundation Trust, London, United Kingdom
DOI 10.1055/s-0046-1821637

Aims Anastomotic (marginal) ulcers appear in 16 % of patients post-bariatric surgery [1]. Patients commonly present with abdominal pain, dyspepsia, nausea and even bleeding [2]. Standard treatment is high-dose PPIs (with or without sucralfate) with endoscopic surveillance, yet some patients experience refractory chronic ulcers (> 12 months), which require surgical resection and anastomotic revision [3]. PuraStat, a transparent synthetic peptide gel, supports haemostasis and mucosal repair of ulcers by forming a nanofibre scaffold upon contact with bodily fluid [4]. A previous case series demonstrated success in anastomotic ulcer healing [2], and an observational study showed efficacy in gastrointestinal bleeding management [4]. Light brushing of the ulcer surface can induce capillary bleeding, theoretically enhancing PuraStat's efficacy, but this technique has not been explored in current literature. This single-centre case series of patients who had anastomotic ulcer brushing followed by PuraStat application during endoscopy aims to describe efficacy of this technique in terms of symptom resolution, endoscopic evidence of healing and need for follow-up endoscopy.

Methods Fourteen adults with anastomotic ulceration post-gastric bypass surgery, who underwent endoscopy with ulcer brushing followed by either 3mL or 5mL PuraStat application at Homerton University Hospital between 2018 and 2025, were included. Data retrospectively collected from patients' electronic records included demographics, smoking status, bariatric history, presenting symptoms, diagnoses of chronic ulceration, complications (gastrointestinal bleeding or perforation), and concurrent medical therapy (PPIs and sucralfate). Outcomes were recorded as documented symptomatic improvement, evidence of healing on subsequent endoscopy, and discharge from endoscopic surveillance (▶ **Table 1**).

▶ **Table 1**

Characteristic	*No. (%)*
Smoking	5 (36)
Previous bariatric revision surgery	3 (21)
4 + PuraStat-assisted OGDs	7 (50)
Chronic / recurrent ulceration diagnosed	8 (57)
Long-term PPI therapy	14 (100)
≥ 1 Two-week course of sucralfate	10 (71)
Clinical symptom resolution	12 (86)
Endoscopic evidence of ulcer healing	12 (86)
Discharged from endoscopy follow-up	9 (64)
Complications (gastrointestinal bleed / perforation)	0 (0)

Results All patients received high-dose PPI therapy, with the majority also receiving sucralfate. Most patients (10/14, 71.4 %) demonstrated both symptomatic and endoscopic improvement. Of the two patients without endoscop-

ic healing, one had symptom resolution and did not need further OGDs, while the other had stent insertion for stricturing, with revision surgery planned. Of two patients with ongoing symptoms, one is currently awaiting clinic follow-up to check for symptom resolution after a recent OGD, and one underwent six OGDs due to refractory symptoms related to a gastric intra-thoracic remnant. Other patients requiring four to six PuraStat-assisted OGDs (7/14, 50 %) had persistent symptoms, with two awaiting revision surgery, or were smokers (3/7, 42.9 %). There were no complications observed.

Conclusions Endoscopic PuraStat application after ulcer brushing was well-tolerated and had favourable clinical and endoscopic outcomes. Prolonged follow-up occurred in smokers and those with complex postoperative anatomy, but even slowly progressing patients showed endoscopic evidence of ulcer healing. No major complications were observed, supporting the safety of repeated applications. However, this study lacked a control arm, limiting comparison with standard therapy as exact PPI and sucralfate regimes varied between patients, and limiting investigation into the efficacy of ulcer brushing versus using PuraStat alone. Overall, PuraStat with ulcer brushing is a promising option for anastomotic ulcers, but prospective comparative studies are needed to cement the efficacy and safety of this technique.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

Aims The occurrence of esophageal stenosis becomes unavoidable with endoscopic submucosal dissection (ESD) conducted on large superficial esophageal squamous cell neoplasia (SESC). The aim of this study was to assess the impact of neo-adjuvant radiotherapy administered prior to ESD for SESC.

Methods This was a retrospective cohort study in a single tertiary referral center. Medical records were reviewed from January 2017 to November 2023. Inclusion criteria comprised; 1) identification of SESC through endoscopic and pathologic examinations; 2) radiotherapy prior to ESD; 3) no further treatment immediately after ESD. Exclusion criteria encompassed; 1) advanced esophageal carcinoma; 2) esophageal adenocarcinoma; 3) radiotherapy administered after ESD.

Results In this study, a total of 15 lesions from 14 patients were included. The male-to-female ratio was 11:3, with an average age of 67.4 ± 7.8 years. The mean follow-up period was 29.7 ± 12.3 months. The initial lesion width before radiation therapy averaged 26.7 cm^2 and averaged 13.0 cm^2 after ESD. The curative *en bloc* resection rate was 93.3 %, and no submucosal invasion was observed pathologically. Throughout the follow-up period, peri-gastric lymph node metastasis was detected in one patient. Importantly, none of the patients experienced esophageal stricture or disruption in the passage of food materials.

Conclusions The application of neo-adjuvant radiotherapy before ESD may help prevent post-ESD stricture.

eP312 Is Octreotide a Salvage Therapy for Preventing Recurrent Bleeding From Gastrointestinal Angioectasias?

Authors Abreu Marques I[1, 2, 3], Cláudia M[1, 2, 3], José C[1, 2, 3]

Institutes **1** Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Portugal, Guimaraes, Portugal; **2** Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Guimaraes, Portugal; **3** ICVS/3B's – PT Government Associate Laboratory, Guimaraes, Portugal

DOI 10.1055/s-0046-1821639

Aims Gastrointestinal angioectasia is a significant etiology of recurrent gastrointestinal bleeding, often requiring hospital care. Octreotide has been proposed as a therapeutic option in patients in whom endoscopic treatment is insuficiente, particularly in those with small bowel or diffuse angiectasia. This study evaluates the clinical efficacy of long-acting intramuscular octreotide in the recurrency of gastrointestinal bleeding from angioectasia [1].

Methods A sample of 21 patients receiving monthly octreotide, either 10 mg or 20 mg, were retrospectively analyzed. Clinical efficacy was assessed by comparing the frequency of hospitalizations, urgency department visits, red blood cell (RBC) transfusions and intravenous iron infusions during the 6-month and 12-month intervals that preceded and followed the start of treatment. Additional contributing factors, including anticoagulation therapy and underlying diseases, were also examined.

Results The sample studied has an mean age of 78 years, with 13 males and 8 hypocoagulated patients. The Charlson Comorbidity Index averaged 5.6 points, with 5 patients having cirrhosis and 5 patients Osler-Rendu-Weber Syndrome. Hospitalizations significantly decreased after octreotide initiation at both 6 and 12 months of treatment ($p < 0.001$; $p = 0.019$). Urgent care visits and RBC transfusions were significantly lower in the first 6 months of treatment ($p < 0.001$; $p = 0.007$), though this effect was not sustained at 12 months. Intravenous iron requirements did not differ statistically between pre- and post-treatment periods. Patients receiving 10 mg of octreotide had significantly fewer urgent care visits and iron infusions at 6 months of treatment compared to the 20 mg group ($p = 0.031$; $p = 0.026$).

Conclusions In recurrent bleeding from angioectasias, when endoscopic treatment is ineffective, a 12-mounth course of octreotide therapy significantly reduces hospitalizations. Additionally, treatment in the first 6 months proves to be effective in reducing the number of urgency department visits and red blood cell transfusions.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP313 Diagnostic yield of standard upper endoscopy in 196 patients with dysphagia: a real-world comparative analysis of esophageal vs oropharyngeal presentations

Authors Espinoza Villalobos ID[1], Silis CJC[1], Zavala CJC[1], López Pérez RY[1]

Institute **1** General Hospital of Mexico Dr. Eduardo Liceaga, Ciudad de México, Mexico

DOI 10.1055/s-0046-1821640

Aims To compare the diagnostic yield of upper endoscopy between esophageal and oropharyngeal dysphagia, and to characterize the spectrum of structural, inflammatory, and motility-related findings in a real-world tertiary care setting (▶ **Table 1**).

▶ **Table 1** Endoscopic findings stratified by dysphagia type

Endoscopic finding	Total (n = 196)	Esophageal dysphagia (n = 123)	Oropharyngeal dysphagia (n = 73)
Hiatal hernia	48 (24.5 %)	44	4
Esophagitis	44 (22.4 %)	40	4
Peptic stricture	16 (8.2 %)	16	0
Malignant tumor	8 (4.1 %)	8	0
Schatzki ring	4 (2.0 %)	4	0
Eosinophilic esophagitis (EoE)	2 (1.0 %)	2	0
Achalasia (HRM-confirmed)	4 (2.0 %)	4	0
Ineffective esophageal motility (IEM)	7 (3.6 %)	7	0
Normal endoscopy	70 (35.7 %)	5	65

Methods We conducted a retrospective study of adults undergoing upper endoscopy for dysphagia between March and November 2025. Dysphagia was clinically categorized as esophageal or oropharyngeal. Endoscopic findings were classified as structural, inflammatory, motility-suggestive, or normal. Associations between dysphagia type and relevant endoscopic abnormalities were analyzed using chi-square tests and odds ratios (OR). High-resolution manometry was performed when motility disorders were suspected [1–7].

Results Among 196 patients, 123 (62.8 %) had esophageal dysphagia and 73 (37.2 %) or oropharyngeal dysphagia. The overall diagnostic yield was 64.3 %. Frequent findings included hiatal hernia (24.5 %), esophagitis (22.4 %), peptic strictures (8.2 %), malignancy (4.1 %), Schatzki ring (2.0 %), eosinophilic esophagitis (1.0 %), and HRM-confirmed achalasia (2.0 %); ineffective esophageal motility was identified in 3.6 %.

Relevant abnormalities were significantly more common in esophageal than in oropharyngeal dysphagia (96.0 % vs 11.0 %, respectively), indicating a strong association (OR 32.1, 95 % CI 12.8–80.5, $p < 0.001$). In oropharyngeal dysphagia, endoscopy was predominantly normal.

Conclusions Standard upper endoscopy provides high diagnostic yield in esophageal dysphagia, identifying a broad spectrum of clinically actionable abnormalities. In contrast, oropharyngeal dysphagia demonstrates low yield, supporting selective endoscopic referral. These real-world findings reinforce the utility of conventional endoscopy—without enhanced imaging—as an essential diagnostic tool in dysphagia evaluation in resource-limited settings.

Conflicts of Interest Authors do not have any conflict of interest to disclose.

eP314 A Retrospective Cohort Analysis of Optimal Lumen-Apposing Metal Stent (LAMS) Removal Timing in Necrotizing Pancreatitis

Authors Paladiya R[1], Khataniar H[2], Prateek H[2], Adam K[2], Abhijeet K[2], Manish D[2]

Institutes 1 UConn Health, Farmington, United States of America; 2 Allegheny General Hospital, Pittsburgh, United States of America

DOI 10.1055/s-0046-1821641

Aims Lumen-apposing metal stents (LAMS) have transformed endoscopic management of walled-off necrosis (WON) and large pseudocysts by permitting wide, stable cyst-gastrostomy and direct necrosectomy. Current societies advise retrieval at 3–5 weeks, yet these statements are based on limited data and conflicting single-center series.

Methods All adults who underwent trans-gastric Hot AXIOS placement for WON or symptomatic pseudocyst between January 2017 and March 2025 were retrospectively reviewed. The composite 30-day adverse-event (AE) endpoint captured any post-removal bleeding, migration/burial, new or recurrent fluid collection > 4 cm, unplanned readmission or death. Clinical success required radiographic resolution without further intervention. Categorical outcomes were compared with Fisher's exact test; absolute risk differences (RD) carry 95 % CIs.

Results Forty-nine patients met inclusion (median age 57 yr, IQR 48–66; 65 % male). Twenty-seven had WON and 22 pseudocysts. Twelve stents were removed early, 17 in the standard window and 20 after > 28 d, yielding median dwell times of 11, 21 and 47 d, respectively. Composite 30-day AEs occurred in 2/12 (16.7 %) early, 9/17 (52.9 %) standard and 4/20 (20 %) delayed removals; RD standard–early = + 36.3 % (95 % 4.5–68.0) and RD standard–delayed = + 32.9 % (3.4–62.4), whereas early and delayed differed less (–3.3 %, –30.8–24.1). Bleeding was uncommon (8 %) and evenly distributed, but unplanned readmissions were highest with standard timing (35.3 % vs 8.3 % early, 15.0 % delayed). Clinical success was achieved in 10/11 early (90.9 %), 12/15 standard (80.0 %) and 17/17 delayed cases (100 %). Multivariable analysis in 44 patients retained a non-significant but directionally consistent effect for standard removal (adjusted OR 4.95 vs early, 95 % 0.67–36.3); no demographic or procedural covariate independently predicted AE. Subgroup analysis reinforced the pattern: in WON, AEs were 14.3 % early, 54.5 % standard and 33.3 % delayed, while pseudocyst rates remained ≤ 25 % irrespective of timing (▶ **Table 1**).

Endoscopy 2026; 58: S1–S1041

▶ **Table 1** Baseline Characteristics by Indwell-Time Group

Characteristic	Early(n = 12)	Standard(n = 17)	Delayed(n = 20)	*p*-value†
Age, yr (mean ± SD)	56.0 ± 13.1	59.0 ± 12.6	53.5 ± 12.8	0.44
Male sex, %	83.3 %	64.7 %	55.0 %	0.26
Charlson index (mean ± SD)	2.50 ± 1.62	2.71 ± 1.45	2.45 ± 1.67	0.88
Stent diameter, mm (mean ± SD)	18.2 ± 2.5	17.7 ± 2.6	15.8 ± 1.9	**0.02**
Plastic pigtail stent, %	83.3 %	88.2 %	90.0 %	0.85
Balloon dilation used, %	91.7 %	100 %	100 %	0.15
Necrosectomy sessions, median (IQR)	2 (1-3)	2 (1-3)	1.5 (1-3)	0.30‡
Collection size, cm (mean ± SD)	13.2 ± 5.6	12.6 ± 5.8	11.5 ± 5.4	0.71
Pseudocyst pathology, %	41.7 %	23.5 %	65.0 %	0.17

†χ^2/ANOVA where appropriate; ‡Kruskal–Wallis for counts.

Conclusions In patients with large pseudocysts and WONs, removal of LAMS early (< 14 days) in showed lowest AE rates when compared to "standard" (14-28 days) and delayed (> 28 days) without compromising clinical success. Additionally, delayed removals also had lower AE rates when compared to standard window of removal. These findings question current LAMS removal timing and indicate that earlier removal may be safe in selected patients, warranting prospective validation.

eP315 Abstract: Peptic Ulcer Status and Associated Risk Factors Among Patients Undergoing Hemodialysis

Authors Ganbaatar S[1], Baatar G[2]
Institutes **1** Shinonmed hospital, Ulaanbaatar, Mongolia; **2** Shinonmed hospital, Uvurkhangai, Mongolia
DOI 10.1055/s-0046-1821642

Aims To investigate the status of peptic ulcers and the associated risk factors among patients undergoing hemodialysis

Methods This hospital-based retrospective study was conducted from October 1, 2018, to March 24, 2024, among patients undergoing renal replacement therapy who received endoscopic services at the endoscopy unit of Shinonmed Hospital. We reviewed their upper gastrointestinal endoscopy findings and hemodialysis-related medical history. To calculate the malnutrition index, we used the calculator developed by Dr. Gordan P. Buzby from the University of Pennsylvania Health System, which is published on PubMed [1–8].

Results 1. General Characteristics of the Study Population

A total of 103 cases were included in the study. The mean age was 48.7 ± 12.8 years. By sex distribution, 47 % (n = 48) were female and 53 % (n = 55) were male, yielding a male-to-female ratio of 1:1.

Among the 103 patients, 35 % (n = 36) had peptic ulcer disease (PUD), while 65 % (n = 67) did not.

Assessment of the association between **H. pylori** infection and PUD showed that 84.7 % (n = 87) had no *H. pylori* infection. The association with PUD was not statistically significant (p = 0.15).

Malnutrition Index and Peptic Ulcer Disease

PUD was detected in 34.9 % (n = 36) of all cases. Based on the malnutrition index, 75 % (n = 27) of patients with peptic ulcers had moderate malnutrition. Therefore, protein–energy malnutrition was found to be significantly associated with the development of peptic ulcers (p = 0.000*).

Age and Peptic Ulcer Disease

Among patients with PUD, 69.4 % (n = 25) were aged > 40 years, while 77.6 % (n = 52) of non-PUD patients were also over 40 years of age. There was no significant association between age and PUD (p = 0.23).

Comorbidities and Peptic Ulcer Disease

Among patients with PUD, 47.2 % (n = 17) had three or more chronic comorbidities, compared with 23.8 % (n = 16) among those without PUD. Thus, the presence of multiple comorbidities was significantly associated with the development of PUD (p = 0.038)

Risk Factors for PUD in Hemodialysis Patients

Comparison of risk factors among hemodialysis patients revealed that the malnutrition index was strongly associated with PUD (p = 0.000*). Additionally, comorbid conditions increased the risk of PUD by **35.1 times**

Conclusions A total of 103 patients undergoing renal replacement therapy were evaluated by endoscopy, of whom 36 (34.95 %) had peptic ulcers and 98 (95.1 %) were diagnosed with chronic gastritis.

A total of 103 patients undergoing renal replacement therapy were evaluated by endoscopy, of whom 36 (34.95 %) had peptic ulcers and 98 (95.1 %) were diagnosed with chronic gastritis.

Peptic ulcer disease was present in 34.9 % (n = 36) of the cases. Based on the malnutrition index, 75 % (n = 27) of patients with peptic ulcers had moderate malnutrition. This indicates that protein–energy malnutrition contributes to the development of peptic ulcers.

eP316 Large polypectomy case report

Authors Ganbaatar S[1], Baatar G[2]
Institutes 1 Shinonmed hospital, Ulaanbaatar, Mongolia; 2 Shinonmed hospital, Uvurkhangai, Mongolia
DOI 10.1055/s-0046-1821643

Background: With the increasing use of endoscopy, visually discernible abnormalities, such as polyps in the gastrointestinal tract, are encountered more often. Gastric polyps most frequently originate in the mucosa but encompass a broad spectrum of pathologic conditions that may even be submucosal or extrinsic. Found in 6 % of upper endoscopies, gastric polyps are a heterogeneous group of epithelial and subepithelial lesions that can vary in histology, neoplastic potential, and management. Most have no risk of cancer, but there are certain subsets of polyps with malignant potential, necessitating further endoscopic treatment and/or periodic surveillance 1. Gastric adenomas, or gastric polypoid dysplasia, are true neoplasms and precursors to gastric cancer. Due to the increased risk of malignancy associated with these polyps, recommendations include complete removal of the adenoma, with further examination of the entire gastric mucosa for abnormalities, all of which should be biopsied [1–3].

Case report: Introduction: Patient description- Age: 65 Gender: male Race: Mongolian Height-168cm Weight- 80kg
Case history- Occasionally abdominal pain 2023.12.11 Gastric large polyp was diagnosed No chronic deseases Did not use alcohol or tobacco Gastroscopy 2023.12.12 Pedunculated large polyp on the middle part of body Yamada type IV 2023.12.21 Pedunculated large polyp size 4.5x6,5 cm on the middle part of body Removed this polyp by hot snare and seven clips where done on the polyps base 2023.12.22 : Histology result Well differentiated adenocarcinoma arising in villous adenoma IC10-C16 2023.01.15 Abdominal contrast CT Result: SPO gastric polypectomy with surgical clips along the stomach body, no significant abnormal wall thickness or enhancement of the stomach.
ConclusionsAround 10 % of stomach polyps are adenomas, making them the most common precancerous type. They're typically sporadic and solitary. But they can sometimes occur in greater numbers in association with familial adenomatous polyposis. Polyps are common in gastrointestinal endoscopy and are usually asymptomatic and do not progress to cancer, but histological examination is required to determine the presence of dysplasia. In this case, tissue analysis revealed a hyperplastic polyp, but post-operative material revealed a adenocarcinoma arising in villous adenoma of the stomach 2. Endoscopic removal of a large adenoma crop has fewer complications and recurrences, but it cannot completely eliminate the risk of cancer, so it is necessary to regularly monitor H. pylori for treatment. As long as the size of gastric adenoma is 2 cm or larger, there is a 40-50 % risk of turning into cancer, so it is necessary to regularly monitor with an endoscope .

Conflicts of Interest Authors do not have any conflict of interest to disclose.
